*Electronic whiteboards as blackboard replacement.* As mentioned before, today’s electronic whiteboards are larger in size, offer a higher resolution, are technically more reliable, and are easier to handle. However, their absolute size still remains an issue when compared to traditional blackboards. As a consequence, some people started placing two boards next to each other in order to increase their writing space by forming a large electronic whiteboard (Prante, Streitz, & Tandler, 2004). Examples of such “twofold” whiteboard installations at our university can be found in Figure 5. The boards shown at the top and bottom left of Figure 5 are integrated into the front wall of the lecture room thus hiding the required technology from the presenter and providing an environment, where the computing functionality can be directly accessed by the teacher through interacting with the electronic whiteboards, but the...
whole technology does not interfere with regular teaching. All technologies are hidden as much as possible in order to let the presenter concentrate on the talk without distraction from any of the hardware. In our installation, both boards can be connected to one computer. People are able to place one application window (e.g. from the used presentation software) over two boards thus creating one large “virtual” electronic whiteboard. Experience with users has shown that the border in the middle of these two boards is generally not considered critical since most presenters prefer to write on the board in columns anyway. While connecting several input and output devices to one computer was still considered critical a few years ago (MacIntyre & Feiner, 1996), today’s windowing systems generally support this kind of functionality without any problems.

When observing how people are using such an installation, we realized different approaches. Some presenters like to have just one application window that extends over both whiteboards, either using it to present two slides next to each other or to start with two empty slides and an increased writing surface. Others prefer to have two separate applications running, for example, in order to show an overview slide of the lecture on the left board while presenting the current slide on the right side. Some teachers use one board for slides and the other one to show a different application, such as a player for video clips or animations. People can also connect their own laptop to one of the boards, which is used, for example, by some presenters to show their slides from the laptop, while referring to the other board (and the connected computer in the classroom) when accessing and presenting information from the Internet. Using the two output devices for different applications is a common practice often chosen when using multiple monitors for desktop computing as, for example, Grudin’s studies pointed out; there, participants used multiple monitors rather for partitioning than to increase space (Grudin, 2001).

Overall, we can observe that people take great advantage of the additional working space. No single trend in using this installation can be ob-

Figure 5. Putting two electronic whiteboards next to each other, in order to form a larger input and output area, resemble traditional blackboards.
served, but a variety of different usage scenarios exists. Hence, instead of having the teachers adapt to a certain interface or style of interaction, this setup enables them to choose among different approaches and to use the respective tools in the way they personally prefer.

*Integrated interactive LCD panel as overhead projector replacement.* In addition to the boards, we built a high desk or lectern with integrated computing facilities that can serve as a true replacement of the traditional overhead projector (cf. Figure 6). As input device, a horizontally mounted LCD display with pen-based interaction functionality is integrated into the surface of the lectern. All other equipment needed for a talk is embedded into the lectern, but again hidden to the user as much as possible. This includes even audio recording facilities if the presenter wants to record the lecture with some lecture recording software (Müller & Ottmann, 2000) and preserve it for further, off-line usage. Hence, the normal user just has to connect the lectern to the power source and data projector and press a button to turn it on. Including all required equipment into the lectern provides several advantages, because it enables us to make the whole device mobile by putting it on wheels. Thus, it can be easily maintained and replaced by technical staff if necessary. In addition, it can be transferred to different rooms, which is important in case not all rooms can be provided with the full range of technical equipment. It also allows one to easily put it away and lock it, in case it is not possible to always lock the room.

Considering the usage by the presenters, most of them reported that handwriting and making annotations is much easier, since they can do this on a horizontally mounted surface placed in front of them. Some also expressed their appreciation that they can face their material and the audience at the same time and do not have to continuously turn their back to the students when presenting their material. Meanwhile, several of these lecterns were built and used in various lecture halls at our as well as other institutions.

Both the lectern as well as the large interactive whiteboard described before turned out to be reasonable replacements for traditional devices used

*Figure 6. Lectern with integrated computing facilities and pen-based input device. The interactive LCD panel is integrated into the surface in order to support freehand writing on the presented slides and pen-based operation of the used applications.*
in classrooms, that is, blackboards and overhead projectors. If integrated into the environment as shown, for example, in Figure 5 and 6, they do not interfere with the normal teaching process of the presenter while at the same time offering full access to the computing functionality offered by the underlying computing system and network infrastructure.

SOFTWARE-RELATED ISSUES: INTERACTION PARADIGM

Background: Digital Ink

In the previous section we argued that the pen is the natural choice for interaction with wall-mounted boards and interactive tablets. It enables users to interact directly with the respective tools instead of remotely as with a mouse pointer. Freestanding writing proves to be more intuitive and flexible to enter content during a lecture than a keyboard. Hence, handwriting becomes a “first-class” data type, on an equal footing with text entered via keyboards. However, common interface designs and graphical user interfaces (GUIs) usually follow the desktop metaphor and are therefore optimized for input devices such as keyboard and mouse. For example, navigation through nested menus can easily be done with a mouse, but is hard to do with a pen. For pen-based interaction, earlier research on pie menus proved an advantage for users of digital screens, as people tend to better remember the cyclic position, and as such expedites the selection process (Callahan, Hopkins, Weiser, & Shneiderman, 1988). Hence, we see ourselves confronted with two different demands: on the one hand, the aim of using pen-based input devices in order to present information to the students, while on the other hand, the need to rely on traditional, mouse-based input in order to interact with the ICT and to operate the respective programs. To avoid the unfavorable switching between different devices, we propose a new interaction mode purely based on pen input and the notion of digital ink described in the following sections.

Digital Ink. Motivated by the treatment of handwriting as a “first-class” data type, we introduce the notion of digital ink, which is used not only to enter and represent contents, but also to operate the ICT via gesture commands. A gesture command is the resultant process of invoking gesture-like movements with the pen, that resemble special shapes drawn in a certain distinctive way, recognized by the program as certain predefined instructions for it to carry out. The digital ink derives its name from the data class that represents any kind of information created when using a digital pen to draw strokes on a screen of a pen-based input device. While the strokes received on the pen-computer’s surface get recorded as digital ink, its consequential markings are reflected noticeably onto the screen simultaneously. Any digital ink that was written is either kept in its raw form or goes through a process that translates it into recognizable texts or graphic objects. Often, in many pen-based applications, the ink goes further to be tried as a possible pen-gesture. In this case, when the ink is confirmed to be a gesture command, its visual trace on the screen is removed upon the execution of the respective gesture command.

Digital ink in its raw representation as processed by the respective hardware and software holds far greater amounts of information than are immediately apparent. These include, among others, the type of pen tip, the amount of pressure used to create a stroke, the height of the pen above the screen surface, opacity value, color, and timing data. As a result, the digital ink is acknowledged in serious enterprises such as one for secure handwritten signatures (Cyber SIGN, Inc., 2005; Gries, 2000; Hangai, Yamanaka, & Hamamoto, 2000), as well as in everyday norms of handwriting e-mail messages (Pen&Internet® LLC, 2005), sketching design posters (Corel™, 2005), and annotating digital documents (GRAHL...
As more electronic devices with pen interfaces continue to become available for entering and manipulating information, efforts have been made to ensure that supporting pen-applications are effective at leveraging this method of input. Handwriting is an input modality that is very familiar for most people since everyone learns to write in school. So, there is a high tendency for people to use this mode of input and control not only in the classroom scenario described previously, but for a great variety of different applications as well.

**Ink traces and symbolic representation.** The domain of the digital ink is unlike any others, such as text and graphics, that can have all its related information easily organized and cross-referenced, and be presented in front of users to allow them direct manipulation of the data. A trace refers to a trail of digital ink data made between a successive pair of pen-down and pen-up events representing a sequence of contiguous ink points—the $X$ and $Y$ coordinates of the pen’s position. If the sampling property of the input device is not constant, it becomes advantageous to include timestamps for each pair of the sampled coordinates. A sequence of traces symbolically accumulates to meaningful graphics, forming what we humans perceive as characters, words, drawings, or gestures representing commands. Each trace can be categorized in terms of the timings noted for its duration, lead, and lag times.

The importance of digital ink has also been recognized by the Internet community, leading to the specification of the World Wide Web Consortium’s Ink-Markup-Language (InkML) standard (Russel, Chee, Seni, Yaeger, Tremblay, Franke, Madhvanath, & Froumentin, 2004). InkML allows the description of precise digital ink information that is not only interchangeable between systems, but also allows the convenient “archival” and “streaming” of ink data between applications. Among many of its properties, it is important to note that:

- InkML provides a common format for the exchange of ink data between components such as handwriting and gesture recognizers, signature verifiers, and ink-aware modules;
- InkML supports the representation of hand-drawn ink with full attributed information, on top of capturing the pen positions over time;
- InkML allows the specification of extra information for additional accuracy such as pen tilt and pen tip force (pressure) for the enhanced support of applications such as character and handwriting-style recognition, and authentication;
- InkML provides the means for extension—by allowing application-specific information to be added to the ink files to support issues of compatibility.

**Active digital ink in recordings and replay.** One of the advantages of the usage of ICT in classrooms is the possibility to record and archive the live event for further usage and studying. Today, numerous systems exist for automatic lecture recording that automatically turn the live event into a multimedia document. These files are used, for example, by students to reflect a lecture. Others use them to deepen their understanding of particular topics. They can even be used as the core for building Web-based online courses.

Independent of the respective application scenario, the studies mentioned previously (Mukhopadhyay & Smith, 1999; Zupancic & Horz, 2002) highlight the importance of the development of thoughts through freehand writings. They also confirm the evidence that simply capturing the static end-result of the lecturer’s annotations for recalling the subject at a later time is inferior to unambiguously maintaining the whole sequence and dynamics of those freehand annotations when recorded for interactive replay.

As a consequence, user interfaces that allow replaying of real-time multimedia documents...
usually include command buttons to quickly “fast-forward” and “rewind” their data sets for systematic browsing. We see this very often in many learning applications that try to cater to both students and teachers in assisting them to effectively retrieve desired segments of those documents. Random access navigation, that is, the ability to access any position along the time-line by using, for example, a slider interface, provides an additional advantage on top of this simple fast-forward and rewinding of real-time information. It gives users the ability to straight away focus on the intended portions of their documents without having to wait a second longer for these processes to arrive at the stipulated point of time, albeit the processes being a little faster than the normal replay mechanism. Hence, users should be able to navigate through digital ink recordings along the timeline. However, realizing such a random visible scrolling is a challenging task.

Summary. In this section, we introduced digital ink as a notion to describe pen-based input, which is used not only to model chalk or markers in the digital world, but also to interpret particular ink traces, which are the building blocks of digital ink, as gesture commands. In such a setup, we need sophisticated techniques, not only to represent, process, and manipulate traces of ink, but also to store, access, and replay them. The ability for random access navigation poses a particular challenge in this context.

In the following section, we first describe aspects about the personalization, archival, and streaming of digital ink. Subsequently, we introduce a new paradigm for interaction with electronic whiteboards via ink traces that are interpreted as gesture commands.

Personalizing Digital Ink for Archival and Streaming

In addressing the proper support interfaces for digital ink mediums that are to be stored and indexed in accessible archives or streamed in broadcast networks, appropriate tools are required for practical personal manipulation of the digital ink within multimedia and multivalent materials (Phelps & Wilensky, 1997). These tools are for the producing, capturing, and replaying of freehand writings, and should therefore contain features deemed to let users feel that their digital handwritings are acceptable substitutes for their normal ones when applied on digital documents. We have identified six main feature-themes that relate to what users perceive in the contents of the formulated digital strokes and what they would expect when interfacing with them. These feature-themes refer to the personal flavor, manipulation in pixels, manipulation by objects, compactness of representation and scalability, replay and synchronization, and facilities for random-access.

1. Personal flavor: Every individual person has a unique and particular writing style. This is portrayed in the calligraphic output characteristics from their written works. A handwriting tool needs to allow the expression of this style, as accurately as possible. The recording samples and the replay stream of this tool should maintain all these personal calligraphic attributes. Various pen tip styles, such as coarse whiteboard marker-pens or fine pencil leads, and pressure-sensitive information should be supported during both recording (creation) and replay. Note that most currently available digital ink software offered in presentation tools is either nothing more than fixed-size pixel-traces on screen, or does not support the capture and replay of traces in a manner that maintains the dynamics of the generation process. That being mentioned, users should also expect simple anti-aliasing techniques on the interface tool to improve the stroke appearance of the traces rendered on screen (Klassen, 1991).

2. Manipulation in pixels: Removing traces, or parts of it, and inserting empty spaces
on the grid-like digital screens are typical examples of pixel-oriented operations.

3. **Manipulation in objects:** Generating or selecting whole objects, stretching, contracting, reflecting, pivoting, copying, and pasting are typical examples of object-oriented operations applied to trace-objects. Arguably, the typical editing commands in modern graphics tools (insert, copy, paste, and the like), however, may also be considered as pixel-based operations.

4. **Compactness of representation and scalability:** Extensive writing ultimately generates large volumes of data if the complete transcript of the raw digital ink is stored in an uncompressed form. Inevitably, eliminating any superfluous information will be a reasonable course of action. One way to ensure that the integrity of the data remains intact would be to try and symbolically represent the handwritten letters/alphabets as spline-curves that are independent of the screen resolution. That is, scaling such spline-curve-writings up or down would preserve and not deteriorate the rendering quality of the letters/alphabets during replay of the recorded traces.

5. **Replay and synchronization:** At this point, it should now be possible to replay all recorded handwritings in their best quality, the same way as they were first recorded/presented. Here, both the inter- and the intra-stream time constraints should be observed, such that the full dynamics of the generation process of handwritings are maintained in exactly the same way as they appeared at generation time. Furthermore, the interface must allow all (time-stamped) data streams to be synchronized with other recorded data streams, particularly with the audio stream of the lecturer’s voice. The latter is usually considered to be the *master* stream in a master-slave synchronization model for replay (Müller & Ottmann, 2000), whereas the recorded ink traces are considered as the *slave* stream that is synchronously replayed with the master stream.

6. **Facilities for random-access:** Easy navigation, particularly “random visible scrolling” (cf. previous) through a recorded document, requires random real-time access to the entire data collection. Metaphorically, this ideology resembles the thumb-flipping of a book. Given an instance of time, the complete list of objects visible at this time instance must be made available for display almost “immediately.” That is, it should be possible to compute and display all of these objects fast enough, so that the user gets the impression of immediacy, as opposed to making the user wait due to latency issues.

Table 1 summarizes the following discussion about how current enterprise tools fulfill these six requirements.

The Web tool **riteMail** (Pen&Internet® LLC, 2005) allows for handwritten messages in an interactive, electronic ink e-mail application. Users can create high resolution, fully interactive handwritten notes and drawings on hand-held devices, Tablet PCs, as well as on every Java-enabled desktop or laptop computer. The notes can then be sent to any e-mail address. The riteMail software employs unified Extensible Markup Language (XML)-based protocols for digital ink transmission between all components of the service. However, a replay facility is not included within (and, in order to be fair, not essential for its purpose).

**Corel Grafigo™** (Corel™, 2005) targets pen-computers and is designed specially for the Windows XP Tablet PC Edition. It supports pressure-sensitive pens, allows the marking up of documents and images individually, and provides the features of shape recognition, and gesture-based commands. Data are saved in SVG format.
Painter™ Classic, marketed by Corel (Wacom, 2005), is an excellent paint program for graphic designers that simulates the various graphic markers and coloured pencils and pens, as well as water color and oil paints. As an image-editing program, it offers numerous high performance functions (edged and smooth drawing, distorting, cloning, etc.).

The AOF-tools and their commercial spin-off, Lecturnity (imc AG, 2003), fulfill many of the interface requirements discussed in the previous section, except that they do not fully preserve and regurgitate their user’s personal style of writing. Moreover, the data volume on recorded documents with extensive handwritings is intolerable. The reason is its highly redundant storage method; for while Lecturnity offers a real-time random access facility during replay, it also computes the entire list of visible objects on the screen for every single time instance.

Using Digital Ink on Electronic Whiteboards

In the preceding discussion about input devices we already described different usage scenarios of electronic whiteboards in a ubiquitous computing classroom. Now we take a closer look at the actual applications running on those devices, how people are operating them, and what kind of interaction takes place.

Instructors and students in class do not only see the prepared course materials projected onto the electronic whiteboards, but also the “active” annotations made by the instructors using the digital pens as the lessons progress. Combined with dedicated software applications, the supporting whiteboard technologies can be made to function more effectively with better pen control, and appropriately displaying both static and moving images at suitable resolutions. Among other things, these applications generally offer:

- “Flipchart” capabilities to save and print images as well as annotated ink-trace markings;
- A “blackboard” to manipulate primitive handwritten text and drawings;
- Integrated slides and blackboard “environment”;  
- “Movie screens” to showcase video and software demonstrations;
- “Tools” to facilitate discussions and group work; and
- Access to the network, where shared teaching resources may be available.

More importantly, the way the electronic whiteboards are utilized will shape the kind of impact they will have on the overall learning environment. The basic guidelines highlighted by Glover and Miller (2001) for good practices and outcomes of engaging classroom interaction and participation with the electronic whiteboards across the curriculum are:

- To increase efficiency by enabling teachers to draw upon a variety of ICT-based resources without disruption or loss of space;
- To extend learning by using more engaging materials to explain concepts; and
- To transform learning by creating new learning styles stimulated by interaction with the electronic whiteboards.

All of the previously mentioned technological and social benefits have positive indications from the wider observational point of view. Nevertheless, there are also subtle cases that can make instructors hesitant to change their pedagogy to incorporate the electronic whiteboards into their lesson plans, if practical considerations hinder their perspectives. We already pointed out that it requires effort in commitment to develop media-enhanced teaching contents for the electronic whiteboards, which could be considerably taxing on the teachers’ initial workload. Also, according to the studies compiled by BECTA (2003), while the act of teaching with electronic whiteboards instills anxiety in the students to learn, it unduly places the pressure onto the teachers when it comes to delivering the contents. This is especially true if the writing environment of the electronic whiteboards is not sufficiently supported with the necessary interfacing tools. We have thoroughly discussed this in the preceding sections.

Good electronic whiteboard contents are generally those that can display themselves immediately in highly visual terms, which can be most effectively understood by a group of individuals (BECTA, 2003; Clyde, 2004). The ability to easily modify and change these content materials is all about the personalization of the electronic whiteboard environment. In relation to this, and in order to achieve good content presentation, there needs to be good software applications to manage and control the content data with enhanced features and functions. Currently, makers of the electronic whiteboards ship out accompanying software that is embedded into their systems for use in classroom environments. Examples include those that are listed on Smart Technologies Inc.’s Web site such as notebook whiteboarding software and SMART Board tools. These intuitive programs support numerous operations that are categorized into many menu items under several options that teachers can use while delivering their lessons. So much so, that they tend to become more of a distraction to the teachers rather than an assistance to them in front of a live audience.

Writing and “feeling in control” of the board environment. Now, we are particularly interested in the part where the previous support interfacing software allows teachers to write on the electronic whiteboard freely as if it were a normal blackboard. The situation described previously may not necessarily pose as a problem if the screen-size of the electronic whiteboard is small. However, when these programs are maximized to full screen, then teachers will bump into the problem of “hand-and-eye coordination.” This is a cross between uncomfortable peripheral views for the eyes, and awkward bodily positions to access the menus without disturbing the flow of the lesson, or blocking the audience. This problem for a single large screen worsens when we cascade the electronic boards in the learning environment in series next to each other as described in one of the previous case studies (cf. Figure 5).

Without investing in additional tracking devices such as motion-detectors or cameras, the large interconnected, high-resolution, wall-mounted, multiple displays are by themselves receptively sensitive to the teachers’ touch. Properly configured, this electronic whiteboard
environment offers an extended desktop metaphor quite unlike the ones that we presently know and have grown used to. Further incorporating the pen-input technology into this setup accords teachers a higher level of personal presentiment than a conventional monitor, in a way that it allows them to directly touch the active-screens and see immediate reactions through the digital pens. The electronic whiteboards are meant to be an active presentation medium for a congregation of audience in a large room. While there is always a desktop console that controls the electronic whiteboards, through the mouse and keyboard, freeing up this mode of interfacing lets teachers communicate directly with the screen using just a digital pen.

Judging by the dominant metaphor that what we have today is a mismatch for the computer environment we are dealing with tomorrow, it is difficult to place this huge screen scenario (alone) into any pronounced categories of user interface debates on concepts of adaptivity and adaptability (Shneiderman & Maes, 1997). For instance, the sphere of influence of the hand-and-eye coordination needs to be enlarged, and perhaps include the body, to follow the claims of direct manipulation of adaptable interfaces. Furthermore, while the audience have it easy watching from a distance, the teacher does not: standing so close to one part of the multiple huge screens often leads to the interface widgets he or she may require to be out of reach, or worse still, because the teacher cannot see those widgets, he or she may assume that such actions or commands represented by those widgets do not exist within the board application. We point out here that this may affect the flow of the delivery of the lesson contents. In this case, we may be left to rely on the adaptivity of the interface for the electronic whiteboards to proactively assist the instructor while at the same time ensuring that they still feel in control of the whole process.

**Interacting with Electronic Whiteboards Through Gestures**

In order to solve the problems previously described, we now describe an interaction concept that realizes a modeless interactivity by deriving gestures from digital ink traces. We define *modeless interactivity* for the digital ink environment on the electronic whiteboards as the seamless integration of both the “writing” and “gesture-command” modes on a common, unified platform. On top of this, they further encompass the conventional on-screen widgets such as the fixed pull-down and pop-up menus as “interaction modes” that can be minimized on their usage or done away with completely when not needed in the most cumbersome of circumstances. They go by the notion that instructors should not always need to go between different sections of the boards in order to effect a menu action.

*Deriving gestures from digital ink traces.* It is possible to convincingly anticipate, based on the lead and lag times obtained, that the latest ink component is more of an instance of a trace, rather than a gesture. Advanced recognition techniques have been introduced to the digital ink domain, and while a number of works have gone into handwriting and sketch recognition (Rubin, 1991), there are among these works that use the same techniques to attempt to recognize hand-drawn pen gestures.

Hence, the “writing” mode as well as the “gesture” mode can help out with the current interface issues. “Gesturing to the system” refers to the actual gesticulated actions resulting from the pen movements that represent a command, and not merely the “tap-and-drag-the-icon” movements. The prospects of gesturing commands in ink-domain applications are encouraging. So much so that many authors think that this is the epitome of the final interface for pen-based applications. Although it is agreeable to a certain extent, that this mode of ubiquitous interfacing may form the fundamentals of future (more enhanced) hardware
devices, we should not anticipate this to be the trend in this current context. The perceptual user interface (PUI) guidelines should be adopted and used to create the first steps of the bridging between fully packed screens of user interface widgets to that of a ubiquitous one (Shneiderman & Maes, 1997).

**Deriving interfaces from gestures.** For the same technique that a right-mouse-click can bring up a popup menu on documents that contain menu-items “generally” related to the application it serves, pen gestures have the relative capability to have this metaphor extended. They make it possible to provide more “specific” menu-commands that are currently in context. By this, we mean the placing of directed (or pointedly explicit) “context-specific” menu-items that should obviously take precedence on the front-most tier of the multi-cascading popup interface by virtue of what is currently being displayed on screen. The rest of the more “general” menu-items, however, are neatly tucked away in the lower-priority cascades to ensure that they are still accessible, as is required by the specifications of perceptual user interfaces. For example, right-clicking anywhere on a Word document (or most Windows applications for that matter) brings up menu-items generally affiliated to the Edit-menu on the application’s main menu-bar. The advantage here is that users do not have to skit their mouse over a distance to access the main menus. This same advantage is magnified many times over when working in front of a series of large wall-mounted, hi-res digital screens where the pen is the primary input modal.

The extension we mentioned previously for this technique will involve additional information we can gather from the background environment, and is designed mainly for the convenience of the wall-mounted SMART electronic board users. We discussed this thoroughly in our previous work that deals with digital whiteboard-applications for classroom scenarios, where the sole objective is to assist lecturers in delivering their lessons comfortably and not worry about the support technology.

We incorporated an active program module called the Context-Assembler, running in the background of the main program application, that keeps track of all “items” that are visible on the digital board’s writing area. These include all digital ink-entities that constitute drawings, writings, illustrations, and so forth, and other screen-related widgets like images, fonts, and the writing canvas itself. These “items” are ordered and cross-referenced with each other in an efficient way in the Context-Assembler to give optimal background support information known as “context-information.” That is, if we ask the Context-Assembler about one particular trace that we wrote earlier on the writing canvas, it will tell us when and where the trace was created and located, which other “items” are its immediate neighbors, which are the other items’ it is overlapping with, which group(s) of “paragraph” it is connected to, the probability of the trace being a gesture, and all other “items” that are similar to it in terms of appearance, size, color, and style. Based on this context-information that can be retrieved off any “items” in the Context-Assembler, we designed a “context-oriented” popup menu interface.

The mechanism that determines what menu-items receive higher priorities over others, in order to appear on the front-most tier of the cascading popup menu interface, is an application-defined mapping function that uses the context-information as its input parameters. For example, in Figure 7, the latest ink-element is queried for its context-information. Among other things, the Context-Assembler replies by telling that the ink-element in question is on top of another ink-element created at time \( (t-m) \), is on top of an image known as “slide p28,” is on top of the writing area known as “p9,” stretches horizontally across these three previous “items”—from left to right—and has a very high probability of being a “right-arrow” gesture. Putting these into the mapping function returns a list of thematically categorized menu-items that interprets the last ink-element as a command gesture. The top few
Figure 7. The latest ink-element in (a) is interpreted as a gesture that can have several interpretations. The current context of the board (writing area p9, slide p28, and ink@time(t-m)) is determined and assembled appropriately in (b). The output of the mapping function is then rendered onto the screen as support interface on-demand (c).

high-priority menu-items in the list will suggest that the command gesture advance to the next “slide,” or to the next “page,” or to next “slide” and “page,” or to move the overlapped ink-elements identified in the context-information to a new location.

To complete the visualization of the on-demand assistance, we bank-in on the last known coordinate position of that ink-element in-context. Popping up dynamic-content pie menus and/or other static command buttons, with respect to the list of menu-items returned by the mapping function, in that vicinity seems most appropriate and serves as a convenience to the user. As said before, pie menus proved an advantage for users of digital screens as earlier research pointed out (Callahan et al., 1988). Our command button (toolbar) interface is logged to the bottom of the screens, appearing on-demand with only an array of anticipated widgets. The combined lengths of the number of widgets will not exceed the arm length of the user’s to ensure that all widgets are within reach and within the user’s line of sight.

CONCLUSION AND FUTURE TRENDS

Freehand writing is a natural way of exchanging viewpoints and communicating visual ideas between teachers and students in a classroom. Motivated by this, we identified the value of pen-based computing for the usage of ICT in classroom teaching. By presenting an historical overview of the usage of pen-based input devices in classrooms and lecture halls and two case studies with currently available technology, we demonstrated that today’s hardware equipment can be used to greatly improve the teaching experience. Using them, we are able to build a ubiquitous computing environ-
Human Computer Interaction for Computer-Based Classroom Teaching

ment in the classroom that offers teachers full interaction with the respective technology using a pen while at the same time not interfering with the interaction between teacher and students.

As a trend of moving toward natural environments in the digital world, such a setup encourages freehand writings to become the bridging tool that encompasses portable and synchronizable standards of manipulating ink data between mediums and documents. Hence, we introduced the digital ink as a new “first-class” data type serving two purposes, first, the representation and preservation of information through freehand writing and annotations on the board. In this context we discussed issues about the personalization of digital ink as well as its archival, later access and streaming replay. Subsequently, we described the second purpose of digital ink—the operation and control of the classroom’s ICT via pen-gestures. By interpreting ink traces as gestures, users can interact with the ubiquitous computing environment in a more interactive and intuitive way than with regular interface designs using traditional graphical user interfaces developed and optimized for desktop computing. This has also been proven to be the case for multi-user interaction on the horizontal table-interface: (cf. Figure 8) recognizing a gesture in its respective interpretation also tells us the side of the table it originated from, thus simultaneously identifying the user seated at that corner without having to install additional sensing devices.

For the future, we expect further improvements in the respective hardware and the development of new devices that might further improve the usage of ICT in the classroom. Although current devices and hardware configurations provide a real alternative to the traditional blackboard and overhead projector equipment, as we described in the hardware-related part of this chapter, there is always room for improvement in terms of size, quality, and production costs. At the same time, new technology keeps evolving. Interesting developments with great potential for classroom usage include, for example, the so called electronic paper/electronic ink approaches (see Jacobson, Comiskey, Anderson, & Hasan, 2005 and Xerox Parc, 2005).

Wireless networks are more and more installed at universities, and although not directly related to input devices, this infrastructure will have great influence on the ICT usage in classrooms and thus on the HCI. For example, it is not clear how to seamlessly integrate different devices with different sizes into the overall communication and learning process. Lecturers write on large electronic whiteboards, while students connect mobile devices, such as laptops, Tablet PCs, or even very small PDAs and SmartPhones, to the wireless LAN. How to represent and exchange information between such devices that differ in size and processing power is an open research problem (MacIntyre & Feiner, 1996) where convincing solutions are still missing.

In addition, there exists an obvious trend toward computer-supported group work in classrooms. Instead of purely instructional presentations and lectures, which have been the focus of this chapter, other ways of teaching, such as seminars and group work, can benefit from the usage of ICT as well. Important research in this area has been done, for example, by the Interactive Workspaces Project at Stanford University (Johanson, Fox, & Winograd, 2002). In our own research lab, we are currently exploiting the usage of an “interactive table” where a data projector is mounted on the ceiling, projecting the content of a computer screen onto a horizontally mounted electronic whiteboard (cp. Figure 8). While the respective hardware to build such a table is already available, many open questions and problems remain regarding the design of the software side of the user interface, such as dealing with different orientations when people sit on different sides of the table, enabling people to reach remote objects on the virtual table’s surface (i.e. the projected computer screen), and so forth. Such horizontally mounted interactive computing systems are an ac-
Human Computer Interaction for Computer-Based Classroom Teaching

NOTE

Some of the notions for tools and devices described in this article are registered Trademarks of the respective companies or organizations. We kindly ask the reader to refer to the given references. All features and characteristics of these systems have been described to the best of our knowledge. However, we do like to mention that specific characteristics and technical specification frequently change, and therefore discrepancies between the descriptions in this article and the actual systems are possible.

Chapter 4.3
Wikis as an Exemplary Model of Open Source Learning

Robert Fitzgerald
University of Canberra, Australia

ABSTRACT

In their simplest form, Wikis are Web pages that allow people to collaboratively create and edit documents online. Key principles of simplicity, robustness, and accessibility underlie the wiki publication system. It is the open and free spirit of Wikis fundamental to open source software (OSS) that offers new contexts for learning and knowledge creation with technology. This chapter will briefly consider the role of technology in learning before discussing Wikis and their development. The emerging literature on the application of Wikis to education will be reviewed and discussed. It will be argued that Wikis embody an exemplary model of open source learning that has the potential to transform the use of information communication technologies in education.

INTRODUCTION

Wikis are an instance of what is known as a read/write technology. They allow groups of users, many of whom are anonymous, to create, view, and edit Web pages. In many cases, these pages are online, but there are instances of Wikis used as personal notebooks (e.g., Tiddlywiki, http://www.tiddlywiki.com/). All wiki systems use a simplified html markup language, but as their use spreads, so does the appeal of more user-friendly java-based WYSIWYG editors. It will be argued that the simplicity, accessibility, and openness of wikis support a model of collaboration and knowledge building that represents an exemplary model of learning with technology. This model is congruent with many of the key principles embodied in free and open source software (FOSS) and sociocultural theories of learning (Lave & Wenger, 1991; Vygotsky, 1978; Wenger, 1998). Many Internet-based communities and groups are already finding ways to embrace these forms of learning as a part of their ongoing process of community capacity building. In contrast, formal places of learning such as schools and universities have been slow to explore the potential of this technology. This chapter will briefly consider the role of technology in learning before discussing Wikis and their development. The chapter argues that FOSS and Wikis in particular offer education
far more than just low-cost software or even sound principles of practice; they open up a space for new models of learning and knowledge creation with technology. The emerging literature on the application of Wikis to education will be reviewed before considering Wikis as an exemplary model of open source learning.

TECHNOLOGY AND LEARNING

While the application of computing technology to teaching and learning has at least a 30-year history, there is a large body of literature that suggests education is still struggling to use technology effectively (Cuban, 2001; Healy, 1998; Oppenheimer, 2003; Postman, 1993; Stoll, 1999). Results from large international studies show that the dominant use of technology tends to focus on skills and involves learners as content users and not content creators (Kozma, 2003). Part of the problem is that formal places of learning by their very nature are highly structured contexts. The role of context is important because there is a direct relationship between form and quality of the pedagogy and the form and quality of the resultant learning. Different teaching approaches and learning contexts result in different outcomes for students. In Boaler’s (1997) study of mathematics classrooms, she showed that teacher-centered and rule-based teaching approaches not only produce low levels of student engagement but work to effectively limit the scope of the learning outcomes. There is a strong suggestion from her work that routine-style classrooms generate routine knowledge and that this is neither of the quality nor quantity required for real-world mathematical problem solving. Her key finding is that context matters. The Russian neuropsychologist Alexandra Luria understood this relationship well when he argued that cognition is a function of context. “Cognitive processes … are not independent and unchanging ‘abilities’ … they are processes occurring in concrete, practical activities and are formed within the limits of this activity” (Luria, 1971, p. 266). In effect, Luria was saying that cognition is plastic, a finding that has subsequently been confirmed by contemporary neuroscience (Goldberg, 1990, 2001). The activities and tasks we set for learners not only determine the type and quality of knowledge that is produced but, more importantly, set the parameters for the development of their cognitive processes. Therefore, from a philosophical and practical design point of view, the contexts or settings of learning should be as open and free as possible.

There is also a growing body of literature suggesting that young people learn in different ways to past students and, therefore, require (and even demand) different teaching approaches (Gee, 2003; Oblinger, 2004; Prensky, 2001). Chris Dede (2005) has written extensively in this area, and in his assessment, these learners seek to co-design their learning experiences and prefer communal learning over individual learning. Anyone who has recently studied in schools or universities will know that despite institutional rhetoric to the contrary, these new modes of teaching and learning are not widespread. The pedagogical challenge is to use technology in ways that build upon learners’ existing experiences and foster the creation of what von Krogh, Ichijo, and Nonaka (2000) refer to as communities of knowledge. In education, there is widespread recognition of the need to explore more collaborative approaches to learning (Jonassen, Peck & Wilson, 1999; Kozma, 2003; Laurillard, 2002; Sefton-Green, 2004; Somekh, 2004). Wikis offer one such tool, which is already a part of many learners’ everyday lives as are a wide variety of other social software such as blogs and social networking applications like MySpace (http://www.myspace.com/).

BACKGROUND TO WIKIS

The founding developer of the World Wide Web (WWW), Sir Tim Berners Lee, first conceived of
the Internet as a way for people to both read and write data. The reality of nonintuitive operating systems, html-based coding, clunky file transfer tools, and security restrictions guaranteed that while we could all read the Web, very few of us were able to easily write and publish material. To address some of these issues, Ward Cunningham developed the first Web-based Wiki (http://en.wikipedia.org/wiki/WikiWikiWeb) in 1995 as part of the Portland Pattern Repository (PPR). The origin of wikis, however, goes back much earlier to the 1980s and Cunningham’s work on hypertext using Hypercard™ (eWEEK, 2006). In his original formulation (see Table 1), Cunningham developed wiki software to adhere to a number of core design principles (http://c2.com/cgi/wiki?WikiDesignPrinciples).

These basic principles result in a Web publication system that is simple, robust, and accessible. The system is designed to position users differently from traditional publishing models—from a Web reader to a Web author. This can be seen particularly in the universal principle in which any writer is automatically both a space organizer and an editor.

**FREE AND OPEN LEARNING**

Free and open are key principles underpinning FOSS. This chapter argues that these also underpin learning with Wiki technology. For a piece of software to be open source, it must also adhere to four freedoms summarized in Table 2 (http://www.gnu.org/philosophy/free-sw.html).

While these freedoms relate to OSS, they are enacted within a community of software developers in which community learning and knowledge construction is central. In this sense, open can be used to refer to something that is visible and without barriers. In relation to FOSS, it also refers to a principle of practice that embodies an attitude of generosity. This is perhaps best thought about in terms of an individual (or group) that makes himself or herself available to others and is free and willing to think about new ideas. The notions of free and open have much to offer our conceptions of learning and the underpinning processes of collaboration and knowledge construction with Wikis.

**Table 1. Wiki core design principles**

<table>
<thead>

</table>
EXAMPLES OF WIKI PROJECTS

The use of Wikis had a significant development when Jim Wales launched Wikipedia (http://en.wikipedia.org) and the Wikimedia Foundation (http://wikimediafoundation.org) in 2001. For the first time, this project made Wiki technology and tools freely and readily available to the public while also offering a series of projects to which they could contribute. The most recognized Wiki is the free-content encyclopedia Wikipedia (http://en.wikipedia.org/wiki/), which is maintained by a group of volunteers from around the world and is generally regarded as a rich information resource (LeLoup & Ponerio, 2006; Lih, 2004).

Jim Wales explained:

Wikimedia’s mission is to give the world’s knowledge to every single person on the planet in their own language. As part of that mission, Wikipedia is first and foremost an effort to create and distribute a free encyclopedia of the highest possible quality. Asking whether the community comes before or after this goal is really asking the wrong question: the entire purpose of the community is this goal. (Wales, 2005)

Wikipedia currently comprises 1,315,437 English language articles and nearly two million registered accounts (http://en.wikipedia.org/wiki/Special:Statistics). Roughly 25% of these articles have been translated into other languages (nine at last count). Since July 2002, Wikipedians have made more than 70 million edits. Web traffic statistics rank Wikipedia as the 17th most popular Web site (out of 250 million) on the Internet with more than 2.9 billion page views in the month of August 2006 (http://www.alexa.com). Currently there is a number of related Wikimedia Foundation projects that are in development, including Wikipedia (http://www.wikipedia.org/); Wiktionary (http://wiktionary.org/); Wikibooks; Wikinews (http://www.wikinews.org/); Wikiquote (http://www/wikiquote.org/); Wikicommmons (http://commons.wikimedia.org); Wikisource (http://wikisource.org/); Wikispecies (http://species.wikimedia.org) and the soon to be officially established Wikiversity (http://en.wikibooks.org/wiki/Wikiversity). Each of these projects takes the basic wiki model and extends it into a specific area with a specific goal. For example, Wikibooks (http://en.wikibooks.org) is a project designed to produce open-content textbook modules to create global curricula. To date 21,019 book modules have been developed for more than 1,000 books. Some of these books are available in PDF format.

The large-scale application of wikis to community knowledge building can also be seen in Wikia (http://www.wikia.com) and Wikispaces (http://www.wikispaces.com/). The aim of these initiatives is to provide individuals and communities with a Web site they can use to create open content around their areas of interest. For example, establishing a Wikia site requires the topic to appeal to a large number of people and

<table>
<thead>
<tr>

<tr>
<td>3</td>
<td>The freedom to improve the program, and release your improvements to the public, so that the whole community benefits. Access to the source code is a precondition for this</td>
</tr>
</tbody>
</table>
that its content will have some longevity. Computer game players have been particularly active, creating communities around their games. One example of how this is used can be seen in the ways that players of the massively multiplayer online game Runescape (http://www.runescape.com/) have built encyclopedic knowledge about all aspects of the game (http://www.wikia.com/wiki/Runescape).

**LITERATURE REVIEW ON WIKIS**

Many of the applications of Wikis are entirely congruent with the so-called Web2.0 and social software models that attempt to offer simple and robust technologies to non-expert users so they are able to create content and build communities. The last few years have seen a proliferation of simple tools for authoring Web content, particularly in the area of personal blogging. Wikis are still without peer when it comes to the large-scale collaborative authoring of Web content (Lamb, 2004; Wagner, 2004). A literature based on the application of Wikis is beginning to emerge, although to date it is primarily conceptual and descriptive. Generally, there is widespread agreement that Wikis represent an innovative and potentially powerful tool for collaborative content creation and sharing (Lamb, 2004; Wagner, 2004). There have been few studies that have tested empirical propositions, although many of these have been exploratory in nature.

Wikis have been studied in language learning (Godwin-Jones, 2003; LeLoup & Ponerio, 2006; Wang et al., 2005; Wei et al., 2005) as tools in higher education (Augar, Raitman, & Zhou, 2004; Bold, 2006) to promote forms of participatory journalism (Lih, 2004), as a tool for story-telling in primary schools (Désilets & Paquet, 2005), and examined for their potential role in increasing citizen participation in e-government initiatives (Wagner, Cheung, & Ip, 2006).

In summary, the empirical work finds the following:

- The effective use of Wikis appears dependent on a clear goal matched to a group of committed uses (Godwin-Jones, 2003).
- Highly structured environments that rely on top-down approaches (as opposed to bottom-up) limit the potential of Wikis as a tool for learning (Engstrom & Jewett, 2005; Wagner, 2004).
- Wikis such as Wikipedia are a rich source of information that can promote content creation, sharing, and discussion (LeLoup & Ponerio, 2006, Lih, 2004).
- It is important to augment students, Wiki work with strategies to promote deep and critical thinking to ensure high quality work emerges (Engstrom & Jewett, 2005).
- Wikis support a short edit-review cycle that ensures the rapid development of content (Lih, 2004).
- Employing the user as organizer and editor (many “eyeballs”) is a highly effective strategy for ensuring quality (Lih, 2004).

There have been widespread calls for more research on Wikis (Lih, 2004; Wagner, 2004; Wei et al., 2005). It will be particularly important to develop research methods that are sensitive to both the quality of content produced in concert with how this content emerges within a community of learners. There is encouraging work on the development of metrics to assess the quality of Wiki (see Wikipedia) articles based on edit histories (Lih, 2004), but we also need to examine and assess the quality of the articles. Wiki edits are easily quantified, but what they relate to is not always clear. For example, a recent study found an inverse relationship between the quantity of Wiki edits and final exam scores (Wang et al., 2005). The authors advised caution against interpreting these findings as evidence that wikis are counter-productive to learning, but it does highlight the
need for more nuanced and in-depth empirical studies on Wikis.

Wikis have generated considerable interest in education because they appear to support more collaborative models of teaching and learning. It is fair to say that there is considerable anecdotal evidence that Wikis can and should play a key role in e-learning in support of a more conversational and dialogic approach to knowledge creation and sharing.

AN EXEMPLARY MODEL OF OPEN SOURCE LEARNING

Wikis offer a different model of creating, editing, and sharing knowledge that is consistent with the educational push toward what have become known as sociocultural or constructivist approaches to learning. A founding thinker in these areas, Lev Vygotsky (1978), contended that learners neither receive knowledge nor simply discover it. They learn in social contexts in interaction with both humans and tools. A key concept for Vygotsky was the zone of proximal development (ZPD) in which he said all learning takes place. In Vygotsky’s basic model, it is adults who scaffold young learners, helping to extend their thinking and learning. However, as the technological tools develop and evolve, we are beginning to see ways that both humans and their tools can scaffold learning. The technological spaces that make up wikis enable new forms of sociotechnological ZPDs that support both individual and community knowledge creation.

This focus on community and the power of joint construction is taken up in The Wisdom of Crowds (Surowiecki, 2004). Surowiecki argues that the collective knowledge of large groups is often unrecognized and almost always undervalued by society. He explains that many everyday activities, from voting in elections and the operation of the stock market to the way Google locates Web pages, depend on the collective input and knowledge of large groups. Of course, not all crowds are smart, but Surowiecki believes that under the right conditions, crowds can act more wisely than an expert individual. To achieve the best results, crowds must be able to support diversity of opinion, relative independence in an individual’s thinking, a model of decentralization that allows individuals to draw on their local knowledge and aggregation; that is, embody a process whereby individual knowledge can be combined into an integrative whole. The ways technology might be used to support the development of smart crowds is a relatively unexplored area; however, applications such as Wikis, blogs, and multiplayer games certainly show how large groups of people can productively interact online. While there is a huge qualitative difference between group interaction and wisdom, there is a relationship to be explored that highlights the importance of developing large-scale social technologies such as Wikis.

The previous discussion suggested that collaborative knowledge creation should be an important feature of formal learning; however, to date, and particularly with reference to the use of technology, it has not been. Some of the uses of technology by young people in their everyday lives seem to get closer to this goal. The way they work in their communities around multiplayer games to talk to each other and build knowledge is one example. The next section considers the potential that Wikis offer to achieve this goal.

One of the strengths of Wiki software is its capability to document and record aspects of the knowledge creation process. From an educational point of view, this can provide valuable insights to the knowledge construction process. In most Wikis, an article features a number of views: the article page, a discussion page, article editor, and history. A rich edit history features full revision history permitting comparison between current and last entry. Edits can further be identified via flags and commenting, helping others understand the changes that have been made. To help assure quality, edits also appear on a recent-changes page.
Rules can be set up to show pages that have been changed since the last visit. A list of contributions by users offers various analyses, often with full history and comparison tools. In combination, these tools open up the possibility of exploring the relationship (and tension) between individual and group constructions.

Surowiecki said:

*Any “crowd”—whether it be a market, a corporation, or an intelligence agency—needs to find the right balance between the two imperatives: making individual knowledge globally and collectively useful (as we know it can be), while still allowing it to remain resolutely specific and local. (Surowiecki, 2004, p. 140)*

Wikis allow both individual contributions and the evolving group product to sit alongside each other. The examples of Wikis outlined here seem able to create new forms of sociotechnological ZPDs for learners. These zones support both individual and community knowledge creation in ways that are consistent with the notion of communities of practice (Lave & Wenger, 1991; Wenger, 1998).

Wikis appear well suited to building knowledge in which the representation of balanced opinion is valued. While there is no guarantee that this prevents wikiwars, it does seem that strong opinion is better suited to other spaces such as blogs. It is clear from the work of the Wikimedia Foundation that there are no hard and fast rules to using Wikis. What is apparent, though, is that many of the more successful projects embody a spirit of community characterized by openness and freedom.

**CONCLUSION**

In the end, the success of innovations in learning such as Wikis will be seen in the increased capacity of individuals and their communities to create and apply new knowledge. Incorporating tools that not only facilitate but also document the effective management of information and creation of knowledge is now essential for an innovative and productive 21st-century society. Wikis are significant and innovative because they attempt to position learners as knowledge creators rather than simply content users. They also represent the application of new collaborative technologies in ways that are free and open. In terms of education, the Wiki model locates the challenge of improving information, data management, and knowledge creation processes within a community model. It also builds on strategies for increasing the capacity of all community members to expand their ways of thinking creatively and working collaboratively.

A key feature of this approach is that knowledge and practice are shared in a spirit of generosity. The extensive use of Wikis in education begs the question: Are we really prepared to engage in this form of open source learning?

Wagner, C. (2004). Wiki: A technology for con-
versational knowledge management and group collaboration. *Communications of the Association for Information Systems*, 13, 265-289.

**KEY TERMS**

**Constructivist:** An approach based on the work of Lev Vygotsky, who contended that learners neither receive knowledge nor simply discover it. They learn in social contexts in interaction with both humans and tools.

**Free and Open Source Software (FOSS):** A term first described by Richard Stallman referring to a software development process in which the software source code is made freely available for subsequent modification and development.

**Hypercard:** A hypermedia program developed by Apple Computer in the 1980s.

**Open Source Learning:** A model of learning inspired by the key principles or freedoms embodied in the FOSS movement.

**Web2.0:** A term coined by Tim O’Reilly (http://tim.oreilly.com/) referring to a range of second-generation Web publishing and social networking technologies.

**Wiki:** A form of read/write technology that allows groups of users, many of whom are anonymous, to create, view, and edit Web pages.

**Wikia:** A project to provide communities with Wiki-type Web sites (see http://www.wikia.com).

**Wikimedia Foundation:** An international nonprofit organization run by Jim Wales, using wiki technology to promote free and open large-scale collaborative content creation projects (http://wikimediafoundation.org).

**Wikipedia:** A free-content encyclopedia (http://en.wikipedia.org/wiki/).

**Zone of Proximal Development (ZPD):** The difference between what learners can do by themselves and with the assistance of more capable adults or peers.

ABSTRACT

Over the past 15 years a considerable amount of research has been devoted to study of the socioeconomic aspects that affect the use of technology in the mathematics classroom. With the call for curricular and instructional reform, educational institutions have embarked on the process to reform their educational practices to aid the urban student in their quest to obtain quality mathematics and science based education with the integration of technology. The study performed was to reexamine the socioeconomic disparities in the mathematics classroom as it relates to implementing technology interventions to support quality teaching and active student learning. This article is to provide empirical evidence of whether these disparities continue to exist and their effects on student achievement in the mathematics classroom. The results of this study showed an overall positive relationship regarding the use of technology interventions within the mathematics classroom with levels of student achievement,
showing a clear signs of continued disparities within mathematics classroom.

INTRODUCTION

The introduction of microcomputers into classrooms during the 1980's was heralded by many as the dawn of a new era in American education. Proponents argued that technology had the potential to fundamentally transform the nature of teaching and learning (Papert, 1980; U.S. Congress, Office of Technology Assessment, 1988). However, over time, it has become apparent that it is far easier to acquire hardware, software, and Internet access (Becker, 1991; Dividing Lines, 2001) than it is to capture the potential of technology in significantly meaningful outcomes (Cuban, 2001). Likewise, educators concerned about the chronic underachievement of students often fall prey to the allure of technology as a tool for reversing the historical influences of poverty, discrimination, inequity, chronic underachievement, and lack of opportunity. However, 25 years after the introduction of the computer into the classroom, many of the expectations associated with technology in education remain unrealized to some but to other, technology has proven to be an effective tool in the efforts to provide students with opportunities for quality teaching and active student learning and engagement.

Educational institutions have called for instructional and curriculum reform that includes active engagement of students, quality assessments, and the increased and innovative use of technology applications to promote quality teaching and active student learning (U.S. Department of Education, 2001). This is true in the field of mathematics where organizations such as the National Council of Teachers of Mathematics (1989, 2000), Mathematical Science Board (MSEB, 1991), and Mathematics Association of America (1991) have stressed that technology is essential in teaching and learning mathematics. The underlying assumption of these organizations and math educators alike is that technology will enable students to explore mathematics with a greater depth and will allow them to study topics that were previously impractical (Garofalo, Drier, Harper, Timmerman, & Shockey, 2000). However, in order for technology to have greatest impact on our educational system, all students must have access to technology. For that reason technology has the potential to narrow the achievement gap, if equally distributed or widen the gap if only accessible to selected groups in the educational system (Kulik, 2002; Waxman, Connell, & Gray, 2002).

REVIEW OF LITERATURE

Over the past 15 years a considerable amount of research has been devoted to sociocultural disparity in technology availability and use in the mathematics (Becker, 2000; Garofalo et al., 2000; Means et al., 2001; Manoucherhri, 1999; National Center for Educational Statistics, 2004; Owens, 1993; Owens & Waxman, 1994, 1995; U.S. Department of Education, 2001; Huang & Waxman, 1996). Past studies conducted by Becker (2001) and Coley, Cradler, and Engel (1997) found students from higher income families have been found to use computers in school and in their homes more frequently than students from lower-income families. Students of color from urban schools have also been found to have less access to computers compared to Anglo-suburban students (Owens & Waxman, 1993, 1994). More recently, lower SES schools are only half as likely to have high speed Internet compared to high SES schools (Advanced Telecommunications, 1997). Consistent with this idea of access are the issues within the digital divide itself. Within the past decade, a growing body of evidence supports the ever-widening technological gap among members of society, in particular children and the elderly (NTIA, 1995, 1997, 1999), with a important emphasis on urban...
schools with the inner cities. The groups identified who lack access to information and technological resources include people of color, specifically African American and Hispanic Americans, those who are poor and of the working class, individuals of low-income, those who possess less than a high school level of education, children of single parents, and residents of inner-cities (NTIA, 1995, 1997, 1999, 2002, 2004). Access is key in this issue.

Despite the constraints on school funding in most states, schools have devoted an increasing percentage of their annual budgets to technology. The majority of the efforts of the educational community over the past decade to acquire hardware, software, and Internet access have been successful (Dividing Lines, 2001; Education Week, 2004). However, clear evidence of a digital divide, parallel to historical disparities, continues to distinguish urban schools from their affluent counterparts (Chen & Thielemann, 2001; Guttentag & Eilers, 2004; National Center for Education Statistics, 2004). Historical measures of digital equity have been based on the ratio of the number of computers divided by the number of students. A more recent measure involves determining levels of Internet access. Another dimension of this problem relates to questions about differences in home access to technology, therefore impacting urban student achievement.

A second source of disparity in technology use is how technology is used. Previous studies conducted by Becker (2001) and Finneran (2000) found that low SES schools are more likely to use technology for drill and practice, whereas high SES school uses technology in innovative teaching strategies. This idea is consistent with the ideas of curriculum reform and reconceptualization put forth by Pinar (2002). Pinar (2002) suggests that the instruments of computer technology are used to drill and kill students into passing standardized test, not actually being integrated effectively into classroom instruction or pedagogical practice that promote quality teaching and active student learning. He further explains that the current use of computer technology in urban schools generally serve to turn its users (students) into disembodied and alienated subjects. Furthermore, as explained in Becker (2001) high SES students are more likely to use technology for school assignment, use e-mails, and use educational programs.

Finally, educational reform programs such as the No Child Left Behind Act of 2001 has focused on accountability and high-stakes testing. The renewed importance of test scores will fundamentally alter the attention and activities of low-achieving schools as they seek to achieve the required benchmark scores (Johnson, 2002). As a result, it was anticipated that previous technology buying sprees will be redirected. One approach to this redirection is that there is new emphasis placed on technology initiatives that enhance schools’ assessment and early intervention efforts (Education Week, 2003) that feature learning activities with instructional objectives and record keeping.

A third source of disparity in technology use deals with the nature of technology adoption and organizational change. A thorough analysis of major research related to technology and teacher motivation, adoption and usage uncovered important factors that are involved in determining their willingness to use such approaches in the teaching and learning process (Braak, 2001; Chiero, 1997; Fabry & Higgs, 1997; Solomon & Wiederhorn, 2000). The literature indicates that teacher’s willingness to adopt and implement learning technologies for the teaching and learning process varies, but all share the same denominator—proper internal and external motivation (Braak, 2001; Chiero, 1997; Fabry & Higgs, 1997; Mooji & Smoot, 2001; Solomon & Wiederhorn, 2000). The top reasons teachers choose to use technology for the teaching and learning process dealt with the notion of continuous training and development, proper technology support from technology personnel, encouragement from school administration, and an organizational structure that sup-
ported teachers using technology (Grank, Zhao, & Borman, 2004). While these are the key issues ascertained from the research study, the ideas of change management, technology adoption and innovation, self-efficacy and motivation, support, and the computing experience are relevant to this discussion. The American Council of Education (1999) report noted that the quest to optimize the use of technology in schools could not be fulfilled by the mere supply of more hardware and software. The report suggested that what needs to be addressed first are ways identify, motivate, and equip teachers with the skills necessary for effective use of educational related multimedia technologies in their classroom practices.

In contrast to the indicators that profile the acquisition of technology, less information is typically available to reflect progress toward implementing technology applications that enhance the teaching and learning process (NTIA, 1995, 1997, 1999, 2000, 2002; CEO Forum, 1997). It is rather a task of ease to promote and profile computer-to-student ratios in school reform experiments with little regard to how technology is used in the urban classroom (Brainbridge, Lasley, & Sundre, 2004; Guttentag & Eilers, 2004). The use of technology in the classroom has moved through definable periods involving programming, computer-assisted instruction, problem-solving environments, personal productivity, Web-based instruction, and hypermedia. Problems associated with limited opportunities for teacher professional development to learn about new innovations (Lonergan, 2001), as well as limited funds for new hardware and software, often result in the routine use of student learning activities that have been abandoned by high-performing schools (Burnett, 1994). As a result, it is essential that questions be raised about the nature of technology learning activities in urban schools when expectations are held that technology is used to enhance academic achievement. While looking into the use of technology in the urban school environment, it has been noted that the use of these tools does not reflect innovative uses in integration into the curriculum for active student learning, engagement or to enhance the teaching process. Typically urban schools have antiquated resources and in adequate technological support for the use of technology in classroom.

Although these studies have established a pattern for technology disparities in the past, most of these studies rely on data collected in the mid to late 1990’s. Moreover, the last national report on the status of technology use entitled “Teachers’ Tools for the 21st Century: A Report on Teachers’ Use of Technology” was published in 2000, however, it used data from the 1999 FRSS survey (National Center for Educational Statistics, 1999). Therefore, updated studies are needed that examine current data to determine where we are in the quest to narrow the achievement gap with the aid of technology. The purpose of the present study is to reexamine technology use and to provide evidence of whether or not disparity issues still exist using the latest national survey produced by the National Center for Educational Statistics (2002). Our focus in this report is on the technology practices in the mathematics classroom.

METHODS

The data for the present study was drawn from the base year of the Educational Longitudinal Survey of 2002-2004 (ELS: 02). The ELS:02 is a national survey administered by National Center for Educational Statistics to provide an overall picture of the present educational experience of high school students in the U.S. The survey has four subcomponents completed by students, teachers, parents, and school administrators. The design used to collect the data was a two-stage, stratified national probability sample. The survey included 1,052 public and private school representing about 12,000 students across the country. For the present study, only the student survey data was used.
The student survey provided items used to measure how often technology is being used in mathematics classrooms along with how this technology is being used as reported by students. The items used to measure how often technology is being used in the classroom were the following: (a) how often do you use calculators in your mathematics classroom?; (b) how often do you use graphing calculators in your mathematics classroom?; and (c) how often do you use computers in your mathematics classroom?. The outcome measures for these items were a five-point Likert scale, ranging from “never” to “everyday or almost.”

To measure how technology is being used in mathematics classrooms the following items were used: (a) how often do you use a computer to review your math work in your mathematics classroom?; (b) how often do you use a computer to solve math problems in your mathematics classroom?; (c) how often do you use a computer for graphing of math problems in your mathematics classroom?; (d) how often do you use a computer to practice math drills in your mathematics classroom?; (e) how often do you use a computer to analyze data in your mathematics classroom?; (f) how often do you use a computer to apply learning in your mathematics classroom?; (g) how often does your math teacher use a computer for one-on-one instructions in your mathematics classroom?; and (h) how often does your math teacher use computer to show new topics in your mathematics classroom?. The outcome measures for these items were also a five-point Likert scale, ranging from “never” to “everyday or almost”. The survey also provided a measure of student’s socioeconomic status. This measure was developed as a composite variable constructed from five equally weighted, standardized components: father’s education, mother’s education, family income, father’s occupation, and mother’s occupation. The distribution of these SES values were divided into four quartiles, ranging from lowest to highest. To determine if an association exists between technology use and students’ socioeconomic status a Pearson’s chi-square was used.

RESULTS

Table 1 reports the results of the frequency of calculator and computer use in mathematics classrooms. The results indicated that students are using more calculators in their math classrooms compared to computers. 58% of the students reported that they had used calculators every day in their math classroom compared to 8% that indicated they were using computers on a daily basis. 30% of the students reported using the graphing calculator on a daily basis. One-third of these students reported they never use the graphing calculator in their classroom. 61% of the students indicated they never use computers in their math classroom. Finally, 7.4% indicated they were using computers on a daily basis.

Table 2, compares calculator and computer use across socioeconomic levels. The results indicate that a significant association (p<.001) exists between calculator use and socioeconomic levels. In this case, the lowest SES group reported using calculators on a daily basis the least. On the other hand students in the highest SES group reported using calculators on a daily basis more often. 48% of the lowest SES group reported using calculators compared to about twice as many students (68%) classified in the highest SES group. There was also a significant association (p < .001) between daily use of graphing calculators and SES group membership. 21% of the students classified in the lowest SES reported using the graphing calculator on a daily basis compared to about twice as many students (42%) classified in the highest SES group. The final comparison looked at computer usage across SES levels. The results also indicated a significant association exists (p < .001) between computer usage and SES levels. In this case, students classified in the lowest SES group were more likely to use computers computer compared to those students.
Re-Examining the Socioeconomic Factors Affecting Technology Use in Mathematics Classroom

Table 1. How often technology is being used in mathematics classrooms overall frequency

| N=11,618 | How often do you use calculators in your math class | 6.2 | Never |
| | | 12.0 | Rarely |
| | | 7.7 | Less than once a week |
| | | 18.0 | Once or twice a week |
| | | 58.0 | Everyday or almost |
| | How often do you use graphing calculator in your math class | 33.1 | Never |
| | | 19.6 | Rarely |
| | | 3.3 | Less than once a week |
| | | 2.2 | Once or twice a week |
| | | 8.8 | Everyday or almost |
| | How often do you use computers in your math class | 60.7 | Never |
| | | 2.2 | Rarely |
| | | 7.7 | Less than once a week |
| | | 7.8 | Once or twice a week |
| | | 7.4 | Everyday or almost |

Table 4 compares computer use across socioeconomic levels. The results indicated that the higher computer use was significantly associated with low SES classification. Moreover, as SES Levels increased computer usage decreased. The most frequent use of computers was to solve math problems. The results indicate that about 21% of the low SES students compared to about 10% of the high SES students reported they used computers to solve math problems everyday or almost everyday. Students classified as second and third SES levels reported about 18% and 15% of the times they used computers to solve math problems everyday or almost everyday respectively. The next most frequent use of computers was to apply learning. Students classified as low SES indicated that used computers for this purposes everyday or almost everyday about 18% and 15% of the times they used computers to solve math problems everyday or almost everyday respectively. The next most frequent use of computers was to apply learning. Students classified as low SES indicated that used computers for this purposes everyday or almost everyday about 17% of the times compare to about 9% for the high SES students. The second and third level SES students indicated they used computers everyday or almost everyday to apply learning about 15% and 13% of the times respectively. Similarly, about 17% of the lowest SES group reported using computers to practice math drills compared to about 10% of the high SES students everyday or almost everyday. Furthermore, about 30% of the students reported that they never used the computer for graphing math problems.

Table 3 reports the frequency of how computers are being used in math classrooms. The overall results indicate that the daily use of computers is very low. The highest percentage of daily use for computer use was to solve math problems (16.3%). The next two popular uses for computers in mathematics classrooms on a daily basis were for “to apply learning” and “to practice math drill”. The percentages were 14% and 13% respectively. However, over one-third of the students (34%) reported they never used the computer to practice math drills. The least daily use for computers was to provide “one-on-one instruction”. The reported percentage was 7%. On the other hand, 52% of the students indicated that their teacher never uses the computer for one-on-one instructions. Over 50% of the students reported they never used computers to review math work. Similarly, 52% of the students indicated that their teacher never uses the computer for one-on-one instructions. About 41% of the students indicated that there teacher never uses the computer to show them new topics. Over one-third of the student (35%) reported that they never used the computer to analyze data. Finally, about 30% of the students reported that they never used the computer for graphing math problems.

students reported that they never use computers to review their math work.

Twice as many low SES students reported that their teacher used the computer to provide one-on-one instructions everyday or almost everyday compared to students in the high SES group. The reported percentages for the two levels were 11% and 4% respectively. Additionally, 63% of the high SES students compared to 43% of the low SES students indicated that their teacher never used computers for one-on-one instructions. About 50% of the second and third level SES students indicated that their teacher never used computers for one-on-one instructions. Finally, about 11% of the lowest and second level of SES students reported using computers to analyze data everyday or almost everyday compared to only 5% of the students in the high SES group. About 10% of the third level SES students reported using computers to analyze data everyday or almost everyday.

DISCUSSION

The use of technology in the math and science classroom has been a main focus in improving student learning outcomes. Technology not only can provide visual learning in the classroom, it also opens the door to improve higher level thinking skills. The results of the present study indicate that 10th graders use more calculators on a daily basis compared to computers. Moreover, calculator use far outweighs the use of computers in today’s math curriculum. This is also true for the use of the graphing calculator.

The results of the present study suggests that there are important differences in the use of technology in 10th grade mathematics classrooms associated with levels of SES status. Students from low SES families are less likely to use calculators on a daily basis compared to students from high SES families. This also includes the use of the graphing calculator on a daily basis. Low SES students also reported that they were more likely to use computers on a daily basis compared to high SES students. This may dispel previous findings that low SES students have a less opportunity to use computers compared to high SES students. However, the findings do raise a new issue of disparity in calculator use, which there may be need for further exploration.

Another important finding from this study describes students’ overall use of computers. The results from the present study suggest that overall 10th grade students do not use computers often in their mathematics class. This suggests that schools across the country need to do a much better job in integrating technology in the secondary school curriculum. Depending on its use, technology can be very useful in the mathematics classroom. In fact, operating a computer can be simple compared to designing a scientific experiment and solving challenging math problems, that is, as long as the student and the teacher have the tools. For those who do not use the tools, technology can become a diversion or a simple device for entertainment. Access to technological resources in the classroom is only part of the solution (Feldman, 2001). According to Feldman, research leads us to surmise that teachers who feel more prepared to use technology are more likely to use it in instructional activities (Feldman, 2001). If we want to help students from low SES backgrounds, our emphasis should be on providing nourishing support, specifically, providing well-trained teachers and a rigorous curriculum that integrates the use of technology.

Implementing Technology in Urban Schools

One of the major concerns for urban teachers when integrating educational technology in the classroom is the identification of appropriate principles that help achieve high student learning outcomes. Recent research synthesis efforts by the Center for Applied Research in Educational Technology (2006), the International Society for Technology
in Education (2003), and Roblyer (2006) provide principles for appropriate ways to use education technology in urban schools as supported by the education technology research.

Recent research in educational technology (Boster, Meyer, Roberto, & Inge, 2002; Bracewell & Laferriere, 1996; Coley, Cradler, & Engel, 1997; Cradler & Cradler, 1999; Koedinger & Anderson, 1999; Kulik, 2003; White & Frederiksen, 1998) has shown that the effective use of educational technology occurs when the application directly (a) supports the curriculum objectives being assessed; (b) provides opportunities for student collaboration and project/inquiry based learning; (c) adjusts for student ability and prior experience, and provides feedback to the student and teacher about student performance; (d) is integrated throughout the lesson; (e) provides opportunities for students to design and implement projects that extend the curriculum content being assessed; and (f) is used in environments where the organization leadership supports technological innovation.

Some examples of the strategies that have proved successful in influencing student academic performance include students working in pairs on lessons at the computer assisted instruction through social interactions and teamwork (Bracewell & Laferriere, 1996); digital video clips, audio, and graphics to supplement instruction (Boster, Meyer, Roberto & Inge, 2002); mathematics curricula focusing on mathematical analysis of real-world situations supported by computer assisted instructional software program (Koedinger & Anderson, 1999); multimedia creation involving research skills to locate content resources, capability to apply learning to real world situations, organizational skills, and interest in content (Cradler & Cradler, 1999); software programs that allow students to be aware where they are in the inquiry process and to reflect upon their own and other students’ inquiries (White & Frederiksen, 1998); word processing software that utilizes writing prompts (Kulik, 2003); and online feedback among peers who know one another allows learners to feel more comfortable with and adept at critiquing and editing written work (Coley, Cradler, & Engel, 1997).

CONCLUSION

As educators and educational technology professionals demand for research-based evidence about the effectiveness of specific instructional practices has created renewed interest in educational research (Edyburn, Higgins, & Boone, 2005). As a result, there is an urgent need for research that provides evidence about the effectiveness of various educational technology interventions applied to specific subject domains. This is especially needed in mathematics, where we are still trying to get a handle on the achievement gap of students in urban and suburban communities. Research is a critical piece to the puzzle to fully understanding the impact of technology on student achievement. As a result more research is needed on a large scale that will focus and assess some of the following questions not addressed in the present study:

- What instructional design models will help instructors design effective strategies for student learning success specifically in the mathematics classroom?
- What type of professional development experiences do educators need in order to design successful learning experiences for urban students for mathematics?
- How can educators locate innovative and effective interventions for enabling urban students to achieve high academic standards through the use of educational technology in mathematics?
- What is the impact of race, ethnicity, culture, and language as it relates to the use of technology in urban environments?
- What works, for whom, and which conditions does technology impact student achieve-
Re-Examining the Socioeconomic Factors Affecting Technology Use in Mathematics Classroom

ment in urban environments relating to mathematic instructions?

• What new technologies are needed for routine classroom activities for urban learners?
• How can effective strategies be developed to enhance the teaching and student learning process to reflect active learning in an inquiry/project-based environment?

As we look to the future, technology is often viewed as an enticing means of closing the achievement gap. It is seen as a magic bullet to solve all instructional and learning related issues in an educational environment. However, this is not the reality. Statistics on the digital divide have shown are that the use of technology is often based on simple computer-to-student ratios that have little relevance in describing the quality of the technology experience of the use of the intervention in the classroom. Recent advances in educational technology have the potential to significantly enhance the learning and achievement for all students in the urban environment. However, these contributions hold for diverse urban learners suggests unlimited potential for their application in urban schools. Finally, the current accountability environment demands significant attention to questions of efficacy, which must be addressed in the context of using technology to enhance student achievement.

The current literature has implies that innovative approaches used in teaching with technology leaves students with a more effective learning environment that promotes quality teaching and active student learning. Consequently education planners and policy makers must think beyond providing more hardware, software, and connecting schools to the Internet, but instead thinking about keeping urban schools and teachers well-informed and trained in the effective use of technology for educational purposes. One of these investments is meaningless without the other. High-speed connections, complete digital services, and modern computers are basic to every professional workplace and are essential to student learning in the 21st century. However, technology will fail to meet its educational promise if we neglect to equip teachers with the skills they need to understand and use it and transmit this knowledge and skills to the urban learner.

Adhering to these procedures, educators will be able to grow as practitioners in the field and use educational technology to support quality teaching and active student learning. The research examined in this discussion provides teachers with a relevant framework to understand the factors that affect the urban learner and the power of technology in the teaching and learning process can offer the urban learner, thus leading our educational system to fulfill the promise of providing quality teaching and student learning for a more consistent and dynamic educational learning environment that continues to support the ideals and concepts of the great American education system.

Chapter 4.5
Let Them Blog:
Using Weblogs to Advance Literacy in the
K–12 Classroom

David A. Huffaker
Northwestern University, USA

ABSTRACT

This chapter introduces the use of blogs as an educational technology in the K-12 classroom. It argues that blogs can be used to promote verbal, visual, and digital literacy through storytelling and collaboration, and offers several examples of how educators are already using blogs in school. This chapter also reviews issues such as online privacy and context-setting, and ends with recommendations for educators interested in implementing blogs with current curricula.

INTRODUCTION

As Internet technologies continue to bloom, understanding the behaviors of its users remain paramount for educational settings. For teachers, parents, school administrators, and policymakers, learning what types of activities and applications students are using on the Internet is only the surface. Understanding how they are using these applications can provide innovative strategies for learning environments.

Previously, many scholars have explored how Internet users communicate and present themselves online, using computer-mediated communication venues such as e-mail, chat rooms, instant messaging, newsgroups, multi-user domain (MUDs), and personal home pages to examine communication patterns, online identity construction, and even gender differences (Crystal, 2001; Döring, 2002; Greenfield & Subrahmanyam, 2003; Herring, 2000; Lee, 2003; Turkle, 1995; Witmer & Katzman, 1997).

Internet technologies continue to evolve, and it is important for scholars to examine the latest CMC arenas in comparison with past research in hopes of finding new ways to find creative learning solutions and enhance pedagogical method in educational technology. Weblogs, commonly referred to as blogs, represent one of the latest advances in CMC.

A blog can be simply defined as an online journal. Made up of reversed chronological entries...
infused with text, images, or multimedia, blogs embody a place where individual expression and online community development coexist. Not only do the authors, or bloggers, post thoughts and feelings on a Web page for the world to view, but blog readers can comment, creating a dialogue between the blogger and the community he inhabits. Furthermore, bloggers link to other bloggers, creating an interwoven and perhaps interdependent online community of writers and readers. Blog popularity continues to resonate throughout the media, with many scholars suggesting an evolution in individual self-expression, education and research, online journalism, and knowledge management (Alterman, 2003; Blood, 2003; Herring, Scheidt, Bonus, & Wright, 2004; Lasica, 2003; Moore, 2003; Mortenson & Walker, 2002; Oravec, 2002; Pollard, 2003b; Schroeder, 2003).

In a recent survey, Perseus Development Corporation found that among the four million published Weblogs, almost 53% are created by children and adolescents between ages 13-19 (Henning, 2003). With such a strong population of young bloggers, understanding its potential uses within a classroom remains an exciting prospect for educators and parents. Can blogs be used to enhance learning? In what ways can they be used in the classroom?

This chapter hypothesizes that blogs can be effective educational tools in the following ways: (1) they promote verbal and visual literacy through dialogue and storytelling, (2) they allow opportunities for collaborative learning, and (3) they are accessible and equitable to a variety of age groups and developmental stages in education.

In order to evaluate this hypothesis, this chapter will proceed as follows. First, it will provide a thorough explanation of what blogs are, fundamental blog features, how they are used, and the demographics of the blog population. Second, this chapter will define verbal, visual, and digital literacy, and their importance in learning. Third, it will explain how blogs foster literacy through storytelling and peer collaboration. Fourth, this chapter will describe examples where blogs are used in K-12 classrooms, with an emphasis on the previous concepts of storytelling, peer collaboration, and literacy. Finally, this chapter will provide specific recommendations for educators and school administrators interested in implementing blogs in their schools and classrooms.

WHAT IS A BLOG?

Blogs are personal journals written as a reversed chronological chain of text, images, or multimedia, which can be viewed in a Web page and are made publicly accessible on the Web (Huffaker, 2004a; Winer, 2003). As depicted in Figure 1, blogs typically contain text in the form of a “blog post,” offer the ability for readers to comment or provide feedback, contain archives to past blog posts, and link to other blogs and bloggers.1

Blogs are inherently different from personal home Web pages. First, bloggers post entries through manual software, such as a Web browser, or automatic software, which is downloaded off the Internet and used to instantly publish content to the Web. Therefore, bloggers do not need to understand HTML or other Web programming

---

1. Figure 1. An example blog
Let Them Blog

languages to maintain their blogs. Second, the resulting blog page resembles a personal diary with entries sorted by time and date, a much stricter format than personal Web pages of the past.

Blog Features

David Winer, a fellow at Harvard Law School, considered one of the more visible writers and developers of Weblogs, describes some of the more important features of blogs:

- **Weblog Posts**: Weblog posts include a subject title and a body message. Posts can be relatively short in length such as one or two paragraphs, or they could be a long, thoughtful exposé, encompassing a dozen paragraphs. They can comprise a variety of media objects, including text, pictures, graphics, or multimedia, and even popular file formats such as Microsoft Office documents or Adobe PDFs (Winer, 2003). These posts receive a timestamp to denote time and date of the post. Figure 2 demonstrates the format of a typical blog post.

- **Comments**: Readers of a Weblog have an opportunity to respond to a blog post through a comment or feedback link. These comments create a thread, as many readers can comment on a single post (Winer, 2003). They contain a timestamp and are viewable to the public. Bloggers can also respond back to reader comments. Figure 2 highlights the comment section. Blog readers can click “Post a Comment” to add a new comment or “1 Comment” to read previous ones.

- **Archives**: The front page of a blog contains only a certain amount of posts, sometimes two or three and sometimes twenty. For authors who have maintained their blogs for longer periods of time, they can store past blog posts in an accessible, often searchable archive. As depicted in Figure 3, archives can be organized by month, by week, or even by number of posts.

- **Templates**: Another useful feature for Web authors is a set of presentation tools that allow pages to be built from preexisting templates. Blog authors can choose from a variety of graphical layouts, typography, and color schemes. This allows complete customization and a feeling of personalization for bloggers without any sophisticated technical expertise (Winer, 2003). However, some bloggers like to tinker with a Web programming language, to add third-party applications or other bells-and-whistles to their blogs, and the capability to reprogram a blog is available. Figure 4 represents the types of templates Blogger.com, one of the most popular blog-hosted sites, offers.

Figure 2. Blog post with comment link
What is the Blogosphere?

Although some studies suggest the majority of blogs are still highly personalized venues for self-expression (Herring et al., 2004), many blogs contain links to other bloggers, creating an online community that is often referred to as the blogosphere. These blog communities typically share a common purpose or responsibility (Carl, 2003), for example, a group of friends spread out across the world may use blogs as a means to communicate with each other, or a support group might encourage each other’s therapeutic development, or a group of amateur journalists might be spreading news on situations of political strife or violent conflict in an area that a global news agency may be unaware of.

The blogosphere also represents the total population of bloggers, an Internet culture that is continuing to grow. Several reports and Web sites that gather information on blog statistics, which estimate between two and four million blogs, demonstrate the vastness of the blogosphere; many expect this growth to continue (Henning, 2003; Herring et al., 2004; Kumar, Novak, Raghavan, & Tomkins, 2003). Certainly, the acquisition of population blog software or services within online commercial giants such as AOL, Yahoo, and Google suggest that the world may be on the cusp of a blog saturation in Internet culture (Munarriz, 2003; Olsen, 2004; Shirpy, 2003).
Size of the Blogosphere

Blogs continue to be created and abandoned each day, so the exact population figures on the size of the blog population remains in transit. The population size is captured using software that indexes blogs or comes directly from sites that host blogs such as LiveJournal or Blogger. It must also be considered how many blogs are “active” or updated within the last three months, because many blogs become abandoned (Henning, 2003).

- **Blogcount** (http://dijest.com/bc/), a Web site dedicated to understanding how vast the Weblog community is, collects scholarly and industrial reports that discuss technical and demographic issues, from frequency of blog posts to mapping the blog community. By June 2003, Blogcount estimated there were 2.4 to 2.9 million active Weblogs (Greenspan, 2003).

- **BlogCensus** (http://www.blogcensus.net/) uses a software program to search and locate Weblogs and categorize them by language and authoring tool. As of April 2004, the BlogCensus has indexed 1.83 million blogs and estimates at least 1.21 million of these are active.

- **LiveJournal** (http://www.livejournal.com/) publishes daily statistics direct from its servers, citing that there are over 2.9 million “livejournals,” with 1.4 million active, as of April 2004 (specific data can be found at http://www.livejournal.com/stats/stats.txt).

- **Perseus Development Corporation**, which offers enterprise-level surveys regarding software and technology, recently published a white paper that estimates there are 4.12 million blogs, but at least 2.7 million have been temporarily or permanently abandoned (Henning, 2003).

Age and Gender Demographics of the Blogosphere

Most of these surveys suggest that a significant portion of the total blog population is made up of teenagers, and almost evenly partitioned between genders. The largest age distribution of bloggers typically ranges between 13 and 20, which assumes most bloggers are either in early secondary school or beginning college or university. There are some subtle discrepancies in gender within the studies listed below; however, the margins are not far enough apart to suggest severe differences in gender use of blogs.

- Perseus Development Corporation, for instance, finds blogs are dominated by the youth, with 51.5% of all blogs being developed and maintained by ages 13-19. They also find 56% of the total bloggers are female and 44% are male (Henning, 2003).

- A recent academic study of 203 randomly selected Weblogs revealed 54.2% male authors and 45.8% female authors, as well as 40.4% of blog authors being under age 20 (Herring et al., 2004).

- Another academic study of 358 randomly selected blogs found 52% male and 48% female bloggers, and 39% of bloggers are less than 20 years old. However, they also found there are more females than males in the ‘teen’ category (Herring, Kouper, Scheidt, & Wright, 2004).

- BlogCensus randomly sampled 490,000 blogs to find 39.8% male and 36.3% female, with the rest of the blogs unidentifiable in terms of gender (see http://www.blogcensus.net/weblog/).

- Finally, Jupiter Research found that blogging is split evenly among genders (see http://www.jup.com/bin/home.pl) (Greenspan, 2003).
Let Them Blog

Use of Blogs

Understanding the features of the blogs helps distinguish them from other Internet applications, and grasping the size of the blogosphere signifies the popularity of blogs in Internet culture. The next question involves the content of blogs. What are bloggers writing about? The answer not only provides a context for online community interaction, but possible application for educational technology. These can be divided into five areas: (a) personal blogs, (b) community blogs; (c) journalism blogs; (d) education and research blogs; and (e) knowledge blogs.

Personal Blogs

The most popular use of blogs are similar to personal Web sites authored by individuals, which include chronological posts as well as links to other Web sites or Weblogs (Lamshed, Berry, & Armstrong, 2002). Despite the popular notion that Weblogs lean toward external events, or remain highly interlinked with the blogosphere, the majority of Weblogs are still individualistic self-expressions written by one author (Herring et al., 2004).

Community Blogs

Virtual communities develop through the use of a blog (Lamshed et al., 2002). Examples might include a community support group, a site for parents to ask questions and exchange answers, a research community sharing resources and data, or a mirror of an offline community, like a softball team or neighborhood newsletter. Although personal blogs may dominate the blogosphere, the ability for individuals to choose their level of community participation may be another reason for blog popularity, as it allows the blog author to explore individual needs while benefiting from community interactions (Asyikin, 2003). The linkages with other Web sites, people, and ideas even form micro-communities with varying levels of involvement.

Journalism Blogs

The idea of alternative forms of journalism manifesting through Weblogs has received increasing attention in media and scholarship (Alterman, 2003; Blood, 2003; Lasica, 2003). Where is Raed? (http://dear_raed.blogspot.com), for instance, is a blog by an Iraqi that discusses what is happening in Iraq since September 2003. He discloses a candid view of the U.S. occupation, but also introduces readers to fellow Iraqi bloggers. For most, the global news agency is the only link to international affairs—having personal, subjective commentary within a foreign world provides a unique view to outsiders.

A different, but equally unique log is J-Log, which provides community critiques and commentary on current journalism and news. The community not only shares interesting news items, but also poses questions such as, “Is this news fair and balanced?” Perhaps J-Log (http://www.mallasch.com/journalism/) and individual reports such as Raed demonstrate new forms of online journalism; critiques, however, as to the viability of these news sources remain an issue, including the resources and references and even the subjectivity amidst objective journalistic philosophy.

A link to http://blogdex.net/, an MIT Laboratory experiment that captures the fastest-spreading ideas in the blog community, typically results in news headlines as the most contagious information.

Education and Research Blogs

Blogs have been heralded as opportunities to promote literacy in learning by allowing students to publish their own writing, whether it is a journal or story, or even comments on class readings (Kennedy, 2003). For more advanced students,
blogs present the same opportunities: writing and thinking with Weblogs, archiving and analyzing past knowledge, and developing a social network to collaborate and critique (Mortenson & Walker, 2002).

Blogs allow educators and students to interact in the same common space and format (Wrede, 2003). Lamshed et al. (2002) find that students believe blogs are easy to use and navigate, and enthusiastic about learning features such as storing and managing information, communicating, reviewing work before posting, and “keeping on track,” which refers to managing time or monitoring progress (Lamshed et al., 2002). If students are eager to adopt blogs in the classroom, teachers may have an opportunity to also keep on track with students, as communication and interactions are visible and accessible anytime-anywhere.

Several sites explore the use of blogs in education. Weblogg-Ed (http://www.weblogg-ed.com/), maintained by Will Richardson, collects ideas about Weblogging in school settings and facilitates dialogue between teachers. Similarly, Edublog (http://edublog.com/) is an initiative to develop and study blog-based tools for the classroom.

Knowledge Blogs

Similar to education and research, blogs provide opportunities for organizations to manage and share content, as well as communicate across the network. Dave Pollard, Chief Knowledge Officer at Ernst and Young, Inc. and popular writer on the role of blogs in the business, suggests that blogs can be used to store and codify knowledge into a virtual file cabinet. But unlike other content management tools, blogs allow authors to publish in a personal and voluntary way, creating a democratic, peer-to-peer network (Pollard, 2003b). Pollard also suggests companies can increase profitability by designing information architecture to embrace the use of Weblogs (Pollard, 2003a, 2003c).

VERBAL, VISUAL, AND DIGITAL LITERACY

Literacy has always been a focus of learning, especially considering that the foundations of education are grounded in reading and writing. In fact, reading and writing, often referred to as verbal literacy, serves as a benchmark for success in education. Reading and writing are not only important in language arts or humanities; they serve as prerequisites for all academic disciplines, including science and mathematics (Cassell, 2004). Verbal literacy is developed even before children enter school as parents read stories to their children, helping them to understand the relationship between words and pictures, as well as helping to develop narrative structure (Bransford, Brown, & Cocking, 1999; Huffaker, 2004b).

Scholars have recognized how communication also takes place in the form of images and symbols, what is referred to as visual literacy (Gee, 2003). As James Paul Glee (2003) suggests, texts are becoming increasingly multimodal, containing both text and images, and can be recognized in everything from the advertisement to the high school textbook (Gee, 2003). Our society is filled with these multimodal symbols, and their coherence is intrinsic for operating in the modern world. Therefore, reading and writing should not only include words but also images, and the development of both verbal and visual literacy is essential for success inside and outside school walls.

The use of technology represents a third type of literacy, equally ubiquitous and important as the other forms. Digital literacy, sometimes referred to as technological fluency, embodies the idea of using technology comfortably, as one would a natural language (Cavallo, 2000). As users of computers and other digital technology become more fluent, they learn to communicate and express themselves explicitly and eloquently using these tools; in effect, technology becomes innate. Furthermore, just as reading and writing are widely hailed as the building blocks for success
in society, digital literacy becomes necessary for success in the technological world we inhabit.

This is what makes educational technology so exciting—it encourages and advances all three types of literacy: verbal; visual; and digital. Blogs, for example, utilize both textual reading and writing, but also involve the use of graphics in the forms of emoticons, or graphical expressions of emotions, images, and multimedia. Blogs also encourage digital literacy, which is grasped from navigating a graphical user interface, and using computers and the Internet in order to publish content.

Some CMC contexts such as e-mail and instant messaging often utilize short pieces of dialog, informal language, and even altered words from spoken language (Crystal, 2001). Educators might complain that using these forms in a classroom might reduce literacy skills, as language development is often paired with precision and formality. Blogs might combat this issue, as its medium involves longer written passages and can be contextualized by educators to promote formal language skills.

### STORYTELLING AND COLLABORATION

Storytelling is a natural part of adolescent development, and children understand the fundamentals of storytelling in their first three years of life (Bransford et al., 1999). Even as a baby, a parent introduces the child to storytelling via bedtime readings or oral tales. By the time a child reaches age four, he can recall many types of stories, whether fictional or autobiographical (Bransford et al., 1999). The stories develop into more mature narrative as the child gets older, thus storytelling provides a way for children’s language and reading skills to develop (Bransford et al., 1999).

Children advance literacy skills through the practice of telling stories to adults and peers alike (Ryokai, Vaucelle, & Cassell, 2003). With adults, children advance language skills because their partners have even more advanced language skills, and children will adapt (Ryokai et al., 2003; Vygotsky, 1980). With peers of similar age groups, children feel more comfortable to collaborate, and enjoy learning together and building on each other’s knowledge (Ryokai et al., 2003). Because peer relations remain quite important to children (Bullock, 1998), effective group dynamics and learning also results in pro-social behavior through a sense of ownership, compromise, and shared responsibility (Calvert, 1999).

Storytelling does not end in childhood, but continues throughout adolescence and even adulthood. Stories help children and adults alike share experiences and feelings in an engaging and even entertaining way (Denning, 2001). From simple sandbox sketches to dinner party yarns, the importance of stories as a catalyst for conversation and dialogue is clear. Furthermore, storytelling helps create connections between people, to engage people, to captivate them. This captivation occurs on both ends—it is just as fun for the teller of the story as the listener. Storytelling fused with peer collaboration is an excellent way to improve language abilities and advance literacy for children and adolescents (Ryokai et al., 2003).

Blogs have the potential to foster both storytelling and collaboration. First, blogs serve as a natural venue for personalized self-expressions. Like diary entries, blogs take form as stories, anecdotes, or vignettes, similar to the types of oral and written stories people encounter everyday. This includes past and present activities, feelings about oneself or other people, or even hyperbolic or fictitious tales.

Secondly, blogs have technical features that offer the potential to create a dialogue between blog author and blog reader, whether it is a reader response, a question-and-answer sequence, or even general brainstorming. In some cases, blog authors discuss candid feelings and readers respond with encouraging statements, providing therapeutic connections. These comments form
a chain between the author and readers, and in essence, an online community. Communities are also built as bloggers link to each other, creating a group of storytellers that provide individualistic expressions, as well as interactions with each other.

EXAMPLES OF BLOGS IN PRACTICE

Blogs are just beginning to infiltrate classrooms, as educators and school administrators consider blogs as a useful tool for communicating between teachers, schools, students, and parents, and as a way to showcase the work of students (Richardson, 2004). These practices are celebrated on the Internet through communities of educators interested in blogging and education. Will Richardson’s “Weblogg-ed: Using Weblogs and RSS in Education” Web site (http://www.weblogg-ed.com/), for instance, is a useful source of information. His site focuses on best practices, offers a quick start guide for teachers, and links to other bloggers concerned with blogs in education. “Edblogger Praxis” (http://educational.blogs.com/edbloggerpraxis/) is another important Web site which unites educators who blog about their experiences or pedagogical philosophies.

This section will look at examples of blogs in practice, separating them into high school (grades 9-12), elementary and middle schools (grades 4-8), and primary school (grades K-3) in order to contextualize blog use by age and developmental stage, and to provide useful models for educators and school administrators interested in viewing how blogs work at different levels of the school system.

High School Blogs

Will Richardson is a teacher and Supervisor of Instructional Technology and Communications at Hunterdon Central Regional High School in Flemington, New Jersey. He not only initiates school-wide policies for blog use in the classroom, but has found success in using blogs for his own literature and journalism classes. In the literature class, students use blogs to comment and critique on reading assignments. In the journalism class, the students collect news stories to post in their blogs; they also comment on each other’s stories while serving in an editorial role. Therefore, in language arts classes, blogs can be used to generate a discussion using critical analysis, or as a collaborative tool where students comment and edit each other’s work. For Richardson, blogs help students become more aware of their writing, as well as their audience (Kennedy, 2003). Figure 5 represents how blogs can be contextualized to provide assignments for students and allow sections for critique and reflection. Each student has an individual blog, which is linked to a homepage where the teacher assigns work and posts relevant news and other information.

Blogs also help create a community of practice among participating students. They can collaborate with each other and build knowledge. These types of discussions, where ideas are synthesized and news ideas created, may be intrinsic to building critical thinking skills. They may also feel that they are “part of a team,” and that each individual has a responsibility to contribute in order to achieve success for the group. Again, effective group behavior involves shared ownership, compromise, and responsibility, which creates pro-social conduct (Calvert, 1999).

Blogs are accessible to the general public, and Richardson found an important side effect as students began blogging. When the class discussed a new novel, the author of the book accessed the blog and posted an impressive response to the questions students were asking (Richardson, 2004). This may have a profound affect on how students view their own work. For instance, this may give students the impression that their ideas and discussion are important in the real world, providing a sense of empowerment and self-ef-
ficacy. Literature and journalism classes and experts are not the only beneficiaries; political leaders, scientists, artists, and philosophers can also directly participate in an educational blog, making students feel their academic work remains valuable, an important consideration for motivating children to learn.

**Elementary and Middle School Blogs**

Blogs can be utilized in many of the same ways in other grade levels. The Institut St-Joseph in Quebec City, Canada, for instance, uses blogs among fifth and sixth graders in order to practice reading and writing. Implemented by the school principal, Mario Asselin, Institut St-Joseph bloggers use a software program to write about anything and everything that is school related. Similar to Richardson’s realization, the fact that blog posts are being read by anyone in the world has an acute effect on students. They felt empowered as their blogs received comments from total strangers and even Canadian celebrities (Asselin, 2004). Similar to Will Richardson’s work, Figure 6 portrays a homepage blog where projects are assigned and school- or project-related links are provided. Students can comment on homework assignments to the entire class, and still post to their own blog space.

At first, some parents and other readers complained that the language of the student blogs was too informal to be considered good writing, and even contained misspelling and grammar errors. Critics complained that blogs were teaching improper language skills, so Asselin (2004) discussed these challenges with the students. The students came up with a system where each blog post would be reviewed by students and a graphic would be posted alongside the text, which served as a stamp of approval. Suddenly, student writing improved dramatically, as no student wanted mistakes after insisting their quality of writing was excellent (Asselin, 2004).

Similarly, Anne Davis’ *Newsquest* involves fourth through sixth graders who practice writing by commenting on news and events. Students felt that blogging helped them write better stories, extend their vocabulary, and even feel ‘grown up’ knowing their voice is on the Internet. After a period of working with blogs, these students
began to collaborate with Will Richardson’s high school journalists, forming the “Georgia-NJ Connection” blog. Now, older journalists and younger journalists can share ideas, comments, and critiques. Again, this resonates with Vygotsky’s notions that children will adapt to more advanced language skills observed in adults (Ryokai et al., 2003; Vygotsky, 1980). Figure 7 demonstrates how blog information can be scaled down to reach a younger audience.

**Primary School**

Mrs. Dudiak, who teaches second grade at Oakdale Elementary School in Maryland, uses blogs to create writing assignments for her students. She might use a picture such as a waterfall and ask students to write a description, a story, or poetry. She also asks them to discuss favorite books, what ‘types’ of books and stories they like, as well as depictions of books into a “movie in our head,” students reply in the comment section of the blog. This is an excellent example of how blogs can be placed in specific contexts to meet the goals of classroom curriculum. Figure 8 exemplifies how blogs can be simplified to reach even the youngest students. Changing colors, enlarging texts, and contextualizing material to reach the needs of primary students represent easy changes for educators to make.

Lewis Elementary School in Portland, Oregon, uses a blog to showcase K-5 student work, as well as to post important information and news for parents. For instance, photo galleries of artwork are displayed alongside weekly classroom notes from each teacher. This demonstrates how blogs cannot only be effective in practicing and advancing writing and language skills, but also in communicating between teachers, students, and parents. Blogs may give parents more direct exposure to their children’s school life, and thus more opportunities to have an impact on their children’s learning. Little Miami Schools (http://www.littlemiamschools.com) in Morrow, Ohio, also uses a blog to communicate school goals and news, as well as spotlighting the successes of its students and teachers.

In sum, blogs can be used at a variety of age and grade levels to promote reading and writing skills, as well as to provide communication links between students, parents, teachers, and schools. Students can use blogs on their own,
finding stories or news they find interesting, as demonstrated with the classes of Mr. Richardson and Mr. Asselin, or they can have specific assignments designed by the teacher, as seen in the case of Mrs. Dudiak’s class. Furthermore, schools can use blogs to bridge the links between students, teachers, and parents, making demonstration of work and student progress available, as well as school news and schedules. Figure 9 demonstrates how blogs can be used as a central communication hub for teachers, schools, parents, and students to share information.

The next section will address some of the issues and considerations for educators interested in implementing blogs in their schools and classrooms.

**ISSUES AND CONSIDERATIONS**

**School- and District-Wide Considerations**

This chapter has mainly approached blog implementation from the educator perspective. However, it is important to examine the schools and districts that encompass the individual classroom. Not only do school and district administrators remain an intrinsic part to choosing educational technology initiatives, but their choices can have a positive or negative effect on how these choices become applied. For instance, schools and districts have to work within a budget when making choices for technology. Second, they have to choose which hardware and software standards will be equitable across the community. Finally, they have to implement technology within certain ethical, legal, and security issues.

For each of these considerations, blogs still stand as a viable solution. First, most blog software is free and open-sourced, so administrators can host blogs within local technology infrastructure. Second, blogs are delivered via the Web, so standards have already been established—blogs can be implemented anywhere a computer and Internet accessibility is present. Finally, blogs have the option of being available to the public or of being private, an important consideration that will be discussed in the next section.
In sum, the importance of school- and district-wide influence on educational technology implementation cannot be ignored. However, for the same reasons blogs can be a useful tool and practical solution for educators; administrators should also be impressed.

**Issues of Online Privacy**

A key concern for any educator and school system involves student privacy. Cyberstalking or sexual predation is a serious concern for adolescents using the Internet (Earley, 1999; Gilbert, 1995). Many of the blog hosts offer free Web space available to the public on the Internet; information on a blog is publicly accessible. If the content of blogs or identities of students need to remain anonymous or private to the world, blog software and hosts offer other options.

For instance, free blog-hosts such as LiveJournal offer a “Friend’s Only” option, which involves a username and password for entrance. For even more security, blog software such as Moveable-Type, which can be implemented on local school
Web servers, can remain completely in-house, that is, no one outside of school or classroom computers would even have access to the blogs.

While privacy is an important consideration for educators and school administrators, the counter-argument to keeping blogs private would be that making blogs available to the world might generate feedback that will empower bloggers and further develop communication and collaboration. For example, if a classroom is discussing a science project and a professional scientist participates in the discussion, it would add significant value to the learning experience.

Setting Context

One of the primary challenges for using blogs, as with many technologies, in the classroom is the importance of setting a context for learning to occur. While discovery and creativity does abound when adolescents are allowed freedom to explore these CMC venues, some structure needs to be in place to facilitate a learning outcome. For instance, if writing quality is a concern for a teacher, then contextualizing the language to focus on clear and succinct writing skills is a must. Similarly, students have to be encouraged to use the blog on a steady basis and focus on the classroom material.

In sum, contextualizing blogs to the learning experience will serve to produce more exciting and educational blog experiences in the classroom, experiences that parents, administrators, and students alike can observe and reflect upon.

The next section will provide some recommendations for educators interested in implementing blogs in the classroom to promote literacy and learning.

RECOMMENDATIONS

Use free blog software for easy implementation in the classroom. There are several popular Web sites that provide templates, maintenance, and hosting of blogs. Using free blog software makes it an easier decision for educators and school administrators concerned with school budgets and technology requirements. With a computer and an Internet connection, blogs can be set up in minutes. For educators who want to keep blogs inaccessible to the public, most blog hosts offer the opportunity to password-protect blogs. The most popular blog-hosts are:

- **LiveJournal**: [http://www.livejournal.com](http://www.livejournal.com)
- **BlogSpot**: [http://www.blogspot.com](http://www.blogspot.com)
- **Xanga**: [http://www.xanga.com](http://www.xanga.com)
- **MoveableType**: [http://www.moveabletype.org](http://www.moveabletype.org)
- **T-Blog**: [http://www.tblog.com](http://www.tblog.com)

For those who want to implement the blogs on local school servers, there are open source applications such as MoveableType and phpBB which can be altered and used in any expected capacity, although they have technical requirements (documentation are available on these sites).

Open-source applications such as MoveableType and phpBB allow complete customization of the interface and blog application. So educators should feel that blogs can be completely tailored to suit the needs of students and the affordances and constraints of school district policy. The examples of blogs used in this chapter are presented to demonstrate current applications and serve as a baseline for new ideas and implementation. Educators should feel complete flexibility in redesigning blog software for learning experiences.

Fuse emergent learning with curriculum-based assignments. If given the opportunity, students might begin to navigate their own learning paths, a feature that is recommended by the new science of learning as directed by the U.S. National Research Council (Huffaker & Calvert, 2003). Surely, letting students do as they want with blogs will reveal some interesting trends that could be manipulated into important learning
opportunities. However, it may be a better idea to create a hybrid form where students construct their own learning, as well as assignments that teachers feel aid the curriculum. Therefore, students have some flexibility in exploring the medium of blogs, while teachers provide direction and structure in the educational practice.

**Encourage collaboration.** Blogs have great potential as a collaborative environment. As students read and write, they may comment and critique each other’s work. They may even edit each other’s work. Assignments can be created where students have to work as a team to complete the goals, such as a story “train,” or chain of story parts devised by individual students, or literature critiques of different parts of a book, or even a mix of different perceptions on the same experience.

**Develop a system for rating student work before it is published.** One way to maintain the caliber of writing that is expected in formal writing is to create a way to ‘proof’ student work before it goes into the public. Most blogs contain a preview area before publication takes place. The teacher does not necessarily need to be the final editor—students can edit each other’s work and provide the final stamp of approval before the world sees the writing. This may be more difficult at early ages, but the metaphor provides accountability for students, which the Institut St-Joseph found dramatically improved writing quality (Asselin, 2004).

**Create interactions between students and the outside world.** One way to make students feel their work is valuable is to demonstrate how their words are being read outside the classroom. For instance, if parents or even total strangers provide feedback on student work, children and adolescents might become more aware of their writing, as well as their audience (Richardson, 2004). Perhaps even more empowering are experts such as authors, poets, artists, scientists, engineers, or other professionals who may comment on student work or add to the discussion. These linkages are not only useful for learning and achievement, but are not difficult tasks to achieve when using blogs, especially considering their accessibility by the public sphere.

**Link with other educational blogs.** As exemplified in the Georgia-NJ Connection, students using blogs may connect with other classrooms despite geographic constraints, in order to expand the community of practice. Even regardless of age, students can share with other students, providing an online learning community that may become self-motivating and self-sustaining. Blogs provide an easy way to do this with built-in options for linking to other blog communities.

**Get parents involved in reading and participating with blogs.** As previously mentioned, getting parents to provide feedback to student work might be an excellent way for students to feel their work is valuable and even appreciated. Yet this has a two-fold benefit—parents may feel they have more exposure to, and thus more interaction with, their children’s learning. Therefore, both students and parents benefit.

Furthermore, blogs can provide links between schools, classrooms, teachers, students, and parents. Parents who visit a classroom blog may encounter the latest third-grade arts and crafts, see the latest school news, or see what is on for lunch that day. This helps bridge communication between all parties responsible for educating children and adolescents.

Creating linkages between all the classrooms in the school creates an interwoven community where everyone feels connected and accessible. This community of practice may have a paramount effect on increasing the efficiency and success of learning in K-12 educational settings.

**CONCLUSION**

This chapter has sought to demonstrate how blogs can be a useful tool for promoting literacy in the K-12 classroom. Literacy most noticeably takes
form in reading and writing, but visual literacy as well as digital literacy may be just as important for success in education and beyond school walls (Cassell, 2004; Cavallo, 2000; Gee, 2003). As an Internet technology, blogs involve the reading and writing of texts, but also the creation and interpretation of images and multimedia, as well as the need to navigate a graphical user interface, all of which serve to advance skills in verbal, visual, and digital literacy.

Storytelling, a natural part of children’s language development, serves as a catalyst for promoting literacy (Bransford et al., 1999; Huf- faker, 2004b). Children and adults alike use stories to express thoughts, feelings, and experiences in an engaging and entertaining way (Denning, 2001), and storytelling helps create collaborations between the teller and listener. Collaborations, whether between children and adults or among peers, are also important aspects of learning, producing ways to adapt or scaffold learning (Ryokai et al., 2003; Vygotsky, 1980). Blogs, which resemble personal journals, create a perfect environment for sharing stories and other forms of writings, and provide ways for others to participate through feedback or critique on student work.

Currently, blogs in practice highlight that blogs can be used in a broad range of age groups and developmental stages in education. Second graders and high school teenagers alike can use blogs to practice reading and writing, and help develop language skills. Blogs can also be used in a variety of disciplines, from literature and journalism to arts and sciences. Anywhere language is used to promote discussion, blogs serve as an arena where thoughts can be published and made available to everyone for additional feedback. Not only can students use the blogs, teachers, parents, and experts can collaborate alongside them, which may help develop a sense of empowerment and self-efficacy for children and adolescents.

Finally, this chapter has recommended several concepts for educators interested in implementing blogs in the classroom. These concepts embrace collaboration, online community building, interlinking parents with schools, student accountability, and ways to monitor student progress. Because blogs are readily available for free at a selection of blog hosts, implementation into the class does not require a high level of technical expertise or an extravagant school budget. Therefore, the benefits of advancing language skills or bridging communication between teachers, parents, and schools far outweigh the costs.

“Let them blog” is a simple idea—blogs provide a computer-mediated communication context where students can practice and advance different types of literacy, use storytelling to express themselves, and collaborate with peers and adults as they complete assignments. “Letting them blog” is even simpler—blogs are easy to use, free, and extremely accessible for anyone with a computer and Internet access. Teachers may find blogs to be one of the easiest educational technology applications to implement, and since adolescents are already using blogs outside the classroom, it may be an excellent time to connect the two.

ACKNOWLEDGMENTS

The research of this chapter was funded in part by a grant to the Children’s Digital Media Center at Georgetown University (http://cdmc.georgetown.edu) by the National Science Foundation (Grant #0126014). Special thanks to Sandra Calvert for all her mentorship and support.

ENDNOTES

1 Except where noted, all examples of blogs were created by the author in order to avoid any privacy or copyright issues.

2 Blogcensus was developed by the National Institute for Technology and Liberal Education (NITLE), a non-profit organization funded by the Andrew Mellon Foundation.

This work was previously published in Handbook of Research on Literacy in Technology at the K-12 Level, edited by L. Tan and R. Subramaniam, pp. 337-356, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).
ABSTRACT

With the development of technology, new roads have been opened in education. An interesting idea is to use computers in teaching and learning procedure. Students will have the opportunity to gain access to information resources in a timeless and limitless way. Teachers will be able to transform their classes in a student-centered environment, avoiding the drawbacks of the traditional teacher-centered model. In this direction, ubiquitous computing has significant advantages. Ubiquitous means that computational devices are distributed into the physical world, giving us boundless access to communication and information channels. Now, knowledge can be built based on collaboration, communication, experimentation, and on students' experiences. Research has shown positive impacts on learning. This chapter deals with issues directly connected to ubiquitous computing, such as its features, types of devices used, and pedagogical goals. The advantages and disadvantages of ubiquitous environments are fully examined and some initiatives are referred.

INSIDE CHAPTER

With this effort we try to cover the subject of ubiquitous or pervasive computing in education. We present important issues related to it. The first is the features of this technology. It is important to see and understand them. We also describe the connection means in a pervasive environment. Devices are basic elements of such systems because all educational activities are based on them. Devices vary from those with small screens to those with larger screens. Another separation may be given based on their computational capabilities. We also deal with the pedagogical goals that must be implemented. It is a crucial part of such efforts because the desired result is to assimilate and efficiently teach the students. We describe the advantages and disadvantages of the referred technology. As we will see, ubiquitous computing offers a lot of interesting advantages, but on the other hand, there are open issues that must be taken into consideration. The last part is devoted to the description of some initiatives that take or took place in universities and schools. We describe some platforms that may be used to
construct learning environments, most of which originated in the USA. Of course, there are common characteristics between these attempts, but their number is large enough to force us to describe only a few. These were randomly selected.

**INTRODUCTION**

New technologies have brought many changes in teaching, and of course in learning. Traditional classrooms are being transformed in order to utilize the advantages of the technology.

Ubiquitous computing (also known as “Pervasive,” “Ambient,” “1 to 1,” or “one to one”) is about distributed computing devices in the environment, with which users are able to gain access to information resources. These devices can be wearable computers, or sensors and computers embedded in everyday objects. On the other hand, ubiquitous computing involves the necessary infrastructures needed to support pervasive computing applications.

Ubiquitous computing integrates technology into the environment, giving the opportunity to users to utilize it anytime and anywhere. It differs from traditional systems where the user is bonded to a computer in a specific place. Now it is possible for a user to utilize the technology without the restriction of place or time.

Ubiquitous computing may provide significant advantages in the application domain of education. It can offer continuous access to a wide range of software, or the Internet, to all students, as well as teachers. As we will see below, the main targets of using pervasive techniques in education are efficiency in teaching and learning, equality between all students as to access to technology, regardless of their economical state, increased student engagement with their lessons, and different approaches according to the students’ needs (Bonifaz & Zucker, 2004).

This chapter is organized as follows. The next section gives information about the examined technology, and the third section describes its basic features. In the fourth section, a full description of the means that are being used in order to help a user connect and utilize ubiquitous facilities is given. The fifth section describes the pedagogical goals of the use of pervasive computing, and in the sixth section, the advantages and disadvantages of the emerged technology are given. In the seventh section, we outline some initiatives in this research area, and in the eighth section, we give a specific case study. Finally, our conclusions are depicted in the last section.

**BACKGROUND**

Ubiquitous computing environments are different from what one traditionally finds in most school settings. It offers to all students and teachers continuous access to a wide range of software, electronic documents, the Internet, and other digital resources for teaching and learning. These initiatives’ goals include increasing economic competitiveness, reducing inequities in access to computers and information between students from wealthy and poor families, and raising student achievement through specific interventions. Other reasons cited for supporting laptop initiatives include improving classroom culture, increasing students’ engagement, making it easier to differentiate instruction according to students’ needs, and solidifying home-school connections (Bonifaz & Zucker, 2004).

The UK government and Scottish executives have listed a number of priorities for ubiquitous education for the 14+ age range. This list is discussed in Smith (2002) and Sutherland (2002). According to authors, the priorities posed are:

- Widening participation of students
- Increasing the diversity of students in education
- Quality and standards through the use of ubiquitous computing
Ubiquitous Computing Applications in Education

• Employability in students’ life
• Accessibility to various resources through the emerged technology
• The globalization of learning and the emergence of alternative HE (Higher Education) suppliers
• Provision of education in more accessible forms on a part-time basis
• Employers wanting more workplace learning
• Professionalisation of teaching
• Student awareness of quality teaching and pastoral care
• Increasing IT literacy of younger students and higher students’ expectations
• Staff handling larger groups

Similar priorities have been posed in other countries recognizing the need to change the traditional educational model that has important disadvantages. To this target, the International Society for Technology in Education (ISTE) published a list (ISTE, 2002) with the most commonly referred conditions to create a learning environment for the use of technology. These factors are:

• Shared vision: This means that the commitment to technology is systemic and continual. Also, there is a proactive leadership and administrative support for the entire system.
• Access: Teachers must have limitless access to current technologies, software and telecommunications networks.
• Skilled educators: The educators that are called to instruct students, who use the technology in their tasks, must be skilled and familiar with the technology and with its use in the teaching procedure. Hence, learning will be more efficient.
• Professional development: Educators must have consistent access to professional development in support of technology use in teaching and learning.
• Technical assistance: Educators and students must have limitless technical support for maintaining and using the technology. Usually a technical helpdesk is established in order to meet these needs.
• Content standards and curriculum resources: Teachers must be knowledgeable in their subject and up to date with the content standards and teaching methods in their courses.
• Student-centered teaching: Ubiquitous access to technology drives the transformation of the traditional teacher-centered system to student-centered. Educators’ methodologies must comply with these new requirements.
• Assessment: There must be continuous assessment of the effectiveness of technology for learning. All the problems and the progress of each program must be recorded and encountered in the programs’ implementation.
• Community support: The community and every school’s partners must provide expertise, support, and resources.
• Support Policies: There must be policies for financing, accessing in networks, and rewards structures that must be in place to support technology in learning.

As we can see, there is an intention to use ubiquitous computing to help students learn in a more productive way. Ubiquitous access to technology by teachers and students has the capacity to transform not only the physical learning environment, but also the learning process, the role of students, and the role of teachers (Fullan, 1999).

Results of some 1 to 1 computing initiatives have shown:

• Improved writing skills.
• Increased student motivation and interest
Ubiquitous Computing Applications in Education

in school.
• Students that are more engaged in their learning.
• Teachers increasingly utilizing project-based and hands-on curriculum and teaching methods.
• Increase of math and science scores in the eighth grade.
• Children born since 1980 process information differently than children born before 1980. They learn best with multisensory input.

A case study is presented later in this chapter. It can be very helpful because it depicts valid results taken from questionnaires and interviews.

There are several research efforts in the field of ubiquitous computing in education. Especially with the spread of the wireless and handheld technology, these efforts become more intensive due to the advantages it can offer to learning process. Current research focuses on the impact of pervasive computing in teachers and students (Bayon et al., 2002). As for the teachers, the goal is to make them use effectively the new technology in their lessons' design in order to produce a student-centered class (Becker & Riel, 2000). This is the basic characteristic of constructivist theory, where students learn based on their collaboration and experimentation. Students build their knowledge based on their experiences and their research.

Regarding students, researchers study the effect ubiquitous learning has on them in terms of when and how they use the technology, how much the technology affects their behaviour, and how the new attempt is received by parents and the school community (Diggs, 2004). Interviews and observations have shown positive effects on students and this way of learning is accepted from the entire school community. There is an enhanced motivation, collaboration, and communication between students. This is also supported in Vahey, Enyedy, and Gifford (2002).

The research results are very optimistic, but there must be careful design and systematic observation to achieve the ultimate goal, which is more productive student learning.

FEATURES

The use of ubiquitous computing in education has characteristics very important in learning. An educational policy can be based on these features in order to achieve a high level of learning. These features are:

• **Information Access**: Students have access to their documents, and also to various information sources from everywhere. All students may search the information needed in order to complete a task. Of course, the initiative is on them. They pose questions and take the results. The final step is to combine the results and extract the final conclusion.

• **Time and Place Immediacy**: This feature is allocated in the place and time in which the information can be reached. Whenever and wherever a student needs to access information is feasible. There are no limits in time or in place. This has the advantage of easy and useful access to resources, increasing the productivity of the work.

• **Interactivity**: Students are able to interact with teachers or experts with a synchronous or asynchronous communication. Hence, they have the opportunity to approach other people's knowledge, without the one teacher's limitation, of the traditional system. They may search, find, and pose questions to specific domain experts, and afterward combine the answers to effectively build their knowledge.

• **Student Activation**: A system in which all students have their own device and work by themselves demands activation. Every student has to work and learn, experiment-
Ubiquitous Computing Applications in Education

ing with software and searching to find the information needed to complete specific tasks.

- **Adaptability:** Learners can get the right information at the right time and at the right place. In this direction, the Intelligent Agent technology may be very useful. Intelligent software may learn from the owner’s habits or instructions and work as its representative, searching and find information. Even further, this software can be used to adapt the information presented to the users based on their learning style.

**CONNECTION MEANS**

When computers first arrived in educational environments, they brought a lot of challenges in the form of space for electrical cords, attachments, peripherals, and other entanglements (McKenzie, 2001). It is obvious that in recent years there was a ‘blast’ in wiring and cabling in school networks.

The ultimate goal of ubiquitous computing in education is the use of a computer for all students and teachers. This means that we need a more flexible way to connect all the devices. The development of the technology in the domain of wireless radio connections, which gives a high speed communication channels, can give us a means to efficiently interconnect devices in large areas.

We believe that a wireless connection will be more appropriate and efficient than a wired network where the users will be bound to specific spots in the area. Using wireless connection, students may have access from anywhere. They may have access in the cafeteria, in the library, in the class or outside.

In McKenzie (2001) authors provide a list of advantages of the wireless technology. They are:

- Ease of movement
- Relaxed fit
- Strategic deployment
- Flexibility
- Cleanliness
- Low profile
- Convenience
- Simplicity
- Speed (especially nowadays)

Synoptically, we can say that the greatest advantage of wireless technology is that it offers continuous access to the networks from anywhere in school. One can see a “wireless” scenario in Figure 1. All the devices can connect to access points and thus can have access to all the network resources. It can be implemented with either infrared rays or wireless Ethernet (e.g., 802.11b, or 802.11g with greater speed). Unfortunately, infrared rays have a disadvantage because they do not penetrate opaque objects. Hence, they may only be used in the classroom. On the other hand, wireless ethernet offers access to the network at a high rate, at any time or place.

The devices that can be used for wireless access vary, from a device with small screen and limited computational capabilities, like Blackberry RIM, to a device with larger screen and increased computational capabilities, like a laptop (Deters, 2001). Some pictures of these devices are shown in Figure 2.

The first kind of device usually allows simple interactions, like message passing, and so forth, but on the other hand, its use is very easy, even for a beginner. It may be used to help beginners enter into this new technology.

Bigger devices like Palm computers, Pocket PCs, or laptops offer increased computational capabilities, giving users the opportunity to utilize more complex software. They have greater memory size and a more powerful processor, and they comprise miniaturization of a desktop machine.
Figure 1. A wireless network example

Figure 2. Portable devices: (1) Laptop, (2) small $100 laptop (3) PocketPC, (4) BlackBerry RIM, (5) handheld laptop, (6) palm computer
The most important matter with respect to devices and their software is compatibility, because students working in groups must exchange messages, files, or even more programs. Their devices must be compatible in order to facilitate the communication between them. Otherwise, there will be a significant problem that may be critical to the entire effort.

PEDAGOGICAL GOALS

Today’s generation of students looks at technology as part of their everyday environment. It is important to understand the difference between today’s life in school in contrast to the past, where students only occasionally used computers. In the future, pupils will own a handheld device, which will be their partner to complete tasks. This means that these devices must be used in a correct manner in order to help them in the learning procedure.

To fully meet the students’ needs, technology should be pervasive—always available. In one-to-one learning, each student has access to a wireless laptop to use at school or at home, enabling communication and collaboration among peers and teachers, and connecting parents to their children’s learning. Educators are provided digital tools to create learning plans, manage educational content, track student progress, and more.

The most important point is that full attention to learning methodologies, with the help of the digital world, must be given. Technology is the mean to learning. A possible mistake will be to pay attention in technology rather than learning. For this reason, policy makers must grapple with several issues concerning appropriate and effective integration of computers into schools (Eagleton, 1999). In the referred list, one can distinguish financial, equality, curricular, and literacy issues.

The ultimate goal of such efforts is to improve the assimilation ability of the students. To this target, there are two critical factors. The first is teachers and their ability to transform their teaching. Teachers must know how to utilize the technology in their courses. They must apply new educational techniques oriented to the use of technology. This procedure needs careful design. It is useless to leave children to play for hours or aimlessly browse the Web. A specific scope must be posed.

The other factor is students. Research indicates that constant exposure to multiple, overlapping sights and sounds has affected the neural pathways of the brains of digital kids (Apple Education—http://www.apple.com/education). In fact, some researchers contend that multisensory input helps kids learn, retain, and use information better. However, the use of technology does not mean that all the students would do their learning with computers. For this reason, it is crucial what type of technology will be distributed to students. Students must be driven to collaborate with their classmates, to use learning software for their courses, to use their devices for communication, or to research with resources useful to complete their tasks. They build their knowledge by experimenting and testing their ideas based on their experiences. The true value of technology for learning lies not in learning to use technology, but in using technology to learn (Educational Research Service, 2001). A technology-using attitude must be cultivated in students in order to enhance their achievement and engagement.

Moreover, computers may help in the direction of the relevancy of schooling (Muir, 2005). Children always wander if what they learn in school may be useful in their future. Laptop initiative makes learning to appear more relevant to life’s requirements. This is because students, with the help of technology, learn based on projects that allow students to use their own learning style. A typical project may be the searching for information in the network and the configuration of it to cover their needs. Hence, students see the
connection between things they learn and their use in real life.

Furthermore, computers are an object that can be used in many ways related to the personal needs of each student. For example, some students may learn better by searching for information, as we described, while others may need multimedia information in order to assimilate the concepts. It is obvious that in such cases the most appropriate and efficient way for learning is working in groups, where all the students can contribute.

Thus, careful design of courses from the teachers’ side may offer significant advantages in learning procedure. Unfortunately, many classrooms do not work that way. Pencil, paper, lecture, textbook, review, and test are still the norm. However, there are important attempts that show us the road to the ubiquitous computing revolution. Some of these tries are presented in Ubiquitous Computing Initiatives.

In summary, ubiquitous computing environments provide portability, flexibility and efficiency for collaborative learning projects (Sottilo, 2003). Teachers have the ability to integrate computers to every aspect of teaching and learning.

**ADVANTAGES – DISADVANTAGES**

In this point, it is necessary to describe all the advantages and disadvantages of the emerged technology. It is critical to identify these issues because it is a key to the road of the embodiment of computers in the learning procedure.

Some advantages are:

- **Teaching efficiency**: With the use of ubiquitous computing, teaching style has to change. Teachers must adapt their methods to the new environment. This active environment gives the opportunity for students to build their knowledge on their own. Therefore, it is imperative that teachers change their lessons plan in order to reflect the new situation. They will have the convenience to adjust the lessons to each student’s needs and the lessons’ goals. Educators can now implement a broader range of new approaches to learning that are proven to be more effective. Also, teachers must encourage and support their students more vigorously, due to the different nature of teaching.

- **Learning efficiency**: One of the most important findings in past years is that student engagement is one of the most critical factors to learning achievement. It is obvious the traditional teaching method has significant drawbacks for its efficiency. A teacher-centered class does not provide the opportunity for students to learn to build their knowledge through collaboration or experiments. Ubiquitous computing offers an environment where students use their devices to access a class from anywhere, collaborate with other students, experiment with appropriate software, and pose questions to their classmates or their teacher. This method is more productive because the knowledge is built on students’ experiences. Students are more active in the course and their engagement is compulsory in order to achieve the goals that are posed to them. Hence, the traditional model is transformed to a student-centered model, where the teacher becomes a consultant to their students. The procedure that we described reflects the method of constructivist pedagogy.

- **Access to technology**: Today, there are many computers in schools placed at labs, but students do not have limitless and timeless access to them. Consider the scenario where all the students have their own device to access teaching resources either from their class or from their homes. In this scenario, all the students are fluent with the use of technology. This is a very attractive idea because in such a class students are technologically equal. This equality can be allocated in the
use of technology. In past years, there was a gap in technology access that translated into inequalities in different fields among people. This is known as “Digital Divide” (Digital Divide.org, 2005). Now, each student has a device and limitless access to digital information augmenting their productivity. The new technology gives more opportunities to students from previously disadvantaged groups. Also, research has shown that giving students a personal device can make learning more efficient (Vahey et al., 2002). Students become more autonomous and self-directed in their learning.

• **Easy to use:** Today’s children are familiar with technology, especially with games. Gameboys™, Playstations™, and even computers are used for gaming. Thereby, it is easy to provide learning devices to students for their use. Of course, instructions must be given to them for the right use of the tools in order to avoid problems from inappropriate use, as we see below. Students want personal devices that, like a toy, are easy to operate.

• **Productivity:** With the emerged technology students can raise their productivity. This is because they build their knowledge based on techniques that are proven by research to give better results. Students become active, taking initiatives and working with their own pace. Also, the interaction with classmates of whom they share common interests plays an important role in the learning process. Finally, we must note that in such cases experimentation is another factor that builds knowledge. Students have boundless access to the Internet or to specific software, and may perform their own tasks with their devices or search information in various resources, such as the Internet or digital databases, and so forth.

• **Portability:** Students, during their time spent in schools, must be familiarized with tools, software, and devices that differ due to the different architecture of each computer. Computers are used mainly in labs devoted to a specific lesson. They spend significant time learning the use of each device and applications that detaches them from the actual learning activity. With their personal devices, they can focus on the learning procedure without worrying about the differences between various tools and applications. They can connect to the network from any place at any time.

Just like all the other domains of technology, ubiquitous computing has some drawbacks. These drawbacks must be taken into consideration by educational policy makers, and by the implementers of this technology, in order to anticipate and avoid problems that may appear in the implementation phase.

• **Cost:** Initiatives such as ubiquitous computing in education, where every student will have their own device in order to perform tasks, have a cost, detected at two points. The first is the financial cost. The provision of a big amount of devices is very costly, but, of course, their prices are reduced as the technology evolves, making them affordable. On the other hand, there is cost in the transformation of the traditional system into the new. A lot of things must change, such as the lesson plan, the teaching style, and the assessments model. This requires much effort from the teachers and the policy makers. It is important to note that the new model requires a careful design of all the teaching parts because in this environment students will be able to act freely.

• **Teachers’ Expertise:** This kind of program needs teachers’ expertise with the technology and with the design of the new kinds of lessons. Teachers must be fluent with this type of education. There is a fear that they will not know how to use the technology and how to design their lessons. Also, there
is a possibility that they may not use the technology in their teaching methodology in an appropriate way. A solution to these problems is to further educate teachers in coping with the new situation.

- **Inappropriate use of Technology:** There is a fear that students may use the electronic devices with which they are provided inappropriately. For this reason measures must be taken. A lot of programs have the mechanisms to control the network access in order to avoid problems. Firewalls are in the front line of security. With them the administrators can check the traffic and discover the cases that are dangerous to students, and even more, to the system.

- **Equipment damage:** Devices are basic elements in ubiquitous computing environments. They are means for access in information sources. Also they are used for communication purposes. Communication and collaboration are the keys to succeed with the pedagogical goals we described in Pedagogical Goals. Hence, problems will arise when technical inefficiencies occur. In such cases, technical support is important for the program’s success; otherwise the participants’ faith may be unsettled.

All these advantages and disadvantages must be taken into consideration from the policy makers, and a specific policy must be set up according to each case’s characteristics.

**UBIQUITOUS COMPUTING INITIATIVES**

This section will present some initiatives and tools originating from all over the world. Of course, it is impossible to present all the efforts. A full list of the schools that apply the laptop initiative is available at [http://www.k12one2one.org/initiatives.cfm?initID=97](http://www.k12one2one.org/initiatives.cfm?initID=97). We present some of them, in order to describe basic characteristics of ubiquitous computing in education. We must note that most of them originate in the United States, where first attempts appeared in the late 90s. Tools for a learning environment’s construction are also presented. All these initiatives are being held in elementary schools or universities. The common characteristic between them is that the majority use portable devices (see *Connection Means*) with wireless access to the network. On their Web sites, evaluations are given for every one of the programs in order to discern their results and identify the advantages and disadvantages. However, it is commonly the conviction that the use of a computing environment in which the students complete their tasks, offers positive remarks in learning procedure, augmenting the enhancement and engagement of the pupils.

**Ulysses**

This is an effort from the University of Laval, in Quebec, Canada (Mantha, 2001). All the students and teachers are provided with a laptop. In the academic year 2001-2002, there were approximately 1800 laptops in the school. Students and teachers invested money to buy the devices. In Ulysses, the laptop is to a large extent a communication tool, and thus there is a need to be able to connect to the network. The connection is established in the classrooms, in the cafeteria, in hallways, and so forth. For financial reasons, the system uses wired connections to the network. There are 17 wired classrooms, of which 11 have the U shape. There are 6 classrooms with movable tables with network connections on the periphery of the room, allowing the grouping of tables for team work. In every classroom there is a console in which one can find a computer and multimedia tools. An intranet was developed to store all the material needed for courses, like exercises, examples, and
Ubiquitous Computing Applications in Education

so forth. Tools used for communication are e-mail, forums, course management utilities, and Athena. Athena is a tool with which the instructor is able to poll the class in a small amount of time and get the students’ opinion about a question. The answers can be short texts, yes/no or a selection in a multiple choice question. Also, the instructor can display the answers on the projection surface at the front of the class. This capability may be very useful in the teaching process.

For user support, two helpdesks were set up. There is a technical helpdesk and a pedagogical. The first is responsible for hardware and software problems. Common issues encountered are computer parts replacement, systems configuration, network connection parameterization, or systems and applications installation. The second helpdesk is responsible for answering questions concerning the use of technology from teachers and students in a pedagogical setting. There are a lot of means to access this support center. One can get support from the desk, from the Web site, over the phone, or via e-mail. This center can help tutors find and apply new means of uses of technology in their lessons.

**eFusion**

This system consists of an initiative of the University of Illinois that originated in the spring of 2002 (Peiper, Warden, Chan, Capitanu, & Kamin, 2005). eFusion is an interactive classroom learning environment where all students and teachers have access to computing devices inside and outside the class. During the lesson, educators present their notes and examples with the help of presentation tools that eFusion provides. Consequently, teachers send their notes to students’ devices through a wireless network and students may make their remarks in presentations and store them for future access. The system supports interactive newsgroups and communication tools that give the opportunity for students to communicate with their instructors or their assistants and take answers during a lecture or asynchronously at a later time.

The most important part of the system is the facility for incorporation of active learning exercises into the lectures, giving instructors a mean to see the comprehension level of the learners in real time. As we understand, it is about a system that has the ability to facilitate teachers to diagnose their students’ needs in a real-time manner during lectures. This is a critical factor because, based on results taken from quizzes or other forms of questions, instructors may change the teaching methodology in order to achieve a better comprehension level.

**WIL/MA Toolkit**

This is a toolkit written in Java and initiated by the University of Mannheim (http://www.lecturelab.de/UCE_4.html). It is a client-server application, where a server provides connection management, user management, and service management. The first supports the establishment of a connection to the users and gives the capability for administrators to monitor the entire communication in and out from the server. The second is used for user identification and authentication. Finally, the service management unit is responsible to inform users of what services are available and also to control data flow.

The system is based on wired connections, but in order to avoid extensive use of cables, students are able to connect to the network with wireless LAN. The devices used by the students are PocketPCs. On the other hand, teachers are able to publish their material, which can be presentations, slides, or files, and furthermore, they can broadcast image and voice to remote places. During their lectures, teachers can also use tools like call-in (spontaneous questions), or quiz and feedback (from the students in real time). Asynchronous tolls are messaging and chat/forum channels.

**University of Texas**

In 2002, the University of Texas initiated a requirement for all teacher education students to obtain a prescribed laptop and software for use throughout their academic preparation (Resta & Tothero, 2005). The goal is the preparation of a new generation of teachers who would be able to use new tools and practices in their teaching. This program’s vision is to prepare the future teachers to enhance their future students to learn in technologically rich classrooms. Its official name is LIFE (Laptop Initiative for Future Educators).

All the students are provided with laptops and software that meet specific requirements, and wireless access to network in their classrooms or throughout the building. The involvement with the technology creates two critical needs. The first is the need to train the students to use the new hardware and software tools. For this reason, in the start of every semester, workshops are offered to familiarize new students with the systems and applications. The second is the need for technical support. For this, a Students Laptop Helpdesk was established. It provides equipment, supplies, and instruction for both students and teachers.

**Maine Public Schools**

This is one of the first programs that try to embody ubiquitous computing in education and is considered the single largest 1 to 1 educational technology program in the world (http://www.maine.gov/portal/education/educ_tech.html). It is a project of the Maine Department of Education. Every 7th and 8th grade student and teacher has a wireless laptop with a rich set of software. Students have the capability to work with word processing, spreadsheet creation, movie processing, e-mail clients, Internet browsing, and other multimedia software. Also, students can take laptops to their home, where they can have access to the network. There are now 37,000 laptops in Maine’s 239 middle level schools. Additionally, there is a small group of educators, educational technologists producing research, documentation, evaluation, and advocacy of 1 to 1 learning. Evaluations have shown that student engagement and attendance are up and behaviour referrals are down (Silvernail, Harris, Lane, Fairman, Gravelle, Smith et al., 2003). The most prominent result is that parents can see this positive effect on their children’s behaviour. The key to the success of this program is to focus on the initiatives as a computer enhanced learning procedures and not merely as technical training. The technology initiatives must focus on teaching and learning, and not on technology, in order to be successful (Schacter, 1995).

Recently, there was an agreement to upgrade the hardware and software tools. The most important change is the wireless network transition to Airport Extreme 801.11g, giving a 54 Mbps speed and improving performance.

**Vermont Public Schools**

This is an initiative developed by the Vermont Department of Education (http://www.k12one2one.org/www.oakgrove.k12.vt.us). Vermont teachers and students have access to ubiquitous technology, which is available on an “as needed” basis. The results of the first year of the program were:

- Teachers were more comfortable with implementing more technology integrated lessons.
- Students were better organized.
- Students created better quality work.
- Students experimented with various tools.
- An impact on student learning because of the full access to the technology.

All the teachers and students are provided with laptops, with which they can have access to the network and to various software tools. They may process text, databases, spreadsheets, video, mu-
Ubiquitous Computing Applications in Education

sic, or even more images. Finally, Web browsing and communication tools are available.

**New Hampshire Schools**

This attempt concerns all the 7th grade students in six of the state’s neediest schools (http://www.nha-dvantage.com/laptop.htm). Approximately 400 students participated in the program the first year. All these students are provided with a laptop and wireless network access. Additionally, cameras, printers, and videoconferencing tools are available to students and teachers. Teachers can control the children’s laptops during classes while students do their assignments. The analysis of the results concerning the first year evaluation indicates many of the most frequently cited benefits of 1 to 1 computing, such as: increased involvement with technology from both teachers and students, increased student engagement, achievement, and motivation, and improved interactions between teachers and students.

**Talbot County Public Schools**

This is a laptop initiative in which all pupils hold a portable device with which they can cope with school tasks. This project has four goals, which are:

- Increased student achievement
- Effective technology for instruction
- Increased student engagement in the learning process
- Improved educational access for and participation by high-risk students and their parents

The program’s drift derives from classroom observations, teacher competencies identified by National Education Technology Standards (NETS) for teachers, lesson plans that utilize technology, and examining students’ work and performances.

Computers were provided to each ninth grade student at the beginning of the 2005-06 school year (http://www.teps.k12.md.us/index.php?page=l_to_1_laptop_initiative). Teachers were given extensive training on the computers and on instructional software.

Students have access to network from any place, in school or at home. Also, a helpdesk is available to students for technical and insurance issues.

**Alexandria City Public Schools**

The Alexandria City Public Schools High School Technology Integration Project provides a 1 to 1 computing environment for all students in grades 9-12 (http://www.acps.k12.va.us/tip/index.php). A laptop is provided to each student, who has the opportunity to keep the device for the duration of the school year. Students have access to a wireless network with which they can access resources and material useful for their tasks. A set of applications is installed on laptops that is useful for common tasks like word processing, as well as a variety of teaching material and applications. Teachers can leave their material in a students’ server, enhancing the electronic exchange of information. In this server, students have personal work folders where they can store their assignments. Printing support is available for students and teachers. Finally, we must note that for the program’s support, there is a help desk that is responsible for repairing damages.

**Hopkins Public Schools**

This pilot program involves approximately 600 students and 30 staff members. The program’s goals are to enhance student’s achievement and engagement. Each student owns a laptop with which to complete his or her assignments. Teachers can give their files and presentations in electronic mode (http://weblogs.hopkins.k12.mn.us/one2one/). Students having wireless access
Ubiquitous Computing Applications in Education

can take the material and, using software like office, Web browsing tools, database, video, music, image processing, and communication software, can cope with their commitments. It is worthwhile to mention that students cannot have access to the Internet from their homes except in the cases that the family has its own Internet provider. Technical support is provided on a full-time basis.

Other Areas in the United States

There are laptop initiatives in 30 states in the United States (http://www.k12one2one.org/initiatives.cfm?initID=97). These states are:

- Alaska
- Arizona
- Arkansas
- California
- Connecticut
- Florida
- Georgia
- Illinois
- Indiana
- Iowa
- Kansas
- Maine
- Massachusetts
- Michigan
- Minnesota
- Missouri
- New Hampshire
- New Jersey
- New Mexico
- New York
- North Carolina
- Ohio
- Oregon
- Pennsylvania
- South Carolina
- Texas
- Vermont
- Virginia
- Washington

These programs either came as district or school initiatives. Like the previously described examples, they are programs that offer wireless access from portable devices to their students and teachers. The goals and the characteristics of these programs are the same as we described in the previous cases.

Kaifu School – Hamburg

The project started in 1999 and lasted until 2003, and it is among the first in Europe (http://www.hamburgmediaschool.com/pages/p118328_v1.html). Since then, the school chose to continue using portable devices in three classes. However, the entire effort is characterized as positive. All the students were provided with wireless laptops and specialized software. Students that continue this program are specialized in organizing themselves and in learning to use technology, which was the goal of the project.

Minervaskolan School

Since 1999, pupils in Minervaskolan have used laptops with wireless access to the network (http://www.minervaskolan.se/). The program’s technical specifications are similar to the others as we described. The most important is that from the project’s evaluation students’ non-attendance approaches to zero and scores to national tests are remarkable. Also, students’ grades appear to be to a continuous increment advocating to the program’s success. Now, Minervaskolan is one of the top schools in Sweden.

CASE STUDY: THE MAINE LEARNING TECHNOLOGY INITIATIVE – TEACHER, STUDENT, AND SCHOOL PERSPECTIVES, MID-YEAR EVALUATION REPORT

In this section, we synoptically show the results taken from the evaluation of the Maine learning technology initiative (Sirvenail et al., 2003). Three core areas are investigated: Teachers and teaching, students and learning, and schools and community. In order to derive useful conclusions for each area, specific questions were posed. The goal of these questions is to identify the impact, the use, and the obstacles of the technology. Therefore, there are three key questions.
Ubiquitous Computing Applications in Education

- How are the laptops being used?
- What are the impacts of the laptops on teachers, students, and schools?
- Are there obstacles to full implementation of the initiative?

We give a short presentation of the evaluation results with regard to each core area.

The evidence in the area of teachers and teaching indicates that the majority of teachers use their laptops in lesson development and classroom instruction. They utilize their devices to prepare and present their lessons. Of course, they agree that the use of the merged technology has positive impacts on their teaching. Now, they are aware of up-to-date information critical to present a meaningful course. On the other hand, they see an obstacle to this effort concerning the technical support. They feel that technical problems and the lack of technical support sometimes limit the use of laptops. This is a critical factor for the program’s success. They also felt that they need time to learn the new technology and its applications and professional development activities designed to help them in the teaching process. Of course, time must be given in order to overcome the limitations.

Students report that they use their laptops to complete tasks, to search for information sources, and to communicate with teachers and classmates. More importantly, they feel an increase in the benefits of their work, both in and out of school. The new technology has increased their interest in school activities, but there are some problems in coping with technical difficulties.

Positive impacts of the application of new technology in learning procedure are recognized from the school community. The difference in children’s interest is visible to their parents. Financial matters are obstacles to this effort, but through creative solutions many schools find ways to minimize the overall cost.

As we have seen, there are many positive impacts in introducing these new technologies to education. Teaching focuses on students’ generating a new environment, where learning comes from collaboration, experimentation, and research. At the same time there are obstacles, especially in technical support, that in time will be eliminated.

CONCLUSION

Ubiquitous computing changes the field of education. It offers a timeless access to information resources and allows learning methods that are difficult to apply in traditional classrooms. Research has shown it has positive impacts on students’ learning. Also, a lot of advantages exist in teaching, and school communities see these positive impacts of the new technology.

In order to integrate computers in education smoothly, careful design is necessary. The focus must be on the pedagogy and not on technology. This is because the final goal is to accomplish a high level of learning. For this reason, we speak about technology enhanced learning, and not about technical training.

Ubiquitous or pervasive computing has significant advantages over traditional teaching methods, and we must work on them to reach the desired results.

Chapter 4.7
Unraveling the Taste Fabric of Social Networks

Hugo Liu
The Media Laboratory, USA

Pattie Maes
The Media Laboratory, USA

Glorianna Davenport
The Media Laboratory, USA

ABSTRACT

Popular online social networks such as Friendster and MySpace do more than simply reveal the superficial structure of social connectedness—the rich meanings bottled within social network profiles themselves imply deeper patterns of culture and taste. If these latent semantic fabrics of taste could be harvested formally, the resultant resource would afford completely novel ways for representing and reasoning about web users and people in general. This paper narrates the theory and technique of such a feat—the natural language text of 100,000 social network profiles were captured, mapped into a diverse ontology of music, books, films, foods, etc., and machine learning was applied to infer a semantic fabric of taste. Taste fabrics bring us closer to improvisational manipulations of meaning, and afford us at least three semantic functions—the creation of semantically flexible user representations, cross-domain taste-based recommendation, and the computation of taste-similarity between people—whose use cases are demonstrated within the context of three applications—the InterestMap, Ambient Semantics, and IdentityMirror. Finally, we evaluate the quality of the taste fabrics, and distill from this research reusable methodologies and techniques of consequence to the semantic mining and Semantic Web communities.

INTRODUCTION

Recently, an online social network phenomenon has swept over the Web—MySpace, Friendster, Orkut, thefacebook, LinkedIn—and the signs say that social networks are here to stay; they
constitute the social Semantic Web. Few could have imagined it—tens of millions of Web users joining these social network sites, listing openly their online friends and enlisting offline ones too, and more often than not, specifying in great detail and with apparent exhibitionism tidbits about who they are, what music they listen to, what films they fancy. Erstwhile, computer scientists were struggling to extract user profiles by scraping personal homepages, but now, the extraction task is greatly simplified. Not only do self-described personal social network profiles avail greater detail about a user’s interests than a homepage, but on the three most popular sites, these interests are distributed across a greater spectrum of interests such as books, music, films, television shows, foods, sports, passions, profession, etc. Furthermore, the presentation of these user interests is greatly condensed. Whereas interests are sprinkled across hard-to-parse natural language text on personal homepages, the prevailing convention on social network profiles sees interests given as punctuation-delimited keywords and keyphrases (see examples of profiles in Figure 1), sorted by interest genres.

It could be argued that online social networks reflect—with a great degree of insight—the social and cultural order of offline society in general, though we readily concede that not all social segments are fairly represented. Notwithstanding, social network profiles are still a goldmine of information about people and socialization. Much computational research has aimed to understand and model the surface connectedness and social clustering of people within online social network through the application of graph theory to friend-relationships (Wasserman, 1994; Jensen & Neville, 2002; McCallum, Corrada-Emmanuel, & Wang, 2005); ethnographers are finding these networks new resources for studying social behavior in-the-wild. Online social networks have also implemented site features that allow persons to be searched or matched with others on the basis of shared interest keywords.

Liminal semantics. However, the full depth of the semantics contained within social network profiles has been under-explored. This paper narrates one such deep semantic exploration of social network profiles. Under the keyword mediation scheme, a person who likes “rock

Figure 1. Examples of social network profile formats, on Orkut (left) and Friendster (right). Note the similarity of categories between the two.
climbing” will miss the opportunity to be connected with a friend-of-a-friend (foaf) who likes “wakeboarding” because keyword-based search is vulnerable to the semantic gap problem. We envision that persons who like “rock climbing” and “wakeboarding” should be matched on the basis of them both enjoying common ethoi (characteristics) such as “sense of adventure,” “outdoor sports,” and “thrill seeking.” A critic might at this point suggest that this could all be achieved through the semantic mediation of an organizing ontology in which both “rock climbing” and “wakeboarding” are subordinate to the common governor, “outdoor sports.” While we agree that a priori ontologies can mediate, and in fact they play a part in this paper’s research, there are subtler examples where a priori ontologies would always fail. For example, consider that “rock climbing,” “yoga,” the food “sushi,” the music of “Mozart,” and the books of “Ralph Waldo Emerson” all have something in common. But we cannot expect a priori ontologies to anticipate such ephemeral affinities between these items. The common threads that weave these items have the qualities of being liminal (barely perceptible), affective (emotional), and exhibit shared identity, culture, and taste. In short, these items are held together by a liminal semantic force field, and united they constitute a taste ethos.

**What is a taste ethos?** A taste ethos is an ephemeral clustering of interests from the taste fabric. Later in this paper we will formally explain and justify inferring a taste fabric from social network profiles, but for now, it suffices to say that the taste fabric is an \( n \times n \) correlation matrix, for all \( n \) interest items mentioned or implied on a social network (e.g., a book title, a book author, a musician, a type of food, etc.). Taste fabric specifies the pairwise affinity between any two interest items, using a standard machine learning numeric metric known as pointwise mutual information (PMI) (Church & Hanks, 1990). If a taste fabric is an oracle which gives us the affinity between interest items as \( a(x_i, x_j) \), and a taste ethos is some set of interest items \( x_1, x_2, \ldots, x_k \), then we can evaluate quantitatively the strength, or taste-cohesiveness, of this taste ethos. While some sets of interest items will be weakly cohesive, other sets will demonstrate strong cohesion. Using morphological opening and thresholding (Serra, 1982; Haralick, Sternberg, & Zhuang, 1987), standard techniques for object recognition in the image processing field, we can discover increasingly larger sets of strong cohesiveness. The largest and most stable of these we term taste neighborhoods—they signify culturally stable cliques of taste. Visualizing these interconnected neighborhoods of taste, we see that it resembles a topological map of taste space!

Taste neighborhoods and taste ethoi, we suggest, are novel and deep mechanisms for taste-based intrapersonal and interpersonal semantic mediation. Rather than mapping two persons into interest keyword space, or into a priori ontological space, the approach advocated in this paper is to map the two persons first into taste-space, and then to use their shared ethoi and neighborhoods to remark about the taste-similarity of these persons.

**Emergent and implicit semantics.** While our work builds directly upon age-old language modeling techniques in Computational Linguistics, and graph-based associative reasoning in Artificial Intelligence (Collins & Loftus, 1975; Fellbaum, 1998; Liu & Singh, 2004), it is also sympathetic to trends in the Semantic Web literature—away from formal semantics, and toward an embrace of emergent and implicit semantics. In Volume 1 of this journal, Sheth, Ramakrishnan, and Thomas (2005) distinguish between formal, implicit, and powerful (soft) semantics for the Semantic Web movement. Whereas formal semantics must be manually specified, implicit semantics can be readily mined out of the unstructured Web using statistical approaches. Upon further refinement, implicit semantic resources can be transformed into powerful (soft) semantic resources that afford the ability to mediate informal and formal
entities. Related to implicit semantics, emergent semantics is an evolutionary approach to knowledge management (Staab et al., 2002; Aberer et al., 2004) that advocates semantic organization to be shaped from the ground-up, \textit{a posteriori}, and in accordance with the natural tendencies of the unstructured data—such a resource is often called a \textit{folksonomy}. We suggest that online social network profiles give an implicit semantics for cultural taste-space, and that taste fabrics afford a semi-formal, soft semantics appropriate for semantic mediation between informal and formal entities. Finally, arising out of correlation analysis, topological features of the taste fabric—such as taste neighborhoods, identity hubs, and taste cliques—constitute an emergent semantics for taste-space.

**Paper’s organization.** The rest of the paper has the following organization. Section Two lays out a theoretical foundation for representing and computing taste, framed within theories in the psychological and sociological literatures. In particular, it addresses a central premise of our taste-mining approach—“is the collocation of interest keywords within a single user’s profile meaningful; how does that tell us anything about the fabric of taste?” The section titled “Weaving the Taste Fabric” narrates the computational architecture of the implementation of taste fabric, including techniques for ontology-driven natural language normalization, and taste neighborhood discovery. The section “What Is a Taste Fabric Good For?” describes three semantic functions of a taste fabric—semantically flexible user modeling, taste-based recommendation, and interpersonal taste-similarity—within the context of three applications—InterestMap (Liu & Maes, 2005a), Ambient Semantics (Maes et al., 2005), and IdentityMirror. The following section evaluates the quality of the taste fabric by examining its efficacy in a recommendation task, and also entertains an advanced discussion apropos related work and reusable methodologies distilled from this research. The final section in the paper is the conclusion.

**THEORETICAL BACKGROUND**

This section lays a theoretical foundation for how taste, identity, and social network politics are approached in this work. For the purposes of the ensuing theoretical discussion, social network profiles of concern to this project can be conceptualized as a bag of interest items which a user has written herself in natural language. In essence, it is a self-descriptive free-text user representation, or harkening to Julie Andrews in \textit{The Sound of Music}, “these are a few of my favorite things.” A central theoretical premise of mining taste fabric from social network profiles by discovering latent semantic correlations between interest items is that “the collocation of a user’s bag of interest items is meaningful, structured by his identity, closed within his aesthetics, and informs the total space of taste.” Next, the paper argues that a user’s bag of interests gives a true representation of his identity, and enjoys unified ethos, or, \textit{aesthetic closure}. This is followed with a section which plays devil’s advocate and betrays some limitations to our theoretical posture. The section theorizes a segregation of user’s profile keywords into two species—identity-level items vs. interest-level items. This distinction has implications for the topological structure of the taste fabric.

**Authentic Identity and Aesthetic Closure**

In the wake of this consumer-driven contemporary world, the proverb “you are what you eat” is as true as it has ever been—we are what we consume. Whereas there was a time in the past when people could be ontologized according to social class, psychological types, and generations—the so-called demographic categories—today’s world
Unraveling the Taste Fabric of Social Networks

is filled with multiplicity, heterogeneity, and diversity. The idea that we now have a much more fine-grained vocabulary for expressing the self is what ethnographer Grant McCracken, echoing Plato, calls \textit{plenitude} (McCracken, 1997). In a culture of plenitude, a person’s identity can only be described as the sum total of what she likes and consumes. Romantic proto-sociologist Georg Simmel (1908/1971) characterized identity using the metaphor of our life’s materials as a broken glass—in each shard, which could be our profession, our social status, our church membership, or the things we like, we see a partial reflection of our identity. These shards never fully capture our individuality, but taken together, they do begin to approach it. Simmel’s fundamental explanation of identity is Romantic in its genre. He believed that the individual, while born into the world as an unidentified \textit{content}, becomes over time reified into identified \textit{forms}. Over the long run, if the individual has the opportunity to live a sufficiently diverse set of experiences (to ensure that he does not get spuriously trapped within some local maxima), the set of forms that he occupies—those shards of glass—will converge upon an authentic description of his underlying individuality. Simmel believes that the set of shards which we collect over a lifetime sum together to describe our true self because he believes in authenticity, as did Plato long before him, and Martin Heidegger after him, among others.

While Simmel postulated that earnest self-actualization would cause the collection of a person’s shards to converge upon his true individuality, the post-Freudian psychoanalyst Jacques Lacan went so far as to deny that there could be any such true individual—he carried forth the idea that the ego (self) is always constructed in the Other (culture and world’s materials). From Lacan’s work, a mediated construction theory of identity was born—the idea that who we are is wholly fabricated out of cultural materials such as language, music, books, film plots, etc. Other popular renditions of the idea that language (e.g., ontologies of music, books, etc.) controls thought include the Sapir-Whorf hypothesis, and George Orwell’s \textit{newspeak} idea in his novel \textit{1984}. Today, mediated construction theory is carried forth primarily by the literature of feminist epistemology, but it is more or less an accepted idea.

At the end of the day, Simmel and Lacan have more in common than differences. Csikszentmihalyi and Rochberg-Halton (1981), succeed in the following reconciliation. Their theory is that the objects that people keep in their homes, plus the things that they like and consume, constitute a “symbolic environment” which both echoes (Simmel) and reinforces (Lacan) the owner’s identity. In our work, we take a person’s social network profile to be this symbolic environment which gives a true representation of self.

If we accept that a user profile can give a true representation of self, there remains still the question of closure. Besides all being liked by a person, do the interests in his bag of interests have coherence amongst themselves? If it is the case that people tend toward a tightly unified ethos, or \textit{aesthetic closure}, then all the interests in a person’s bag will be interconnected, interlocked, and share a common aesthetic rationale. If there is aesthetic closure, then it will be fair for our approach to regard every pair of interest co-occurrences on a profile to be significant. If we know there is not any closure, and that people are more or less arbitrary in what interests they choose, then our approach would be invalid.

Our common sense tells us that people are not completely arbitrary in what they like or consume, they hold at least partially coherent systems of opinions, personalities, ethics, and tastes, so there should be a pattern behind a person’s consumerism. The precise degree of closure, however, is proportional to at least a person’s ethicalness and perhaps his conscientiousness. In his \textit{Ethics} (350 B.C.E.), Aristotle implied that a person’s possession of ethicalness supports closure because ethics lends a person \textit{enkrasia} or continence, and thus the ability to be consistent. Conscientiousness, a
Unraveling the Taste Fabric of Social Networks

dimension of the Big Five personality theory (John, 1990), and perhaps combined with neuroticism, a second dimension in the same theory, would lead a person to seek out consistency of judgment across his interests. They need not all fall under one genre, but they should all be of a comparable quality and enjoy a similarly high echelon of taste. Grant McCracken (1991) coined the term Diderot Effect to describe consumers’ general compulsions for consistency—for example, John buys a new lamp that he really loves more than anything else, but when he places it in his home, he finds that his other possessions are not nearly as dear to him, so he grows unhappy with them and constantly seeks to upgrade all his possessions such that he will no longer cherish one much more than the others. Harkening to the Romantic hermeneutics of Friedrich Schleiermacher (1809/1998), we might seek to explain this compulsion for uniformity as a tendency to express a unified emotion and intention across all aspects of personhood. Indeed, McCracken termed this uniformity of liking the various things we consume, Diderot Unity. Diderot Unity Theory adds further support to our premise that for the most part, a person’s bag of interests will have aesthetic closure.

Upper bounds on Theoretical Ideal

From the above discussion, we could conclude a theoretically ideal situation for our taste-mining approach – (1) a user’s bag of interests is an authentic and candid representation of what the user really likes, and (2) none of the interests are out-of-place and there is strong aesthetic closure and share taste which binds together all of the interests in the bag. Here, we raise three practical problems which would degrade the theoretically ideal conditions, thus, constituting an upper bound; however, we suggest that these would degrade but not destroy our theoretical premise, resulting in noise to be introduced into the inference of the taste fabric.

A first corruptive factor is performance. Erving Goffman (1959) posed socialization as a theatrical performance. A social network is a social setting much like Goffman’s favorite example of a cocktail party, and in this social setting, the true self is hidden behind a number of personae or masks, where the selection of the mask to wear is constrained by the other types of people present in that setting. Goffman says that we pick our mask with the knowledge of those surrounding us, and we give a rousing performance through this mask. In other words, the socialness of the social network setting would rouse us to commit to just one of our personae, and to give a dramatic performance in line with that persona. Performance might strength aesthetic closure, but it could also be so overly reductive that the bag of interests no longer represent all of the aspects of the person’s true identity.

A second corruptive factor is publicity. In her ethnographic review of the Friendster social networking site, Danah Boyd (2004) raises concerns over the quality and truth of profiles in light of the fact that a personal profile is public, not only to strangers, but also to one’s high school friends, college friends, professors, ex-girlfriends, and coworkers alike. Because social networking sites generally make a profile visible to all these different social circles at once, Boyd suggests that some users are cowed to the fear of potentially embarrassing exposure—for example, teacher exposing to his students, or teenager exposing to his mother. As a result, users may be cowed into a lowest-common-denominator behavior, sanitizing the personal profile of all potentially embarrassing, incriminating, or offensive content.

Finally, a third corruptive factor also raised by Boyd, concerns the integrity and timeliness of social networks themselves. Boyd claims that Friendster profiles and friend connections are not frequently updated, leading to stale information which could distort the taste fabric if we were interested in looking at the temporal animation of the fabric. Boyd also writes about a phenom-
enon known as Fakesters—the creation of bogus user profiles such as for celebrities. However, the scope of Fakesters is arguably limited, and since Fakesters are chiefly imitations of actual people, aesthetic closure should still be observed and learning over Fakester profile examples should not greatly compromise the integrity of the meaning implied by the taste fabric.

**Identity Keywords vs. Interest Keywords**

While each social network has an idiosyncratic representation, the common denominator across all the major web-based social networks we have examined is the representation of a person’s broad interests (e.g., hobbies, sports, music, books, television shows, movies, and cuisines) as a set of keywords and phrases. But in addition, more than just interests, higher-level features about a person such as cultural identities (e.g., “raver,” “extreme sports,” “goth,” “dog lover,” “fashionista”) are also articulated via a category of special interests variously named, “interests,” “hobbies & interests,” or “passions.”

As shown in the web page layout of the personal profile display (Figure 1), the special interests category appears above the more specific interest categories. We suggest that this placement encourages a different conceptualization for the special interests category—as a container for descriptions more central to one’s own self-concept and self-identification. Of course, syntactic and semantic requirements are not enforced regarding what can and cannot be said within any of these profile entry interfaces, but based on our experiences, with the exception of those who are intentionally tongue-and-cheek, the special interests category is usually populated with descriptors more central to the self than other categories. For example, a person may list “Nietzsche” and “Neruda” under the “books” category, and “reading,” “books,” or “literature” under the special interests category. In the profile normalization process, identity descriptors are inferred from descriptors listed under the special interests category (e.g., “dogs” → “Dog Lover,” “reading” → “Book Lover,” “deconstruction” → “Intellectual”).

Theoretically speaking, it is desirable to have two different granularities of description for a person. Identity descriptors are more general and constitute a far smaller ontology than interest descriptors, thus, the resulting effect is to create a taste fabric structured according to a hub-and-spoke topology. Identity descriptors serve as hubs and interest descriptors serve as spokes. The advantages to such an organization are revealed in a later section on applications, and in the evaluation of the taste fabric in a recommendation task.

Having established a theoretical premise for mining taste fabric from social network profiles, and having argued for identity descriptors to be separate from interest descriptors, the following section dives into the architecture and techniques of the taste fabric implementation.

**WEAVING THE TASTE FABRIC**

The implementation of the taste fabric making system was completed in approximately 3,000 lines of Python code. As depicted in Figure 2, the architecture for mining and weaving the taste fabric from social network profiles can be broken down into five steps: (1) acquiring the profiles from social networking sites, (2) segmentation of the natural language profiles to produce a bag of descriptors, (3) mapping of natural language fragment descriptors into formal ontology, (4) learning the correlation matrix, and (5) discovering taste neighborhoods via morphological opening, and labeling the network topology. The following subsections examine each of these phases of processing more closely. A condensed description of the mining process, sans neighborhood discovery, can be found in Liu and Maes (2005a).
Acquiring Profiles from Social Networking Sites

The present implementation of the taste fabric sources from a one-time crawl of two Web-based social network sites, which took place over the course of six months in 2004. The shortcoming of this approach is that we were only able to mine 100,000 personal profiles from the sites, and only approximately 80% of these profiles contained substantive content because about 20% of users elected to not make their profile details publicly visible to our robotic crawler. Also, the one-time crawls prevents us from being able to engage in more interesting dynamic tracking of profiles which would potentially allow us to animate taste fabrics through time. At press time, we are in discussions with two social network Web sites to gain research access to their user profiles, which should allow for the implementation that we discuss in this paper to be deployed on a larger scale.

At every step of mining, we are careful not to compromise the anonymity or personal information of social network users. In fact, in the end product, all traces of individual users, as well as their idiosyncratic speech, are purged from the taste fabric. From our 100,000 seed profiles, we used only the text of the categorical descriptors and none of the personal information including names and screen names. We chose two social networks rather than one, to attempt to compensate for the demographic and usability biases of each. One social network has its membership primarily in the United States, while the other has a fairly international membership. Both however, have nearly identical descriptor categories, and both sites elicit users to specify punctuation-delimited descriptors rather than sentence-based descriptors. One cost to mining multiple social networks is that there is bound to be some overlap in their memberships (by our estimates, this is about 15%), so these twice-profiled members may have disproportionately greater influence on the produced fabric.
Segmenting Profiles

Once profile texts are acquired, these texts need to be segmented. First, texts are easily segmented based on their interest categories. Recall in Figure 1 that texts are distributed across templated categories, e.g., passions/general interests, books, music, television shows, movies, sports, foods, “about me.” Experience with the target social network websites tell us that most users type free-form natural language text into “about me,” and natural language fragments for the specific interest categories. For the passions/general interest category, text is likely to be less structured than for specific interest categories, but still more structured than “about me.” Perhaps this is due to the following psychology—for specific interests, it is clear what the instances would be, e.g., film names, director names, and film genres for the films category, yet for the general interest category, the instance types are more ambiguous—so that field tends to elicit more idiosyncratic speech.

For each profile and category, its particular style of delimitation is heuristically recognized, and then applied. Common delimitation strategies were: comma-separated, semicolon-separated, stylized character sequence-separated (e.g. “item 1 \.. item 2 \..”), new line—separated, commas with trailing ‘and’, and so on. Considering a successful delimitation as a category broken down into three or more segments, approximately 90% of specific categories were successfully delimited, versus about 75% of general categories. We did not attempt to segment “about me.” Unsegmentable categories were discarded.

Ontology-Driven Natural Language Normalization

After segmentation, descriptors are normalized by mapping them into a formal ontology of identity and interest descriptors (Figure 3). Newly segmented profiles are represented as lists containing casually-stated natural language fragments referring to a variety of things. They refer variously to authorships like a book author, a musical artist, or a filmmaker; to genres like “romance novels,” “hip-hop,” “comedies,” “French cuisine”; to titles like a book’s name, an album or song, a television show, the name of a sport, a type of food; or to any combination thereof, e.g., “Lynch’s Twin Peaks,” or “Romance novels of Danielle Steele.” To further complicate matters, sometimes only part of an author’s name or a title is given, e.g., “Bach,” “James,” “Miles,” “LOTR,” “The Matrix trilogy.” Then of course, the items appearing under the general interest categories can be quite literally anything.

Figure 3 presents the ontology of descriptor instance types for the present taste fabric. At the
top-level of the ontology are six specific interest categories plus one general interest category (i.e., “identities”). Also, as shown, there are roughly 25 second-level ontological types. There are a total of 21,000 recognizable interest descriptors, and 1,000 recognizable identity descriptors, sourcing from ontologies either scraped or XML-inputted from The Open Directory Project (dmoz), the Internet Movie Database (imdb), TV Tome, TV Guide, Wikipedia, All Music Guide, AllRecipes, and The Cook’s Thesaurus. Figure 3 only lists the primary sources, and lists them in order of descending saliency. The diversity and specificity of types ensures the maximal recognition capability over the free-form natural language in the profiles.

Ontologizing identity. The ontology of 1,000 identity descriptors required the most intensive effort to assemble together, as we wanted them to reflect the types of general interests talked about in our corpus of profiles; this ontology was hand-engineered out of a few nomenclatures and folksonomies—most prominently Wikipedia’s extensive list of subcultures and The Open Directory Project’s hierarchy of subcultures and hobbies. We also generated identity descriptors in the form “(blank) lovers” where blank was replaced with major genres in the rest of our ontology, e.g., “book lovers,” “country music lovers,” etc. Some profiles simply repeat a select subset of interest descriptors in the identity descriptors category, so having the “(blank) lovers” template would facilitate the system in recognizing these examples. The mapping from the general interest category into the identity descriptors ontology is far more indirect a task than recognizing specific interests because the general interest category does not insinuate a particular ontology in its phrasing. Thus, to facilitate indirect mapping, each identity descriptor is annotated with a bag of keywords which were also mined out from Wikipedia and The Open Directory Project—so for example, the “Book Lover” identity descriptor is associated with, inter alia, “books,” “reading,” “novels,” and “literature.” Because we employed two parallel mechanisms for identity descriptors, i.e., cultures versus “(blank) lovers,” we cannot be completely assured that these do not overlap—in fact, they are known to overlap in a few cases, such as “Book Lovers” and “Intellectuals” or “Indie Rock Music Lovers” (genre of music) and “Indie” (subculture). Most cases of overlap, however, are much more justified because the cultural lexicon, just as natural language, cannot be flattened to a canon. Perhaps the most debatable choice we made was—for the sake of bolstering recognition rates—up-casting descriptors until they could be recognized in the identity ontology. For example, while “Rolling Stones” is not in the ontology of identity descriptors, we automatically generalize it until it is recognized, or all generalizations are exhausted—in the case of “Rolling Stones,” it is up-cast into “Classic Rock Music Lovers.”

Popularity-driven disambiguation. To assist in the normalization of interest descriptors, we gathered aliases for each interest descriptor and statistics on the popularity of certain items (most readily available in The Open Directory Project) that the system uses for disambiguation. For example, if the natural language fragment says simply “Bach,” the system can prefer the more popular interpretation of “JS Bach” over “CPE Bach.”

Situated semantic recognition. Once a profile has been normalized into the vocabulary of descriptors, they are relaxed semantically using a spreading activation (Collins & Loftus, 1975) strategy over the formal ontology, because more than simply being flat wordlists, the ontological instances are cross-annotated with each other to constitute a fabric of metadata. For example, a musical genre is associated with its list of artists, which in turn is associated with lists of albums, then of songs. A book implies its author, and a band implies its musical genre. Descriptors generated through metadata-association are included in the profile, but at a spreading discount of 0.5 (read: they only count half as much). This ensures that
when an instance is recognized from free-form natural language, the recognition is situated in a larger semantic context, thus increasing the chances that the correlation learning algorithm will discover latent semantic connections.

In addition to popularity-driven disambiguation of, e.g., “Bach” into “JS Bach,” we also leverage several other disambiguation strategies. Levenshtein (1965/1966) edit distance is used to handle close misspellings such as letter deletions, consecutive key inversions, and qwerty keyboard near-miss dislocations, e.g., “Bahe” into “Bach.” Semantically empty words such as articles are allowed to be inserted or deleted for fuzzy matching, e.g. “Cardigans” into “The Cardigans” (band).

Using this crafted ontology of 21,000 interest descriptors and 1,000 identity descriptors, the heuristic normalization process successfully recognized 68% of all tokens across the 100,000 personal profiles, committing 8% false positives across a random checked sample of 1,000 mappings. Here, “tokens” refer to the natural language fragments outputted by the segmentation process; a recognition is judged successful if after stripping away semantically empty words, the token finds correspondence with an instance in the ontology, while remaining within the heuristically-specified tolerances for misspelling and popularity-driven disambiguation. We suggest that this is a good result considering the difficulties of working with free text input, and with an enormous space of potential interests and identities.

**Correlation: Weaving the Raw Fabric**

From the normalized profiles now each constituted by normalized identity and interest descriptors, correlation analysis using classic machine learning techniques reveals the latent semantic fabric of interests, which, operationally, means that the system should learn the overall numeric strength of the semantic relatedness of every pair of descriptors, across all profiles. In the recommender systems literature, our choice to focus on the similarities between descriptors rather than between user profiles reflects an item-based recommendation approach such as that taken by Sarwar et al. (2001).

Technique-wise, the idea of analyzing a corpus of profiles to discover a stable network topology for the interrelatedness of interests is similar to how latent semantic analysis (Landauer, Foltz, & Laham, 1998) is used to discover the interrelationships between words in the document classification problem. For our task domain though, we chose to apply an information-theoretic machine learning technique called pointwise mutual information (Church & Hanks, 1990), or PMI, over the corpus of normalized profiles. For any two descriptors \( f_1 \) and \( f_2 \), their PMI is given in equation (1). The probability of a descriptor, \( \Pr(f) \), is defined here as the frequency of global occurrences of \( f \) divided by the summed frequency of global occurrences for all descriptors.

\[
PMI(f_1, f_2) = \log_2 \left( \frac{\Pr(f_1, f_2)}{\Pr(f_1) \Pr(f_2)} \right)
\]

Looking at each normalized profile, the learning program judges each possible pair of descriptors in the profile as having a correlation, and updates that pair’s PMI. What results is a 22,000×22,000 matrix of PMIs, because there are 21,000 interest descriptors and 1,000 identity descriptors in the ontology. After filtering out descriptors which have a completely zeroed column of PMIs, because there are 21,000 interest descriptors and 1,000 identity descriptors in the ontology. After filtering out descriptors which have a completely zeroed column of PMIs, and applying thresholds for minimum connection strength, we arrive at a 12,000×12,000 matrix (of the 12,000 descriptors, 600 are identity descriptors), and this is the raw interest fabric. This is too dense to be visualized as a semantic network, but we have built less dense semantic networks by applying higher thresholds for minimum connection strength, and this is the reason why small clusters seem to appear in the InterestMap taste fabric visualization.
Criticisms and limitations. A common critique heard about our approach is one that questions the efficacy of using the PMI metric for association. It has been suggested that we should look at collocations of greater rank than binary. Following our initial InterestMap publication, we extended the work by using morphological opening plus thresholding, as is done in image processing, to try to discover larger blocks of collocations which we call neighborhoods. This is to be discussed imminently. Additionally, another suggestion we are considering is negative collocation, that is, the collocation of a descriptor’s absence with other descriptors. This would address an apparent flaw of pointwise mutual information, which is that it “overvalues frequent forms” (Deane, 2005), and would shed a new interpretation on the Semiotician Ferdinand de Saussure’s structuralist enunciation that meaning must be ‘negatively defined’ (1915/1959).

Looking at Topological Features

The raw fabric has two extant topological features worthy of characterization—identity hubs and taste cliques. In addition, we describe what we believe to be a novel application of mathematical morphology (Serra, 1982; Haralick, Sternberg, & Zhuang, 1987) in conjunction with spreading activation (Collins & Loftus, 1975) to discover the taste neighborhoods we hinted at in Section 1.

Identity hubs behave like seams in the fabric. Far from being uniform, the raw fabric is lumpy. One reason is that identity hubs “pinch” the network. Identity hubs are identity descriptor nodes which behave as “hubs” in the network, being more strongly related to more nodes than the typical interest descriptor node. They exist because the ontology of identity descriptors is smaller and less sparse than the ontology of interest descriptors; each identity descriptor occurs in the corpus on the average of 18 times more frequently than the typical interest descriptor. Because of this ratio, identity hubs serve an indexical function. They give organization to the forest of interests, allow interests to cluster around identities. The existence of identity hubs allows us to generalize the granular location of what we are in the fabric, to where in general we are and what identity hubs we are closest to. For example, it can be asked, what kinds of interests do “Dog Lovers” have? This type of information is represented explicitly by identity hubs.

Taste cliques as agents of cohesion. More than lumpy, the raw fabric is denser in some places than in others. This is due to the presence of taste cliques. Visible in Figure 5, for example, we can see that “Sonny Rollins,” is straddling two cliques with strong internal cohesion. While the identity descriptors are easy to articulate and can be expected to be given in the special interests category of the profile, tastes are often a fuzzy matter of aesthetics and may be harder to articulate using words. For example, a person in a Western European taste-echelon may fancy the band “Stereolab” and the philosopher “Jacques Derrida,” yet there may be no convenient keyword articulation to express this. However, when the taste fabric is woven, cliques of interests seemingly governed by nothing other than taste clearly emerge on the network. One clique for example, seems to demonstrate a Latin aesthetic: “Manu Chao,” “Jorge Luis Borges,” “Tapas,” “Soccer,” “Bebel Gilberto,” “Samba Music.” Because the cohesion of a clique is strong, taste cliques tend to behave much like a singular identity hub, in its impact on network flow. In the following Section, we discuss how InterestMap may be used for recommendations, and examine the impact that identity hubs and taste cliques have on the recommendation process.

Carving Out Taste Neighborhoods with Mathematical Morphology

From the raw fabric, another step of processing is needed to reveal taste neighborhoods—patches of taste cohesion that are larger than taste cliques.
Unraveling the Taste Fabric of Social Networks

and more stable than ephemeral taste ethoi. Taste neighborhoods of course, overlap with one another, and the discovery and definition of taste neighborhoods seems even prone to the Ptolemaic dilemma—some nodes must be designated as “center of the universe,” and the choice of these centric nodes can greatly affect the resultant neighborhood definition. Two taste neighborhoods with different Ptolemaic centers are shown in Figure 4.

Taste ethos from spreading activation. While the technical details for the discovery process are potentially lengthy, we sketch a conceptual overview of the implementation here. The raw n by n correlation matrix is reviewed as a classic spreading activation network (Collins & Loftus, 1975). That is to say, activation spreads outward from an origin node to all the connected nodes, then from all connected nodes to each of their connected nodes. The obvious observation here is that in our correlation situation, all nodes are connected to a large percentage of the graph, so our graph is super-connected. However, what makes the spreading activation meaningful is that the strength of the spread activation is proportional to the strength of the PMI along any edge in the graph. The energy of the spreading is also inhibited as the number of hops away from the origin grows, according to a per hop discount rate (e.g., 50%). So, spreading with a low tolerance (or, a high threshold for activation), and outward from “Jazz,” “Yoga” (two-hops away) is reachable, but the energy attenuates before the “Football” (also, two-hops away) node can be activated.

Spreading activation outward from an origin node, the result can be likened to that node’s defeasible (default, in the absence of other inputs or biases) taste ethos. This taste ethos is too small when spreading activation is configured with a modest tolerance. On the other hand, if the tolerance is increased too dramatically, the taste ethos will grow in size but its stability will be undermined due to this well-known problem in graph-based inference: beginning at two hops away, reached nodes lose their semantic relevance to the origin node very rapidly. Think of this as the telephone game effect—playing the childhood game of telephone, the first couple of hops are still recognizable, but recognition often rapidly tapers off after the first couple of hops. The effect is also observed by Google in their PageRank algorithm (Brin & Page, 1998) for scoring the salience of web pages by voting. They noted that high-rank pages tended to link to high-quality

Figure 4. Two Ptolemaically-centered taste neighborhoods, computer generated with the follow parameters—a maximum of 50 nodes in each neighborhood, up to the first three instances of any category type are shown. Spatial layout is not implied by the neighborhood; nodes are manually arranged here.
Unraveling the Taste Fabric of Social Networks

pages, and those to other high-quality pages, but after distance=2, reliability tapered off rapidly.

Mathematical morphology. To discover neighborhoods of taste which are larger than particular node-centric ethoi, but which are still nonetheless stable, we borrow two techniques from the field of mathematical morphology (Serra, 1982; Haralick, Sternberg & Zhuang, 1987) and that are widely used in the image processing literature which appropriates them for object segmentation—morphological opening and thresholding. Morphological opening is the mathematical composition of two operators erosion and dilation, in that order. The intuition is that erosion ‘eats away’ at the boundaries of an object, whereas dilation ‘grows’ the boundaries of the object. However, erosion and dilation are not inverses because both erosion and dilation are injective, that is, they are many-to-one and lossful transformations. The effect of morphological opening is also quite intuitive—it removes small objects ‘disturbances’ and opens up gaps when they are located near a boundary. There is morphological opening and there is also morphological closing which is dilation composed with erosion; closing fills in holes and around boundaries more than opening. We employ opening because it is a bit crisper. Opening eliminates blemishes while closing magnifies blemishes. The other technique, thresholding, is frequently used to post-process an opened image. Applying a fixed threshold to an opened image simply turns every pixel above the threshold to 1, and below the threshold to 0.

Erosion and dilation over spread activations. We choose identity nodes as the centric origins for spreading because they are in general more stable places to start from. This follows the rationale that identities are stronger cultural fixtures than a book or a music album, generally speaking. From the identity nodes, we apply a relatively lenient discount, e.g., 0.8, and spread to define a fairly relevant neighborhood. This is repeated over all identity nodes, begetting an ethos for each identity node. Where ethoi overlap, the max of the node’s energy is taken, rather than the sum of the node’s energies. Now, erosion is applied, trimming back the weakest boundary nodes, followed by a dilation, growing the boundary by adding some energy to all nodes connected to the boundary, pushing some of them over the activation threshold and thus growing the mass. In the current implementation, two iterations of opening are performed, though the meaning of this varies widely with the choice of thresholds and other considerations.

In this manner, larger stable masses of nodes, termed taste neighborhoods, are discovered. Thresholding can help us trim a neighborhood to an arbitrary node-size. For visualizations such as InterestMap, neighborhoods comprised of up to thirty nodes seem visually appropriate. We believe that the application of morphological opening and thresholding to a spreading activation network in order to discover larger stable neighborhoods is a novel use, though we do not evaluate this claim within this paper’s scope.

Summary. This section discussed an implementation of weaving the interest fabric out of social networks. Profiles mined from two social network websites were heuristically segmented and normalized according to a heterogeneous ontology assembled together from a variety of data sources. After normalization, correlation analysis learned the affinities between descriptors, and mathematical morphology over the “raw” fabric enabled taste neighborhoods to be discovered and overlaid onto the fabric. Next, we demonstrate the semantic uses of the taste fabric within application contexts.

WHAT IS A TASTE FABRIC GOOD FOR?

As a rich tapestry of interconnected interests and identities, the taste fabric brings us closer to improvisational manipulations of meaning, and affords us at least three semantic functions—the creation of semantically flexible user representa-
tions, cross-domain taste-based recommendation, and the computation of taste-similarity between people. This section explores these three basic semantic functions in the context of a survey of three applications we have developed. InterestMap is a taste-based recommendation system that leverages interactive visualization of neighborhoods to make the recommendation mechanism transparent, thereby enhancing users’ trust perceptions of the recommender. Ambient semantics uses the taste fabric to facilitate social introductions between two strangers, based on their shared taste. IdentityMirror is a digital mirror for identity self-management. Whereas a real mirror shows you what you look like, IdentityMirror shows you who you are. It explores semantically flexible user representations by allowing time, orderliness, and current events in the world to nuance the representation of the viewer.

Figure 5. Two screenshots of the InterestMap interactive visualization. 5a (top) depicts a user browsing neighborhoods of taste visually. 5b (bottom) depicts a user visualizing his own taste ethos by dragging and connecting interesting nodes to the “who am i?” node.
InterestMap

InterestMap (Liu & Maes, 2005a) visualizes the topology of the taste fabric, and in particular it depicts taste cliques, identity hubs, and taste neighborhoods as a navigatable map. As shown in Figure 5a, users can browse InterestMap’s tapestry of neighborhoods, cliques and identity hubs, or, as depicted in Figure 5b, they can interactively build up their own taste ethoi, by searching for and attaching descriptors to a stationary “who am i?” node. The act of connecting a descriptor to the self is deeper than making a mere superficial keyword association since each descriptor is actually something more like a semantic cloud. Once a user has connected several descriptors to his self, those semantic clouds begin to intersect, overlap, and mingle. They begin to imply that other descriptors, which the user has not selected himself, should be within the user’s taste. Hence, the notion of a visual recommendation.

Taste-based recommendation. InterestMap can, given a profile of the user’s interests, recommend in a cross-domain way, books, songs, cuisines, films, television shows, and sports to that user based on taste. The user’s interests are normalized according to aforementioned processes and mapped into the taste fabric. These nodes in the fabric constitute a particular activation configuration that is unique to the user, and the total situation described by this configuration is the fuzzy taste model of the user. To make recommendations, activation is spread outward from this configuration, into the surrounding nodes. Some nodes in the surrounding context will be activated with greater energy because they are more proximal to the taste signature of the starting configuration. The nodes activated with the highest energy constitute the user’s recommendation. Figure 5b shows a visualization of the recommendation process. The user’s self-described interests are the descriptors directly connected to the “who am i?” node. Each of these interests automatically entails other strongly connected descriptors. This is visually expressed well in the InterestMap visualization because a node getting pulled toward “who am i?” will tug a whole web of nodes behind it. Since the visualization starts with just the “who am i?” node visible on the screen, specifying just a couple of interests can literally fill up the screen with its taste entailments. To visualize the spreading activation mechanism, the size and yellowness of nodes diminishes as activation spreads outward from the “who am i?” node.

Visual recommendation enhances transparency and trust. That a user trusts the recommendations served to him by a recommender system is important if the recommender is to be useful and adopted. Among the different facilitators of trust, Wheeless and Grotz (1977) identify transparency as a prominent desirable property. When a human or system agent discloses its assumptions and reasoning process, the recipient of the recommendation is likely to feel less apprehensive toward the agent and recommendation. Also in the spirit of transparency, Herlocker, Konstan, and Riedl (2000) report experimental evidence to suggest that recommenders which provide explanations of its workings experience a great user acceptance rate than otherwise.

Unlike opaque statistical mechanisms like collaborative filtering (Shardanand & Maes, 1995), InterestMap’s mechanism for recommendation can be communicated visually. The idiosyncratic topology of this taste fabric symbolizes the common taste tendencies of a large group of people. For example, in Figure 5a, it is plain to see that “Sonny Rollins” and “Brian Eno” are each straddling two different cliques of different musical genres. The rationale for each recommendation, visually represented as the spreading of flow across the network, is easily intelligible. Thus it may be easier for a user to visually contextualize the reasons for an erroneous recommendation, e.g., “I guess my off-hand taste for Metallica situated me in a group of metal heads who like all this other stuff I hate.”
Although we have not yet implemented such a capability, the ability to interact with the Interest-Map network space would also afford the system an opportunity to learn more intelligently from user feedback about erroneous recommendations. Rather than a user simply stating that she did not like a particular recommendation, she could black out or deprecate particular clusters of the network which she has diagnosed as the cause of the bad recommendation, e.g., “I’ll black out all these taste cliques of heavy metal and this identity hub of ‘Metal Heads’ so the system will not make that mistake again.”

**Ambient Semantics**

Ambient Semantics (Maes et al., 2005) is a wearable contextual information system that supports users in discovering objects and meeting people through pithy just-in-time feedback given in the crucial first moments of an encounter. Here is an example of a use case involving the discovery of a new book: Wearing the Ambient Semantics RFID reader wristband, you pick up a copy of Marvin Minsky’s “Society of Mind” book. Through your cell phone display, the system tells you that you would be particularly interested in section 3 because it is relevant to your current research topics. It would tell you that your friends Henry and Barbara listed this book among their favorites, and that the author’s expressed opinions seem sympathetic to your own, based on semantic analyses of both your writings. The system can indicate that you would find the book tasteful because it can use taste fabric to detect that it is indeed within close proximity to your taste ethos, translating to a strong taste-based recommendation.

**Exposing shared taste-context between two strangers.** The second use case concerns the system facilitating social introductions by breaking the ice. This scenario demonstrates using the taste fabric for the quantification and qualification of the taste-similarity between two strangers. First, a scenario. You are at a business networking event where Ambient Semantics wristwatches have been given to the attendees. You are tired of the same old conversation starters—what’s your name—who do you work for—how do you like it here?—so you head to the Ambient Semantics kiosk where people are meeting each other in a new way. You introduce yourself to a lady standing next to you. By virtue of your handshake, the physical surroundings are transformed. The music and lighting in the area change to suit the shared aspects of yours and the lady’s tastes. Some graphics of kayaking are thrown up on the kiosk display, as well as the faces of some people. The lady says to you, ‘so you know Bob and Terry too? Are you in the Boston Outdoor Society too?’

**Calculating taste-similarity: quantitatively vs. qualitatively.** There is more than one good way to use taste fabric to calculate the taste-similarity of two people. The more direct way is to measure the intersection of two spread activations. Taking each person’s seed profile of interests and mapping it into the taste fabric, we arrive at an initial configuration. Spreading activation outward from this configuration defines a semantic neighborhood, which earlier in the paper we referred to as a person’s taste ethos. Taking the semantic intersection of two or more persons’ ethoi, we arrive at the quantitative calculation of taste-similarity.

However, another intriguing possibility is to make a qualitative calculation about taste-similarity. Although the intersection of two taste ethoi is mathematically satisfying, it is not easily explainable and articulated. In other words, having the system explain that “the two of you share taste because you both have interests x, y, and z in your spreading activation clouds” is inappropriate. More articulate would be to cite a shared habitation of taste neighborhoods, for example, this explanation—“the two of you share taste because both of you are adventurers and lovers of wine.” Here, the mechanism of the recommendation feels more transparent. To calculate qualitative similarity, each person’s
taste ethos would be used to score the degree of a person’s habitation across the various taste neighborhoods, which as you recall, are centered around identity nodes. Like the classic k-nearest neighbors classification scheme, here we classify persons by their k-nearest taste neighborhoods. Having completed this mapping, the subset of neighborhoods shared among the two or more persons become those persons’ shared situation. To communicate shared neighborhoods to the persons, the neighborhoods could be effectively visualized on a screen, or, neighborhoods are safely summarized by stating the identity nodes which live within that neighborhood.

**IdentityMirror**

What if you could look in the mirror and see not just what you look like, but also who you are? Identity mirror (Figure 6) is an augmented evocative object that reifies its metaphors in the workings of an ordinary mirror. When the viewer is distant from the object, a question mark is the only keyword painted over his face. As he approaches to a medium distance, larger font sized identity keywords such as “fitness buffs”, “fashionistas”, and “book lovers” identify him. Approaching further, his favorite book, film, and music genres are seen. Closer yet, his favorite authors, musicians, and filmmakers are known, and finally, standing up close, the songs, movies, and book titles become visible.

The Identity Mirror learns and visualizes a dynamic model of a user’s identity and tastes. Looking into it, the viewer’s face is painted over with identity and keywords, sourced from this dynamic user model. Taste fabric is used to interpret an initial seed profile into a semantic situation within the fabric. For instance, the viewer specifies that he listens to “Kings of Convenience” and enjoys the fiction of Vladimir Nabakov, and using this, taste fabric situates the viewer within its multiple neighborhoods of taste. The keywords which paint over the viewer’s face represent his context within taste-space.

**Dynamic model of taste.** The richness of connections in the taste fabric allow for a truly dynamic model of a user’s taste—one that can evolve over time, and can absorb the influence of each morning’s world events. First, we explain how world events effect the dynamic user model. In Liu (2003), one of the authors gave a model of context-sensitive semantic interpretation for noun phrases. The phrase “fast car,” under a default context, would mean “a car that is moving fast,” but uttered at a carwash, it could also mean “a car that is washed fast.” Similarly, a person’s identity can be interpreted differently based on each morning’s news. For example, supposing that the morning news reveals an international...
conspiracy, that event could tease out from the user’s taste ethos her one-time penchant for Tom Clancy mystery and suspense novels, even though on any other day, that part of her taste would not have been visible. IdentityMirror implements a feature to allow world events to bias who you look like. It operationalizes this by parsing each morning’s news feed for major topics, and activating those topics in the taste fabric as contextual biases. When the user’s taste ethos is generated by spreading activation away from a starting configuration, the activation would now flow in an unusual way because of the new contextual biases. Thus, the image of the user’s identity has been biased by world events.

Second, we explain how the user’s model can evolve over time by recording the history of changes that a viewer makes to himself in the mirror. By gazing into IdentityMirror, a viewer can glean his identity-situation. Is his hair out of place? Are one of his interests out of place? How do his facial features combine to compose a gestalt? How do his various interests come together to compose an identity or aesthetic gestalt? We implement a feature called Identity Fixing which allows a viewer to “fix” himself as he would fix his hair. Keywords are distributed between a hearth (keywords that are taste-cohesive) and a periphery (outlier keywords seemingly out-of-place about a person); the hearth covers the face, the periphery covers the hair. A person with a strong degree of taste-coherence has ruly hair, whereas a postmodernist with scattered interests has unruly hair. The viewer can use his hands to adjust his hair—he can dishevel those unwanted peripheral keywords, or accept them by packing them into his hair. In the user model, rejecting a keyword de-energizes that keyword in the user’s taste ethos, whereas affirming the keyword energizes that keyword in the user’s taste ethos. As world events tease out new and hidden aspects to the viewer’s taste over time, and as the viewer continues to fix his identity, over time, the viewer’s identity will be well groomed and even well vetted.

ADVANCED DISCUSSION

In this section, we present an evaluation of the taste fabric, present related work, and discuss other ways in which this work is of consequence to the semantic mining and Semantic Web communities.

Evaluation

We evaluate the quality of the taste fabric apropo a telos of recommendation, scrutinizing the performance of recommending interests via spreading activation over the taste fabric, as compared with a classic collaborative filtering recommender. Much of this discussion is adapted from (Liu & Maes, 2005a).

In this evaluation, we introduced three controls to assess two particular features: (1) the impact that identity hubs and taste cliques have on the quality of recommendations; and (2) the effect of using spreading activation rather than a simple tally of PMI scores. Notably absent is any evaluation for the quality of the produced taste neighborhoods, because here we consider only quantitative and not qualitative recommendation. Qualitative recommendation is not claimed to outperform quantitative recommendation in terms of accuracy—our suggestion was that linguistically identifying and visually illustrating two persons’ cohabitations of taste neighborhoods should facilitate trust and transparency in the recommender’s process.

In the first control, identity descriptor nodes are simply removed from the network, and spreading activation proceeds as usual. In the second control, identity descriptor nodes are removed, and \( n \)-cliques where \( n > 3 \) are weakened. The third control does not do any spreading activation, but rather, computes a simple tally of the PMI scores generated by each seed profile descriptor for each of the 11,000 or so interest descriptors. We believe that this successfully emulates the mechanism of a typical non-spreading activation
item-item recommender because it works as a pure information-theoretic measure.

We performed five-fold cross validation to determine the accuracy of the taste fabric in recommending interests, versus each of the three control systems. The corpus of 100,000 normalized and metadata-expanded profiles was randomly divided into five segments. One-by-one, each segment was held out as a test corpus and the other four used to train a taste fabric using PMI correlation analysis. The final morphological step of neighborhood discovery is omitted here.

Within each normalized profile in the test corpus, a random half of the descriptors were used as the “situation set” and the remaining half as the “target set.” Each of the four test systems uses the situation set to compute a complete recommendation—a rank-ordered list of all interest descriptors; to test the success of this recommendation, we calculate, for each interest descriptor in the target set, its percentile ranking within the complete recommendation list. As shown in (2), the overall accuracy of a complete recommendation, $a(CR)$, is the arithmetic mean of the percentile ranks generated for each of the $k$ interest descriptors of the target set, $t_i$.

$$a(CR) = \frac{1}{k} \sum_{i=1}^{k} \text{percentile}(t_i, CR) \quad (2)$$

We opted to score the accuracy of a recommendation on a sliding scale, rather than requiring that descriptors of the target set be guessed exactly within $n$ tries because the size of the target set is so small with respect to the space of possible guesses that accuracies will be too low and standard errors too high for a good performance assessment. For the TASTEFABRIC test system and control test systems #1 (Identity OFF) and #2 (Identity OFF and Taste WEAKENED), the spreading activation discount was set to 0.75. The results of five-fold cross validation are reported in Figure 7.

The results demonstrate that on average, the full taste fabric recommended with an accuracy of 0.86. In control #1, removing identity descriptors from the network not only reduced the accuracy to 0.81, but also increased the standard error by 38%. In control #2, removing identity descriptors and weakening cliques further deteriorated accuracy slightly, though insignificantly, to 0.79. When spreading activation was turned off, neither identity hubs nor taste cliques could have had any effect, and we believe that is reflected in the lower accuracy of 73%. However, we point out that since control #3’s standard error has not worsened, its lower accuracy should be due to overall weaker performance across all cases rather than being brought down by exceptionally weak performance in a small number of cases.

We suggest that the results demonstrate the advantage of spreading activation over simple one-step PMI tallies, and the improvements to recommendation yielded by identity and taste influences. Because activation flows more easily and frequently through identity hubs and taste cliques than through the typical interest descriptor node, the organizational properties of identity and taste yield proportionally greater influence on the recommendation process; this of course,
is only possible when spreading activation is employed.

**Related Works**

*A cultural metadata approach to musical taste.* Whitman and Lawrence (2002) developed a metadata model for characterizing the taste coherence of musical genres. Mining adjectival and noun phrases collocated with musical artist discussions in newsgroups and chatrooms, they applied machine learning to automatically annotate music artists with what they termed “community metadata.” Then Whitman and Smaragdis (2002) applied community metadata to build cultural signatures for music genres that could be used, in conjunction with the auditory signal, to classify unknown artists based on style similarity. Their notion of a metadata signature for musical styles is sympathetic to our notion of taste ethos and taste neighborhood, and both systems take a bottom-up metadata-driven view of meaning definition. A chief difference between our two works is that taste knowledge is located in descriptive word-choice in their system (e.g., “wicked,” “loud”), and located in interest-choice in our system, that is, the choices of what people consume (e.g., “Britney Spears”, “Oreo cookies”).

**Social information filtering.** In prior work, one of the authors co-developed a well-known technique for item recommendation based upon nearest taste-neighbor, the approach known variously as social filtering, or collaborative filtering. Shardanand and Maes (1995) represent users as vectors of (item, rating) pairs, and compute taste-similarity as statistical correlation between user vectors, or alternatively as cosine similarity of vectors in n-dimensional item space. In their Ringo social music browsing system, users were recommended a list of potential ‘tastemates’ on the basis of taste-similarity. One difference between our two approaches is that social filtering maintains distinct user profiles, whereas taste fabrics dissolves user boundaries, and is, in their terminology, a ‘content-based filtering’ approach. In distilling a reusable knowledge resource out of social network profiles that can be reappropriated for a variety of other purposes not concerned with the original social network community, it is necessary to protect the privacy of the original users, and we suggest that taste fabrics serves as a model for doing so. Also relevant is Sarwar et al.’s (2001) item-based collaborative filtering approach to recommendation, which, like taste fabrics, relies upon item-item correlation rather than user-user correlation. Taste fabric exceeds item-based filtering by use of extensive metadata to ‘relax’ the meaning from the item itself, by defining identity descriptors as supernodes, and by representing users as k-nearest neighborhoods. In general, collaborative filtering is more representation-opaque whereas spreading activation over neighborhoods can be visualized and more easily debugged.

**Social network analysis and relational mining.** Much research has examined the explicit structure of social networks, and studied their topologies via graph theory. Newman (2001) mined scientific coauthorship networks and found that collaborations ‘funneled’ through gatekeeper scientists. In taste fabrics, identity hubs, and hubs created around particularly salient interest descriptors constitute a similar topological feature. Jensen and Neville (2002) mined structured metadata relations from the Internet Movie Database (imdb.com) called ‘schema’ and learned a Bayesian network model to represent and predict item distances probabilistically. They also model the relational semantics of social network relations implied between movie actors from the Internet Movie Database and the Hollywood Stock Exchange (www.hsx.com). Finin et al. (2005) examine how the FOAF (“friend-of-a-friend”) ontology applies Semantic Web concepts to enable efficient exchange of and search over social information, illustrating how social networks could develop with its semantics already explicit. Finally one work which considers the semantic
content entailments of social network users is McCallum, Corrada-Emmanuel, and Wang’s (2005) modeling of Author-Recipient-Topic correlations in a social network messaging system. Given the topic distributions of email conversations, the ART model could predict the role-relationships of author and recipient. The work considers group clusters and dyadic relationship dynamics but does not consider cultural aggregates as is the concern of our present work.

**Large-scale commonsense knowledge networks.** Taste fabrics are a rich tapestry which define the meaning space of taste and interests. They are represented as semantic networks and reasoning is performed via spreading activation over this network. This approach to knowledge representation and reasoning builds upon previous work in large-scale semantic knowledge bases such as WordNet (Fellbaum, 1998) and ConceptNet (Liu & Singh, 2004). WordNet is a semantic network whose nodes are words, and edges are various nymic lexical relations between the words, e.g. a “dog” has the hypernym of “canine.” ConceptNet is a semantic network of commonsense knowledge whose 200,000 nodes are verb phrases (“eat burger”, “take shower”), and 1.6 million edges are one of 20 kinds of world semantic relations (e.g., “EffectOf,” “PropertyOf,” “DesireOf”), e.g., (EffectOf “be hungry” “cook food”). ConceptNet and taste fabrics reason similarly by activating a seed configuration of nodes, and spreading activation outward to define a semantic context. Both resources are densely connected, semantically extensive within their respective domains, and allow for improvisational manipulations of meaning to take place atop them.

**Reusable Methodologies**

**Sanitary semantic mining.** The sanitariness of a mined knowledge resource is the degree to which it is purged of idiosyncrasy, especially idiosyncratic traces of user-specific information, and also idiosyncrasies which implicate the original application domain from which the resource was mined. When a knowledge resource is sanitary, assurances can be made that private user data is not recoverable, and that the resource is sufficiently context-free so that it could potentially be used to solve problems across a variety of domains. Taste fabrics are an illustration of how a sanitary knowledge resource can be mined out of a highly idiosyncratic and application-specific data source such as self-descriptive social network profiles. Because it is sanitized, taste fabrics can be publicly distributed and used to power applications living in other domains.

When mining social network data, concern for privacy and copyrights of user data make derivative works especially problematic; yet there is a great need and opportunity to infer valuable semantic knowledge from these sources. Ensuring data anonymity in the produced knowledge resource is a particularly sensitive issue. An early phase of the taste fabric construction process is to normalize the casually-stated keywords and phrases into formal ontologies of non-idiosyncratic form (e.g., “Nietzsche” into “Friedrich Nietzsche”, “dogs” appearing under the “passions” category into “Dog Lover”). Already, the unrestricted idiosyncratic language which bears traces of an authorship are beginning to be wiped away. In contrast, collaborative filtering systems maintain ratings for each user, and while users do not have to be named, even unnamed users are not anonymous, they are only pseudonymous. A user’s name is simply wiped away and replaced with a unique id (renamed from “John Smith” to “User #123”), but the profile’s integrity is intact. Because the number of instances is quite large in the space of tastes, it may be possible to recover the identities of pseudonymized users because the constitution of profiles are quite unique. At the very least, maintaining any information structured around the notion of a user lends itself to the perception that privacy of the source data may be violated.
Rather than preserving individual profiles, the taste fabric simply uses these profiles to learn the strengths of connections on a network whose nodes already exist (they are simply an exhaustively enumeration of all features in the ontology). The method of the learning is non-linear so explicit frequency counts cannot easily be recovered. Thresholding and neighborhood definition are further lossful transformations which make details of the original application data virtually unrecoverable. The final structure is sanitary—it assures the anonymity of the data source, and is much easier to distribute.

Instance-based semantic webs and ethotic representation. In the Semantic Web community, ontology and metadata systems are often seen as top-down and bottom-up approaches to knowledge representation, respectively. To draw parallels with the artificial intelligence literature, ontology is a category-based representation, and metadata is a feature-based representation. However, taste fabrics introduces the notion of an instance-based representation, which we feel to be a promising methodology for the Semantic Web community that warrants further study, especially into the issue of scalability. An instance-based representation lacks categories or features, having only items and dense numerical connections between them. Knowledge is thus unpacked from the linguistic symbolism of a category or feature’s name, and instead, is found in connectionism—the flow of semantics through a graph of items. The shift from symbolic interpretation toward continuous interpretation parallels Zadeh’s efforts in attempting to soften the bivalence of logic representation by giving a fuzzier, more continuous account of meaning (Zadeh, 2004).

Instance-based representations are more appropriate for semantic recognition and semantic mediation because they offer continuous numerical interpretation of entity similarity. In taste fabrics, users, groups of users, and cultures can all be represented uniformly as clouds of node activations in the fabric. A taste fabric allows the meaning of a user’s keyword profile to be ‘relaxed’ into a semantic cloud which we term an ethos. Using ethotic representation, semantic mediation between two users or entities in the fabric can be computed quite easily as shared activation, and even effectively visualized. By interpreting an ethos as a membership into k-neighborhoods, the resource can be used to classify users or entities into an ontology of neighborhoods (the organizing force of ontology, in fact, is still present in the resource via neighborhoods and identity descriptors). Instance-based representations and ethotic representations would be well-suited for semantic resources meant for mediation and classification in the Semantic Web.

CONCLUSION

This paper presented a theory and implementation of taste fabrics—a semantic mining approach to the modeling and computation of personal tastes for lifestyle, books, music, film, sports, foods, and television. Premised on philosophical and sociological theories of taste and identity, 100,000 social network profiles were mined, ontologically-sanitized, and a semantic fabric of taste was weaved. The taste fabric affords a highly flexible representation of a user in taste-space, enabling a keyword-based profile to be ‘relaxed’ into a spreading activation pattern on the taste fabric, which we termed a taste ethos. Ethotic representation makes possible many improvisational manipulations of meaning, for example, the taste-similarity of two people can be computed as the shared activation between two ethoi. Taste-based recommendation is already implied by a taste ethos, as all items within an ethos are intrinsically relevant to the taste of the individual. Indeed, an evaluation of recommendation using the taste fabric implementation shows that it compares favorably to classic collaborative filtering recommendation methods, and whereas collaborative filtering is a opaque mechanism,
recommendation using taste fabrics can be effectively visualized, thus enhancing transparency and cultivating user trust.

Two models of taste-based recommendation—one quantitative based on shared activation, and one qualitative based on k-nearest neighborhoodswere presented. Recommendation, time and world-sensitive user representation, and interpersonal taste-similarity, were illustrated within a survey of three applications of taste fabrics.

This paper makes three contributions to the literature. First, it presents a novel mechanism for mining and modeling the taste-space of personal identities and interests. Second, the mining and weaving of taste fabrics from idiosyncratic social network profiles raises the issue of sanitation of knowledge resources, and this paper illustrated how ontology and non-linear correlation learning can be used to purge idiosyncrasy and prepare a general-purpose grade knowledge resource. Finally and third, in addition to ontology-based and metadata-based knowledge resources, taste fabrics introduces a novel third approach to the literature—instance-based fabrics, where the notion of ‘knowledge’ is a purely relational one. Fabrics, we suggest, excel at semantic mediation, contextualization, and classification, and may play a valuable role as a context mediator in a recently complicated Semantic Web of formal, semi-formal, and now, informal, entities.

Chapter 4.8

Computer-Mediated Communication: Enhancing Online Group Interactions

J. Michael Blocher

Northern Arizona University, USA

ABSTRACT

Advancements in information technology have transformed much in all aspects of today’s society. In particular, synchronous and asynchronous electronic communication systems support countless interactions every day. However, these communication systems have specific limitations that can cause miscommunications as well. Because of that, computer-mediated communications (CMC) has been a robust research agenda in many disciplines. This is especially true of education, where online learning has become common place in all but a few universities, thus requiring learners to interact via CMC within virtual learning environments. This chapter will use educational CMC research as a lens to promote and support an understanding of how to better utilize and facilitate electronic communication, regardless of the field or endeavor.

BACKGROUND

Over a decade ago, Rheingold (1993) described how the Internet, specifically, synchronous and asynchronous electronic communication could create a non-linear and level environment that provides the conduit for human interaction that is culturally neutral—where members meet in virtual communities judged by ideas, thoughts, and contributions, rather than by race, gender, age, physical appearance, or national origin. In particular, CMC was described as a venue where participants could engage in discussions on bulletin boards and listservs with equal impunity and have the opportunity to create a cyber community. Due to the lack of visible and contextual cues, participants engaging in this, somewhat, anonymous form of communication were free from prejudice and able to speak their mind more freely and openly than in traditional face-to-face
group interactions. However, this turned out be only somewhat correct, and the literature provides ample examples of how CMC group interactions follow similar patterns and styles that have been identified within traditional face-to-face group interactions.

Communication Style Differences

Communication style differences, particularly, gender-based differences have been identified as one area that has been investigated in more historic group interaction literature. Specifically, women tend to engage in group interactions with a style distinctly different than men. Eakins and Eakins (1978) in researching gender styles within group interactions discovered that women tend to be more engaged in developing intimacy and maintaining relationships than their male counterparts. In other words, women tend to be more interested in building relationships and developing closeness within their group than men do. For example, women are more apt to ask for another’s opinion, desiring to engage others within the conversation. Men, on the other hand, tend to be more directive and less apt to draw out the interaction (Fishman, 1983). Perhaps this is because, in general, women are more interested in the social aspects of group interaction. For example, Carli (1984) reported that women are more social-oriented, while men are more task-oriented in their interactions. Furthermore, Briton and Hall (1995) reported that women tended to be better at using nonverbal cues, being more expressive, utilizing body language, eye contact, and gestures to send and receive subtle messages to promote and enhance communication in group interactions. Men, on the other hand, leaned toward competitiveness and dominance seemed more apt to be more competitive and less socially motivated in their group interactions—using fewer subtle nonverbal cues.

In terms of group interactions where productivity is at issue, Maguire (1999) reported that within studies of marketing executives women work more to build consensus while men tended to make faster decisions. One could argue that one style is better than the other at supporting communication in group interactions, as both have benefits and limitations. For example, being more direct could be seen as a way to improve communication by not clouding the issue with possibly vague nonverbal cues. On the other hand, by providing more information via other channels (e.g., body language, facial expressions, etc.), the verbal message might be further enhanced, with less chance of misunderstandings. Furthermore, by utilizing a communication style that seems competitive and dominating, issues of power may cloud or hinder the real message. Again, on the contrary, using less direct verbal communication could be seen to hinder one’s ability to provide leadership. Which style makes a better communicator—one who builds community or consensus through social group interactions enhanced with non-verbal cues, or one who improves productivity with more directive style communication?

It could be argued that it might be better to try to understand these communication style differences, rather than trying to debate which might be more effective, as each has benefits and limitations. This is especially important within the CMC environment. As we will see in the next section, CMC group interactions have other issues based upon the various CMC media, which can greatly impact these more traditional communication style differences.

CMC Communication Style Differences

Of course, these gender differences are generalities. One’s individual group communication style is just that, individual. However, these gender-related communication style differences seem to parallel a CMC environment as well. As in all social environments, membership within a CMC group environment can be dominated by
more spirited individuals, and certain hierarchies can develop or emerge based upon the members’ interactions within that virtual community. Of particular note, Herring (1993) details that virtual communication spaces may not be the democratic spaces described earlier—primarily because of the communication style differences brought naturally to the environment by the various group members and the community ethos that the group develops. For example, her study reported that men generally made “strong assertions,” engaged in “self-promotion,” asked “rhetorical questions,” came from an “authoritative orientation,” provided “challenges and humor.” Women, on the other hand, tended to ask “questions,” provided “attenuated assertions,” had a “personal orientation” and provided “support” in their CMC. As discussed above, these two gender-based communication styles mirror those of the traditional research. Generally, women tend to foster consensus and community building, while men tend to demonstrate a communication style that is more directive in nature.

While this supports the argument that men are more apt to utilize a more directive CMC style, perhaps more interesting are specific investigations into chat (synchronous communications) that have detailed how gender communication style differences were power-based in particular. Soukup (1999) stated that in his study, “Masculine participants were aggressive, argumentative, and power oriented. While feminine participants sought relationships and intimacy, they were often dominated and overpowered by the aggressive discourse of the masculine members (p. 169).” Perhaps, even more disturbing, findings were reported by Herring (1999). She described male-dominated harassment of female participants in two case studies, stating: “Due perhaps to the youth and sexual preoccupations of the majority of its users, Internet relay chat (IRC) tends to sexualize female participants, and to involve them in flirtatious interactions. Accordingly, the ideal for female interactions in IRC appears to be cooperative flirtation, as it is also in many off-line recreational social realms” (p. 163).

One would think that this type of interaction might inhibit female members when engaging in online communication, perhaps making them more apt to adjust or change their online communication engagement; perhaps even hide or mask their gender identity in CMC environments to guard against this type of interaction. To answer that question, Jaffe, Lee, Huang, and Oshagan (1999) investigated how participants, when given opportunities, chose to select anonymous pseudonyms for their CMC. Some participants chose pseudonyms with same gender, others chose pseudonyms that were cross gender, and finally some chose pseudonyms that were gender neutral. Gender-neutral and cross-gender pseudonyms then collapsed into gender-masking, thus providing two categories as same-gender and gender-masking. They reported that, “Seventeen (81%) of the 21 male participants in the pseudonymous conference chose pseudonyms that retained their gender identification. In contrast, 13 (81%) of the 16 females in the pseudonymous conference chose pseudonyms that masked their gender identification” (1999, p. 227). This significant difference (p < .001) between men and women demonstrates a greater tendency, by women, to utilize a pseudonym that masked their gender. The authors of this study saw this as evidence of a direct strategy to level the playing field stating:

*This finding is interpreted to reflect an effort to rectify an imbalance, felt by women, of social parity when interacting in mixed-gender situations. An especially pertinent example of previous gender-based naming practices provides historical justification for such sentiments. In anecdotal recollections within the scientific research profession, female authors were often referred to by first and last names, while only initials and last name identify males.* (Jaffe, Lee, Huang, & Oshagan, 1999, p. 230)
The CMC literature provides examples where group interactions within CMC environments seem to exacerbate the communication style differences, perhaps making men aggressive and making women more engaged in building social relationships in their communication styles. However, it seems that if given the opportunity, women tend to mask their gender for strategic purposes.

**Summary**

Although the CMC technology does have the potential to provide a non-linear and level environment that provides the conduit for human interaction that is culturally neutral, it seems that it may not. Indeed, the studies described above strongly indicate that CMC may not be the level playing field that it was once thought to be. In particular, there are communication style differences within the CMC environment that parallel traditional communication styles, thus creating a group communication environment where the communicators interact in similar ways that they would in traditional face-to-face environments—where gender, power, and communication style may have a strong impact on one’s communication within group interactions.

It is important to remember that these are general tendencies and that not all CMC group interactions are destined to exhibit the type of interactions described above. Rather these are tendencies that could impact one’s experience engaging in CMC, which might be exacerbated by some of the unique communication issues that are specific to current text-based CMC. For example, often a message is sent that is totally benign. However, the message even when taken simply for the written text may be taken for a completely different meaning than originally intended, because the sender and recipient engaged in the communication at different times, locations, and states of mind. Being more knowledgeable about the tendencies and limitations of CMC could help limit more adversarial interactions that were based upon miscommunication due to CMC issues or communication styles. In particular, becoming aware of and monitoring one’s personal communication style could help make the individual more thoughtful and strategic about their communiqués, thus reducing the tendencies for miscommunication to occur. The next section will discuss specific issues at work within the current CMC environments that might hamper communication and strategies that could be implemented to enhance more equitable and clear CMC engagement.

**ISSUES**

As described, gender, power, and communication style can impact one’s personal communication interactions within a CMC environment. Although these elements parallel traditional face-to-face communication interactions, there are issues with CMC that are unique to that environment. In particular, the discussion will focus on current CMC issues in terms of how asynchronous and synchronous electronic communication tools limit the capacity of communication cues and meta-information as well as communication styles in terms of gender, and whether these issues can be influenced to help ameliorate those limitations.

**Media Richness**

Much of the CMC literature suggests that communicating within electronic messaging systems, which are primarily text based, limits communication because of the lack of other communication cues or components. Media richness theory (Daft & Lengel, 1986) defines communication media in terms of face-to-face communication elements. These elements include immediacy of feedback, non-verbal, and other cues that enrich communication. In other words, a medium is considered richer or thicker when it can sup-
port a greater number of cues to communicate a person’s ideas (e.g., facial expressions, gestures, voice inflection, etc.). In light of media richness theory, current CMC is defined as being “lean” because much is asynchronous communication, lacks immediacy of feedback and generally lacks “multiplicity of cues.”

In terms of immediacy of feedback, imagine a face-to-face interaction where participants give and receive concurrent and instant feedback while they monitor the message reception and consider its impact. Compare that to asynchronous CMC where interactions are often delayed by hours, if not days. Indeed, can a sender remember the exact meaning of a message or state of mind they were in upon sending a message when they receive the reply a day or two later? Even synchronous CMC (chat) lacks in immediacy, where there is a lag time of waiting for the individual to complete their typing. Furthermore, synchronous chat is dependent upon the individual’s keyboarding skills.

In addition to the limitations of asynchronous communication, text-based CMC also does not include non-verbal cues, inflection, and other elements of face-to-face interactions. As most current CMC messages are text only, they are devoid of very rich communication cues that can cause miscommunication. These missing cues can impact CMC with possible miscommunications in several ways. For example, often in verbal communication of most languages inflection describes how the message is to be taken. English speakers often use inflection to relay whether something said is a statement or a question. Punctuation provides cues in the written language to account for this issue. However, many times in CMC group interactions, communicators use less than formal writing styles, which often can cause confusion. An additional example is sarcasm. While one might fully understand one’s intent of a sarcastic statement in a verbal interaction, the message can very easily be mistaken in a written interaction.

**Media Richness’ Impact on Communication Style**

Can media richness in CMC impact one’s ability to communicate, depending upon an individual’s communication style? In other words, if one’s communication style utilizes communication cues that are missing in the leaner CMC media, will it create a less equal communication environment? To help answer that question Dennis, Kinney, and Hung (1999) investigated decision-making task performance in terms of media richness and gender differences. In particular, they attempted to answer questions of the impact of media richness on performance in terms of “decision time,” “decision quality,” “consensus change,” and “communication satisfaction.” The study investigated gender-based teams performing equivocal decision-making tasks both in synchronous chat and face-to-face. As women tend to better utilize and read non-verbal cues, which are missing in CMC, they were especially interested in the results of the impact of gender on the performance tasks. Teams of all male, all female, and mixed gender were formed and compared performing equivocal decision-making tasks in both face-to-face and chat environments. The results indicated that only “decision time” was impacted by the use of CMC. Indeed, “decision quality,” “consensus change,” and “communication satisfaction” were not significantly impacted by the use of CMC. Interestingly, the all-female team took five times as long to complete an equivocal task of reaching a decision utilizing CMC than it did face-to-face. This supports the idea that CMC has a more profound impact on women than men due to the lack of cues that women tend to better utilize as they needed more time to complete the tasks. More interesting, however, is that the decision quality of the all-female team utilizing CMC was higher than the all-male and mixed-gender team; second only to the all-female face-to-face decision-making team. In other words, while missing the nonverbal cues, it took this team much longer
to perform the task, but the female members still took the time to perform at a high level regardless of media—suggesting that they could, and did, modify their engagement to successfully complete the task.

This study provides evidence that media richness, or leanness of, in this case, does impact one’s ability to engage in CMC group interactions. More specifically, since women tend to utilize nonverbal communication cues more often, a CMC medium that strips out those communication cues, can provide a distinct gender disadvantage. However, it is very important to remember here that these are tendencies. Indeed, anyone who utilizes a communication style that is supported by nonverbal communication cues and engages within a CMC group interaction where those cues are missing due to the medium’s leanness is at a disadvantage—regardless of gender.

**CMC Strategies**

From the study detailed above it seems that the participants modified or enhanced their communication within the limited media in some way to better perform their tasks. While it is clear that various CMC media have limitations, users can and do use strategies that can help ameliorate the limitations of a particular media. There are specific examples of communicators modifying their communication to better fit a medium. As a case in point, text shortcuts, such as: btw = by the way, irl = in real life, cu ltr = see you later, and imho = in my humble opinion, have been developed and utilized within in CMC environments providing evidence of communicators utilizing new methods to speed up and facilitate their interaction. The practice of abbreviated-text messaging and instant messaging has become common place. Indeed, mobile phone text messaging has become a social phenomenon practiced by young people in many parts of the world. For example, Grinter and Eldridge, (2003) describe how British teenagers are similar to teenagers in other parts of the world in their use of a meta-language of shortened words to send text messages for a variety of purposes, including coordinating future communications within other media, generally phone calls. This trend suggests that these young communicators have developed an understanding and the strategic utilization of various media for a variety but connected purposes.

The above example shows modifying a simple communication method to be more strategically purposeful of the specific communication media. However, as discussed above, gender-based communication style is much more complex. Will one utilize CMC strategies to reduce the limitations of CMC media? Fahy (2003) investigated supportive CMC strategies within an online learning environment to see if participants utilized strategies that would increase interaction and reduce interpersonal distance within the leaner CMC media. Specific strategies were defined as supportive and were seen to replace or approximate “sociolinguistic devices and strategies, including nonverbal elements normally available in face-to-face interaction, (Ridley & Avery, 1979)” (Fahy, 2003. pg. 5). The results suggest that these participants were able to and took the time to utilize important CMC strategies. As Fahy states: “One-quarter (25.9 per cent) of all interaction in these conferences was classified as supportive, a proportion which, though it must be tested against wider and larger conferencing samples, indicates the importance attached to the interpersonal in these online interactions” (Fahy, 2003, p. 11). Students who engaged in these online conferences did, in fact, utilize the CMC strategies that approximated the missing cues, thus enriching the lean medium that promoted a more supportive group interaction.

**Gender-Based Communication Style Identification**

While the CMC literature suggests that men and women tend to utilize different communication...
styles in CMC, one might ask: How strong are these tendencies and can the communication style give away the author’s gender identity in an anonymous interactive environment? Can one judge the gender of a CMC author based on the CMC style without knowing the author or his/her gender? Does one’s awareness of CMC styles provide a tool to distinctly judge an author’s gender? In other words, is a person’s gender given away by his or her communication style even in an anonymous CMC environment? Savicki, Kelley, and Oesterreich (1999) detail a series of studies where participants were grouped in male-only, female-only and mixed-gender groups for CMC interactions. Their anonymous messages were then provided to participants to be judged as to the author’s gender based upon the communication style analysis. They analyzed messages that included a greater number of “I” statements, statements of personal opinion, self-disclosure, and coalition language. “Since this pattern of communication was related to high levels of satisfaction with the group process and high levels of group development, it was labeled the high group development communication style (HCS) and contrasted with the opposite style, low group development communication style (LCS)” (p. 187).

As might be predicted, participants were quite accurate in judging a LCS message authored by men (.708), while significantly less accurate (p < 0.001) in judging an HCS message authored by men (.395). In opposition to prediction, however, participants were significantly less accurate (p < 0.05) in judging HCS messages authored by women (.549) than LCS messages authored by women (.662). These results support the finding that participants were significantly more accurate when judging LCS messages than HCS messages, regardless of the gender of the author. In this study, if a message exhibited HCS it was more difficult to accurately judge the author’s gender than messages that exhibited LCS. They also reported that the judge’s gender or CMC experience did not seem to factor into the level of accuracy as no significant differences for these variables were found.

These mixed results suggest that, while gender identification may be possible, it is quite limited. In other words, if authors utilize HCS within their anonymous CMC messages, there is less likelihood of being identified as male or female. If one’s communication style includes HCS in the CMC messages, they may well be taken for their information and not for their gender. This may have an impact on helping promote a more democratic communication environment based on gender inequities previously discussed.

**Gender-Based Communication Style Training**

Certainly, promoting more democratic CMC group interaction seems a prudent thing to try to achieve. However, can one be trained, and more importantly to become motivated, to utilize HCS to support participation, satisfaction, and group development within a CMC environment? Savicki, Kelley, and Ammon (2002) investigated that question by grouping participants in male only (MO), female only (FO), and mixed gender (MIX). They examined how HCS training would impact participation, satisfaction, and group development. The results were mixed. For example, while they reported that the FO groups scored higher on group development, it may have been due to the potential of gender-based communication style tendencies for that group of females rather than HCS training. However, HCS training for the MIX groups had a greater impact than the MO. The authors state that:

. . . the MIX groups responded somewhat more to the training than the MO groups. The combination of men and women in the same group seemed to change the norms toward more acceptance of HCS communication. Gender is an important variable influence communication in
online groups (Savicki & Kelly, 2000). Gender communication norms seem to be quite strong and should be taken into account when selecting participants for virtual teams. (p. 267)

It seems logical to presume, and from the findings of this study, that it is possible to provide HCS training to impact user engagement. The MIX groups did provide some evidence of the success of the training. However, the HCS training MO groups had less success, according to the authors, because of previously established gender norms. Training individuals to change their communication style for group interactions, in terms of developing higher group development communication skills, may be more complex than first thought. For example, it may not be as simple as providing HCS training, as more social communication interaction norms are at play. However, this study also instigates a question. What interactions in the MIX groups promoted consensus or community building to change the communication norms of accepting increasing use of HCS communication more than the MO groups?

**Summary**

The studies described above detail some of the major issues of CMC. Specifically, current CMC systems tend to be lean media in terms of media richness theory, which can impact certain populations based upon their communication strengths. However, it also would seem that communicators believe it is important and take steps to ameliorate the limitations that the lean media present by utilizing communication methods and strategies that are supportive in nature. Interestingly, utilizing higher group development communication style (HCS) might limit the identification of the communicator, thus possibly providing a more level communication venue in terms of gender. More importantly, however, it seems that the studies above demonstrate that communication styles, although tend to be gender-based, may be a matter of choice. Furthermore, although it seems possible to provide training to support more HCS communication, the process may be quite complex. Indeed, higher group communication development may be greatly impacted by the membership of that group. Although this might seem logical and somewhat simplistic, it could have very complex implications. For example, in becoming knowledgeable about, and strategic in the use of their communication style, CMC users could become better more effective and thoughtful communicators by utilizing a style that is more engaging, supportive, and more likely to foster group development. However, they may not be motivated, or perhaps do not believe they have the permission to do so based upon the membership and communication norms of their virtual group.

**RECOMMENDATIONS**

From the review of the literature there are several issues that dominate the various common CMC systems and the participants who engage in group interactions within them. In particular, there are issues of media richness and communication style differences. In addition, there is the issue of a group’s communication norms. These factors can impact the group’s communication norms, which might be defined by: (A) the makeup of the group membership, (B) the purpose of the group, and (C) the media they employ to communicate. These issues can provide some challenges for CMC users. Drawing from distance or distributed learning theory will provide some recommendations to help support electronic communication by building online communities where group interaction is enhanced by developing membership within a community of practice. In addition, the literature suggests CMC strategies that might help communicators better their electronic communiqués, thus reducing miscommunications.
and more equitable group interactions. Finally, current CMC technologies generally provide for text-only communication. In particular, there is the issue of media richness with communication environments that utilize a suite of tools that include only the traditional text-based synchronous and asynchronous e-communication systems. Utilizing multimedia CMC systems that include audio and/or video in addition to the lean text-based synchronous and asynchronous systems can help thicken the communication media, thus alleviating some of the limitations and issues discussed above. All of these will be discussed in the next section.

**Community Building**

As discussed earlier in this chapter, Rheingold (1993) described virtual communities where members interact using CMC within a level social environment. Although this ideal may have been suggested prior to having a greater understanding of some of the media limitations and how group interactions are impacted by them, it does not mean that the idea should necessarily be abandoned. This is especially important as group communication norms can dictate the membership engagement of communication style. One only needs to look at the incredible growth in online tools like, MySpace (n.d.), Orkut (n.d.), and the plethora of blogs to see that people want to communicate and engage in CMC group interactions. For example, more advanced robust open-community CMC systems, such as BuddySpace, are being developed to provide the users with greater flexibility, in terms of connectivity with other platforms. In addition, BuddySpace provides the users’ location, which can help group individuals who might have similar interests because of their locale. However, as with any community, online community members may not be as supportive to one another as they ultimately could, or perhaps should. Therefore, it would be wise to understand the elements of community building as it may impact CMC group interactions in online communities.

In a very well-established text, Kim (2000) provides details and recommendations of community-building strategies that are supported by three underlying design principles: (a) design for growth and change, (b) create and maintain feedback loops, and (c) empower members over time. These principles suggest that the placement of responsibility of community development begins with the designers or developers rather than members. However, it supports the cultivation of member ownership by its three design principles. For example, designing for growth and change, allows for the community to be molded by the feedback received from the members as they gain empowerment. With the empowerment of the members over time, the organizational ownership and responsibility of the community will be cultivated and be accepted by its members. That it not to say, however, that in an online community, the members cannot be the designers and or developers. Regardless, in Kim’s recommendations the members will assume responsibility and ownership of the community.

Another example of community building is detailed in the work of Wenger (1998). In defining a “community of practice,” he provides a detailed outline that identifies a more complex view of communities, stating:

A community of practice defines itself along three dimensions:

- **What it is about:** It’s joint enterprise as understood and continually renegotiated by its members.
- **How it functions:** Mutual engagement that binds members together into a social entity.
- **What capability it has produced:** The shared repertoire of communal resources (routines, sensibilities, artifacts, vocabulary, styles, etc.) that members have developed over time. (p. 54)
Wenger’s description of a community of practice suggests that “members bind together in a social entity” by sharing routines, sensibilities, artifacts, vocabulary, and style. Wenger goes on to say, “Even when a community’s actions conform to an external mandate, it is the community—not the mandate—that produces the practice. In this sense, communities of practice are fundamentally self-organizing systems (p. 2).” The concepts outlined in Wenger’s community of practice have very interesting implications in light of the HCS training findings of Savicki et al. (2002). In that study, the mixed-gender groups moved toward building a community of practice by changing their norms to accept and use more HCS in their CMC within their group interactions. However, one could also argue that the male-only group members also moved toward building a community of practice by not changing their group’s communication norms to accept and use the HCS communication strategies. The HCS training had little or no effect on the male-only group. On the contrary, the group maintained their communication style regardless of the training, perhaps because of the strong influence of the male group communication norms. The external mandate, as Wenger describes, could be seen as the training to change to HCS communication, which was not accepted by the male-only groups, but was more so by the mixed-gender groups. In this case, the CMC norms were developed and determined by the group. This supports the idea, in terms of online communities, that the ownership and responsibility for the practice of the community lays within the members of the community, not the administrators or developers of an online space.

To provide an example in practice, let us look at designing and developing an online course of study, which utilizes CMC systems to build communities of practice that support enhanced group interactions. It is important to remember that online course delivery has its roots in the distance learning model originally developed that utilized the traditional mail system to send materials to learners in remote locations in the early part of the 20th century. As technology developed, course material delivery moved to more advanced systems: radio, television, CD-ROM, and, eventually, to the Internet. As the delivery methods advanced, opportunities for learner interaction became greater because of the possibilities for group interactions using CMC. Distance learners were no longer limited to primarily one-way information dissemination for their learning experience.

Distributed learning is a term that has been used to replace distance learning by some. Dede (2004) defines distributed learning communities where learners engage collaboratively to develop knowledge as they interact within the various electronic communication and information delivery systems. In this concept of community building, group interactions are distributed via CMC and other more advanced electronic tools, to help members actively engage with one another for the specific purpose of learning. Here, learners within the distributed learning community utilize a variety of resources in a highly structured learning environment. Learning management systems, such as WebCT (n.d.) and BlackBoard (n.d.) include the tools to support this definition of distributed learning.

Although the use of the CMC systems will provide the opportunity for group interactions within a distributed learning environment, the members within the community are still responsible for their interaction and, thus, for their learning. Therefore, designing and developing an online course of study that utilizes distributed learning elements is more complex than using a system to make course materials and opportunities for group interaction available. The key to a distributed learning environment, accordingly, is building communities of practice through the utilization of multiple electronic communication systems that advances the opportunities for the
Computer-Mediated Communication

members to engage, thus making CMC the vital means of group interaction.

In this example, the designer, developer, and/or the instructor begin by selecting the interactive communication systems to utilize. They also will need to design learning activities and assignments that will have the learners engage with the course materials and activities. Finally, they also provide guidelines for group interactions the learners will have with the instructor and their peers. Palloff and Pratt (1999) described effective strategies for building and the cultivation of an online learning community that fosters greater group interaction that augments online learning. They outline a framework for online instruction that provides for: (a) mutually negotiated guidelines, (b) focused outcomes, (c) active creation of knowledge and meaning, and (d) collaborative learning. Interestingly, these elements echo the communities of practice work of Wenger (1998) in terms of sharing the responsibility of community building and, in this case, learning throughout the membership of the community. All of the members, including learners and instructors, become responsible for developing the community of practice. For example, by promoting mutually negotiated guidelines, learners are given the opportunity to share ownership of the learning environment that will bind the members together in a joint enterprise. Learners utilize CMC to communicate with their peers and instructors to mutually produce the shared repertoire of communal resources and learning guidelines that will structure their social entity—the learning community. Through their collaborations they actively create knowledge and meaning based on the focused outcomes, as defined by the community. Designing an online learning environment with these four strategies will then support the members in building a community of practice for learning that utilizes the pedagogy and technology of distributed learning. Here members become responsible for and have the tools to “bind together in a social entity” where they share routines, sensibilities, artifacts, vocabulary, and style.

As learners collaboratively build their learning community of practice through the construction of artifacts, vocabulary, routines, sensibilities, and style, they are building shared knowledge.

The idea of building shared knowledge is at the heart of the distributed cognition work of Hutchins (2000). Distributed cognition theory suggests that knowledge and knowledge acquisition go beyond the individual. Rather, knowledge is constructed through the social interactions, where individuals share and co-construct knowledge. In other words, knowledge is not constructed by the individual alone, but instead by the interacting members engaged in the learning process. This is an important characteristic of distributed learning that supports the concept of communities of practice producing a “shared repertoire of communal resources (routines, sensibilities, artifacts, vocabulary, styles, etc.) that members have developed over time” (p. 54). If the joint enterprise of that online group is that of learning, then membership within that community supports and fosters shared knowledge construction. This suggests that, in terms of community building, through their group interactions the social entity and its members build knowledge as they build community.

This section has focused on the elements of community building within online groups, emphasizing that through the development of an online community of practice where group interaction is enhanced by members negotiating the communication norms and behaviors and working collaboratively to build and distribute knowledge. In doing so, through enhanced group interactions the social entity builds community, shares elements and resources that support the individuals within that community. Therefore, to support the initial building of community, it is suggested that administrators and developers of those groups provide ample tools and, perhaps structure, but that it is ultimately the membership that makes the rules. This does not fully address issues of power, as individuals who tend to be more aggressive may still dominate discussions.
and communications. Although the CMC administrators of the online community could censure inappropriate individuals, and some communities may decide that some form of policing is appropriate, still, here, the membership should be responsible for the decision making of that policy. It is recommended that by building an online community of practice, inequities, and disagreements would be settled by the membership of that community, based upon that group’s agreed-upon norms. The next section will outline various communication strategies that will help reduce miscommunications that can often be the cause for online disagreements.

**Utilizing CMC Strategies**

Building a community that shares and co-constructs knowledge could be enhanced by what has been learned about CMC strategies. Although, as has been argued above, the membership of an online community is responsible for setting the communication norms of their group, it still seems prudent to be aware of helpful communication strategies. For example, if the membership of the online community creates routines, sensibilities, artifacts, vocabulary, styles, as Wenger (1998) suggests, it would seem that communicators would benefit from understanding, being aware of, and utilizing CMC strategies within their messages that support more personal interactions. By doing so, there may be less miscommunication, which can often erupt into disagreements.

To better understand communication interactions, Fahy, Crawford, and Alley (2001) developed the transcription analysis tool (TAT), which provides five CMC interaction categories, three of which have subcategories.

- **T1 – Questioning**
  - T1 (a) vertical
  - T1 (b) horizontal

- **T2 – Statements**
  - T2 (a) direct
  - T2 (b) answers or comments

- **T3 – Reflections**

- **T4 – Scaffolding**

- **T5 – References, Authorities**
  - T5 (a) references, quotations, paraphrases
  - T5 (b) citations or attributions

In a later study, Fahy (2003) utilized a specific subset of the categories from the TAT, listed above, to investigate participant use of supportive communication strategies. The supportive communication strategies investigated included:

- **T1 (b) horizontal questions**, which promote more discussion as this type of question does not presume one correct answer, but rather invites any plausible answer.
- **T2 (b) referential statements**, message statements that directly or indirectly refer to another’s message, thus engaging more than just the author of the message.
- **T4 scaffolding and engaging comments** including:
  - **Acknowledgement**: Recognizing or acknowledging comments or statements from prior messages.
  - **Agreement**: Expressing agreement.
  - **Apology, or self-criticism**: Making an apologetic statement.
  - **Closing**: Using some sort of summary or closing (e.g., later).
  - **Emoticon**: Using emoticons (e.g., ;-)).
  - **Humor**: Using humor to lighten the mood.
  - **Invitations**: Statements that invite a response.
  - **Rhetorical questions**: Posing a rhetorical question.
  - **Salutation**: Using a greeting, especially with the individual’s name.
  - **Signature**: Using a signature or nickname.
  - **Thanks**: Expressing thanks.
He found that participants believed that supportive CMC strategies were important and utilized them within an online learning environment in 25.9% of the interactions. In particular, he found that the most commonly used supportive communication strategies utilized by his participants included: (a) referential statements, (b) signatures, (c) greetings, and (d) horizontal questions.

Within a community of practice or learning, it is recommended that members become aware of and begin to utilize these strategies. While it might seem logical to use some of these strategies in group interactions, messages are often received that do not include any closing and, at times, not even something as important as the sender’s name. In utilizing these strategies the CMC message will include more communication cues to help enrich the medium with more information. As described earlier, a lack of nonverbal cues can be a possible issue for female members of a community, and this simple strategy might better support a member’s understanding of a particular message. Simply utilizing emoticons to replace the nonverbal cues (e.g., facial expressions) missing from CMC can provide more information to the recipient of the message. For example, utilizing the winking emoticon can provide information to the recipient that the statement was not meant to be taken seriously. Other more complex strategies, such as stating acknowledgement and agreement, provide the recipient with information that might replace a head nod or other gestures, not communicated in text-only CMC. Furthermore, apologies for miscommunications or other miscues provide “I” statements and self-disclosures that are associated with higher group development communication style (HCS). The use of horizontal questions, inviting responses, and providing referential statements of another’s message support the notion of enhancing social interactions, which encourages additional participant engagement in group interaction. With the use of these more supportive CMC strategies, members will engage in richer CMC to better understand one another, and, thus, augment community building. Again, it is the membership of the community that decides upon the communication norms of that community. However, with more members of the online community being aware of and utilizing these communication strategies the membership is more apt to adopt them, making them a routine of their social entity’s repertoire of vocabulary and style.

Although the various CMC strategies adopted and utilized by a community might improve text-based communication, advances in Internet technologies have brought about the development of multimedia CMC tools also could improve communication. The next section will deal with some of types of current multimedia tools that can better support the needs and predilection of the community.

**Multimedia CMC Tools**

Although computer desktop video conferencing and telephony have increased the media options for CMC, they still do not provide all of the rich aspects of face-to-face interaction. However, these multimedia technologies do add additional communication cues beyond the text-based communication strategies mentioned above. Therefore, it does seem prudent and is recommended to utilize advanced online multimedia communication technologies to the traditional tool set to thicken the communication conduit when possible and, perhaps more importantly, when appropriate.

By utilizing a video conferencing, for example, communication can be enhanced with facial expressions, hand gestures, voice inflection and other cues missing from text-only CMC. In addition, many of these tools provide interactive whiteboards for shared graphic demonstrations. These tools can be used to provide more graphic elements to enhance one’s ideas or concepts. Furthermore, some of these tools also permit document or application sharing. This can be a
valuable tool that can provide technical support and foster online collaboration.

Although these tools can provide the added communication support, they also can complicate the communication process. In terms of video conferencing, for example, some individuals may dislike being on display and this use may cause some discomfort. Also, utilizing the audio and video components, one must have a camera and microphone for each individual, which requires the users, to some extent, to be more technically proficient to set up and use these multimedia peripherals. In addition, high speed Internet connectivity for all parties interacting within the group communication is really a must. Although it is possible to utilize these tools with low bandwidth, it can become very stilted and, thus, very frustrating, perhaps negating the advantages. Furthermore, some of these multimedia CMC tools are open systems allowing one to communicate with anyone, while others are more closed to specific group membership. Because the various types of systems, it is important to know the strengths and weaknesses, and to understand their relative costs and benefits, as they have specific requirements and individual features—keeping in mind the purpose or objective of the group’s communication. The multimedia CMC tools listed below were chosen to provide examples of the different types currently available and are not inclusive of all tools.

**Skype**

Skype™ (n.d.) is an Internet telephony service that utilizes a computer with Internet connectivity, primarily for audio, provides computer to computer Internet Telephony. Although it does provide a video option, it currently is in the beta version. However, once connected users also have a chat window available for synchronous messaging as well. Users can set up conference calls with up to four participants plus the host.

Skype client software includes all of the features one might expect in such a tool, such as an address book of contacts for organizational and ease of use purposes. Skype accounts also provide several services for various fees, such as SkypeIn, which provides the user a phone number much like a tradition phone including voicemail, and Skype-Out, which permits users to make phone calls to both land and cell phone lines, including SMS, a form of instant messaging. Requirements include a headset with microphone, which is used instead of a microphone and speakers to keep feedback from occurring. The easy-to-use client software can be downloaded for free. More importantly, is that computer-to-computer communication is free. There is a fee to utilize calls to and from land or cell phones; users need a pre-paid account. However, the costs are quite inexpensive, especially for international calls. Because this form of Internet Telephony primarily focuses on audio, Skype might be a good tool to consider when beginning utilizing multimedia CMC, as it only requires a headset and the easy-to-use free software to get started.

**iVisit**

iVisit (n.d.) combines a variety of CMC tools including, video conferencing, instant messaging, file sharing, and desktop sharing. Although server licenses are available, most users have to obtain access to the software application in the traditional server/client relationship, where iVisit provides the server access, and users download client software and sign up for one of two types of accounts, Light and Plus. The software includes several windows, including: the video feed with controls, an address book that lists both people and places (available conferences), and a chat window for both the individual and all chatting within a conference.

An iVisit Light is a free account that permits users to interact as guests in open or public con-
ference rooms or invited into private conference rooms. iVisit Plus accounts are yearly subscriptions that permit the ability to host a conference room that can accommodate eight visitors, including the host. Although this can be increased to 16 simultaneous users for no extra fee, it is not recommended due to the complexity of managing that many in an online video conference. In addition to being able to host a conference, the iVisit Plus account provides greater audio quality and video resolution, plus other benefits. One rather interesting feature of iVisit is the ability to make recordings of participants audio and video feeds. Although the Light account only permits saving the file into an iVisit proprietary file format, the Plus account provides for QuickTime recordings. While using iVisit for multimedia, CMC provides greater cues that video provides, it also is more complex to setup, requiring a camera, microphone, and/or headset. Depending upon the technical sophistication and needs of the particular community, this tool may be worth the complexity.

**Microsoft NetMeeting and Messenger**

For quite a few versions, Microsoft Windows-based operating systems have provided multimedia CMC tools that include various features depending upon the particular version. The tools range from earlier versions of Microsoft NetMeeting (n.d.) to, most recently, Microsoft Live Messenger (n.d.). While Live Messenger is quite similar to Yahoo Messenger and focuses on instant messaging (IM), audio-video Internet telephony (somewhat like Skype), and file sharing, NetMeeting also includes application sharing. NetMeeting, will no longer be part of the new Windows Vista operating system. Instead, Microsoft will include a new suite of CMC tools called, Windows Meeting Space for home and home office users, Office Live Meeting Windows Meeting Space for small and medium business users, and Office Live Meeting Office Communications Server 2007 for large enterprises (Microsoft NetMeeting, n.d.). Each level of the application will work similarly to NetMeeting in that it will still support desktop, application, and file sharing across networks. One of the biggest changes from earlier versions of NetMeeting, however, will be the increase in the number of users that can connect simultaneously. One of the biggest advantages of the Microsoft multimedia CMC tool set is that it is readily available within one’s operating system. However, with the newer versions, outlined on the Microsoft Web site, members within online communities will need to decide which tool best suits their needs and available resources.

**Elluminate®**

Elluminate® (n.d.) is a comprehensive online multimedia-conferencing tool that includes audio, chat, interactive whiteboard, application sharing, file transfer, and direct messaging. It truly goes beyond the tools previously listed, as its primary focus is to support group interactions. As such, Elluminate includes additional features designed to provide greater user interactivity, such as: (a) participant profiles to provide greater information (photo & bio) about the participants, (b) polling, which permits a moderator to get some feedback regarding an issue, question, or comment, and (c) breakout rooms, a great feature should users want to break up a large conference for smaller group discussions. One important feature is that it utilizes full duplex audio, meaning that more than one individual can speak at the same time. However, the tool also provides for moderator control, should that be desired. In addition, the tool is designed for assistive access with closed-caption transcript and key stroke configurability. Elluminate also provides for input from a Web cam, which provides video feed of the speaker, although this feature is not the primary focus as with iVisit.
Elluminate provides multimedia CMC on a much more enterprise scale, and, as such, the cost is commensurate. There are several versions available, each appropriately priced, including Lite, Academic, and Enterprise editions, depending upon the user’s size and needs. Currently, Elluminate is being utilized by corporate trainers and universities. In addition, Elluminate has partnered with WebCT Vista, eCollege, Blackboard, and others to devise power links that permit Elluminate to work seamlessly within these course management systems. This multimedia CMC tool is designed for communities that want to focus on the synchronous interactive components that this tool provides. The software also provides for asynchronous delivery by including a session recording feature, which makes sessions available for later viewing. Although Web-delivered video via a Web cam is available, Elluminate does not focus on multiple, simultaneous video feeds such as iVisit. Depending upon need, this tool might provide users with a very interactive multimedia CMC tool, but as with any complex tool, deployment and implementation are a consideration. Again with this tool, users will be required to have a microphone, speakers, or headset to interact with the multimedia elements.

**Multimedia CMC Uses for Support and Collaboration**

The level of multimedia CMC tools available varies from those that are very simple to those that are much more comprehensive and quite very complex. As mentioned, it should be the membership of the community that selects the CMC tools. In addition to increasing the number of communication cues engaged users receive due to the addition of audio and video, there are further ways to utilize the multimedia CMC tools. In particular, the application-sharing feature of some multimedia CMC tools better support collaborations that enhance community building and augment the shared construction of knowledge. For example, one of the primary uses for Microsoft Application Sharing is to provide remote technical assistance. When individuals are having difficulties with a computer application they can be supported by sharing that application with a distant help agent. The user can watch and listen as the help agent provides instruction and demonstrates the application elements that caused confusion. In this way the utilization of a multimedia CMC tool for remote assistance can be used to help members by any more knowledgeable member within the community.

A more collaborative example of utilizing multimedia CMC tool to support a distributed learning environment is using the application sharing for group authorship. In this case, team members can schedule synchronous online meetings where they utilize application sharing to show and discuss Web resources. They also can use application sharing to work collaboratively on the same file to produce a shared Word document or presentation. In doing so, they are collaboratively engaging in the production of an artifact, thus, co-constructing knowledge.

**Summary**

This section provided recommendations that could enhance CMC group interactions. Specifically, it is recommended that the users of CMC consider fostering the building online communities of practice where members co-construct, hopefully, equitable communication norms in their online group interactions. It also is recommended that the members engaged in group interactions become aware of and utilize CMC strategies that enhance their interactions by fostering more clear communications. Finally, it is recommended that multimedia CMC tools be considered to enhance and enrich CMC when practical and appropriate.
FUTURE TRENDS

This chapter has discussed the issues and recommendations of current CMC group interactions. Over the past few years, incredible advances in communication technologies have become available and have been embraced by our society. So what does the future hold? In reviewing the literature of those who’ve studied aspects, issues, and elements of CMC group interaction, one observation is evident—electronic computer-mediated communication has expanded in use, sophistication, and reach. More people now use various types of computer-mediated communication than ever before to communicate with others in all parts of the world. However, the literature provides evidence that online group interactions can suffer the same issues as traditional face-to-face group interactions. With that in mind, one could predict that future trends in CMC group interaction will include the continued expanding use, advancement, and sophistication of CMC tools to an even more global scale than currently exists. With the expanding global reach, users’ skills, in terms of more sophisticated tools and more strategic use, will need to increase as well. With more diverse users making use of the various CMC tools, communicators will need to become better accomplished CMC users to compensate for the limitations of the various CMC systems. In addition, they will need to be more knowledgeable about possible group interaction issues that pertain to newer systems. If that prediction holds true, future global CMC users would benefit from greater investigation of cultural communication differences and global CMC interactions as they relate to the various media that transmits their messages.

Expanding and Changing CMC Skills

Computer-mediated communication has become an important aspect of our society. However, as detailed in this chapter, there are issues that are embedded within CMC group interactions that may impact one’s ability to clearly communicate via the various asynchronous and synchronous systems. It would seem that being aware of the strengths and limitations of the CMC tools and having skill using those strategies, would provide an advantage. For example, having knowledge of, monitoring, and then intentionally utilizing some of the communication strategies listed above may make one more apt to better communicate within a lean or limited CMC system. By utilizing some of the CMC text-based strategies listed above, regardless of gender, one could promote his or her higher group communication style (HCS), thus enhancing the message with richer, more engaging levels of communication. In other words, those individuals who are more CMC savvy, in terms of being able to more purposefully utilize communication strategies would be better able to foster and support persuasive arguments, promote agenda, and clearly share their ideas. Given knowledge of the specific strengths and weaknesses of various communication styles within specific CMC media would provide a powerful advantage to those who might strategically adjust their own communication style accordingly.

Parallel events are beginning to happen within the use of mobile phones for text messaging. For example, users are utilizing text messaging with their mobile phones or instant messaging on their computers for quicker, asynchronous communication when they cannot talk aloud or in lieu of e-mail or other slower CMC systems. When thinking about future possible trends, it seems logical to focus future practical efforts toward educating members of communities engaged in CMC to better understand the limitations of various CMC systems and how best to understand, monitor, and promote clear, concise, and perhaps strategic CMC style. This may become much more important as higher-speed Internet bandwidth becomes more widely available making multimedia CMC tools more common place.
Expanding Need for Global Understandings

This chapter has focused upon detailing specific issues of CMC style differences and media issues, and has provided some recommendations on building communities of practice within these CMC systems. For the most part, the discussion has focused on the research literature that discusses CMC style issues as they relate to group interaction differences and the various media available that might impact the communication cues available. As education, business, and industry extend their reach to more global markets, CMC will be utilized more extensively for interaction by members of various cultures and languages. While certain elements of CMC may better support these endeavors, there will be other issues that could compound good CMC group interaction. For example, asynchronous CMC better supports members in various time zones allowing for business to operate at their normally desired time. With more synchronous multimedia utilization globally, users will be required to interact 24/7. In addition, more global group interactions will require users to be sensitive to diversity in both language and culture. For example, an international student from China was concerned when his advisor sent him an e-mail where some of the text was colored red. He thought she was angry with him—when in truth, she simply was trying to emphasize a point by making it stand out. From her perspective, this was a very benign strategy. Because the color red has specific connotations within the Chinese culture, there was a pretty serious cultural miscommunication for this Chinese student. While no harm was intended by this communication strategy, its use created an unintended consequence of causing great alarm for the student.

Future research in CMC utilization will continue to include the issues of gender and communication style. However, these issues are bound to be expanded by cultural differences as CMC tools are used by members across a more global society trying to build communities of practice with various cultural differences. A very powerful example of building community within a multi-ethnic online discussion group is described in the work of Kadende-Kaiser (2000). She examined CMC interactions of members of Burundinet, a multiethnic discussion forum for Burundians in the Diaspora. Most of the discussion focused on the terrible ethnic violence between the Hutus and Tutsis by members that spoke Kirundi (the native language), French (the colonial language), and English. In addition to their language differences, members came from very different perspectives on a very divisive topic. In this example, social rules were changed to provide more equitable social interactions. “This would not be the case in Burundian social settings, where seniority and social status determine who can interact with whom, or who is even excluded in the interaction. . . . In internet communication, however, these cultural rules regarding turn-taking on the basis of age and social rank are irrelevant; any subscriber can play the role of social mediator” (p. 131). Indeed, the membership of Burundinet fashioned the rules as she states:

"Mutual respect and politeness, on the one hand, and the freedom of expression, on the other, do not have to be mutually exclusive. Therefore, many Burundinet members seek to preserve individual subscriber rights to express their opinion, regardless of what views they have in mind. As one net member advised: ‘It seems more wise that we try to preserve a minimum of formal politeness toward the others, and at the same time we need to allow every Burundinetter to express his/her opinion on Burundi, regardless of what this opinion is’ (Author I, 1996). These statements and individual opinions serve as the foundation for message composition and they contribute to the establishment of the rules for interaction on Burundinet. (p. 134)"
Although cultural differences, such as this, may cause issues when filtered through the lean medium of current CMC technologies within a more global community, the membership of Burundinet demonstrated how it established unique rules for CMC interaction within their virtual community to permit discussion regardless of their differences. This provides a very good example of how the CMC group interaction communication norms are established by the membership.

Summary

This section provided some ideas of what the future might hold for CMC group interactions. Certainly, we can presume that CMC usage will increase and become more complex and, perhaps, robust. CMC users will be required to become more technically proficient. A more important concern, however, will be that as the usage of CMC expands more globally, the communities that will better prosper will be those that trend toward the development of communities of practice, where members think about their responsibility in the development of their shared repertoire of communal resources in light of possible cultural differences. It will be vital for members engaged in CMC group interactions to be aware of, and provide consideration for, cultural differences. While the CMC strategies outlined above may work well for certain cultures, will they work well within a global community? Or, will they have unintended consequences?

Future Research Directions

There is a history of research that has investigated face-to-face group interaction that supersedes the CMC tools that are now employed. The findings from that earlier research seems to parallel research findings of those engaged in CMC group interactions. For example, gender-based CMC style differences can impact those engaged in online group interactions. However, there are strategies that users can and do employ to adjust their CMC group interactions in an attempt to replace missing nonverbal cues, thus supporting and fostering better communication. Therefore, future research that further investigates how users manipulate their CMC style strategically by employing CMC techniques and/or adjusting their CMC group interactions, based upon the medium, could prove very enlightening. Because members engaging in CMC group interactions can and do take responsibility for developing their community of practice, researchers also would be advised to study the process of defining and developing communication norms within an online community of practice.

As technologies continue to advance, richer media will become commonplace for CMC group interactions. Regardless of new, more advanced multimedia electronic communication systems, there still will be a filtering of sorts on communication cues within CMC systems. Future researchers would be advised to focus their investigations on how multimedia might hinder or enhance group interactions based upon gender, and perhaps more importantly, culture. In particular, it seems essential to investigate global CMC group interactions in light of cultural and language differences. For example, community systems like BuddySpace, that provide the users’ location could provide cues to support those engaging in group interactions within that type of online community space.

Researchers should be encouraged to take advantage of the known CMC issues and focus their investigations on more global issues that are bound to emerge as communities expand. While gaining knowledge of how more robust, multimedia CMC might impact various individuals it vital, future research should go beyond and also focus on how to best educate members of global communities of practice to provide clear, concise communication within those more advanced electronic communication systems. With continued knowledge of the advanced CMC systems and the diverse
cultural interactions that happen with them, this form of information technology will better serve the expanding global community.

Finally, instant messaging (IM) and text messaging has become widespread, globally. This form of asynchronous communication is novel in that it changes the type and, perhaps, the reason for a particular communiqué. For example, one might “text” or “IM” another because they are busy—working, in class, or talking with others—and cannot be interrupted with a traditional phone call or chat. Furthermore, this form of communication has developed its own lexicon and syntax. While people may have wanted to communicate in similar ways in the past, this technology has changed the way many communicate, as evidenced by its overwhelming use. Specifically, this technology has provided the opportunity for people to multitask in many areas of life, which brings up an interesting question. How will this new form of communication impact or change more traditional forms of communication? With that in mind, an interesting opportunity for future research would be to investigate how technology advances have impacted or changed more historical forms of human communication and social interactions.

Chapter 4.9
Mobile Phone Use Across Cultures: A Comparison Between the United Kingdom and Sudan

Ishraga Khattab
Brunel University, UK

Steve Love
Brunel University, UK

ABSTRACT

Recently, the ubiquitous use of mobile phones by people from different cultures has grown enormously. For example, mobile phones are used to perform both private and business conversations. In many cases, mobile phone conversations take place in public places. In this article, we attempt to understand if cultural differences influence the way people use their mobile phones in public places. The material considered here draws on the existing literature of mobile phones, and quantitative and qualitative work carried out in the UK (as a mature mobile phone market) and the Sudan (that is part of Africa and the Middle East culture with its emerging mobile phone market). Results indicate that people in the Sudan are less likely to use their mobile phones on public transport or whilst walking down the street, in comparison to their UK counterparts. In addition, the Sudanese are more willing to switch off their mobile phones in places of worship, classes, and meetings. Implications are drawn from the study for the design of mobile phones for different cultures.

INTRODUCTION

Economic globalization and the widespread use of mobile phones have changed the way people live and manage their lives, and cut down the virtual distance between countries, regions, and time zones. New ways of using mobile phones are constantly emerging (e.g., downloading music to listen to on the train), and the pervasive use of mobile phones in public places for private talk...
Mobile Phone Use Across Cultures

(both business- and socially-oriented) is a clear example of how mobile phones are changing our economic and social lives. As a result of this, there is an emergent body of research on the use of mobile phones in social spaces. For example, Ling (2004) highlights how their use in public places has raised questions of what the appropriate or inappropriate behaviour is in public places. In this study, he found that people perceived mobile phone use in places such as restaurants as unacceptable, partly because mobile phone users tend to talk louder than usual so that people nearby feel intruded upon, embarrassed, and have a sense of being coerced into the role of eavesdropper on a private conversation.

Research has also shown that mobile phones can occupy concurrent social spaces, spaces with behavioural norms that sometimes conflict, such as the space of the mobile phone user, and the virtual space where the conversation takes place (Palen, Salzman, & Youngs, 2000). This feeling of conflict has led researchers in this area to propose that the use of mobile technology in public places is creating a new mixture of public and private space that has yet to be accommodated by for users of mobile technology and bystanders in terms of what is acceptable or unacceptable behaviour.

This phenomenon has been analysed predominately using concepts drawn from Goffman’s analysis of social interaction in public places (Goffman, 1963). In this work, Goffman suggested that people have specific “public faces” and personas for different public social locations. The idea behind this is that individuals have rules that determine their behaviour in public places, or what Burns (1992) refers to as the “observance of social propriety.” For example, Murtagh (2001) presented findings from an observational study of the nonverbal aspects of mobile phone use in a train carriage. Murtagh found that changing the direction of one’s gaze—turning one’s head and upper body away from the other people sitting next to you in the carriage—was a common feature of mobile phone behaviour on trains. These behavioural responses were seen as being indicative of the subtle complexities involved when using mobile phones in public locations. This study suggests that mobile phone users are actively engaged in trying to distance themselves from their current physical location in order to enter a virtual environment with the person they are having a mobile phone conversation. In relation to this, Love and Perry (2004) used role-play experiments to investigate the behaviour and attitudes of bystanders to a mobile phone conversation. They found that participants had strong views on embarrassment, discomfort, and rudeness. They also report that the actions of those who were put in the position of overhearers followed a pattern: they acted as though they were demonstrably not attending, even though they were all able to report accurately on the content of the conversation.

However, to date, most of the research reported in this area has tended to focus on what is termed the developed world. Mobile phones are also transforming people’s lives in the developing world. In Africa, the unreliable and inefficient landline telecommunication infrastructure has made the mobile phone the solitary available communication tool for many people (BBC, 2003). However, as mobile phone use in Africa continues to grow, there is a need for mobile phone companies who are entering this market to consider the possible impact of cross-cultural differences in people’s attitude towards mobile phone and service applications.

This article first briefly reviews relevant literature about the use of mobile phones in public places. The concept of culture and cultural models are explored in the second section. In the third section, the methods of this study are presented. Techniques of collecting the data and the procedure of this study are presented in the fourth and fifth sections, respectively. Some key findings from the study are presented and discussed in the
sixth and seventh sections with reference to how cultural differences might affect mobile phone use in public places. Finally, the conclusion of this study is presented in the last section.

WHAT IS CULTURE?

Culture is a complicated paradigm that is difficult to accurately define. According to some researchers, culture must be interpreted (van Peursson, in Evers & Day, 1997). Hofstede (1980) conceptualized culture as “programming of the mind,” suggesting that certain reactions were more likely in certain cultures than in others, based on differences between the basic values of the members of different cultures (Smith, Dunckley, French, Minocha, & Chang, 2004). Culture can also be seen as a collection of attributes people acquire from their childhood training. These attributes are associated with their environment, surroundings that influence the responses of people in that culture to new ideas, and practices and use of new technology (such as mobile phones). Given that culture may affect the way people behave and interact in general, Ciborowski (1979) identified a close link between knowledge and culture. In the context of mobile phone communication, it may be argued that culture influences knowledge—or the individual’s general experience—therefore affecting, in this instance, their attitude towards mobile phone use in public places.

Another explanation of culture has been offered by Hofstede (1980). He produced a cultural model that focuses on determining the patterns of thinking, feeling, and acting that form a culture’s “mental programming.” This model has been adopted for the study reported in this article, as researchers in the area of cross-cultural differences and technology use consider it a valid and useful measure of systematic categorization (e.g., De Mooij, 2003; Honald, 1999). In addition, it is also considered to be directly related to the relationship between product design and user behaviour (De Mooij & Hofstede, 2002). An explanation of Hofstede’s cultural dimensions is as follows:

- **Power distance**: the extent to which less powerful members expect and agree to unequal power distribution within a culture. The two aspects of this dimension are high and low power distance.

- **Uncertainty avoidance**: discusses the way people cope with uncertainty and risk. The two faces of this dimension are high uncertainty avoidance and low uncertainty avoidance.

- **Masculinity vs. femininity**: refers to gender roles, in contrast to physical characteristics, and is usually regarded by the levels of assertiveness or tenderness in the user. The two aspects of this dimension are masculinity and femininity.

- **Individualism vs. collectivism**: deals with the role of the individual and the group, and is defined by the level of ties between an individual in a society. The two aspects of this dimension are individualism and collectivism.

- **Time orientation**: deals with the extent to which people relate to the past, present, and future. The two aspects of this dimension are short-term orientation and long-term orientation.

A number of cross-cultural studies have investigated differences in attitudes towards new technology. Smith, French, Chang, and McNeill (2001) carried out a study using Hofstede’s model. They adapted the Taguchi method—a partial factorial experimental design method—in order to investigate differences between British and Chinese users’ satisfaction and preferences for Web sites. They found significant differences between British and Chinese users in their prefer-
ence of detailed e-finance product information. For example, Chinese users tended to adopt a more holistic approach to viewing Web content, as compared to British users.

In another study, Honald (1999) found that German mobile phone users preferred clearly-written and inclusively rich user manuals, whereas Chinese mobile phone users focused on the quality of the pictorial information.

Evers and Day (1997) found that there are clear cultural differences between user acceptance of interfaces for different cultural groups. In their study, they found differences between Chinese and Indonesian users. Indonesians were found to like soft colours, black and white displays, and pop-up menus more than Chinese users. Also, Indonesians seemed to prefer alternative input and output modes (e.g., sounds, touch screens, data gloves, and multimedia) in comparison to the Chinese who preferred the use of many different colours for the interface design.

Despite the importance and the relevance of cultural factors and its impact on the use of global products and services (such as mobile phones), little research has compared the effect of cultural differences on issues such as social usability of mobile phone use in the developing and the developed world. Sun (2003) argues that variation in cultural states will cause different attitudes or ways of using mobile phones.

The practice of the “missed call” is a clear example of how users from different cultures develop their own usage style. The missed call is when the caller places a mobile phone call and purposely hangs up before the recipient can answer the call. Donner (2005) investigated the phenomenon in Sub-Saharan Africa where the missed call is known as “Beeping.” He found that users have produced elaborated codes and social messages to be exchanged over the network without bearing any cost—or at least not from those who are in a less secure financial situation.

Another exclusive mobile phone cultural attitude is evident in Bangladesh, Uganda, and Rwanda, where a woman, for example, borrows money to buy a special mobile phone designed for multiple user accounts and rural access. After this, she then buys minutes in bulk and resells them to customers in her village. This programme is funded by the Grameen Bank mainly for use in rural areas (Bayes, von Braun, & Akhter, 1999).

The same idea has mutated slightly in the big cities of Egypt and the Sudan where vendors who own fixed contract mobile phones buy a bulk of talk minutes and resell them in smaller chunks to individuals in order to make a profit. This practice is accommodated by their national phone service providers and is known as “balance transfer.” Obviously, this practice cannot be seen in London or any of the developed world cities.

If mobile phone users have different usage patterns, the question that the study in this article addresses is: can we assume that people from different countries use mobile phones in the same way? Thus the question arises: are there any roles for cultural differences in the way people use their mobile phones in public places? Therefore, the attitude of the British (a mature mobile phone user market) and the Sudanese (an emerging mobile phone user market) were examined in relation to their attitudes towards the use of mobile phones in public places.

**METHODOLOGY**

**Participants**

88 participants took part in the study: 43 British (22 male, 21 female) and 45 Sudanese (20 male, 25 female), ranging in age from 15 to 63 years old, with the average age of 30 years. All participants were mobile phone users. The range of mobile phone use for the Sudanese participants was from 2-5 years, whereas the British participants had used mobile phones for 4-12 years.
Data Collection

Data was collected in this study using a questionnaire and an interview. The development of the questionnaire went through several stages. First, the generation of the questionnaire was collated by employing an exhaustive review of the literature generally on mobile phones, human-computer interaction (HCI), and cultural issues in mobile phone use. Second, an in-depth session was conducted with participants from both countries (the UK and the Sudan) to develop the questionnaire. Initially, a total of nine Likert-type questions were developed. The scale was then tested for content validity, which can be defined as the extent to which a test actually measures what it is supposed to measure (Rust & Golombok, 1989). This was undertaken using what is known as the judgemental approach, with three mobile HCI experts.

As a result of this process, the questionnaire was subsequently revised to consist of six Likert-type questions. The six Likert statements focused on attitudes towards the use of mobile phones in public places. An example of the Likert statement used in this study is as follows:

Mobile phones should not be switched off during meetings:

- Strongly agree
- Agree
- Neutral
- Disagree
- Strongly disagree

The attitude scale had a combination of positive and negative statements in order to control for any possible acquiescence effect from participants when they were completing the attitude questionnaire. This is a phenomenon whereby participants in a study may unwittingly try to respond positively to every question in order to help the investigator with their study. This type of questionnaire format is one of the most common methods used to elicit attitudes from users in HCI research (Love, 2005).

In addition to the questionnaire, a semistructured interview was carried out. The interview questions included open-ended and closed questions, and were designed to gather information on the use of mobile phones in public places, the practice of the missed call, and other features such as the use of mobile phone caller ID. The main points that were covered in the interview were:

1. Attitude towards the use of mobile phones in public places.
2. The use of the missed calls types in the two cultures. For example, the type of missed calls used and the social messages sent through the missed call, and how recipients differentiate between these types of missed calls.

Examples of questions covered in the interview were:

*How do you feel about using mobile phones on public transport?*
*How do you feel about using mobile phones in school during classes?*
*How do you feel about using mobile phones in restaurants?*

**PROCEDURE**

Participants were chosen from an opportunistic sample in both the UK and Sudan and asked to complete the questionnaire and return them to the researcher once they had completed them.

The questionnaires took approximately 15 minutes to complete. At this point, an arrangement was made to interview a subset of the participants who had been selected randomly and volunteered to answer the interview questions. Participants were informed from the outset that the results of
the study would be anonymous, and they would be able to obtain the results of the study from the researcher on request.

RESULTS

An independent sample T test was carried out to compare attitudes towards using mobile phones in public places in the UK and the Sudan. There was a significant difference found in the attitudes for using mobile phones in public transport between the British and the Sudanese ($t=5.99$, $p<0.001$). The British were more willing to use it on public transport than the Sudanese.

Another significant difference was noted between the two countries towards using mobile phones whilst walking on the street. Again, the

**INTERVIEW RESULTS**

The interview results corresponded with the questionnaire data, indicating that there is a difference between the British and the Sudanese attitudes towards the use of mobile phones in public places. Sudanese were found to be less willing to use mobile phones in public places than their British counterparts. In the interview, Sudanese participants revealed various reasons for their uncomfortable attitude towards the use of mobile phones in public places. For example, some of the participants felt that the use of mobile phones in public transport is unacceptable because it can be disturbing to other people in close proximity to the mobile phone user. As one of the Sudanese interviewees commented:

*Using a mobile phone in public places, especially on public transport where you are closely surrounded by people, is not something that you can do comfortably. It is viewed as improper and unacceptable, as it disturbs others.*

Another Sudanese interviewee added:

*The use of mobile phones on public transport may be considered as a sign of disrespect to others. In particular, to older passengers who you have to respect and act quietly around them.*

An added justification that was revealed by Sudanese participants for not feeling comfortable using mobile phones in public places was related to their tight rules in keeping private issues private, as one of the interviewees commented:

*The use of mobile phones in public places to discuss private matters can put you in an awkward situation; because most of the people surrounding you will hear your conversation and this attitude in itself is not acceptable in our community. People are not expected to discuss private issues so publicly.*

On the other hand, British participants were found to be more comfortable using mobile phones in public places as one of the interviewees commented:

*I have no problems using my mobile phone in public places and especially on public transport, as I can make use of time while sitting there doing nothing.*

Another British interviewee added:

*I use my mobile phone in public places all the time and it does not bother me at all that people are listening to my mobile phone conversations. I do not know them and it is unlikely they are going to know more details about the topic I am discussing.*

The results of this study also indicated that Sudanese females were less willing to use mobile phones in public places than British females. Sudanese females felt that the use of mobile phones in public places, especially on public transport, could attract unwanted attention to them in a society that expects females to keep a low profile. This was echoed in one of the Sudanese female interviewee’s comments:

*I do not like using my mobile phone in public places at all as it only magnetizes others’ attention towards me. If you are on the mobile phone in a public place, people start gazing at you unappreciatively.*

Another Sudanese female interviewee added:
Usually, I do not use my mobile phone in public places. I prefer to keep a low profile. For me, this attitude is a sign of respect for my self and others.

British females appeared to have different view—most of the interviewees were found to feel more comfortable using their mobile phones in public places. As one of the British interviewees commented:

*I prefer to use my mobile phone in public places; it keeps me busy and in a way safe, for example when I want to get my car from the car park when it is dark, I always make sure that I am talking to one of my friends on the mobile phone just in case something happens.*

**DISCUSSION**

The results from the study were interpreted in the light of Hofstede’s cultural dimensions to try and gain some insight into the way culture may influence the use of mobile phones in public places.

It appears from the results that the British generally are more comfortable using mobile phones in public places than their Sudanese participants, who are more reluctant to use mobile phones in contexts such as public transport and whilst walking along the street.

The collectivistic culture to which the Sudan belongs to (using Hofstede’s criteria) indicates an inclination toward a tightly-knit social framework (Hofstede, 1980). The priority is for the groups’ needs, rather than the individual wishes. Therefore, perhaps the use of mobile phones in public places for private talks can be seen as a self-centred act, and quite impertinent for the group needs. The group expects the individual to be considerate to the established social etiquette. The mobile phone user in public transport is expected to adhere to the social protocol and to respect other people’s privacy.

Another reason for the British comfortable attitude to mobile phone use in public places may be due to bystanders’ nonverbal communication attitude. This concept is highlighted by Goffman (1963) where he refers to it as “civil inattention.” Civil inattention refers to the ways in which people acknowledge the existence of others without paying them extra attention; he regarded this as a gesture of respect required from strangers. Lasen (2002a) found that “civil inattention” is clearly present in UK culture: the British tend to avoid open and straightforward looking at other people, and keep away from paying direct attention to others, especially on public transport, such as the Underground. He suggested that this attitude may encourage British mobile phone users to talk more freely outdoors without being concerned about others watching them.

In contrast, in the Sudan, it was noted that “civil inattention” is not clearly evident. Sudanese people tend to look at each other directly. Lasen (2002a) suggested that a lack of proper gaze in certain cultures where “civil inattention” does not rule may be viewed as a lack of respect or ignorance. This lack of civil inattention perhaps justifies the reason behind the Sudanese unwillingness to use their mobile phones in public places, as they are influenced by bystanders’ nonverbal communication attitude. One can say the more civil inattention paid to others, the more free and relaxed they might feel towards using their mobile phones, and vice versa.

Another justification for not using mobile phones in public places might be due to the high score that the Sudan attained on Hofstede’s uncertainly avoidance dimension. According to Hofstede, cultures with high uncertainty avoidance scores tend to be expressive—people talk with their hands, raise their voices, and show emotions. These characteristics can play a role in decreasing the need to carry out private conversations in public places because people in these cultures know that they tend to talk loudly and expressively, which attract bystanders’ attention,
Mobile Phone Use Across Cultures

plus there is a high risk of being known to people around you. Another important point is that as Sudanese people in general talk loudly and in an expressive way, this tends to increase the level of external noise for mobile phone users. Therefore, people talking on mobile phones need to raise their voices more to win over competitive speakers. This loud talking may attract bystanders’ attention and invite eavesdroppers, which can cause a feeling of embarrassment on the part of the mobile phone user. In addition, mobile phone users may feel that bystanders might disrespect them if they discuss their private matters publicly.

Additionally, the Sudanese attitude might be related to the high score obtained on Hofstede’s power distance dimension, where a tight set of social rules are established, and people are expected to follow and respect these rules. For example, the social protocol for behaviour in public places is well recognized in the Sudan, and people are expected to behave in certain ways and not to speak loudly in front of others (especially older people). Private issues should be kept private and dealt with in a private manner and in private settings. It is considered improper to breach these norms. Although in the UK, a social protocol for behaviour in public places also exists, the maturity of the UK mobile phone market may have relaxed or altered people’s expectations and acceptance behaviour in public places. Palen et al. (2000) found that a person’s attitude towards public mobile phone use changes (becomes more accepting) as their mobile use increases. In addition, Palen (2002) predicted that as adoption of mobile phones increases, people will be less disturbed about proper use, but will still prefer to have “mobile free” zones.

In terms of specific gender differences, Sudanese females were found to be more uncomfortable about using mobile phones in public places in comparison to British females. This attitude fits in with the “feminine” attribute of the Sudan culture suggested by Hofstede (1980), where the prevailing value is caring for others. The UK, in contrast, is judged by Hofstede to be more masculine-oriented, and the dominant values are achievement and success.

Although the Sudanese females practice all their rights in terms of education, work, leisure, and the like, they are looked after and cared for by the whole society. As a result of this caring perception towards females in the Sudanese culture, their attitudes and behaviours are more controlled and guarded as they are expected to follow social protocols more than men. For example, Sudanese females are expected to keep a low profile and deflect attention from themselves by talking quietly—and preferably avoid talking—in public spaces.

On the other hand, according to the results of this study, British females are more comfortable using mobile phones in public places. This may be due to the feminine attribute of the UK suggested by Hofstede (1980) where women are seen as equal to men, and they are expected to look after and guard themselves more autonomously. In contrast to the Sudanese females, British females can use mobile phones in public places as “symbolic bodyguards” (Lasen, 2002b). In this context, mobile phones are used as a technique to defend your private space within areas that are heavily populated with unknown strangers (Cooper, 2000; Haddon, 2000). As Goffman (1963) has remarked, women especially do not like to show themselves alone in public places, because this may indicate that they are not in a relationship: a condition which (1) provides a bad impression of their social status and (2) leaves them in a vulnerable situation which can be acted upon by unknown males. To deal with these situations, the mobile phone is quite useful, as it works as a safety net and indicates that this person has their social networks and is not isolated (Plant, 2002).

The other significant result reported in this study is that the Sudanese are more likely to switch off their mobile phones in places of worship. Measuring these results against the Hofstede
typology, the Sudanese score high on uncertainty avoidance scale—religion is valued and greatly respected. People’s attitude towards switching off mobile phones in places of worship in the Sudan is therefore expected. It is also related to the high scores Sudan has on power distance, as roles are set, and religious men are very much valued and respected in the society, so both the Muslim and the Christians in the Sudan tend to be aware of the importance of switching off their mobile phones in places of worship. This result could also be related to the reduced number of people in the UK attending places of worship.

The Sudanese also appear more willing to switch off their mobile phones during meetings than the UK participants. This attitude may be related to their high score in the power distance dimension where people are expected to respect the structure, rules, and the norms of the setting where they are currently present.

As for the British disinclination to switch off their mobile phones during meetings, it might be related to the individualistic feature of the British society, where time is valued, and there is a push for making good use of it. It may also be related to the maturity of British mobile phone adoption where mobile phones have blurred the borders between business and social rules. In relation to this, Churchill (2001) found that the mobile phones in the UK are used to form and maintain both work and leisure relationships.

CONCLUSION

The increased use of mobile phones by people from different cultural backgrounds has become an integral part of our world phenomena, yet to date the impact of cultural differences on the way people use their mobile phones—and its implications on mobile phone design—has failed to be investigated comprehensively. As this article illustrates, mobile phone users with cultural differences were found to use their mobile phones in different ways, and their attitudes may have been influenced by their cultural norms. Although one can argue that cultural norms can be reshaped by technology, results obtained from this study indicate that cultural heritage would appear to influence users’ mobile phone behaviour. The results obtained from this study also suggest that mobile phone designers need to develop a richer understanding of culture in order to develop mobile phones that satisfy culturally specific needs, and thus support mobile phone users’ in their current and potential future communication activities. This is an issue we intend to explore in the next phase of our research.

Chapter 4.10
Gender and Computing at University in the UK

Ruth Woodfield
University of Sussex, UK

INTRODUCTION

In the late 1970s, women’s progress and participation in the more traditional scientific and technical fields, such as physics and engineering, was slow, prompting many feminist commentators to conclude that these areas had developed a near-unshakeable masculine bias. Although clearly rooted in the domains of science and technology, the advent of the computer was initially seen to challenge this perspective. It was a novel kind of artefact, a machine that was the subject of its own newly created field: “computer science” (Poster, 1990, p. 147). The fact that it was not quite subsumed within either of its parent realms led commentators to argue that computer science was also somewhat ambiguously positioned in relation to their identity as masculine. As such, it was claimed that its future trajectory as equally masculine could not be assumed, and the field of computing might offer fewer obstacles and more opportunities for women than they had experienced before. Early predictions of how women’s role in relation to information technology would develop were consequently often highly optimistic in tone. Computing was hailed as “sex-blind and colour-blind” (Williams, Cited in Griffiths 1988, p. 145; see also Zientara, 1987) in support of a belief that women would freely enter the educational field, and subsequently the profession, as the 1980s advanced.

During this decade, however, it became increasingly difficult to deny that this optimism was misplaced. The numbers of females undertaking undergraduate courses in the computer sciences stabilised at just over a fifth of each cohort through the 1980s and 1990s, and they were less likely to take them in the more prestigious or research-based universities (Woodfield, 2000).

Tracy Camp’s landmark article “The Incredible Shrinking Pipeline” (1997), using data up to 1994, plotted the fall-off of women in computer science between one educational level and the next in the US. It noted that “a critical point” was the drop-off before bachelor-level study—critical because the loss of women was dramatic, but also because a degree in computer science is often seen as one of the best preparatory qualifications for working
within a professional IT role. The main aim of this article is to examine how the situation has developed since 1994, and within the UK context. It will also consider its potential underlying causes, and possible routes to improvement.

BACKGROUND

In the UK, throughout the 1990s and into the new millennium, the achievements of secondary school-age girls (11-16 years) progressed significantly in the more traditional scientific and technical subjects, and began surpassing those of boys. Before an age when some curriculum choice is permitted (14 years old), girls perform better in science. Furthermore, although fewer of them take science once they have choice, they continue to surpass boys’ achievements in the area. Higher proportions of girls now gain an A-C grade pass in their GCSE examinations in chemistry and biology and physics (Department of Trade & Industry (hereafter DTI), 2005; Equal Opportunities Commission (hereafter EOC, 2004)). In terms of A levels, the qualifications usually taken at the end of the first two-year period of non-compulsory education (16-18 years), girls also proportionately achieve more A-C passes in these subjects (EOC, 2004).

Achievements in computing courses have followed this trend. Over the last decade, girls have gained around 40% of GCSE qualifications in computer studies, and they are now more far likely to gain an A-C pass than their male counterparts (EOC, 1994-2004). Nevertheless, at A level, when students traditionally specialise in three or four subjects, the trend has been for the majority of girls to opt out of computing. In 1993, in England, girls only accounted for 13% of students deciding to further their computing education to A level standard in England (EOC, 1994). By 2003, this picture had significantly improved, with girls comprising 26% of those studying computing or information technology A level (Joint Council for Qualifications, 2004). Although this still represents a substantial “leak” between one educational level and its successor, it is noteworthy that girls have recently become proportionately more likely to gain the top grades in these qualifications as well (DTI 2005; Joint Council for Qualifications, 2004).

COMPUTER SCIENCE AT THE HIGHER EDUCATION LEVEL

As Figure 1 indicates, the proportion of women within computer science courses at tertiary levels remained fairly static between 1994-2003, despite the improving proportion of them taking computer science at A Level over the same period. Although there appears to be a slight increase between 2002 and 2003, this is likely to be due to changes in the way graduate statistics in the UK were calculated between these two years. On average, women comprised 22% of those completing a degree in the area over the period.

In the UK, female applicants to computer science courses differ in key respects from their
male counterparts. They are especially likely to cite their interest in the subject as the main reason for studying it and are committed to finding the right course above other considerations, such as location of university and so forth (Connor, Burton, Pearson, Pollard, & Regan, 1999; Craig, Galpin, Paradis, & Turner, 2002b; Millar & Jagger, 2001). This interest would seem to be intrinsic, as they are less likely to cite future employment prospects as a motivating factor for their subject choice than their male counterparts (Millar & Jagger, 2001). Female computer science applicants have indicated that, in order to aid course choice, they review a wide range of information and are especially influenced by the information provided in university prospectuses and by experiences of pre-entry campus visits. Indeed, information deriving from universities is deemed far more helpful than advice from secondary school teachers and careers advisers (Connor et al., 1999; Craig et al., 2002b; Millar & Jagger, 2001).

Women are slightly more likely to be accepted for a degree within the broad area of mathematical sciences and Informatics, of which computer science is a subset, probably due to their better success rates at A-levels. They are also more likely to complete their degrees (DTI, 2005).

Once on their degree courses, although they are now over-represented within higher education as a whole (comprising 56% of new graduates), as Figure 1 has illustrated, women remain significantly outnumbered within each cohort of computer science undergraduates. This is in a context where computer science is attracting more undergraduates year-on-year whereas physics, chemistry, and engineering are attracting fewer, and mathematical sciences broadly the same numbers (DTI, 2005). As Figure 2 chronicles, between 1994/5-2002/3 the numbers of men and women completing degrees in this area in the UK climbed throughout the period, with the percentage of men climbing slightly faster than the percentage of women. In 1995, 5.5% of all male graduates qualified in computer sciences, as against only 1.5% of all females. By 2003, 11.8% of males were graduating in this area, as against 2.8% of females. While there are grounds for optimism insofar as the proportionate increases during this period for women were comparable to those of men, it remains of concern that while more than a tenth of male graduates take their degrees in this area, less than 3% of females do. This is significant in the context of the link between computer science and professional-level IT work, and the critical role computer science knowledge plays in our society more generally.

Women are also generally under-represented among the academic faculty of computer science at university, although their numbers in Lecturer (28%) and Researcher (30%) ranks remains better than we might expect given their undergraduate representation (DTI, 2005). They are, however, disproportionately underrepresented in the more senior academic ranks (DTI, 2005).

Interestingly, however, as Figure 3 shows, of those taking degrees in this area, women fare no worse than men in terms of classification achieved,
and their performance would seem to be improving. In 1994/5, 9.6% of men achieved the top grade of degree—a First Class—as opposed to 7.6% of women. By 2003, however, 11.9% of men were achieving this grade against 11.6% of men. Furthermore, women have also been marginally, but consistently, more likely to obtain a “good” degree—a First Class or Upper Second—than men since 1994, and by 2003 just over 50% of them achieved this standard as against just under 47% of men.

**FUTURE TRENDS AND CONCLUSION**

Once this picture is digested, we can see that there are some grounds for cautious optimism about the future: an increase in female participation at A level; improvements in female performance in relation to both pre-university and university qualifications; and evidence of above-average interest in computer science on the part of female undergraduates. Notwithstanding these changes, a key question is begged, however, given the context of the overall increase in the importance of the subject: Why is the under-representation of women that established itself in the field in the 1980s and 1990s not correcting itself more quickly?

It is still claimed by some that women are naturally less predisposed than their male counterparts to be attracted to, or to perform well within, the sciences in general (McCrum, 1996) and computer science in particular (Craig et al., 2002b). This position, however, is increasingly difficult to sustain in the light of changes in female participation and performance rates in educational computing, and the fact that there are significant local variations in the uptake and experience of university-level computer science courses (Cahoon, 2001; Craig et al., 2002b; Millar & Jagger, 2001). As Cahoon has suggested, it is much more likely that social factors are at play to explain female under-representation as “women can and do succeed in Computer Science when conditions do not deter them” (2001, p. 1).

These “social factors” would seem from the evidence to fall under two main areas. First, females, including female computer science undergraduates, project a far more negative image of IT work than males. As their educational choices are so closely bound up with their projected career trajectories (EOC, 2001; Miller, Neathey, Pollard, & Hill, 2004), it is reasonable to assume that this tendency has impacted on female recruitment levels to the subject at university. Secondly, female experiences of computer science degrees would seem to be less positive than those of their male counterparts, and it is very likely that the stories of such experiences become part of the information young women draw on when making their decisions about what subjects to study at university.

To take the first point, the available evidence suggests that women taking computer science degrees, and courses that might prepare them for

undergraduate study, are generally not likely to be fully aware of the benefits of a career in IT (Millar & Jagger, 2001; Peters, Lane, Rees, & Samuels, 2003), while simultaneously being more likely to be alive to its real and perceived disadvantages. They are more likely to project, for instance, that it will be solitary work, when they, as a group, have a preference for team-based and socially-embedded computing (Craig et al., 2002b). The problems facing them should they opt for a career in computing cannot be ignored, substantial as they are. Female computer science graduates are less likely than males to find employment at the end of their degrees, despite their tendency to have achieved a higher degree classification, and to be better educated more generally. Once in employment, they are likely to receive less pay for comparable work, and many describe a working ethos that systematically privileges men over women (Millar & Jagger, 2001; Woodfield, 2000). In a context where female educational achievements are outstripping those of males at every level of education in the UK, and female work aspirations are becoming increasingly clear and uncompromising, it is almost certainly the case that the negative perception of IT work plays a critical role in determining the numbers of women choosing courses that qualify them for it. As Millar and Jagger have claimed, problems appear in the relationship between women and the computer sciences “once women begin to structure their education towards a career” (2001, p. A-iv). There are substantial benefits to IT work, however, that could be clarified and communicated to those selecting their GCSE, A level and university courses: salary levels, notwithstanding the gender gap, tend to be higher than average; existing female IT professionals rarely describe themselves as bored or unfulfilled in terms of the work per se. More fundamentally than the need to communicate these benefits, the sector needs to consolidate the beneficial aspects of IT careers for women, and work to eradicate the more negative aspects.

The earlier communication about the advantages of IT work takes place, the better. It is claimed that educational choices, based on projected career costs and benefits, are already taking place when UK teenagers face their first opportunity to specialise, around age 14. This is also an age when young males and females are most sensitive to gender-appropriate and gender-inappropriate career choices. It is of concern then, that there seems to be so few reports of positive representations of professional IT work as a viable career goal for girls (and their parents) by teachers or careers advisers within secondary schools, and that the provision of female-friendly spaces for computing is still considered cutting edge (Craig et al., 2002b; Millar & Jagger, 2001; Peters et al., 2003). Improvements in the knowledge, and sometimes the attitude, of adults playing a key role in pre-university course choices, could make a significant difference to female participation rates at this level.

As well as the role played by the image of IT work, the reported experiences of those undertaking a computer science degree must also partially account for the level of female participation at university. There is a wealth of evidence to suggest that female students’ under-representation on courses creates its own problems in terms of their confidence, adjustment, enjoyment, and achievement levels. They report themselves to feel pressurised to adapt to a male-dominated and male-oriented educational regime in order to survive (see, for example: Bjorkman, Christoff, Palm, & Vallin, 1998; Blum, 2001; Margolis & Fisher, 2002; Peters et al., 2003). Evidence from those institutions that have attempted to make significant changes within their computer science programmes so that women will feel less alienated suggests that the have enjoyed far greater female participation and approval rates as a result (Connor et al., 1999; Margolis & Fisher, 2002; Millar & Jagger, 2001). In doing so, they point to a wish list of best practices for others interested in doing the same. These include building a curriculum that
assumes a minimal level of previous IT experience, providing mentoring systems and female-friendly learning spaces, and ensuring that faculty are sensitive to the needs and abilities of female students (Blum, 2001; Cahoon, 2001; Hefce 2002; Margolis & Fisher, 2002). One course in the UK, where such considerations have been central for some time, reports high rates of female uptake of degree places, but also that 100% of women on the course maintained a desire to become an IT professional after the completion of their degree (Craig et al., 2002).

The finding that women are heavily reliant on the information provided in prospectuses is heartening in this regard. It confirms that there is a clear window of opportunity for the more progressive universities through which they can encourage potential applicants and reduce reliance on general anecdotal or impressionistic information that may not apply to their courses. If more institutions embraced the same ethos, a critical mass of women entering computer science undergraduate programmes could be achieved in the next decade. This, in turn, could impact significantly on the general culture of educational computing and beyond into the workplace, which could lead to improvements in the sector’s image. The beneficiaries of this would not just be the women who would otherwise have turned away from the subject at degree level, but also the UK economy and society which is arguably at present drawing its computing scientists and skilled IT professionals from an artificially restricted pool.

KEY TERMS

Classification of Degree: UK degrees are ascribed “classifications” that usually correspond to the following percentage results (averaged over all assessments contributing to the final grade):

- First – 70%+
- Upper Second or 2:1 – 60-70%
- Lower Second or 2:2 – 50-60%
- Third – 40-50%
- Pass – 30-40% (a bachelor degree without honours)

Equal Opportunities Commission/EOC: The Equal Opportunities Commission is an independent, non-departmental public body, funded primarily by the government. It provides free research reports and statistics chronicling the position of women and men in all aspects of UK life, including work and education. Web address: http://www.eoc.org.uk

GCE A Level: The General Certificate of Education, A level (Advanced Level) is usually taken 2 years after GCSEs and as a non-compulsory, pre-entry qualification for University-level Study. Students usually take 3 or 4 specialised subjects at this level, which they are free to select.

GCSE: The General Certificate of Secondary Education is usually taken by 15-16 year olds in a range of subjects—some compulsory (English, maths, and science) and some optional (including Computer Studies)—at the end of their compulsory schooling. Achieving 5 GCSE grades A-C is considered the desirable educational benchmark to be reached by this age.

Good Degree: A term used in academic literature and common parlance to indicate a degree which has been classified as an “Upper Second” or “First,” (i.e., in the top two degree classifications. It is normally assumed that those going on to postgraduate study will have such a
degree, and they are preferred in many employment contexts.

**HESA (Higher Educational Statistics Agency):** HESA was set up in 1993 by the UK Government to act as a central source for higher education statistics and has become a respected point of reference. Web address: http://www.hesa.ac.uk.

**IT/Computer Professional:** An individual working within the IT/computer sector within a complex and skilled role that is classified within the category “Professional occupations” (e.g., software engineers), or sometimes within “Associate professional and technical occupations” (e.g., computer programmers)—in the National Statistics classifications, Standard Occupational Classification Codes (2004): http://www.statistics.gov.uk

**ENDNOTES**

1. Elsewhere, degrees in mathematical sciences and/or business and administration degrees are included in analyses of gender representation within degrees associated with IT and IT employment (see, for instance, Millar & Jagger, 2001). Here, unless stated otherwise, I will be using the narrower group of “computer science” degrees, defined, according to Higher Educational Statistics Agency programme categories as including: computer science, information systems, software engineering, artificial intelligence, and other programmes within computer science.

2. All of the statistics included within this section are based on original analysis of Higher Education Statistics Agency data provided under *ad hoc data enquiry: 23148*.

Chapter 4.11
Gender and Information Technology in Rural Bangladesh

Lutfor Rahman
Association for Advancement of Information Technology (AAIT), Bangladesh

Nusrat Rahman
University of Dhaka and Association for Advancement of Information Technology (AAIT), Bangladesh

INTRODUCTION

Information technology (IT) is transforming our personal, social, cultural, economic and political lives. But women in developing countries do not have equal access to knowledge, due to the fact that they do not have access to the new technologies at the same level as western European women. They need to understand the significance of new technologies and use them in relevant fields. IT can offer immense opportunities for virtually all girls and women in developing countries, including poor women living in rural areas.

Developing countries like Bangladesh are usually seen as problematic hosts for ITs because most developing regions of the country lack economic resources and indigenous techno-scientific capabilities to develop and deploy IT infrastructures. The regions also tend not to make the best use of opportunities of technology transfer.

The wider adoption of IT in the 1990s promised a globally connected community of equal participants in electronic networks. The Internet has enabled people to communicate regardless of race, sex, physical ability, location and social background (GVU, 1998). IT now offers access to a huge pool of information. The Internet enables worldwide communication that is cheaper, faster and more flexible than older media like e-mail, telephone, telex or fax.

BACKGROUND

In early 2000, an initiative was taken to develop a small river island (char) of Bangladesh through
establishment of a resource centre named Indigenous Science and Technology at Ikrail (ISTI), and using IT as the main vehicle for development. IT is a livelihood to many women of the developed countries but is almost unknown to the women and girls of the river island.

Women in Bangladesh are seen in the frontlines to fight against hunger, poverty and environmental degradation. Because of lack of awareness about the benefits of IT, they cannot raise their problems for solution to the proper authority. IT can benefit women in various ways and can facilitate their participation in different sectors and regions. It can provide information women need to improve their own well-being and that of their families. The introduction of computers in offices can improve the quality of work and scope for women in data entry, analysis, programming, clerical and administrative occupations in Bangladesh. IT could allow them to exchange views, opinions and information with women of other regions and countries.

The situation for rural populations in many regions of the world is characterized by geographical distance from urban centres that offer employment and income, education, cultural events and public services. IT bears the potential to improve the situation of rural people in several ways. For example, it is agreed that early diagnosis of medical issues can prevent many casualties. Once a patient comes to the health centre, using various sensors, information can be collected and communicated to an expert at hospitals in the district headquarters. The primary healthcare centre could be located in a rural area or in a mobile centre installed in a van.

IT offers access to information and extension, to education and training communication and networking in online discussions. IT also offers access to employment and income.

**Infrastructural Problems**

Poor healthcare can result from a lack of good information. Establishing reliable communications may be one of the most important priorities for improving healthcare and education. Many rural areas in the globe have no or outdated telephone lines that can transmit Internet-based data. The lack of infrastructure can be overcome by wireless technology (e.g., radio modems). Mobile telecentres can be a solution for the target group.

**HEALTHCARE IT PROJECT**

A significant number of women scientists, researchers and technologists work in rural Bangladesh. They are disadvantaged and traditionally underrepresented in most respects. Their knowledge and skills are unrecognized, underused and under valued. As such, they are in greater need of upgrading their skills, especially in the fast advancing world of information and communication technologies (ICTs), which might enable them to connect their global colleagues, sources of information and global knowledge wherever they may be located.

A survey conducted in early 2000 among 515 women professionals of various disciplines spanning life sciences, social sciences, physical sciences, mineral sciences, engineering, technologies and medical sciences identified that they are almost illiterate in IT, although they are well qualified and experienced in their respective fields. At the first step, the survey was conducted over the senior professors of the public and private universities, scientists of the Bangladesh Council of Scientific and Industrial Research (BCSIR), researchers of institutes of forest research, housing research, fuel research, jute research and water resource and geological research.
They have very poor knowledge about the power and benefit of IT. This trend was found true at all levels of educational backgrounds. The survey revealed that the illiteracy rate in IT among the medical doctors are high, because the doctors are normally resistant to new technology, particularly IT.

To reach the benefit to the rural communities, participants for IT training were selected from among applicants spanning all sectors, giving priority to the rural community. The representation covered various national economy, especially health, environment, education, natural resources (mineral resources), energy, industry, agriculture, fisheries and forestry. Special care was taken in selection of participants so that the maximum number of organizations and individuals would benefit from the program. Training programs on IT for the duration of 2 weeks were organized in different private universities at a certain interval with 20 participants in each phase. The programs were initially organized at the capital city, and later, the programs were arranged at the regional institutes and universities. The regional programs were mainly organized for the medical doctors working in the local hospitals, clinics, medical colleges and universities. Selection of participants from the women medical doctors was really a tough job. Neither the medical doctors nor their family members wanted to spare 2 weeks for attending a training course that they feel are good for their children, not for the doctors. Strategies were adopted to attract the medical doctors. As soon as they realized the importance of IT, they invested more of their valuable time to learn further applications. Ninety-two percent of the trained medical doctors were found to utilize their gained knowledge intelligently in their respective fields. The result was obtained from the follow-up visit by the project staff.

**FUTURE TRENDS**

Bangladesh is a country of rivers that create islands (chars) of different shapes and sizes. They are created because of river erosion. The ISTI resource centre is located in one such island. The island is circular in shape and its area varies from 20 to 30 square kilometers, depending on seasons. Approximately 15,000 people live in the island community. The people depend on local cultivation for survival. Their average monthly earning is $40 (United States dollars). The area is fertile and rice, wheat, peanut, jute, sugarcane, and different types of vegetables and fruits are common. All work is performed manually. The people are deprived of basic infrastructure. There is no electricity, phone system or sanitation. The only source of water is contaminated with arsenic. There are no health clinics or doctors in the area. Many adults are illiterate, and curable diseases, such as cholera, malaria and tuberculosis, are pervasive.

The ISTI resource centre has been established with the objective of developing this isolated region with proper education, empowering local people with relevant technology, particularly IT, and providing them with medical facilities using modern techniques (such as telemedicine and telehealth care). The ISTI resource centre, equipped with basic medical test equipment like stethoscopes, blood pressure meters and blood testing chemicals, and connected with a hospital located in the district town, might save lives of many women and girls. Just a computer with a modem connected with wireless local loop (WLL) help solve most of the serious problems of local women by the women medical doctors empowered with IT. The ISTI resource centre is working as role model for several million disadvantaged women living in the river islands of Bangladesh.
CONCLUSION

This training program has been particularly suitable and effective for relatively marginalized groups and remote communities in a developing country because of its low cost and the use of local organizers and trainers, courses especially designed to meet the participants’ needs and in situ follow up. The direct involvement in the courses of senior policy makers, employers and local experts has proven to be absolutely crucial in gaining support for the continuation and expansion of the course and, perhaps more importantly, effecting attitude change to women’s roles and capabilities in science and medicine. This was underlined by the increasing cooperation extended by them to the project team during preparation and execution of the project. The outcome of the whole training has been impressive. Participants’ value to the work place has increased, some attained promotions and some changed careers.

The final evaluation report shows that most women medical doctors and other health-related professionals empowered with IT have expressed their opinions that every medical doctor must attend relevant technology—particularly IT—courses if they want to enhance their services and maintain their personal secrecies. Some mentioned that IT is a magic and all-pervasive tool.

KEY TERMS

Information and Communication Technology (ICT): ICT covers computing, electronics and telecommunications.

Medical Professionals: Medical doctors and scientists in health-related subjects, such as nutrition, bio-chemistry, psychology and so forth.

Researchers: Graduates and post graduates engaged in research activities.

Scientists: Science graduate with some research experience in scientific fields.

Technologists: Engineers and scientists with experience in hardware.

University: A university is characterized by a wide variety of teaching and research, especially at a higher level, that maintains, advances, disseminates and assists the application of knowledge, develops intellectual independence and promotes community learning.
Chapter 4.12
Chinese POS Disambiguation and Unknown Word Guessing with Lexicalized HMMs

Guohong Fu
The University of Hong Kong, Hong Kong

Kang-Kwong Luke
The University of Hong Kong, Hong Kong

ABSTRACT

This article presents a lexicalized HMM-based approach to Chinese part-of-speech (POS) disambiguation and unknown word guessing (UWG). In order to explore word-internal morphological features for Chinese POS tagging, four types of pattern tags are defined to indicate the way lexicon words are used in a segmented sentence. Such patterns are combined further with POS tags. Thus, Chinese POS disambiguation and UWG can be unified as a single task of assigning each known word to input a proper hybrid tag. Furthermore, a uniformly lexicalized HMM-based tagger also is developed to perform this task, which can incorporate both internal word-formation patterns and surrounding contextual information for Chinese POS tagging under the framework of HMMs. Experiments on the Peking University Corpus indicate that the tagging precision can be improved with efficiency by the proposed approach.

INTRODUCTION

While a number of successful part-of-speech (POS) tagging systems have been reported for English and many other languages over the past years, it is still a challenge to develop a practical Chinese POS tagger due to the language-specific issues in Chinese POS tagging. First, there is not a strict one-to-one correspondence for a Chinese word between its POS and its function in a sentence. Second, an ambiguous Chinese word can act as different POS categories in different contexts without changing its form. Third, there are many unknown words in real Chinese text whose POS categories are not defined in the dictionary.
Chinese POS Disambiguation and Unknown Word Guessing with Lexicalized HMMs

used. Furthermore, there are almost no explicit morphological features in Chinese words, such as inflexion, derivation, and capitalization in English, that can be used directly for POS disambiguation and unknown word guessing (UWG). All these factors make it much more difficult to achieve a high-performance POS tagger for Chinese.

Recent study on POS tagging has focused on machine-learning approaches, including hidden Markov models (HMMs) (Brants, 2000; Weichedel et al., 1993), transformation-based error-driven learning (TBL) (Brill, 1995), maximum entropy model (Ratnaparkhi, 1996), support vector machines (SVMs) (Nakagawa et al., 2001), and loglinear models (Fu & Wang, 2002). Machine-learning approaches have the advantage of robustness. However, it is difficult for most machine-learning techniques to keep a balance between their capacity and their computational cost (Nakawa et al., 2002). Pla and Molina (2004) have proved that HMM-based taggers have the highest training and tagging speed. However, they usually achieve relatively low tagging precision, because standard HMMs only take into account contextual POS information for tagging. On the contrary, some learning models such as ME and SVMs are capable of handling much richer lexical information for POS tagging. However, they usually require higher computational cost, which inevitably will result in reduction of efficiency in training and tagging. This will be a serious problem in processing a large amount of data or in some online applications. In order to tackle this problem, some recent work, such as Lee, et al. (2000) and Pla and Molina (2004) suggested the use of lexicalization techniques to enhance the standard HMMs. Their experiments have shown that the lexicalized models can improve POS tagging precision without increasing much computational cost in training and processing.

POS disambiguation and unknown word guessing are two key issues in developing a Chinese POS tagger for practical applications. On the one hand, Chinese is highly ambiguous with respect to part of speech. Consequently, the first task of a POS tagger is how to find a proper POS for each ambiguous word in a sentence. On the other hand, there are many unknown or out-of-vocabulary (OOV) words in real Chinese texts whose POS categories are not defined in advance in the system dictionary. So, a practical tagger should be capable of predicting or guessing with accuracy the POS categories for these unknown words in an open-ended text.

Following the line of Lee et al. (2000) and Pla and Molina (2004), we propose in this article a unified approach to Chinese POS disambiguation and unknown word guessing. In order to explore word-internal morphological features for Chinese POS tagging, we introduce four types of pattern tags that indicate the way of a lexicon word to present itself in a real segmented sentence. Further, we define a hybrid tag set by merging these patterns with POS tags, with which Chinese POS disambiguation and unknown word guessing can be unified as a single process of assigning each known word (KW) in input a proper hybrid tag. Moreover, a statistical tagger is developed based on the uniformly lexicalized HMMs. In this way, three kinds of features — contextual tag information, surrounding lexical information, and word-internal word-formation patterns — can be incorporated for Chinese POS tagging under an efficient HMM-based framework. As a consequence, the tagger’s performance can be improved with efficiency in training and tagging.

The rest of this article is organized as follows: The second section presents a novel formulation for Chinese POS tagging. Next a uniform lexicalization technique is introduced to enhance the standard HMMs for POS tagging. The fourth section gives a brief description of the tagging algorithm. Finally, we report our experimental results on the Peking University corpus in the fifth section and give our concluding remarks on this work in the final section.
**UNIFYING POS DISAMBIGUATION AND UNKNOWN WORD GUESSING**

In this section, Chinese POS disambiguation and unknown word guessing is reformulated as one unified process of known word tagging, based on the introduction of word formation patterns.

**Word Formation Patterns**

The input of our current task is a segmented sentence or a sequence of words that might be either known words listed in the system lexicon or unknown words unlisted in the system lexicon. In general, a known word consists of only one lexicon word, while an unknown word is composed of several lexicon words. As discussed in Fu and Luke (2005), a lexicon word has four possible patterns to form a word in a segmented sentence: (1) $w$ is segmented as an independent known word; (2) $w$ is the beginning component of an unknown word; (3) $w$ is a middle component of an unknown word; (4) $w$ is the ending component of an unknown word. In this article, four different tags — ISW, BOW, MOW and EOW — are used to denote these patterns, respectively. Thus, a segmented sentence can be represented as a sequence of lexicon words accompanied with their word-formation pattern tags. For example, an equivalent expression of the POS-tagged sentence 张晓华在工作 (Zhang Xiao-hua is working) is 张/ISW晓/ISW华/MOW在/EOW工作/ISW.

**POS Disambiguation and Unknown Word Guessing as Known Word Tagging**

Given a real word in a Chinese sentence, the position of its component lexicon words is another important evidence that can be used to determine its POS in addition to the contextual information surrounding it. For example, if a word ends with the character 性 (xing4, nature), then it is more likely to be a noun. On the contrary, if a word ends with the character 化 (hua4, change or a suffix such as -ize and -ify), then it should be tagged as a verb in most cases. In order to explore these important position features for POS disambiguation and unknown word guessing, a hybrid tag set is thus designed by merging the above four patterns with POS tags. In our work, a hybrid tag has the following format: T1-T2. Where T1 denotes a POS tag and T2 denotes a word-formation pattern tag.

With this hybrid tag set, an original POS-tagged sentence can be represented equivalently as a sequence of known words accompanied by their relevant hybrid tags. For example, an equivalent expression of the POS-tagged sentence 张/nr晓华/nr在/p香港/ns大学/n工作/v张晓华/nr在/p香港/ns大学/n工作/v is 张/ISW晓/ISW华/MOW在/EOW在/p-ISW在/p-ISW在/p-ISW大学/n-ISW工作/v-ISW.

Obviously, the POS category of an unknown word in a sentence will be determined once each of its components is assigned a proper hybrid tag. At this point, the two subtasks in Chinese POS tagging (i.e., POS disambiguation and unknown word guessing) thus can be unified as a single task of tagging each known word in input, with a proper hybrid tag indicating its POS category and its word-formation pattern.

**LEXICALIZED HMMs**

**Uniformly Lexicalized HMMs**

Given a sequence of known words $W = w_1w_2...w_n$, a statistical tagger aims to find an appropriate sequence of hybrid tags $\hat{T} = t_1t_2...t_n$ that maximizes the conditional probability $P(\hat{T}|W)$; namely,
\[
\hat{T} = \arg \max_T P(T \mid W) = \arg \max_T \frac{P(W \mid T)P(T)}{P(W)}
\]  

(1)

where the probability \( P(W) \) can be dropped in that it is fixed for a specific word sequence \( W \). Thus, we have a general model for POS tagging as follows:

\[
\hat{T} = \arg \max_T P(W \mid T)P(T) = \arg \max_T P(w_{1:n}, t_{1:n})
\]

\[
= \arg \max_T \prod_{i=1}^{n} P(w_i \mid w_{i-1}, t_{i-1})P(t_i \mid w_{i-1}, t_{i-1})
\]

(2)

In theory, the model in Equation (2) can provide the tagging system with more powerful capacity for disambiguation and unknown word guessing. However, it involves too many parameters to be computable in practice. To address this problem, two models—the standard HMM and the lexicalized HMM—are usually employed to approximate the general model in Equation (2).

Actually, the standard hidden Markov modeling follows two well-known independent hypotheses: The appearance of current word \( w_i \) depends only on current tag \( t_i \) during known word tagging, and the assignment of current tag \( t_i \) depends only on its \( N \) previous tags \( t_{i-N}, \ldots, t_{i-1} \). Thus, Equation (2) can be rewritten as

\[
\hat{T} = \arg \max_T \prod_{i=1}^{n} P(w_i \mid t_i)P(t_i \mid t_{i-N}, \ldots, t_{i-1})
\]

(3)

Equation (3) is a general form of the \( N \)-order standard HMMs, where \( P(w_i \mid t_i) \) denotes the so-called lexical probability, and \( P(t_i \mid t_{i-N}, \ldots, t_{i-1}) \) denotes the contextual tag probability. Due to the serious data sparseness in real applications, only the first-order or second-order models are employed in most current POS tagging systems (i.e., \( N = 1 \) or \( N = 2 \)).

At present, standard HMMs have been used widely in many NLP applications such as automatic speech recognition (ASR) and POS tagging, due to their efficiency in training and processing. Furthermore, a variety of theories and algorithms have been proposed for building HMMs with efficiency. However, a standard HMM-based tagger only can take into account contextual category information for tagging. The important contextual lexical features often are ignored. As a consequence, HMM-based taggers usually have relatively low tagging performance. In order to enhance tagging performance and give consideration to efficiency in training and tagging at the same time, we employ the uniform lexicalization technique (Lee et al., 2000) to enrich the standard HMMs with contextual lexical information.

In approximating the general model in Equation (2), the uniformly lexicalized modeling adopts two assumptions: the appearance of current word \( w_i \) is assumed to depend not only on current tag \( t_i \) but also its previous \( N \) words \( w_{i-N}, \ldots, w_{i-1} \) and tags \( t_{i-N}, \ldots, t_{i-1} \), and the assignment of current tag \( t_i \) is supposed to depend on both its previous \( N \) words \( w_{i-N}, \ldots, w_{i-1} \) and the relevant \( N \) tags \( t_{i-N}, \ldots, t_{i-1} \). Thus, a uniformly lexicalized HMM can be formulated as

\[
\hat{T} = \arg \max_T \prod_{i=1}^{n} P(w_i \mid w_{i-N}, \ldots, w_{i-1}, t_{i-N}, \ldots, t_{i-1})P(t_i \mid w_{i-N}, \ldots, w_{i-1}, t_{i-N}, \ldots, t_{i-1})
\]

(4)

In comparison with standard HMMs, uniformly lexicalized HMMs can handle both contextual words and contextual tags for the assignment of hybrid tags to known words, which will result in an improvement of tagging precision. In view of the serious data sparseness in higher-order models, we employ the first-order lexicalized HMMs in our system.
Estimation and Data Smoothing

If a large POS-tagged corpus is available, the lexicalized HMMs easily can be estimated using the maximum likelihood estimation (MLE) technique. In principle, MLE estimates parameters using their relative frequencies that can be directly extracted from the training data. Obviously, MLE has the advantage of simplicity. However, it will yield zero probabilities for some cases that are not observed in the training data. Relatively speaking, a lexicalized HMM-based tagger will be faced with a more serious problem of data sparseness than a standard HMM-based tagger. In order to tackle the problem of zero probabilities in MLE, we employ the linear interpolation smoothing technique to smooth the lexicalized parameters using the relevant non-lexicalized probabilities. This process can be formulated with Equation (5):

\[
\begin{align*}
F'(w_1 | _w_{-1}, \lambda) &= \lambda F(w_1 | _w_{-1}, \lambda) + (1 - \lambda) F(w_1 | _\lambda) \\
F'(\lambda | _w_{-1}, \mu) &= \mu F(\lambda | _w_{-1}, \mu) + (1 - \mu) F(\lambda | _\lambda)
\end{align*}
\]

(5)

where, $\lambda$ and $\mu$ refer to the smoothing coefficients.

THE ALGORITHM

This section describes an algorithm for Chinese POS tagging. The problem of inconsistent tagging also is discussed in this section.

Viterbi Tagging

Given a sequence of words, there might be more than one possible sequence of POS tags. The task of a tagging algorithm is to find the best one that has the highest score according to the models in Equation (3) or (4). In our system, we apply the classical Viterbi algorithm to perform this task, which works in three main phases as follows:

1. **Decomposing of unknown words.** As discussed previously, lexicon words (i.e., known words) are taken as the basic tagging units. In this phase, all unknown words in input are decomposed to a sequence of known words using the forward maximum match (FMM) method (Liang, 1987), and each decomposed known word then is assigned a proper pattern tag in terms of its position in the relevant unknown word. At the same time, each known word in the input is labeled a pattern tag ISW.

2. **Generation of candidate POS tags.** In this phase, all possible POS tags first are generated for each word in the input: For a known word, its POS candidates are generated by looking up the system lexicon; For an unknown word, its POS candidates are created by searching the lexical probability library in terms of its components and their word-formation patterns. In accordance with the format defined in the third section, these POS candidates are then merged with the relevant pattern tags created in phase (1). All these combined candidate tags are stored in a lattice structure.

3. **Decoding of the best tag sequence.** In this step, the Viterbi algorithm is employed to score all candidate tags using the language models given in the fourth section and then to search the best path through the candidate lattice that maximizes the score. This path contains the most probable sequence of POS tags for the input. It should be noted that the direct output of our tagger is represented as a sequence of known words together with a sequence of hybrid tags. For evaluation purposes, such a format will be converted further into the normal tagging format by
removing the pattern tags and reconstructing
unknown words using their components.

**Inconsistent Tagging**

Inconsistent tagging will arise when the components of an unknown word are labelled with different POS tags. For example, the personal name 晓华 in the sentence 张晓华在香港大学工作 (Zhang Xiaohua is working at the University of Hong Kong) might be inconsistently tagged as 晓/Vg-MOW 华/nr-EOW. In this case, the system will be unable to make its decision in determining the POS category of the full word 晓华. Consequently, how to avoid inconsistent tagging is a fundamental issue that relates to the practicability of our system.

To achieve a complete consistent tagging, we develop a rule-based module in our system, which can prevent inconsistent tags from entering into the lattice for storing candidates during the generation of potential POS tags for unknown words. Given an unknown word and its components, our system first creates a set of POS candidates for each of its components in terms of its relevant pattern and its lexical probability. Then, it will continue to generate the POS candidate set for the unknown word using one of the following four rules: (1) if the intersection of all the POS candidate sets for its components is not null, then the intersection is taken as its POS candidate set; or (2) if the intersection of the two candidate sets for its beginning and ending components is not null, then the intersection is its POS candidate set; or (3) if the union of the two sets of POS candidates for its beginning and ending components is not null, then the union is its POS candidate set; and (4) if the three previous rules do not work, then the top frequent POS tag (i.e., noun) is taken as its POS candidates. It should be noted that once the POS candidate set for the unknown word is determined, all its components should share this set as their POS candidates. Rule (2) stresses the importance of the beginning component and the ending component, because according to our intuition, the two components might be more informative than other components in determining the POS category of a Chinese unknown word in most cases.

**EXPERIMENTS AND DISCUSSIONS**

In order to evaluate the effectiveness of our system, we conducted a number of experiments using the Peking University corpus and lexicon. This section reports the results of these experiments.

**The Experimental Data**

The Peking University (PKU) corpus (Yu et al., 2003) contains six months (January to June, 1998) of Chinese newspaper text from the People’s Daily. As shown in Table 1, the PKU corpus has been segmented manually and contains approximately 7.3 million words. Each word in this corpus also has been tagged with one of 45 POS tag in Appendix A. In our experiments, the first month of data (i.e., January 1998) was used for testing, and the remaining five were for training. It should be noted that an original POS-tagged corpus should be converted to the format shown in the second section before using is for training (i.e., a sequence of known words together with their hybrid tags). In addition to the PKU corpus, we employed a POS dictionary of about 75,000 entries in our system, which were mainly from the Grammatical Knowledge-Base of Contemporary Chinese (Yu et al., 1998). In order to make this lexicon complete, a number of non-Hanzi characters and GBK Hanzi were also added to it.

Table 1 also gives a survey of Chinese POS ambiguities and unknown words in the PKU corpus. It can be observed that over 55% of known words are ambiguous in POS, and some 7% of words in the PFR corpus are unseen in the
dictionary used in our system. This shows that high-performance disambiguation and unknown word guessing are very important for a practical Chinese POS tagging system.

Table 2 shows the top 10 frequent types of unknown words in the PKU corpus. It can be observed that noun is the most frequent type of unknown words. We can see that more than 20% of unknown words are nouns in the PKU corpus. As can be seen from Table 2, the top 10 frequent types account for about 93.80% of unknown words in the training corpus and 94.20% of unknown words in the testing corpus.

The Experimental Results

In our evaluation, we conducted two experiments on the PKU corpus in Table 1:

1. Since a lexicalized HMM-based approach can handle richer contextual information for tagging, particularly the contextual lexi-
Table 3 shows the results of our first experiment. We can see that the lexicalized HMMs perform better than the standard HMMs as a whole. In comparison with the standard HMM-based tagger, the lexicalized HMM-based tagger can improve the tagging precision respectively by 2.06% for all words, 1.88% for all known words, 3.37% for ambiguous known words, and 4.42% for unknown words. At the same time, the use of lexicalized models does not lead to a rapid increase of tagging time. This indicates that the lexicalized HMM-based method is able to keep a relative balance between tagging precision and tagging efficiency.

Figures 1, 2, and 3 present the curves of the tagging precision for all words, ambiguous known words, and unknown words, respectively, vs. the size of the data for training. We can see that in comparison with the standard HMM-based tagger, the tagging precision of the lexicalized HMM-based tagger is changing in a sharper ascent curve for all three cases as the size of the training corpus increases, which indicates that the uniformly lexicalized HMMs need much more training data than the corresponding non-lexicalized models in order to achieve a reliable estimation. In other words, the performance of a lexicalized HMM-based tagging system is more sensitive to the size of the training data than that of a standard HMM-based tagging system. Furthermore, it can be observed from Figure 2 and Figure 3 that a larger improvement of tagging precision can be achieved for unknown word

guessing than for the disambiguation of known words. To our knowledge, the reason might be that unknown words in real text form an open set, while known words are a close set. In general, more training data will provide the system with much richer contextual information and word-formation cues for the guessing of different unknown words in an open-ended text. As a consequence, an increase of training data will result in a steady improvement of tagging precision in unknown word guessing.

CONCLUSION

We presented a unified resolution to Chinese POS disambiguation and unknown word guessing. In order to explore word-internal cues for Chinese POS tagging, we introduced four types of word-formation patterns that indicate whether a lexicon word is an independent word or a component word in a specific position of an unknown word in a sentence. We further defined a hybrid tag set by merging these patterns with POS tags, with which we can reformulate Chinese POS disambiguation and unknown word guessing as one single process of assigning each known word by inputting a proper hybrid tag. To do this, we developed a statistical tagger based on the uniformly lexicalized HMMs. In this way, three types of features — word-internal word-formation cues, contextual tags, and contextual words — can be incorporated to resolve different ambiguous words or unknown words in Chinese text. We also evaluated our system using the Peking University corpus and dictionary. The experiments have shown that our system can yield correct results for most ambiguous words and unknown words in question. Our experimental results also indicated that the use of the lexicalization technique is able to improve the
tagging precision without losing much efficiency in tagging.

ACKNOWLEDGMENTS

We would like to thank the Institute of Computational Linguistics, the Peking University for their corpus and lexicon. We also would like to thank the two anonymous reviewers for their helpful and valuable comments.

REFERENCES

ENDNOTES

1 Unlike other languages like English, Chinese text has no explicit delimiters to mark word boundaries except for some punctuation marks. Therefore, word segmentation is usually the first step in performing POS tagging on a text in Chinese. An introduction of Chinese word segmentation can be seen in Fu and Luke (2005). This article focuses on Chinese POS tagging.

2 It should be noted that a normal input word sequence might contain known words and unknown words. In this article, each unknown word will be decomposed into a sequence of known words using the efficient forward maximum match technique (Liang, 1987) before POS tagging.

Chapter 4.13
IT Implementation in a Developing Country Municipality: A Sociocognitive Analysis

Clive Sanford
Aalborg University, Denmark

Anol Bhattacherjee
University of South Florida, USA

ABSTRACT
This article presents an interpretive analysis of the key problems and challenges to technology implementation in developing countries, based on a three-year case analysis of an IT project in a city government in Ukraine. We employ the concept of technological frames of reference as an analytical tool for articulating the group-level structures related to the implementation context from the perspectives of key stakeholders and examine the degree of conflict between these frames using a Fishbone diagram. We report that conflict between technological frames held by key stakeholders in large-scale system implementation projects often create an unexpected, dysfunctional, and politically charged implementation environment, ultimately leading to project failures, even if the project enjoys a high level of financial and management support. This, in turn, creates unique challenges for technology implementation projects in developing countries that are often overlooked in the traditional academic and practitioner literatures based on experiences from developed countries.

INTRODUCTION
Information technology (IT) has long been viewed by central planners in the developing world as an important tool for achieving rapid economic and wage growth, improving operational efficiency and effectiveness, and enhancing political participation and transparency. However, achievement of these objectives is often thwarted due
to incentive structures that are based on existing rules and organizational structures. Improvements in administrative capacity can only be expected when there is a sound institutional base that is supported by operational, technical, and infrastructural facilities. Therefore, planning for the diffusion of IT into a developing country’s administrative strategies presents a challenge that is significantly different from that encountered by developed countries.

The UN Secretary-General has stated, “information technologies can give developing countries the chance to leapfrog some of the long and painful stages of development that other countries had to go through” (Annan, 2002). In other words, IT has the potential to support the development strategy of bypassing some of the processes of the accumulation of human capabilities and fixed investment in order to narrow the gaps in productivity and output that separate industrialized and developing countries (Steinmueller, 2001). Recently, there is also the indication that the creation of an information society and, in particular, e-government implementation would lead to better (or good) governance (Ciborra & Navarra, 2005). However, the public and businesses in developing countries often have a mistrust of governments that are entrenched in hierarchical structures that are often politicized and corrupt, and are rife with cumbersome processes that stunt economic growth and discourage investment in productive business activities. Efforts to restructure government are either in direct conflict with institutional archetypes or have proven difficult for countries with unstable governments to adopt. In addition, government agencies in developing and transitional countries often try to install IT infrastructures that have been designed for private sector firms and/or for governments in other countries.

Globalization, democratization, and economic liberalization have prompted initiatives with IT as the primary lever to stimulate dramatic changes in the role of the state. New freedoms and opportunities, especially prevalent in developing countries, have raised the expectations of individual citizens, and emerging and increasingly vocal and proactive civil societies now do not hesitate to call governments to account. This is somewhat mitigated by the fact that IT in many public sectors has not delivered the value expected (Bellamy & Taylor, 1994; Lenk, 1990; Margetts, 1999; Margetts & Willcocks, 1993; Willcocks, 1994). The literature on IT in developing countries generally reports on planned systems, pilot studies, and failures, and seldom discusses the outcome of projects that are even partially functional (Cecchini & Raina, 2005). Further, even when systems are operational, sustaining operations in an ongoing manner is difficult (Frasheri, 2003).

This article presents a longitudinal case analysis of an IT initiative in the city government of L’viv, a municipality in western Ukraine, to improve governance and service quality for its citizens. The specific system under investigation is a Lotus Notes based document management system (DMS), intended to automate and streamline citizen services such as building construction permits, business license applications, and zoning clarifications. A similar project was rolled out in the Malaysian government Generic Office Environment (GOE) (Karim, 2003). Grant and Chau (2005) used the Malaysian GOE as a case example of service delivery in their strategic focus areas of their e-government framework. While a governmental DMS has an objective that is congruent with e-government to “enable effective constituent relationship management” (Grant & Chau, 2005, p. 9), and in general may qualify as a specific example of e-government, we prefer to orient the discussion of a DMS as an effort to improve e-administration. E-administrative initiatives deal particularly with projects that involve the re-engineering of internal structures and organizational activities. These initiatives include cutting process costs, managing process performance, making strategic connections in government, and “creating empowerment by transferring power,
authority and resources for processes from their existing locus to new locations” (Heeks, 2002b, p. 99). This requires a fundamental restructuring of the public administration’s organization and knowledge management practices by integrating work processes across departments and agencies in order to build a system that simplifies interactions and improves services.

We describe three years of the deployment history of the DMS project (2002-2005), by drawing on the experiences of one of the study’s authors, who was a participant observer in this project at this time. The author was commissioned by the City Mayor as a consultant to provide user training for the DMS and related systems. Based on numerous personal interactions with people involved at all levels of this project, such as the Mayor’s office, end users, the city’s IT department, and external consultants, and direct involvement with the DMS and prior L’viv city projects, this was a unique opportunity to unravel the complex dynamics of the DMS project as it evolved over time. Our interpretive analysis of interview, observational, and documentary evidence revealed several interesting findings and implications about the politics of IT implementation projects in developing countries. Given the unprecedented nature of political, sociocultural and economic change witnessed in Ukraine and other new democracies of eastern Europe over the last decade, this context provided us an ideal testbed for studying the processes and impacts of e-administrative government projects in countries that are seeking to establish western-style democratic reforms.

The structure of the article proceeds as follows. The next section discusses the rationales behind the introduction of IT in developing countries. The third section describes a sociocognitive view of IT implementation, which serves as the theoretical backdrop for our research. The fourth section presents a background of the context of this case study, followed by a historical description of the events in the case. The fifth section describes our research methods, including data collection and analysis approaches. The sixth section presents our research findings, based on interpretive analysis of the case data. The seventh section provides a discussion of the key issues in the case and the final section proposes directions for future research and presents concluding remarks.

THE DIFFUSION OF IT TO DEVELOPING COUNTRIES

Information technology and associated organizational models, which form the basis of information systems and implementation methodologies, have originated and continue to be developed principally in western, developed countries. The unidirectional transfer of IT knowledge and skills from developed to developing countries is a process that characterizes most recent efforts at public sector reform (Minogue, 2001). However, in order to take advantage of technological knowledge of developed countries, developing countries must have acquired sufficient technological capabilities and institutional capacities to identify suitable technologies and to adapt, absorb, and improve the technologies imported from abroad (Ahrens, 2002). Often, they are not appropriate for use in countries that are in transition and have their own realities on the design of technologies that are used to automate and inform their internal and citizen-focused processes. Fountain (2001) addressed this issue in her differentiation between the deployment of already invented technologies that are available to practitioners and the need to recognize the importance of customizing the design to a specific locale.

A rationale that is often used for the introduction of IT is to automate, increase efficiencies, and cut costs. The cost of labor in developed countries is substantially higher than that in developing countries (Dewan & Kraemer, 2000), while the reverse is true with the cost of the IT (Heeks, 2002b). Therefore, replacing inexpensive civil servants with more expensive IT would not be jus-
tifiable for financial reasons alone. Consequently, the choice of projects and their ultimate success is dependent on careful consideration of the embedded web of relations and interactions within a particular socioeconomic context, and their design and implementation requires an understanding of this context (Sein & Harindranath, 2004).

Governmental and international development agencies (IDAs) in the developed world, such as the World Bank, the United Nations, and United States Agency for International Development (USAID), have spearheaded and provided resources for deploying governmental IT technologies in the developing world. Since nearly half the people of the world today are under 25 years old and 90% of these young people live in developing countries (World Bank, 2005), IDAs are seeking to optimize the deployment of their resources to parts of the world where they would have the potential to have the most enduring and significant impact. Their initiatives fit well with the western ideals of globalization, economic liberation, and democratization, with improved governmental functioning in developing countries helping to secure important sources for raw materials or low-cost labor for western businesses and opening up new or growing existing markets in these countries for western goods and services.

IDAs and others believe that the scarcity of IT in developing countries is one of the reasons for decreased opportunities for economic growth and social development in developing countries (Madon, 2004). However, such initiatives are challenged by the lack of integrated information and communication technology infrastructures, antiquated work practices, and perhaps most importantly, organizational obstacles such as conflicting objectives, lack of widespread support, and internal resistance to change within governmental agencies. Madon (2004) explored an alternative perspective of development where conditions are created to encourage individuals to realize their full potential by freely selecting their path to improvements in material, social, and spiritual lifestyles (Sen, 1999). The World Bank (2005) has encouraged such investments that empower people to participate in decisions about development projects that affect their lives and the lives of their families and have an enduring impact on their quality of life.

A Sociocognitive Perspective of Implementation

The sociocognitive perspective is based on the idea that reality is socially constructed through human beings’ interpretation of social reality and negotiation of meaning among social entities (Berger & Luckmann, 1967). Like the cognitive perspective, the sociocognitive perspective emphasizes the role of one’s personal knowledge structures in shaping her cognitive interpretation of the world and consequent actions. However, it differs from the cognitive perspective in the way it views the formation of individual knowledge structures. The cognitive perspective postulates information processing and learning as the key processes shaping individual knowledge structures, while sociocognitive research holds that shared knowledge and beliefs (group-level structures), imbibed through the processes of interaction, socialization, and negotiation within a larger social group, influence individual sense-making and interpretation. These shared knowledge structures, also called “frames” (Goffman, 1974) or “interpretive schemes” (Giddens, 1984), serve as templates or filters for individual sense-making and problem solving, filling information gaps with information that conforms with existing knowledge structures, and systematically rejecting inconsistent information (Fiske & Taylor, 1984). Frames also provide a vehicle for organizing and interpreting complex and sometimes ambiguous social phenomena, reducing uncertainty under conditions of complexity and change, and justifying social actions.
The sociocognitive perspective has seen some applications in prior information systems research. In the context of information systems development, at least three studies (Bansler & Bodkar, 1993; Davidson, 2002; Newman & Nobel, 1990) have posited that requirements for IT applications do not exist a priori but are socially constructed through interactions among system developers, user groups, and other key stakeholders. The language used by participants and the nature of their interaction influences which requirements are identified and legitimized (Boland, 1978).

Drawing from the above research, Orlikowski and Gash (1994) proposed the concept of technological frames of reference as an analytical tool for understanding and articulating group-level structures that guide sense-making and action. Technological frames are defined as “assumptions, knowledge, and expectations, expressed symbolically through language, visual images, metaphors, and stories” that organizational members employ to interpret the role of technologies in organizations and understand the conditions and consequences of such use (Orlikowski & Gash, 1994, p. 176). Technological frames typically operate in the background, and have facilitating or constraining effects on the interpretations and actions of their intended users (Orlikowski & Gash, 1994).

Given the diversity of stakeholders often involved in large-scale IT implementation projects, such as system developers, senior management, and multiple user groups, it is likely that different stakeholder groups have different technological frames that may be partially or wholly incongruent with each other. For instance, technologists often view IT from an engineering perspective, as a tool specifically designed to accomplish a given task such as system development. In contrast, managers tend to take a more strategic view of IT, focusing on its return on investment and long-term value. End users may take a more instrumental view of the same technology, expecting specific work-related benefits from its use. Orlikowski and Gash (1994) suggest that when incongruent technological frames exist, organizations are likely to experience difficulties and conflicts in implementing IT, including breakdowns in communication, lack of user participation, and/or eventual suspension or failure of the project.

In his pioneering work on force-field analysis, social psychologist Kurt Lewin (1951) postulated that social systems such as organizations continuously seek equilibrium between forces favoring change and those opposing change, and that successful change rests on an organizations’ ability to “unfreeze” the equilibrium by altering the dynamics of forces favoring and resisting change. Without explicit attention to and manipulation of the forces opposing change, organizational systems may tend to resist change and retain the status quo (similar to the concept of “homeostasis” in biological systems).

Lewin’s ideas are applicable to understanding IT implementation because organizational introduction of IT is a social change process since it changes the way organizational members work, interact with each other, and make decisions. Given the natural behavioral resistance to change, technological frames once formed tend to be resistant to change. However, contextual changes, such as changes in key stakeholder groups, changes in resource distribution, or emergence of new emergent threats, can trigger shifts in frames by bringing new ideas, assumptions, and knowledge to the forefront of the group sense-making process, forcing the social group to reinterpret old information in new ways. El Sawy and Pauchant (1988) note that such “frame shifting” may be abrupt and of short duration; nonetheless they can engender long-term changes in the group’s overall stance toward IT and IT-enabled work.

In summary, sociocognitive analysis can complement our traditional cognitive view of IT implementation by bringing into focus the role of group-based structures in individual sense-mak-
IT Implementation in a Developing Country Municipality

ing and interpretation of social phenomena during the implementation process. We pursue such analysis using the concept of technological frames as an analytical lens to further explore the role of social structures during IT implementation.

CASE BACKGROUND AND DESCRIPTION

Given that technological frames are time- and context-dependent (Orlikowski & Gash, 1994), in this section, we first present a detailed picture of the social context within which the target IT was implemented, followed by a description of the actual implementation process.

The Sociopolitics of Ukraine

Ukraine is an eastern European country which became independent from the erstwhile Soviet Union in 1991. Limited exposure to free markets and state protection of enterprises from foreign competition since the Soviet days has led to an antiwestern sentiment among many Ukrainians, suspicion of western economic interests, an entrenched governmental bureaucracy, lack of corporate tax reforms, widespread organized crime, and corruption among many government officials. Transparency International (2004) ranks Ukraine as 122nd out of 145 countries on its corruption index. For instance, local elected officials often use their influence over water, electricity, and sanitation departments to force private enterprises to contribute to social programs and other less-productive ends.

Ukraine’s IT infrastructure is ranked 78th out of 102 countries in the Networked Readiness Index (Dutta & Jain, 2004). A United Nations e-government readiness survey (2004) rated Ukraine a value of 0.53 on a 0-1 scale and an overall rank of 45 out of 191 UN member states. This ranking indicates the willingness and readiness among governments to employ the opportunities offered by IT to improve the access and quality of basic social services for sustainable human development. In 2004, Ukraine improved its ranking by nine positions, but further improvements are clearly needed to reduce poverty, unemployment, state control, and corruption, and to create an environment more conducive for private businesses.

Municipal government is an important element in Ukraine’s public administration system. Each city is headed by a Mayor, who is elected by the entire city electorate. The Mayor is answerable to the municipal council (or city council), whose members are elected by the people to four-year terms. At the start of this project, city council members at Lviv were in office for about a year, with three years remaining in their term of office. The city administration consists of the Mayor and directors and division heads nominated by the Mayor for each of the city’s subdivisions, pending confirmation by the city council.

At the time of the project, Lviv’s information systems (IS) department consisted of 35 employees, responsible for supporting the city’s IT infrastructure and application development and maintenance efforts. The director of this department reported to the Organization and Information Subdivision, which in turn, was accountable to the city council. However, like other city departments, the IS department was also highly compartmentalized with little interaction with other departments or awareness of others’ needs. The IS director was often unaware of what software was used by other subdivisions, and therefore did not support its usage. This lack of coordination sometimes led to idiosyncratic IT implementations that were not coordinated across city departments, that lacked any plan for long-term maintenance, and that were sometimes not even useful.

E-Administration at Lviv City Hall

The first phase of the e-administrative initiatives at Lviv started in 1994 as part of a $3 million
USAID grant (see project timeline in Figure 1). The goal of this grant was to improve citizen service and government accountability by streamlining internal operations in three Ukrainian cities: L’viv (population: 850,000), Kharkiv (population: 1.6 million), and Ternopil (population: 230,000). Though no organizational analysis or needs assessment was conducted at Kharkiv and Ternopil prior to technology deployment, L’viv’s IS deployment did follow a minimal analysis conducted by a local consultant group recruited and funded by USAID. The consulting group’s main office is located in the United States, and operated from a branch office in Kyiv that employed local Ukrainians.

The primary directive of the consultant group was to install hardware and software infrastructures per USAID guidelines, leaving subsequent implementation activities, such as user support and training, and ultimate system usage to the grant recipients. Though technically proficient, the consultant group was not adequately experienced in large, complex process re-engineering initiatives of this magnitude. Hence, the city’s IS department was left out of the initial decisions regarding choice of hardware, software, and networking technology, and how they would be deployed. The internal IS department was assigned a role only after the consultant team left at the end of the year 2000. Disenchanted with their omission in key decision processes regarding the city’s IT infrastructure, the IS department had little interest in supporting the city’s IT initiatives.

In 1998, the consulting group designed a conceptual framework for improving internal workflow within the City Hall to serve as the foundation for a new document management system (DMS), and subsequently used the Lotus Notes software to customize the DMS to the city’s needs. Lotus Notes was selected because of its compatibility with both Macintosh and PC operating systems. An internal audit of the DMS-enabled customer service by the Organization and Information Subdivision on a sample of three city departments during the first half of 2003 revealed some surprising inconsistencies in system use and usage outcomes. Though city departments were supposed to record all correspondence in the DMS, this mandate was not enforced and was widely ignored. Less than 20% of the filed requests were actually entered into the DMS, and the remaining requests were retained

Phase 1 | Phase 2
in article format for manual processing. Of the 2,405 citizen requests processed by the DMS during this six-month period, only 184 requests (8%) were completed within 30 days as required by city regulations, and an additional 905 requests (38%) were simply “lost in the system” in that no information was available regarding their final disposition (see Table 1).

Concerned with the above situation, the secretary to the city administration initiated new plans to enhance the levels and outcomes of DMS usage at L’viv City Hall. This second phase of IT implementation at L’viv focused more on change management and garnering user support, than on technology selection or installation. The secretary established a one-stop shop called the “Universal Office” at the city correspondence office to serve as a central clearinghouse for all citizen and business requests. The office was staffed with technically proficient people whose job was to enter and track all incoming user requests into the DMS system right at the source. Further, one of this study’s authors was commissioned by the city at this time to provide technology training to the intended users of the DMS.

As of early 2005 (the end of the case analysis period), the status of DMS usage at L’viv was as follows. Most of about 8,300 citizen service monthly requests received by the City of L’viv were still being hand-delivered or mailed to the appropriate city department by citizens instead of being filed at the Universal Office as originally envisioned. The preferred methods of communication among citizens and city employees still remained telephone and face-to-face meetings. About 25% of city employees used the DMS’s e-mail feature on a regular basis, and another 50% used it occasionally. The DMS was solely used by administrators to track documents, and other document lifecycle features such as version histories and audit trails were not being widely used. Each city department employed a staff member to handle internal correspondence electronically and exchange internal documents and files through a shared file system. Further, no interdepartmental correspondence was being tracked through the Notes system at the time.

DATA COLLECTION AND ANALYSIS

Case studies are particularly suitable for answering “how” and “why” questions, when multiple sources of evidence are needed, and when boundaries between the observable facts and the context are not clearly evident (Yin, 1994).

* A document is in violation if it was either not answered or answered incorrectly.
It also enables researchers to use “controlled opportunism” to respond flexibly to new discoveries made while collecting new data (Eisenhardt, 1989). Such was the nature of this study, where the individual usage of frames was evident in the discourse that was related to IT requirements as well as written artifacts (Moch & Fields, 1985). In addition, a longitudinal case study design is desirable for observation and analysis of processes that change over time (Glick, Huber, Miller, Doty & Sutcliffe, 1990).

We therefore followed Walsham (1993) and Avgerou and Walsham (2000) in applying Pettigrew’s (1985) methodology for examining the embedded web of relations and interactions between the choice of the IT and the context of its use. Thus, the research was conducted as an interpretive case study of the innovation provided by the technology as perceived by the IDA and other stakeholders where the primary purpose was to better understand the complexities of the subjective meanings of human subjects within cultural and contextual situations usually found in field studies (Orlikowski & Baroudi, 1991). Since in interpretive research the data and subsequent analysis are influenced by the researcher’s own preconceptions and inquiry processes (Walsham, 1995, p. 376), the use of technology frames concept guided interpretation of the subjects’ actions and the events in the DMS project. Throughout the study, key informants listed in Table 2 were interviewed and informal discussions about DMS project events were held.

Typical interviews ranged between 20 and 90 minutes, with an average duration of about 45 minutes. During the interviews, open-ended questions were asked with the intent of understanding the missions, goals, visions, and strategies being used, the expected and actual organizational impacts, and the influence of cultural factors in gaining acceptance and usage of the technology. In addition to the face-to-face personal interviews, nine group meetings with both city and departmental administrators were conducted at multiple stages of the project between 2002 and 2005. Given the sensitivity of government personnel and consultants to privacy issues, interviews were not tape recorded. However, the interviewer maintained extensive field notes for each interview, including actual quotes from interviewed personnel, which were used for subsequent data analysis.

Several additional forms of documentation were also employed for data collection. These included the city’s vision statement and planning documents, internal memos, working papers, PowerPoint presentations, and USAID reports.

Further, the researcher observed city employees at work at the city correspondence office and within individual departments, participated in several IT planning meetings, and had numerous informal interactions with key participants that were involved in the DMS project for over two years. This direct involvement provided a holistic understanding of the complex, multifaceted project as well as the individual behaviors, comments, and perspectives of the involved parties, by iterating between the parts and the whole in a “hermeneutic circle” (Klein & Myers, 1999).

The first step in our sociocognitive analysis was to identify the key frame domains. Orlikowski and Gash (1994) asserted that frames should be examined in situ, rather than assumed a priori, via an iterative examination of observed data and experiences. Hence, we analyzed our qualitative data to identify the assumptions, knowledge, or expectations (frames) of the DMS technology implicit in participants’ direct or symbolic words (e.g., metaphors) or actions, and the implications of these frames for participants’ work practices and City Hall’s operations as a whole. Our qualitative data were first separated into groups based on whether it reflected the statements of end users (e.g., project managers or city administrators), executive management (e.g., Mayor’s office, secretary of city administration, etc.), internal (city) IS department, and external consultants. Field notes and interview quotes for each group were coded into frame categories as suggested by the data using an open coding style typical of grounded theory research (Strauss, 1987). Following this exercise, we conducted cross-group analysis, where we compared the categories generated by each group to elicit common themes between groups, as recommended by Eisenhardt (1989).

The iterative examination of data described above resulted in the identification of four common themes or domains that are described here as technological frames. These domains were then examined for similarities and differences between different stakeholder groups. Higher dissonance between these frames was expected to lead to greater inconsistency and incoherence between activities by multiple stakeholder groups, thereby increasing the chances of project failure. The findings of our analysis are described next.

RESEARCH FINDINGS

Four dominant technological frames or common themes, representing the salient perceptions, assumptions, and interpretations of diverse stakeholder groups, emerged from our interpretive analysis of qualitative data from L’viv’s DMS implementation project:

1. **Purpose of technology:** Stakeholders’ perceptions of organizational motivation for implementing a specific IT and the reasonableness of such motivation.
2. **Technology features/capabilities:** Stakeholders’ understanding of the IT’s design, features, and functionalities, whether or not such perceptions were justified or realistic.
3. **Technology implementation process:** Stakeholders’ perceptions of how the IT implementation process was managed, including such issues as user involvement, user training, and change management, and whether or not such implementation is reasonable or effective.
4. **Technology-induced changes:** Stakeholders’ expectations of how IT implementation may change existing work practices, relationships, and responsibilities, and whether or not such changes are justified.

In the following subsections, we describe each of our four proposed frames from the perspectives of five key stakeholder groups involved in L’viv’s DMS implementation project: the sponsor (USAID), the city management (Mayor’s office and the city council), the external consultants,
the internal IS department, and the targeted users (department administrators and staff members).

**Purpose of Technology**

**Sponsor’s Perspective**

The sponsoring agency (USAID) had envisioned a western view of government functions, stressing the importance of citizen service quality, efficient organizational processes, and modern technologies. Government functions, such as business license processing or city zoning clarifications, were viewed as information processing activities that involved complex patterns of information sharing and collaboration among multiple governmental agencies. Such information processing activities were expected to benefit from the deployment and utilization of advanced IT such as a DMS. Additionally, automated e-administration was expected to indirectly increase the transparency of government functioning, enhance public accountability of city functions, and reduce corruption in city administration.

**Consultants’ Perspective**

The external consultants did not play a significant role in shaping the purpose or motivation of IT implementation at City Hall. Their mandate was simply to take USAID’s espoused goals as given and select and deploy a technological infrastructure (hardware, software, and network) within cost and schedule guidelines as specified by the sponsor, similar to the western norms of IT project management.

**City Management’s Perspective**

IT initiatives at L’viv started in 1994, well before the current city administration was elected to office, and hence, the Mayor’s office was not involved in early stages of the project. Initial work on the project was sponsored by USAID, with the support of the then city council. Post-Soviet western influence suggested that building appropriate IT systems were the best way to support cross-departmental data flow at the city hall for faster and accurate processing of customer requests. As stated by the secretary to the city council:

*Our departments need to respond to citizen-centric views that involve cross agency data and processes, and they will need to structure their systems, data and programs to be able to deliver on this objective.*

Additionally, city council members also wanted to portray a pro-technology and pro-reform image of themselves to their electorate in order to enhance their chances of re-election success. However, without strong leadership from the mayor and incentives to actually use the DMS, department heads were not motivated to use a system that they viewed to be a threat to their power. It was primarily the non-utilitarian considerations of citizen perceptions of the city council that amplified the city’s motivation to deploy technologies that support e-administration.

**IS Department’s Perspective**

Even though the city’s IS department had expertise in areas such as needs analysis, technology identification, and technology deployment, it had no role during the initial phase of the project. The department was therefore disenfranchised from the city council’s vision of improving their image to the electorate. Perhaps more importantly, they viewed the introduction of the technology to be incongruent with current workflows and were unprepared to assume responsibility for training city hall staff on its proper usage.

**User Department’s Perspective**

The elected officials of the city had a shared goal of improving government functionalities and
citizen service quality, but the administrators and staff personnel at the city departments did not share similar objectives. One administrator felt that the DMS system did not fit the face-to-face communication needs of his job and was more of an intrusion on his work, rather than benefiting it, though other IT systems such as office productivity software were more useful:

*If the mayor tells us to use the system then I guess we will have to, but I really don’t like it. Computers just get in the way of solving problems in face-to-face meetings. I don’t think that I would want to trust my staff to follow my decisions through the system. These are always matters that I should be handling.*

On rare instances, however, a small number of city administrators appeared to agree on the potential benefits of the DMS system and expressed some enthusiasm toward it. One of them commented:

*This notes system is really interesting. It looks like it will help me do my work faster and make better decisions. With this kind of system it will be easy for me to find answers to my problems.*

**Technology Features/Capabilities**

**Sponsor’s Perspective**

USAID’s goal was to improve government transparency and citizen service through the use of technology. However, being an IDA rather than a technology specialist, USAID was not familiar with different governmental solutions, their specific features or capabilities, or the technological infrastructure required to implement such solutions. Hence, it left technology selection and implementation decisions to the external consultants, who were familiar with the specific technologies as well as USAID policies and procedures for technology deployment in governmental agencies.

**Consultants’ Perspective**

Based on their prior involvement with USAID projects (at other municipalities and cities) and their understanding of western procedures of IT implementation projects (e.g., tracking project costs and schedules), the consultants used a least-cost and shortest-route IT implementation process. Lotus Notes was deployed as the workflow system of choice because of its support for e-mail and file sharing capability, and its history of successful applications in document management tasks in western countries.

**City Management’s Perspective**

The L’viv city administration was not involved in the technology selection process during early stages of the e-administration initiative, though they had approved the deployment of the technology at City Hall under the USAID grant. The city’s administrators became more involved in the project only after the USAID grant expired and the consultants left, when the onus fell on the city to maintain and expand the infrastructure and technologies already installed.

**IS Department’s Perspective**

The city’s internal IS staff were not considered technology experts by other city departments, and were not consulted during key technology acquisition or deployment decisions. Hence, their opinions were of no consequence to the sponsor, the implementers (consultants), or the city, who planned to implement the DMS without the IS department’s assistance. Since they were not participants in either the selection or installation of the technology, they were ambivalent about the technology changes both during and after
IT Implementation in a Developing Country Municipality

deployment, and were not willing to actively engage in its implementation until instructed to do so by the city council.

User Departments’ Perspective

Many of the user departments did not have the technology background or expertise to understand, appreciate, or critique the design elements of the implemented technologies. They viewed IT implementation as a technical process left best to domain experts such as the consultants.

Technology Implementation Process

Sponsor’s Perspective

As noted earlier, USAID maintained a “hands-off” approach to the project. They entrusted the consultants with the task of planning and managing the implementation process.

City Management’s Perspective

Like the sponsor, the city management also left the responsibility of managing initial stages of the project to the consultants. When USAID funding expired and the consultant team left, the city was left with complete ownership of the project and was forced to decide how to implement the rest of the project, upgrade necessary systems and the infrastructure, and enhance system usage among users.

Consultants’ Perspective

The consultants did not understand or see the need for user support, process re-engineering, and change management that often accompany large IT implementation projects. They also failed to engage key stakeholders in the project, namely user departments and the city’s IS department.

IS Department’s Perspective

Excluded from key decisions involving the early planning and deployment of the IT, the city’s IS department did not feel any ownership or obligation toward the project. They always felt that the project was “someone else’s problem,” and did not want to get involved during the second phase of the project when invited to do so by the mayor’s office.

User Departments’ Perspective

Most city administrators and staff did not know much about the DMS, its purpose, or how it could benefit their work. Barring a few exceptions, most city administrators did not feel that the system was necessary to perform their job, and in some instances, when asked to do so, simply passed on the responsibility to their subordinates or secretaries. One departmental administrator commented:

_They do not pay me enough for me to spend time learning computer skills. I will continue to do my job the same as always. Besides, nobody uses the Notes product anyway._

Technology-Induced Changes

Sponsor’s Perspective

Though USAID viewed its role as only a funding agency and was not party to any implementation-related decisions, the fact that it allocated no resources for user training or any other change management process suggests that it may have viewed IT-induced changes that often accompany large IT projects as being less relevant or important, or a process that is best relegated to the user organization (City Hall).
City Management’s Perspective

The city management was largely unaware of the complexities in large IT implementation projects and did not proactively plan for change management initiatives at the start of the project. However, when the low state of system use and usage outcomes were revealed during the 2003 audit, the city administration was forced to take notice. The secretary to the city administration, who had some prior exposure to large projects, commissioned an external trainer (one of the paper’s authors) to train City Hall users. He also instituted a series of steps, such as expanding the Universal Office staff, to try to motivate DMS use among city employees.

Consultants’ Perspective

Like the sponsors, the project consultants were not concerned with organizational changes induced by IT or the need to proactively plan for such changes. They were satisfied with the installation of the IT infrastructure and wrote glowing reports about themselves to USAID. They felt that their role in the project ended with system installation, and that they had fulfilled their objective and satisfied USAID’s project requirements. When informed about problems of non-use and city administrators’ resistance to DMS use in 2003, the director of the consulting group responded:

*L’viv has a successfully integrated system of municipal information management which is sustainable at present and is unique for Ukraine. We have no more funding for this project and cannot justify any further need to assess the ICT infrastructure of City Hall.*

IS Department’s Perspective

The IS department’s initial resentment toward the project and its key stakeholders continued into the implementation period, even after the departure of USAID and outside consultants. They were not convinced of the utility of the DMS system and associated organizational changes instituted by the city secretary, and were not unhappy to see it head toward failure. The IS director summarily rejected the idea of the Universal Office as:

*This is a bad idea and will never work. Changing the way citizens submit their requests and training new employees on how to process citizen requests will be impossible.*

User Departments’ Perspective

City Hall users demonstrated a general apathy toward the system and associated changes in workflows and organizational procedures, which were likely caused by low governmental wages and little opportunity for job growth or promotion. Most were subservient to their supervisors and were not interested in engaging in any critical thinking. They viewed the nature and substance of their tasks and activities at City Hall as being largely inconsequential, and were only intent in logging their work hours into the system to satisfy their supervisor. These users had no interest in any technology-induced changes that could potentially increase their workload, even if it promised improved service quality to the citizenry.

DISCUSSION

The sociocognitive analysis used in this study revealed the presence of dominant technological frames that existed prior to the project and persisted well after the installation and organizational implementation of the DMS system. In our study, we found four such frames—purpose of technology, technology features/capabilities, technology implementation process, and technology-induced changes—that were relevant to the context of DMS implementation at L’viv City Hall. Given the generic nature of these frames,
and their conceptual overlap with similar frames reported in prior research (e.g., Davidson, 2002; Orlikowski & Gash, 1994), we can reasonably infer that these frames are not specific to government projects or to developing countries only, but may be generalizable to many large-scale IT implementation projects at large.

Technological frames act as a “sociocognitive lens” through which key stakeholders in an IT implementation project view and interpret reality, and thereby, also condition their responses and behaviors related to implementation processes and outcomes. Some of these frames may be based on pre-existing worldviews or biases that are extraneous to the project context, such as a typical Ukrainian distrust for western interests, lack of a culture of customer service, and limited opportunities of job growth and career enhancements within governmental bureaucracies. Nonetheless, such extraneous mindsets still play a powerful role in enabling or constraining their perceptions of and behaviors associated with IT implementation projects. Other frames may emerge as key stakeholders observe the process and/or outcomes of the IT implementation project. For instance, the IS department, despite being one of the stronger advocates of modern technologies at Lviv City Hall, decided to oppose the DMS implementation project because they were excluded from the planning and implementation phases of the project. In other words, they adopted a political stance to the project, in contrast to the economic stance of improved customer service, faster processing times, and better document tracking espoused by the project sponsors.

What does the notion of technological frames imply for the process and outcome of IT implementation projects? If the frames of key stakeholders are somewhat convergent with each other, then the implementation process is likely to proceed more smoothly than if the frames were divergent to begin with. There may be challenges and difficulties faced during the implementation process, but the shared sociocognitive frame of key stakeholder groups will ensure the formulation of a coherent strategy that would address most implementation-related challenges and collective action to overcome these challenges. On the other hand, dissonant frames among key stakeholders will limit the amount of consensus building, shared interest in the project outcome, and collective action, thereby hindering the implementation process and outcomes. In the case of IT implementation at Lviv, the latter was clearly the case, which ensured an unfavorable project outcome despite financial sponsorship by an external agency and top management support from the city administration. In other words, large-scale IT implementation projects may fail despite financial and management support, if it engenders conflicts in dominant technological frames held by the major stakeholders. This assertion is consistent with prior academic studies on IT project failures such as Lyytinen and Hirschheim (1987), who contended that organizational politics is a key reason for IT project failures, and practitioner studies such as Heeks (2002a), who observed that government information systems projects often appear to be destined for failure.

We depict the conflict in technological frames in the Lviv case pictorially using a Fishbone diagram in Figure 2. This diagram has four branches, each dedicated to one of the four technological frames underscored in this study. In a sense, each branch represents the “force” of each key stakeholder group on the technological frames in this implementation project. Lewin (1951) posited that such “force-fields” depict a dynamic gestalt psychological environment created by multiple driving and restraining forces in the phenomenon of interest. The driving forces are those frames that positively impact the project’s goals of enhancing citizen service quality, document processing efficiency, and transparent government functioning. Stakeholders’ influence on these forces are indicated in our Fishbone diagram as arrows pointing to the right. Restraining forces act to restrain or inhibit the driving forces, either by negatively influenc-
As shown in the Fishbone diagram, the project sponsor and City Hall management had positive influences on the purpose of technology in the IT project by establishing the mission and goals of the project and by securing an external grant to financially support the project. The consultant, management, and sponsor had positive influences on the technology features/capability of the DMS system in that they viewed the system as one that could contribute to productive ends and improve City Hall functioning. However, the IS department and user departments had a negative perception of the technology’s capability, as evident from their remarks about the technology and the futility of its implementation. As stated before, such negative views may have been caused by their pre-existing biases against western agencies (the sponsor) or by virtue of their exclusion from key phases of the project. Nevertheless, this was a negative force that adversely influenced the project outcome. Only the management had a positive impression of how the technology implementation process was managed, while the remaining four stakeholder groups (sponsor, consultants, IS department, and user departments) had either no involvement or were negatively predisposed toward the implementation process. In particular, the disenfranchised IS department refused to accept the implementation process as legitimate, and the absence of support from the sponsor and consultant group during later stages of the project hurt its long-term sustainability, even with the overt support of officials in the mayor’s office. Finally, the technology-induced changes were viewed as positive by the management, but negative by the IS department and user departments. The user
departments refused to accept any changes in their existing work processes or the transparency of their work, despite the technology’s promise of improved process performance.

The end result of the project was that the million-dollar USAID-sponsored governmental IT project at L’viv City Hall that promised to make government processing more efficient and transparent and improve the quality of citizen services, was headed for failure despite financial sponsorship and overt top executive support for the same. This failure was caused by the lack of buy-in and support of the key stakeholder groups during different stages of the implementation process. While it may be tempting to conclude that such failure may occur only in developing countries or with technologically-deficient governments, similar outcomes may also be observed for nongovernmental IT implementation projects (e.g., in universities, health care organizations) in developed countries as well.

What are the key lessons of this IT project? First, financial sponsorship and top executive support are necessary but not sufficient conditions for success of large-scale IT implementation projects. Indeed, IT projects may fail despite the above conditions if they fail to garner adequate support and buy-in from other key stakeholders. Second, the economic or rational perspective of technologies as a tool for improving organizational efficiency, service quality, and transparency may not be adequate for garnering the support of key stakeholder groups. Large IT implementation projects, or most organizational change initiatives for that matter, are often more dominated by sociopolitical considerations than economic considerations (Ewusi-Mensah & Przasnyski, 1991). Hence, mere communication of tangible benefits to stakeholder groups may be inadequate for obtaining their buy-in, and serious negotiations to understand and address issues of ownership, involvement, and power bases may be needed to enhance the chances of IT implementation success. Third, successful implementation requires intra-organizational policy coordination and implementation across stakeholder groups and organizational departments. Alienation or elimination of key departments such as information systems or circumventing key change management initiatives such as user training in order to expedite project goals, may eventually backfire and contribute to the ultimate demise of the project.

In addition to the conditions listed above, government IT implementation initiatives in developing countries such as Ukraine should devote adequate effort to understanding and overcoming sociocultural, legal, political, or other barriers to implementation. For instance, online documents were not officially recognized by the Ukrainian finance and tax system and only hard copy correspondence was recognized as admissible evidence in Ukrainian courts. Such statutes caused many City Hall employees to avoid electronic handling of business documents entirely, thus contributing to system non-usage. Until such restrictive rules were remedied, say by modifying appropriate legal statutes or governmental policies, electronic document management is likely to fail. Currently, a federal law endorsing the use of digital signatures as an acceptable alternative to signed paper documents is pending endorsement by L’viv’s city government, which, when ratified may help reduce public concerns about electronic documents. In retrospect, it therefore appears that the DMS system at L’viv was implemented ahead of its time, and should have been considered after the passage of relevant city laws.

CONCLUSION

The interpretive power of technology frames becomes more apparent when dominant frames become dependent on the active involvement of influential individuals or groups during project activities. This perspective has been addressed through the lens of analyses of power in IT
IT Implementation in a Developing Country Municipality

development projects (Brown, 1998; Markus, 1983). Future research that could further our understanding of the interpretive power of framing would involve the use of actor-network theory (cf., Latour, 1986; Law & Callon, 1988) concepts in order to provide a sense of power, direction, and causality. This would develop our understanding of how stakeholders influence others in their technology frames and thus engender more enduring support for their own interpretation (Lea, O'Shea & Fung, 1995).

The sociocognitive perspective used in this article supports the conclusion that the greatest constraints to e-administrative initiatives are nontechnical, such as political opposition, deeply ingrained policies and practices, and internal employee resistance. To overcome these constraints, governments require proactive, knowledgeable leaders who have an informed long-term vision of technology-induced organization change, who can help spur bureaucratic action, and who can implement strategies that promote and sustain change. In addition, implementers need to not only educate and motivate key stakeholder groups to use the systems, but also identify and redress political inequities and imbalances that hinder e-administrative acceptance among these groups.

**ABSTRACT**

E-learning has the potential to be a very personalized experience and can be tailored to the individual involved. So far, science museums have yet to tap into this potential to any great extent, partly due to the relative newness of the technology involved and partly due to the expense. This chapter covers some of the speculative efforts that may improve the situation for the future, including the SAGRES project and the Ingenious Web site, among other examples. It is hoped that this will be helpful to science museums and centers that are considering the addition of personalization features to their own Web site. Currently, Web site personalization should be used with caution, but larger organizations should be considering the potential if they have not already started to do so.

**BACKGROUND**

In the past few years, the number of people visiting museums’ Web sites has gone up rapidly. As a consequence, museums have to face the significant challenge of creating virtual environments that are progressively more adapted towards the different needs, interests and expectations of their heterogeneous users. Increasingly, museums and science centers are using their Web sites to augment their learning facilities in potentially innovative ways.
Personalization Issues for Science Museum Web Sites and E-Learning

(Tan et al., 2003). In particular, museums need to provide for differing online requirements such as teaching, e-learning and research (Hamma, 2004). One of the solutions available to help is the introduction of personalization techniques (Dolog & Sintek, 2004) that, by providing differentiated access to information and services according to the user’s profile, make facilities and applications more relevant and useful for individual users, thus improving the overall visitor’s experience. Science museums, by their very technological nature, ought to be at the vanguard of applying new techniques like personalization.

Developed in the early 1990s in an attempt to try to respond to the different needs and characteristics of an ever-growing number of Internet users, personalized or adaptive Web systems have since been exploited in different sectors such as commerce, tourism, education, finance, culture and health. What distinguishes these systems from the traditional static Web is the creation of a user model that represents the characteristics of the user, utilizing them in the creation of content and presentations adapted to different individuals (Brusilovsky & Maybury, 2002). By so doing, personalization becomes a useful tool in the selection and filtering of information for the user, facilitating navigation and increasing the speed of access as well as the likelihood that the user’s search is successful.

The techniques available to collect information about users, as well as the methods used to process such information to create user profiles and to provide adapted information, are varied. A brief description of the different approaches will be presented here before moving on to illustrate different application examples within the science museum world.

PERSONALIZATION TECHNIQUES

A first important distinction concerning the amount of control the user has on the adaptation process can be made between customization and personalization. Customization or adaptability occurs when “the user can configure an interface and create a profile manually, adding and removing elements in the profile” (Bonnet, 2002). The control of the look and/or content of the site are explicit and user-driven; that is, the user is involved actively in the process and has direct control. In personalization or adaptivity, on the other hand, the user is seen as being passive, or at least somewhat less in control (Bonnet, 2002). Modifications concerning the content or even the structure of a Web site are performed automatically by the system based on information concerning the user stored in the so-called user profile. Such information about the user is provided either explicitly, by the user themselves, using online registration forms, questionnaires and reviewing (static profiles) or implicitly by recording the navigational behavior and/or preferences of each user through dynamic profiling Web technologies such as cookies and Web server log files (Eirinaki & Vazirgiannis, 2003).

Once the data concerning the users is collected either implicitly or explicitly, or even in both ways, as is often the case, appropriate information that matches the users’ need is determined and delivered. This process usually follows one or more of the following techniques: content-based filtering, collaborative filtering, rule-based filtering and Web usage mining.

Content-based systems track user behavior and preferences, recommending items that are similar to those that users liked in the past (Eirinaki & Vazirgiannis, 2003). Collaborative filtering compares a user’s tastes with those of others in order to develop a picture of like-minded people. The choice of material is then based on the assumption that this particular user will value information that like-minded people also enjoyed (Bonnet, 2002). The user’s tastes are either inferred from their previous actions or else measured directly by asking the user to rate products. Another common technique is rule-based filtering, which allows
Web site administrators to specify rules based on static or dynamic profiles that are then used to affect the information served to a particular user (Mobascher et al., 2000).

Last but not least, there is Web usage mining, which relies on the application of statistical and data-mining methods based on the Web server log data, resulting in a set of useful patterns that indicate users’ navigational behaviors. The patterns discovered are then used to provide personalized information to users based on their navigational activity (Eirinaki & Vazirgiannis, 2003).

The information provided to the user through any of the above techniques can be adapted at three different levels: content, navigation and presentation (Brusilowsky & Nejdl, 2004). Adaptive content selection is based mostly on adaptive information retrieval techniques: “when the user searches for relevant information the system can adaptively select and prioritize the most relevant items” (Brusilowsky & Nejdl, 2004). By doing so, the user can obtain results that are more suitable for their knowledge capabilities. Adaptive navigation support is founded mainly on browsing-based access to information: “when the user navigates from one item to the other the system can manipulate the links to guide the user adaptively to most relevant information items” (Brusilowsky & Nejdl, 2004).

Finally, adaptive presentation is based on adaptive explanation and adaptive presence, which were largely developed in the context of intelligent systems: “when the user gets to a particular page the system can present its content adaptively” (Brusilowsky & Nejdl, 2004). The possibilities of content and presentation adaptability are a relevant element in the reuse of the same resources for different purpose, provided they have been correctly customized in advance. Considering the high cost of personalization, adaptability of resources can also offer an interesting byproduct in term of reuse of the same resources in different contexts, provided that their description is correctly defined through standard metadata applications to allow interoperability of the same service in different environments.

From the perspective of different platform services, adaptability becomes a strategic issue. It could be decided to personalize content for the relatively small screen of mobile devices, for example. Moreover, whereas personalization and adaptability on the Web is based only on the user, in the case of mobile support there is also the need for adaptation with regard to the user’s environment (Brusilowsky & Nejdl, 2004).

In a museum visit, taking into account the environment where the service will be used can make a notable difference to the experience. For example, an explanation of the items kept in a single room of the exhibition can be offered while the visitor is in that room. There are some projects exploring these opportunities with special regard to mobile devices used by museum learning services (Oppermann & Specht, 1999).

**WHY USE PERSONALIZATION IN MUSEUMS?**

Even if some of the techniques described in the previous section, especially the more sophisticated ones, are employed mainly on commercial Web sites, such as Amazon.com, etc., there is already some awareness of the need for their use in cultural institutions, museums, science centers, etc. Personalized access to collections, alerts, agendas, tour proposals and audio guides are just a few examples of the different applications that have recently been developed by museums all over the world (Bowen & Filippini-Fantoni, 2004). The reasons for such an affirmation are numerous, as personalization can help museums respond to various and different needs.

First of all, personalization has the advantage of improving the usability of a Web site by facilitating its navigation and aiding people in finding the desired information. With some knowledge about the user, the system can give specific guid-
Personalization Issues for Science Museum Web Sites and E-Learning

in its navigation, limiting the visitation space appropriately. The system can supply, or even just suggest, the most important links or content that could be relevant for the user, something that can help prevent them from becoming lost in a Web site’s potentially intricate hyperspace.

Accessibility for the disabled (Bowen, 2004), a specific aspect of usability that concentrates in widening the number of users, can gain from personalization techniques. The ability to select the text foreground or background color, size and font, can make interfaces more easily readable for the partially sighted. A text only view of a Web site may be easier for such users and also those who are completely blind. For example, the London Science Museum has an option from the home page for a text only version of the Web site (www.sciencemuseum.org.uk). The basic content is the same, but the presentation is different. Legislation in the UK, for example, now ensures that learning materials for students in educational establishments, including those provided by university science museums, must be covered by an accessibility strategy (HMSO, 2001).

Personalized systems help to recreate the human element that listens to the visitor with understanding by offering an individual touch; this is another important factor that contributes to the success of Web personalization in museums. It is a particularly important element, especially for audio guides, which must offer a certain level of flexibility in order to adapt the contents to the needs and interests of the users, just like a real museum guide would do. It also helps online, making the visitors feel comfortable and oriented in the virtual space, through virtual avatars for example. Studies indicate that the “social metaphor represented through the presence of personalized animated characters (similar to real life people) can reduce anxiety associated with the use of computers” (Bertoletti et al., 2001).

Personalization could also be a useful tool in the creation and development of online communities for museums (Beler et al., 2004). In fact, thanks to personalized applications such as alerts, thematic newsletters, customizable calendars and recommendation systems providing tailored content to people with specific interests, museums can identify homogeneous communities of users with the same concerns and needs. Once these different online communities have been identified, it is in the museum’s interest to foster them by developing tools and services that aid them in their functioning, especially by stimulating communication. This is when personalization can assist once again. In particular, online forums (Bowen et al., 2003) can benefit from the introduction of personalizing features such as notification of debates or issues that might be of interest to the user, information about other users with interests on specified topics (facilitating the networking between community users), personalized news generation based on personal interests, etc. These kinds of personalized services can increase the value of the underlying museum’s “e-community” beyond a social networking environment: “the website becomes an attractive permanent home base for the individual rather than a detached place to go online to socialize or network, thus strengthening the relation between the user and the institution” (Case et al., 2003).

By providing targeted information to users with different profiles and interests, personalized systems are much more likely to satisfy the visitor, who, as a consequence, is stimulated to come back and reuse the system or to encourage other people to try it as well. This is why personalization is also a fundamental marketing tool for the development of visitor fidelity, as well as new audiences.

Personalization and Learning

Besides helping museums to respond to their usability, marketing and accessibility needs, personalization has much potential when it comes to stimulating learning, as underlined by Brusilovsky (1994) who, early in the development of
the Web, pointed out how personalization techniques could be an important form of support in education. The reasons for this are varied. First of all, visitor studies seem to confirm that learning is encouraged when the information provided is described in terms that the visitor can understand. Using different terms and concepts, that take into consideration the level of knowledge, age, education of the user, etc., can therefore improve the overall didactic experience. This is precisely what happens with personalized applications where the information delivered to the visitors often changes according to whether they are a child, an adult, a neophyte or an expert.

Research also indicates that learning is facilitated when the information provided makes reference to visitors’ “previous knowledge”; that is to say, to what people already know or to concepts already encountered during navigation or exploration (Falk & Dierking, 1992). This suggests that museums should focus on how to activate visitors’ prior knowledge if possible. One of the means at their disposal is personalization, which could open new and effective means for long-term learning by providing adaptive descriptions of artifacts based on objects or concepts that the visitor has already visited or explored. This is, for example, the case in projects like ILEX, Hyperaudio, HIPS and the Marble Museum’s Virtual Guide — see Filippini-Fantoni (2003) for descriptions — that, through dynamically generated text, provide personalized information taking into consideration the user’s history. The description of the object being viewed or selected can make use of comparisons and contrasts to previously viewed objects or concepts. By providing such coherent and contextualized information, modeled on the user interaction with the exhibition space as well as with the system itself, such applications have enormous potential from the learning point of view.

Another mechanism that can be used to justify the use of personalization to stimulate learning is “subsequent experience” (Falk & Dierking, 1992). A number of researchers have hypothesized that repetition is the major mechanism for retaining memories over a long period of time (Brown & Kulick, 1997). This is why, by allowing the visitor to bookmark objects or concepts of interest during their navigation in the virtual or real environment and to explore them more in detail subsequently (see later for further information), personalization can make it possible to further deepen and continue the learning process from home by creating continuity between the visit and post-visit experiences.

Last but not least, learning is stimulated when a person can pursue their individual interests. Researchers distinguish between “situational interest” and “individual interest,” the first being defined as “the stimulus that occurs when one encounters tasks or environments with a certain degree of uncertainty, challenge or novelty” (Csikszentmihalyi & Hermanson, 1995). This is, for example, the case for museums where the presence of incentives like surprise, complexity and ambiguity lead to motivational states that result in curiosity and exploratory behavior (Csikszentmihalyi & Hermanson, 1995).

However this is not enough to guarantee that the visitor is actually stimulated to learn. In order for this to happen, museums have to attempt to respond to their visitors’ “individual interests,” that is “their preference for certain topics, subject areas or activities” (Hidi, 1990), as the pursuit of individual interests is usually associated with increased knowledge, positive emotions and the intrinsic desire to learn more. Personalizing an educational activity in terms of themes, objects or characters of high prior interest to students should therefore enhance the overall learning experience. Take, for example, those personalized applications (see later for details) that provide tailor-made visitor plans with consideration of the individual interests of a single visitor or a group of visitors. By suggesting artifacts relating to the visitor’s individual curiosity, the visit is more likely to result in fruitful learning activity.
In conclusion, by providing information at the right level of detail, stimulating subsequent experiences and taking into consideration individual interests as well as prior knowledge, personalization represents an excellent tool for all those educators wishing to stimulate and facilitate learning. This is why personalization techniques are often exploited in the creation of formal e-learning applications such as long-distance courses that are able to adapt to the student’s level of knowledge, cognitive preferences and interests, etc. For example, see the AHA Project on Adaptive Hypermedia for All [aha.win.tue.nl] at the Technical University of Eindhoven, The Netherlands, and the European IST ELENA Project on Enhanced Learning for Evolutive Neural Architectures [www.elena-project.org].

However, personalization can be also applied to more informal e-learning solutions like the ones that are often available on museums' Web sites or interactive devices, which, although not being actual lessons, represent very useful educational experiences that contribute to increasing the visitor’s knowledge and understanding about a specific issue.

WEB PERSONALIZATION FOR SCIENCE MUSEUMS

Until now, we have discussed more general issues concerning the use of personalization techniques in museums, focusing in particular on its potential to stimulate and facilitate the learning experience. In this section we consider some examples of how science museums in particular are applying these principles online. In fact, even if science museums are not the only cultural institutions to have experimented with personalization both online and on-site in the past few years — for a more general description of personalized applications in museums see Bowen and Filippini-Fantoni (2004) — they are among the ones that have expressed the strongest interest in these techniques. This is because science museums and science centers, whose exhibits are designed to promote playful exploration and discovery of scientific phenomena, have always been relatively aggressive adopters of information technology and innovative approaches; as a consequence, they have also been more eager to experiment with personalization.

Some museums have been focusing more on the usability and marketing aspects of personalization privileging applications such as personalized agendas, alerts and newsletters, which, although having an intrinsic pedagogical value, seem to focus more on promotion. However, science museums have been among the first to understand the real value of personalization as a learning tool, concentrating particularly on stimulating “subsequent experience,” “previous knowledge,” and “individual interest” in such a way as to explicitly encourage the continuity between the pre-visit, visit and post-visit experiences.

The first examples of Web personalization in a museum context were developed in the late 1990s in strict relation with the affirmation of academic research on adaptive hypermedia. Among them (Bowen & Filippini-Fantoni, 2004) was the SAGRES system (sagres.mct.pucrs.br), developed in 1999 by the Museum of Sciences and Technology of PUCRS (MCT), Porto Alegre, Brazil.

The SAGRES system (Bertoletti, 1999; Moraes, 1999) is an educational environment that presents the museum’s content adapted to the user’s characteristics (capacities and preferences). Based on information provided directly by the user or by the teacher (for students), the system determines the group of links appropriate to the user(s) and presents them in a personalized Web page.

The principle behind the project was an attempt to overcome the limitations implicit in the one fits all approach and to take the user’s individual interests as well as their level of knowledge into consideration when delivering information, with the aim of improving the overall learning expe-
Personalization Issues for Science Museum Web Sites and E-Learning

This is possible through an adaptation process that first generates a user model, based on information provided by the user. Once these data about the user have been collected, the adaptation process can select different types of documents conforming to the visitor’s model. This results in a dynamically generated HTML page with links pointing to personalized information: the page is created dynamically during the interaction of the user with the system and presents links to the documents, as well as connections to the communication mural (where users can interact with each other), to the document edition, and to the activities the user should perform (in the case of a group visit).

As well as being designed for individual users, the system is particularly meant for use in an educational setting. Through SAGRES, teachers are given the opportunity to define and register their students’ profiles, to accompany them and to evaluate their performance during the visit, using reports delivered by the system. At the same time, students are allowed to interchange ideas with colleagues in their groups and to work on the activities and subjects determined by the teacher.

PERSONALIZED VIRTUAL WEB SPACES

The main aim of the SAGRES project was to facilitate learning through the provision of information adapted to the level of knowledge and interest of the user. Since then, other methods have been adopted to guarantee a similar outcome.

Figure 1. The architecture of the SAGRES system
Various science museums, for example, provide users with tools that allow them to save images, articles, links, search results, forum discussion topics, as well as other types of information during navigation of the Web site. By doing so, the user creates a personal environment within the museum’s Web site, where they can return, find specific information of interest, and to which new items can be continuously added. This environment can be further equipped with other personalized services such as individual agendas or the ability to send personal e-cards.

Once the page has been created, visitors can log in every time they access the Web site to find all the information they need. By doing so, the user has the chance not only to find information of interest more easily, but also and especially to strengthen the learning process through reuse and repetition. The learning value of these applications for certain categories of users such as students and teachers is even greater. The personal space can offer teachers the possibility of suggesting of exhibits for their students to visit and questions that they would like the students to answer during the exploration. In response, the students can save links to the exhibits that most interest them, as well as making short notes both about questions they had at the beginning and about new questions that arise during the exploration.

One of the most interesting examples of this type of application is provided by the Ingenious project, undertaken by the National Museum of Science and Industry group in the United Kingdom and funded by the UK New Opportunities Fund (NOF) (www.nmsi.ac.uk/nmsipages/nofdigitise.asp). This project, online from mid-2004, aims at creating a learning environment for the public from the digitized collections of the Science Museum (London), the National Railway Museum (York) and the National Museum of Photography, Film and Television (Bradford) in the UK. Users of the Ingenious Web site (www.ingenious.org.uk) can explore and discover the rich collections of these museums through 50 narrative topics.

Figure 2. Ingenious home page
and over 30,000 images and other content-rich resources, such as library and object records. In addition visitors are provided with tools for entering a topical debate and personalizing their experience in the so called “CREATE” area, where registered users can save images and/or links from the debate areas, read sections and search queries. The users can also send personalized e-cards of images by e-mail and create a personal Web gallery from their bookmarked images, including the ability to incorporate personal comments that can be e-mailed to friends and colleagues.

Figure 2 shows a general shot of the Ingenious home page. The facilities include “My E-cards”

---

**Figure 3. Ingenious electronic cards**

---

**Figure 4. Ingenious selected hyperlinks**
Figure 5. Ingenious saved images

Figure 6. Ingenious Web galleries
to sent electronic cards (Figure 3), selected hyperlinks (Figure 4), saved images (Figure 5) and Web galleries (Figure 6).

Even if in the wider picture for Ingenious users, the umbrella group is lifelong learners, the application can be particularly suitable for older age school children, teachers, and researchers who could first explore a topic in the “read” or “see” sections of the site, then use the “save image” and e-card features and gradually progress to Web gallery tools for creating a personal resource. The Web gallery outcome would be used for a project, research, shared among a group of subject enthusiasts or a class (for instance). Community building could follow from this, through the usage of the debate features available on the site.

THE POST-VISIT EXPERIENCE

In some cases, personal virtual spaces can also include information about a visitor’s actual visit to museums, thus creating a direct link between the visit and the post-visit experience. Personalization is an effective tool for stimulating visitors at home to follow up on what caught their attention during the exhibition through a museum’s Web site. For example, the London Science Museum’s “In touch” project allows a record of a visitor’s interaction with various exhibits in the Wellcome Wing including an eye scan, voice, face and fingerprint recognition, photo editing, etc., to be recorded using their fingerprint as an identifier, thus avoiding the need for any physical ticket (www.sciencemuseumintouch.org.uk). The results are made available as part of a personal space within the museum’s Web site that can be accessed via the visitor’s first name and birth date.

Since 2000, when the project was originally implemented, Joe Cutting of the Science Museum reports that (as of January 2004) more than 400,000 Web pages have been created, of which around 8% have been accessed at least once. In order to simplify the system, reduce the operational problems that derive from such a large database, and increase the percentage of visitors using it, the museum has decided to replace the fingerprint method (which is not completely reliable in practice) by “an email it to me” option by the end of 2004. Every time a person wants to save one of the interactions, an e-mail address will have to be provided. By doing so, there will be no more automatically generated personal pages for the visitors. However, the museum is considering the inclusion of a link in the e-mail that would allow the visitors to set up a personal page if they wish. In this way only those who are really interested will set up a page and the museum will not have to maintain a huge and largely unused database. Figure 7 shows two screenshots from the exhibition itself and Figure 8 shows example pages from the associated Web site.

In a similar manner, the Visite Plus service offered by the Cité des Sciences et de l’Industrie (www.cite-sciences.fr) in Paris, which has been used on a number of successive temporary exhibitions, “Le Cerveau Intime,” “Le Canada Vraiment,” and “Opération Carbone,” allows the visitor to configure a personal profile (with information on preferred language, disabilities, etc.) on an interactive kiosk placed at the beginning of the exhibition through a special bar-coded ticket or on a PDA (Personal Digital Assistant). This data can then be used to access adapted information from the different interactive devices and to play various games and quizzes in the exhibitions. The results of such interaction, as well as the path followed by the visitor, are automatically saved by the Visite Plus system on a personal Web page, accessible on the museum’s Web site after the visit through the number of the bar-coded ticket or PDA. In this way, the visitors are able to analyze in more depth the subjects that particularly interested them during the exhibition (through the provision of additional information) and to compare results of their interactions with those of other visitors.
Figure 7. “In touch” exhibition screen shots

Figure 8. “In touch” Web pages
The fact that an important part of the content concerning the exhibition is accessible after the actual visit, at home or in another context, allows the visitor to focus more on experimentation and discovery while in the museum and to leave the more traditional didactic aspects for later. The Visite Plus system also offers the possibility of subscribing to a personalized periodical newsletter that focuses on a series of themes selected by the visitor at the moment of the registration. Options include selecting from a list of available subjects or receiving a complete dossier of the exhibition. See Figure 9 for an example of the view of the exhibit from the personalized Web site. Each square corresponds to a content area in the exhibition. The squares that are in full color represent the ones that have been accessed during the visit to the exhibition while the white ones correspond to the ones that have not been visited.

Similar concepts have been introduced and tested in the framework of the Electronic Guidebook Research Project (www.exploratorium.edu/guidebook), which began in 1998 at the San Francisco Exploratorium in California, in partnership with Hewlett-Packard Laboratories and the Concord Consortium. This is aimed at developing a roving resource to enhance a visitor’s experience at the museum (Hsi, 2003). In particular, the purpose of the project is to investigate how a mobile computing infrastructure enables museum visitors to create their own “guide” to the Exploratorium, using a personalized interactive system. This helps in better planning of their visit, getting the most out of it while they are in the museum and enabling reference back to it once they have returned to their home or classroom. The guidebook allows users to construct a record of their visit by bookmarking exhibit content,

Figure 9. Visite Plus personalized Web site
taking digital pictures from a camera near the exhibit, and accessing this information later on a personal “MyExploratorium” Web page in the museum or after their visit (Figure 10).

The project was designed as a proof of concept study to explore potential avenues for future research and development and therefore was not envisioned to support the implementation of a fully functional system. Nevertheless, the tests that have been run so far revealed interesting conclusions. Above all, the visitors liked the idea of being able to bookmark information for later reference. Both teachers and pupils thought this feature would allow the children to play more during their museum visit, completing related homework assignments after the visit (Semper & Spasojevic, 2002).

THE PRE-VISIT EXPERIENCE

The link between visit and post-visit experience can be also extended to the pre-visit phase through the implementation of systems that allow visitors to create personalized tours based on their interests and needs. Most museum visitors, even those who have not visited before, arrive with expectations about what will happen during the visit. Such hopes might concern specific subjects of interest that the person wants to explore, the physical characteristics of the museum, the types of activities that can be undertaken or the social context in which the exploration takes place (alone, as a family, within a larger organized group, etc.). All these factors merge to create a visitor’s personal agenda (Falk & Dierking, 1992). The success of the museum experience is partially
Personalization Issues for Science Museum Web Sites and E-Learning

defined by how well it corresponds to the visitor’s personal agenda.

Personalization is a useful tool to create such a correlation because it helps a visitor to find out what, within the museum, could fit better with their personal agenda or correspond more to their expectations. This can be done either from home on the museum’s Web site or directly on-site through interactive devices available in the museum. Upon completing a profile, where the intending visitor must indicate different types of information such as how and when they are tentatively planning to visit, with whom, how long they plan to stay, what sort of interest(s) they have and which language they understand, the system will be able to provide a personalized plan for the visit that takes the submitted information into consideration. Personalized museum plans can be very useful, especially for large museums where visitors are likely to be overwhelmed by the number of objects or exhibits available for viewing during a single visit. In such a context, visitors are often disoriented and find it difficult to decide what they want to see or do. Answering a few very simple questions, or defining a few criteria, can help them to overcome these limitations, enjoy the visit more fully and learn more easily.

A number of museums are working on developing online and onsite applications based on these principles. The National Museum of Ethnology in Leiden, the Netherlands (www.rmv.nl), for example, has developed an onsite facility called “The tour of the world in 80 questions” that allows children aged 7 to 13 to print out a personalized tour plan of the museum based on an individual choice of subjects and continents. The tour plan, which is colorful and easy to understand for children, includes a series of maps that help locate the objects, a brief description of the artifacts and a list of questions related to the subjects chosen, which the young visitors need to answer during their museum exploration.

The Cité des Sciences et de L’Industrie in Paris is undertaking a project called “Navigateur” (Navigator), which will allow visitors to create a personalized tour based on an individual choice amid a set of criteria which include the context of the visit (alone, family, group), the language spoken, the particular interests, the time available and the type of experience desired. Once the visitor has set the criteria that are most relevant for them and has checked the offerings on the museum interactive plan, the personalized proposal can be saved on the museum bar-coded ticket, which will be used during the actual visit, when using different interactive devices throughout the museum, to obtain further assistance in finding the recommended exhibits or to reset the criteria based on new interests that might have arisen during exploration. The system will be linked directly with Visit Plus, thus creating continuity between the pre-visit, actual visit and post-visit experience, through the use of personalization.

CONCLUSION

The examples provided here from different science museums all over the world help to prove the potential role that personalization could play in strengthening the overall learning process before, during and after the actual visit, in advance through activities that orient visitors and afterwards through opportunities to continue reflection and explore related ideas. However, despite the obvious potential benefits that these applications can bring to the visitor’s experiences, there is still very little evidence that these systems work in the terms envisaged by their promoters, especially with respect to learning. This is because, due to their relatively recent nature, most of these projects have not yet been subjected to thorough evaluations that focus on establishing, among other things, the long-lasting effects of personalization on the learning process. Until now,
Personalization Issues for Science Museum Web Sites and E-Learning

the very few evaluations that have been carried out have focused mainly on whether people use the systems or not, why they do so, where they encounter most difficulties and on their usability in general. Despite the fact that further studies are needed in order to shed light on the effectiveness of personalization as a pedagogical tool, the first evaluations of these early examples, as well as other similar projects, have given initial help in indicating various pros and cons related to their use.

The overall feedback concerning the introduction of personalizing applications to audio guides and virtual environments seems to be reasonably positive: visitors are spending more time in the virtual and real museum, they access information at the level of detail desired and appreciate the idea of being able to bookmark information for reference later (Semper & Spasojevic, 2002). In particular, a study by Cordoba and Lepper (1996) has evaluated the consequences of personalization with respect to stimulating intrinsic motivation and learning in a computer-based educational environment. The findings provide strong evidence that the students for whom the learning contexts had been personalized, through the incorporation of incidental individualized information about their backgrounds and interests, displayed better gains in motivation, involvement and learning than their counterparts for whom the contexts had not been personalized.

However some drawbacks have also emerged. First of all, there are the issues related to the difficulty and expense of implementation and also problems in practical use by visitors. So far it seems that only a limited number of visitors take advantage of the benefits available through personalization, partly because the systems are not implemented in a clear and easy manner and partly because most visitors are either not ready for technology or not willing to invest time in it. Therefore it is important to remember that personalization should not be implemented for the sake of it but when and because it brings added value to the museum for, if not all, a good percentage of visitors. Only if this occurs can the costs for investment and development be justified.

Some experts have warned against the use of personalization. Nielsen (1998) has argued that personalization is over-rated, saying that good basic Web navigation is much more important. For example, it is helpful to consider different classes of use in the main home page, such as physical visitors, the disabled, children, teachers, researchers, groups, etc., and to give each of these a relevant view of the resources that are available (Bowen & Bowen, 2000). Such usability issues are certainly important, and relatively cheap to address with good design, but even Nielsen admits that there are special cases were personalization is useful.

More recently, there have been further questions about the effectiveness of personalization (Festa, 2003; McGovern, 2003), despite the enthusiasm of some. For example, the costs may be up to four times that of a normal Web site, around a quarter of users may actually avoid personalized Web sites due to privacy concerns and only 8% are encouraged to revisit because of personalized facilities (Jupiter Research, 2003). This compares with 54% who considered fast-loading pages and 52% who rate better navigation as being important. However, other surveys indicate that personalization can be effective, for example in the field of downloadable music (Tam & Ho, 2003).

Another issue that needs to be stressed in personalization is related to standardization procedures and applications. This process is central both for content description and user profile definition using metadata (Conlan et al., 2002). The description process can however be very time-consuming and expensive, but if it is pursued properly it allows the resources to be reused for different purposes and a visitor profile to be created using various different sources of information following evaluation criteria. Museums are sometimes not very quick in adopting new technologies but in some cases the slow perspective allows them to
make the most of other institutions’ initial mistakes and thus to avoid them. Involvement with standards provides a good opportunity to share such knowledge.

Thus it is recommended for museums to use personalization on Web sites judiciously at the moment, although science museums with good funding may wish to be more adventurous. There is a place for personalization in leading-edge Web sites and for certain innovative facilities like advanced Web support for specific exhibits. It is an area that museums should certainly consider, but the costs should be weighed against the benefits. Of course, the costs are likely to decrease as commercial and open source support improves in this area. At the moment, not insignificant development effort is needed for such facilities, but in the future they could be increasingly packaged with standard database-oriented Web support software, such as content management systems, as understanding of what is useful and not useful is gained from practical experience. This is certainly an interesting and fast-moving area that should be monitored by innovative science museums, especially at a national level.

Personalization Issues for Science Museum Web Sites and E-Learning

ENDNOTES

1 A “cookie” is a small piece of data sent by a website and stored on the client-side (browser) computer that can be reused later on the server-side (the Web site that sent the cookie) as unique information concerning a user.

2 A Web server log is a record of each access to a Web server with information such as the name of the client computer, the date/time and the resource accessed.

3 These applications are currently available on a number of different museums’ Web sites such as the Metropolitan Museum of Art, the Whitney Museum of American Art, etc. For a detailed description of these applications (see Bowen & Filippini-Fantoni, 2004).

4 Please note that the distinction between formal and informal education is used here in a rather loose sense. Usually, in the educational sector, classrooms are considered formal learning settings, while museums are considered informal learning settings. As an alternative, we propose here to use the term formal e-learning tools in relation to proper courses meant for students who cannot attend classes; while by informal e-learning tools we refer to online or onsite educational environments.

5 Note that the acquisition of knowledge about the visitor is done in an explicit way: information is directly extracted, through the filling of forms, with direct answers to questionnaires. SAGRES works with two kinds of models: individual model and group model. The group model is built by the teacher and used by students. The teacher
is responsible for the definition of the students’ characteristics, by the definition of the group stereotype (subject, knowledge level and language of the consultation), the activities stereotypes and the classes (name of the students presented in the group).

It is not the intention of this chapter to be negative towards the use of personalization techniques in museums, but to highlight constructively some of the questions that come to light when the social uses and design problems are considered.

For more detailed information on the problems related to the implementation and use of personalization techniques see Filippini-Fantoni (2003).
Chapter 4.15
Personalization and Customer Satisfaction in Mobile Commerce

HY Sonya Hsu
Southern Illinois University, USA

Songpol Kulviwat
Hofstra University, USA

INTRODUCTION

The advancement of wireless technology facilitates both consumers’ activities and business transactions. With the rapid proliferation and widespread use of mobile devices, including mobile phones, personal digital assistants (PDAs), and handheld computers, mobile commerce or m-commerce is widely considered to be a driving force for the next generation of electronic commerce (e-commerce). According to Jupiter Research, the m-commerce industry is expected to be US$22 billion globally by 2005. However, to date many promising technologies—especially m-commerce applications—have failed with the notable exceptions of i-Mode service and short messaging service (SMS).

Popular “i-Mode”, produced by NTT DoCoMo of Japan, is a service that enables wireless Web browsing and e-mail from mobile phones. The “i-Mode service” has been the first successful commercial introduction of 3G (third-generation) mobile applications. It exceeded expectations and acquired over 30 million profitable users in a three-year period (Cohen, 2002).

One of the main goals of most operators might be building customer satisfaction and loyalty by providing one or more ‘killer apps’ to them. One way is to integrate customer relationship management (CRM) into the development of mobile services’ applications. Some firms have tried to target these applications to their customers on an individualized basis. “Personalization” may be the way to achieve that. Specifically, personalization can be regarded as the use of technology and user/customer information to match multimedia content with individual needs with the goal of producing user satisfaction. Personalization can
be presented by an IP services framework that allows operators and subscribers through self-service provisioning approaches to control the types of service and applications they want and are willing to buy.

The purpose of this article is to develop a deeper understanding of personalization, with an emphasis on those factors that lead to customer satisfaction and/or delight. Specifically, this article presents factors contributing to consequences derived from using personalized applications and services in m-commerce.

BACKGROUND

In their pilot study, Ho and Kwok (2003) applied the technology acceptance model (TAM) originated by Davis (1989) to their m-commerce study. They utilized four constructs to predict the service subscribers’ intention to switch: number of generalized messages, perceived ease of use of general advertisements, perceived usefulness of personalized message, and privacy issues about personalized advertisements.

This article extends the thrust of Ho and Kwok’s research to incorporate the effect of personalization on customers’ satisfaction and delight that could contribute to CRM. Customers’ satisfaction and delight are derived from expectancy theory, and they are discussed by Oliver (1981), Oliver, Rust, and Varki (1997), Spreng, Mackenzie, and Olshavsky (1996), and Verma (2003).

Expectancy: Satisfaction and Delight

Expectancy theory is used to frame the evaluation of mobile services users. Oliver (1981) defined expectation to include two components: the probability of occurrence (e.g., the likelihood that a personalized cell service will be available) and an evaluation of the occurrence (e.g., the degree to which the personalization level is desirable or undesirable). The disconfirmation/confirmation paradigm of satisfaction is based on expectancy theory. It can be an emotional response to the comparison of the performance received and the products’ normative standards. When the performance and expectations are at variance with each other, there is a discrepancy. This discrepancy could be either positive (when performance exceeds the expectations), which often causes satisfied state, or it could be negative, when performance is worse off than expected (Oliver, 1981). In other words, the consumer would be satisfied if perceptions match expectations or if confirmations are reached. Consistent with Spreng et al. (1996), satisfaction arises when consumers compare their perceptions of the performance of a good and/or service to both their desires and expectations. As such, satisfaction is a subjective judgment and may imply mere fulfillment.

Delight is a positively valence state reflecting high levels of consumption-based affect. The feeling of delight is experienced when the customer is pleasantly surprised in response to an experienced disconfirmation. It is the feeling state containing high levels of joy and surprise (Westbrook & Oliver, 1991). Further, Oliver et al. (1997) proposed and confirmed that delight is a function of surprising consumption, arousal, and positive effect or a function of surprisingly unexpected pleasure. They empirically confirmed that delight is a “mixture” of positive effect and arousal or surprise. It is associated with the level of arousal intensity. Moreover, it is a reaction experienced by the customer when he or she receives a service and/or a good that does not simply evoke a feeling of satisfaction, but also provides an unexpected value or unanticipated additional pleasure. In other words, delight occurs when the outcome is unanticipated or surprising. It can be marked by pleasurable, unforgettable, and memorable feelings in a service encounter or a product purchase (Verma, 2003). It is thought to be the key to customer loyalty and loyalty-driven profit (Oliver et al., 1997) and is known as the highest level of expectation-disconfirmation paradigm.
Technology Acceptance Model (TAM)

From Davis’ (1989) TAM model, ease of use (EOU), and perceived usefulness (PU) of a technology are factors that either directly or indirectly increase a person’s intention to adopt an innovation. While perceived usefulness is the degree to which a person believes that using a particular technology/system would enhance the outcome performance, perceived ease of use is the extent to which a person believes that using a particular technology/system will be free of effort (Davis, 1989). TAM could be helpful in predicting the usage of personalized applications and services. Greer and Murtaza (2003) adapted the TAM model to study issues that impact the valuation of Web personalization as well as factors that determine customer use of Web personalization. Ho and Kwok (2003) adapted Davis’ (1989) EOU and supported the effect of using a generalized message on changing a service provider. They also used “PU of personalized service” to test the importance of personalization in mobile commerce. They found support for both. Most importantly, the PU of personalized service was the most effective factor, together with ease of locating generalized message and the amount of generalized message that affected the decision to change to a new service (Ho & Kwok, 2003).

MAIN THRUST OF THE ARTICLE

Usually when there are too many generalized messages, customers lose their motivation to read, retrieve, or even locate a useful message. In addition, the amount of space available on the mobile screen limits the amount of options and information. Given this, personalization is considered to be the key factor for success/failure of mobile devices and services. Information and services must become increasingly tailored to individual user preferences and characteristics in order to accommodate limited space and scarce airtime. Personalization is viewed as including “recognition of a customer’s uniqueness” (Surprenant & Solomon, 1987, p. 87), use of a customer’s name, and response to customer needs (Goodwin & Smith, 1990).

Message Format

Carlson et al. (1998) characterized medium richness as the capacity to convey information. It is further defined as the ability to provide immediate feedback to customers’ consumption of media. Rich information can be produced by giving immediate feedback, having a variety of available communication cues, understandable/common language, and foremost, personalization of the medium (Carlson et al., 1998).

Media richness theory postulates that media selection depends on the uncertainty of the task at hand (Kumar & Benbasat, 2002). Both media richness theory and the TAM model have illustrated their relationships with task orientation. Also, social presence theory postulates a particular communication task based on the degree of necessary social presence that links a selection of media (Kumar & Benbasat, 2002). Originally, it referred to the degree to which a medium allows a user to establish a personal connection with the other users. Social presence seems to be moving towards a task orientation at an individual level in the latter theoretical development, such as the para-social concept from Kumar and Benbasat (2002). Para-social is a combination product of social presence and media richness. This article focuses on the PU of personalized messages that employ a task orientation, while two different formats of messages (text and multimedia) were drawn from media richness theory.

Personalization

Personalization can be defined as the use of technology and user/customer information to customize multimedia content so as to match with individual needs and ultimately produce
Personalization translates individual profiles into unique presentations. The individual profiles can be built upon user preferences, the quality of his or her senses, user location/environment, contexts, users’ network, and terminal capabilities. Morris-Lee’s (2002) study on personalization of brochures indicated that personalization helped increase interest and involvement. The more personalized features are, the greater the possibility of increased costs (Greer & Murtaza, 2003). Hence, these increasing costs hopefully should produce greater customer satisfaction and retention, thus a greater return. This is a very important point because, for example, a 5% increase in customer retention costs can translate into a 25%-125% increase in company profitability (Reichheld et al., 2001). Also, personalization of service has been found to have a positive impact on customers’ evaluations of service encounters (Surprenant & Solomon, 1987).

Figure 1 presents the research model of personalization in m-commerce. The model is developed based on the TAM (Davis, 1989) and expectancy theory (Oliver, 1981). Specifically, this research model extends Ho and Kwok’s (2003) research framework. Further, our model integrates customer expectancy as an endogenous variable. The model includes six sets of variables: (1) number of generalized messages, (2) perceived usefulness, (3) text messages, (4) multimedia message, (5) satisfaction, and (6) delight.

**FUTURE TRENDS**

As predicted, text message predictor had a positive association with the dependent variable. Number of generalized messages was negatively related to satisfaction. Multimedia message was not a significant predictor of satisfaction and was deleted in the second model. On the other hand, the analyzes of “delight,” “multimedia message” contributed the most importance to the
equations and was positively related to delight. Text message and PU of personalized message had positive associations with delight, while the number of generalized messages had a negative contribution to the equation (Hsu, Bruner, & Kulviwat, 2005).

According to Santos et al. (2003), even though satisfaction and delight are two different constructs, each serves a dimension of confirmation (satisfaction) at one end and disconfirmation (delight) on the other end. Increasing literature has being drawn in the difference between consumer satisfaction and delight (Kumar & Olshavsky, 1997; Oliver et al., 1997). To compare satisfaction with delight, Oliver et al. (1997) see customer delight as being fundamentally different from customer satisfaction. Compared to satisfaction, delight seems more abstract and more extreme in terms of affection. While satisfaction may be induced by avoiding problems or may meet standard/minimum requirement, delight requires more than that. Oliver et al. (1997) empirically confirmed the distinction between the satisfaction and delight constructs, with delight being a higher level of satisfaction. In fact, customer delight is associated with a strong and positive emotional reaction to a product or service. Thus, both practitioners and scholars should manage customer delight as a separate goal from satisfaction.

Te’eni, Sagie, Schwartz, Zaidman, and Amichai-Hamburger (2001) used three dimensions to define media richness further; these are interactivity, adaptiveness, and channel capacity. Beyond just a different format from a text message, future researchers may look into a deeper understanding of multimedia messages that convey information for possible customers’ delight in addition to satisfaction. Delightedness can be marked with pleasurable, unforgettable, and memorable where customer loyalty is rooted (Verma, 2003; Oliver et al., 1997). With the limitation of student population, future research may investigate some professional group that has reasons to use mobile commerce and/or some population that has more disposable income at hand. Another limitation that can also be addressed in the future is the sophistication of multimedia services and the maturity of users. In other words, future researchers may look into some markets that have rolled out the mMode of AT&T, Mobile Web of Verizon, and/or Sprint’s PCS.

From mobile application point of view, “personalization” can be more sensitive to users’ needs, for example, location-based application as in www.mobull.usf.edu. Local merchants ally to deliver a personalized text message—such as sales, promotion advertisement, coupons—from a Web site to a wireless device based on personal preferences that are set up by each individual. Location-based services utilize location information to provide specialized contents to mobile users (Varshney, 2003). Explicit user permissions should be obtained before “pushing” any advertising contents to particular users (Varshney, 2003). Push and pull advertisement, of course, relates to the issues of privacy and sharing of user information. Therefore, the “trust” matter may surface between a group of local merchants and individual consumers.

**CONCLUSION**

This article identifies the same situation as in Ho and Kwok (2003) that the amount of generalized message had a negative effect on customer satisfaction. Personalized message is more likely related to customer satisfaction and delight. The TAM model and expectancy theory were drawn as the foundation of this research model. Media richness explains the division between text message and multimedia message, whereas TAM contributes the perceived usefulness of personalized message.

Beyond personalization, this article attempts to merge the media richness theory with expectancy
Personalization and Customer Satisfaction in Mobile Commerce

theory. Specifically, it explains the relationships between text/multimedia message and customer’s satisfaction/delight. The article concludes that consumers would like to have a richer media to experience a “delightful” emotion. Consistent with the principle of media richness (Carlson et al., 1998): the more complex media format, the more information can be delivered in a message. If managers would like to increase effectiveness and/or efficiency of mobile services, text message alone would not be sufficient for market differentiation to gain competitive advantage. With personalization, multimedia formats can be a supplement tool to increase the interaction with consumers when launching advertising campaigns. The richer the media, the more effective it is in communication.

REFERENCES

**KEY TERMS**

**Customer Delight:** The feeling of delight is experienced when the customer is pleasantly surprised in response to an experienced disconfirmation.

**Customer Satisfaction:** Based on the consumption, consumer would be satisfied if perceptions match expectations or if confirmations are reached.

**Expectance Theory:** Oliver defined expectation to include two components: the probability of occurrence and an evaluation of the occurrence. The discrepancy of confirmation could be either positive or negative.

**Media Richness:** Media richness theory postulates that media selection depends on the uncertainty of the task at hand. The more complex media format, the more information can be delivered in a message.

**Mobile or M-Commerce:** Both consumers’ activities and business transactions are facilitated by the advancement of wireless technology including cellular phones, wireless PDAs, or any hand-held units.

**Personalization:** Can be regarded as services of the use of technology and user/customer information to customize multimedia content aiming to match with individual needs and ultimately deliver customers’ or users’ satisfaction.

**Technology Acceptance Model (TAM):** From Davis’ TAM model, ease of use (EOU) and perceived usefulness (PU) of a technology are factors that either directly or indirectly increase a person’s intention to adopt an innovation.

ABSTRACT

This chapter discusses contemporary global challenges facing veterinary educators and summarizes some of the economic, social, political, and technological pressures underlying curricular and pedagogical change initiatives. Integrating human computer interaction (HCI) into veterinary medicine curricula, as a strategy for implementing pedagogical transformation, is reviewed. Computer-assisted learning (CAL) projects recently developed at a veterinary college are described. Results of studies evaluating the effectiveness of CAL approaches to HCI integration within the veterinary medicine curricula are reported. Future research directions are proposed.
**INTRODUCTION**

Contemporary veterinary medical education is in a transformative state. Veterinary educators are responding to public demands for the expansion of veterinary roles, for specialized veterinary care, and increased concern for animal welfare, global demands for standardization of veterinary curricula, and veterinary teaching hospital practice in the context of coping with a diminishing pool of academic veterinary researcher/educators who must manage a rapidly expanding knowledge base. Increasingly, veterinary educators are seeking human computer interaction (HCI) solutions to addressing these emergent challenges. This chapter examines these emergent challenges and describes international initiatives focused on integrating HCI into veterinary medical curricula. The chapter includes an in-depth examination of technology-enhanced learning (TEL) research and development program at the Western College of Veterinary Medicine in Canada.

**EMERGENT CHALLENGES**

Contemporary veterinary educators are responding to a series of emergent challenges. Increasing public demands to expand veterinary roles into public health-assurance issues are at the fore of these challenges. Veterinary responsibilities for ensuring a secure, sustainable food supply and managing industrial-scale food animal production—within a climate of public fear of pandemic disease outbreaks—have globalized these issues within veterinary colleges, regions, and governance bodies. Animal welfare concerns, as well as ecological and environmental, issues are affecting not only what is taught in veterinary school, but also the way in which it is taught. Public demand for access to specialized veterinary care and expanding pressures on veterinary teaching hospitals to train specialists and increase caseload have resulted in a predominance of secondary and tertiary cases (referrals from practicing veterinarians) being evaluated at veterinary teaching clinics, decreasing the access of veterinary students to “general practice” cases.

Meanwhile, the pool of veterinary educators is diminishing as more financially rewarding opportunities abound in private practice and the corporate sector. All veterinary colleges cannot secure, in a timely fashion, candidates for open positions in veterinary teaching. Therefore, student access to inter-institutional experts and specialists is an emerging necessity. The veterinary knowledge base is rapidly expanding, so that it is no longer realistic to teach veterinary students “everything they need to know” within their four-year curriculum. Debates about the merits of traditional broad-based curricula versus early specialization, the appropriateness of national and regional versus global credential standards, and even pedagogical approaches to veterinary teaching and learning are recurrent themes in current veterinary literature. The combined effects of these challenges for change in veterinary teaching methodologies have resulted in calls for HCI alternatives to traditional lecture-based pedagogy and to invasive animal use in veterinary educational laboratory exercises (Association of American Veterinary Medical Colleges, 2005; Fernandes, 2004).

**Globalization of the Veterinary Profession**

The veterinary medical profession is increasingly expected to contribute to the development of solutions for global problems. This new responsibility makes the teaching and practice of veterinary medicine a global concern. Societal expectations that the veterinary profession should “undertake roles relevant to the re-assurance of human well-being, in terms of public health,” and address “the increasing consciousness in issues of animal welfare, sustainable animal production and environmental protection” (Rodriguez-Martinez, 2004,
Integrating Human Computer Interaction in Veterinary Medicine Curricula

p. 30) are driving this change. Animal disease crises with implications for human health, such as Bovine Spongiform Encephalopathy (BSE; mad cow disease), Avian influenza, West Nile virus, and Chronic Wasting Disease have brought issues of “food safety, public health, food animal health, and food animal production” (Walsh, 2004, p. 9) to the fore of public attention. As food security, environmental sustainability, and biodiversity (Edwards, 2004) are not subject to national or regional boundaries, veterinary education curricula and credentialing standards have become subjects of international interest.

Concerns about global educational standards in the health science professions in general (Clarkson, 2005; Jackson & Callman, 2006), as well as in veterinary medical education in particular (Edwards, 2004; Hammick, 2005a) have influenced the adoption of evidence-based evaluation of teaching and learning effectiveness. Initiatives, such as the formation of the Best Evidence Medical Education (BEME) and Campbell collaborations, focus on systematic reviews of medical science education for the purpose of “providing teachers, institutions and all concerned with healthcare education” with evidence to support curricular and pedagogical decision-making (Hammick, 2005b, p. 339). Computerized collection, analysis, and dissemination of evidence supporting educational effectiveness have come to the fore in these efforts.

Veterinary Teaching Hospital Challenges

The clinical veterinary profession has dramatically changed during the last 20 years, with increasing public demands and willingness to pay for a higher standard of care and veterinary expertise. The role of specialists has increased, not only within particular species, such as small animals, horses, food animals, exotic animals, and so forth, but also within the disciplines, such as epidemiology, internal medicine, surgery, cardiology, dermatology, dentistry, ophthalmology, neurology, and oncology. Most clinicians teaching at veterinary teaching hospitals are board-certified specialists. Despite the need for veterinary students to “handle routine cases typical of those seen in veterinary practice,” in most teaching hospitals, “the majority of the caseload is based on referrals, and most cases could be classified as receiving secondary or tertiary care” (Brown, 2003, p. 227).

There are many different diseases affecting wildlife, exotic, companion, and food animal health. It is not possible to discuss all of the conditions and their possible clinical presentations within the current veterinary curriculum. Ensuring that all interested students see examples of each condition during their clinical rotations is also not feasible. As a result, learning opportunities are often “hit or miss” with respect to specific case scenarios to which the students are exposed. Computer-assisted learning resources provide one method of addressing this problem by maximizing the use of current and historical case materials to expose students to the “typical clinical presentations” of many common or important diseases in each species (Abutarbush, Naylor, Parchoma, D’Eon, Petrie, & Carruthers, 2006; Clark, 2005).

Information Expansion

Veterinary information has rapidly expanded (Naylor, 2005), making it impossible for veterinary educational programs to teach students everything they will need to know for their career during a four-year veterinary program (Rodriguez-Martinez, 2004). In addition, current information is constantly being updated and changing. As a result, veterinary curricula and the expected competencies of veterinary graduates require constant review (Edwards, 2004). It is a challenge to balance the demands for a broad based curriculum to support professional licensure and provide the “basic training that should be broad enough to warrant
Integrating Human Computer Interaction in Veterinary Medicine Curricula

the graduate to practice, in principle, in any field of veterinary medicine” while also satisfying the increasing demands for specialized knowledge and expertise within the limited timeframe of undergraduate study (Rodriguez-Martinez, 2004, p. 31; see also Fernandes, 2004). Furthermore, preparing students for clinical practice is only part of the picture. Veterinary curricula are also expected to prepare graduates for potential careers in epidemiology, pharmacology, public health, or basic science research. The futility of trying to “teach it all” is clear (Rodriguez-Martinez, 2004, p. 31). Veterinary curricula must make choices, and, above all, veterinary graduates must have the skills, attitudes, and dedication that promote life-long learning and continuing education after graduation.

Veterinary Educator Shortages

While the need for access to veterinary learning opportunities is expanding, the pool of veterinary educators is diminishing. Veterinary colleges “worldwide are facing numerous challenges including increasingly limited resource allocations, difficulties on enrollments, gender changes, keeping up with advances in information and other technologies, remaining aware and responsive to … [learners] and the need to aggressively globalize their teaching, research and outreach programs” (Fernandes, 2004, pp. 9-10). Difficult economic situations in developing countries further exacerbate efforts to meet these challenges. In developed countries, attracting potential faculty clinicians away from fiscally rewarding private specialty practices and positions in the veterinary corporate sector (e.g., food sector, feed, and pharmaceutical industries) into an under-resourced and increasingly demanding academic work environment is a pervasive concern (De Castrol & Zuconi, 2004). “[A]mong veterinary establishments worldwide [there] is [a] worrying lowering number of veterinary graduates enrolling in postgraduate veterinary training” (Rodriguez-Martinez, 2004, p. 36). Most veterinary colleges are actively struggling to replace their retiring professoriate as well as their young faculty who are being lured into non-academic careers.

The Pedagogical Shift

Undergraduate veterinary education in Europe (and perhaps worldwide) is probably still considered one of the most traditional university educations, with extensive formal teaching, based upon rigid curricula, most often teaching facts rather than principles (Rodriguez-Martinez, 2004, p. 32).

Teaching veterinary students the processes of independent and collaborative “problem-identification, problem-solving and decision-making” and transforming pedagogical praxis from traditional fact-based lectures and demonstrations into “active, student-centred learning environments” has become a priority in many veterinary curricula (Rodriguez-Martinez, 2004, pp. 31-32). Computer-assisted learning (CAL) plays an important role in this change initiative. CAL has the capacity to link dispersed veterinary specialists in knowledge-sharing and collaborative teaching ventures, and to provide students with independent and collaborative case analyses and problem solving opportunities.

The use of CAL in veterinary education is expanding, and a range of tools supporting problem-based learning in virtual environments has been developed (Dhein, 2005; Hines, Collin, Quitadamo, Brahler, Knudson, & Crouch, 2005; Schoenfeld-Tacher, Bright, McConnell, Marley, & Kogan, 2005). Based in the United Kingdom, the Computer-aided Learning in Veterinary Education (CLIVE) consortium involves 14 colleges of veterinary medicine around the globe dedicated to developing and sharing electronic resources for CAL. A range of veterinary CAL initiatives have also developed in North America. Examples include Cornell University’s Consultant, a diag-
nositic database “designed to link over 500 clinical signs and symptoms to nearly 7,000 possible diagnoses or disease conditions (White, 2005); the integration of HCI into pharmacology instruction (Kochevar, 2003); large animal veterinary education (Dascanio, 2003), antimicrobial resistance and animal welfare (Bernardo & Malinowski, 2005); systemic pathology (Hines et al., 2005), and an introduction to anesthetic and surgical principles and techniques (Howe, Boothe, & Hartsfield, 2005).

The Animal Behaviour Learning Environment (ABLE), developed in Australia, uses virtual case studies and Web-based resources to support veterinary students in their efforts to diagnose and prepare treatment plans (McGreevy, Della Torre, & Evans, 2003). The Virtual Veterinary Medicine Learning Commons, a Canadian collaboration among the Atlantic, Ontario, and Western Colleges of Veterinary Medicine, has resulted in the sharing of high quality case-based clinical instruction by advanced broadband Internet technology (V2VLC, 2001). The University of Montreal has produced multilingual bovine medicine CD-ROMs, (Carriére, DesCôteaux, Durocher, & Harvey, 2005; Desrochers & Harvey, 2002).

INTEGRATING HCI INTO VETERINARY MEDICAL EDUCATION AT THE UNIVERSITY OF SASKATCHEWAN

The Western College of Veterinary Medicine (WCVM), established in 1964 at the University of Saskatchewan, provides undergraduate and graduate veterinary education to students from the four western Canadian provinces, as well as to national and international students. WCVM is accredited by the Council on Education of the American Veterinary Medical Association. The stated aim of the Doctor of Veterinary Medicine Program at the Western College of Veterinary Medicine is “to provide an excellent education in animal health that meets society’s needs, now and in the future” (WCVM, 2006, Mission statement, para. 1). The WCVM undergraduate veterinary program currently provides a fairly traditional education. In the first three years, a strong foundation in the basic sciences is followed by clinical courses, while the final year consists of clinical rotations through various clinical specialty areas. Within the next three years, however, the WCVM will be moving to a new core-elective curriculum whereby the core content (required to be taken by every student) will be decreased in order to expand elective opportunities available to students. This will allow each student to modify the curriculum to meet his or her own needs. The broad-based core curriculum will encompass the common knowledge, skills, and behaviors that veterinary students need to acquire, regardless of their ultimate career objectives. This approach will provide students with a basic understanding of the common problems facing veterinarians and prepare them for the national licensing examination. Elective opportunities will complement and enhance the knowledge, skills, and behaviors acquired in the core, allowing students to gain the additional knowledge, ability, and experience necessary for confident and successful entry in their chosen career path.

Computer-assisted learning has been a component of the veterinary curriculum at the WCVM for many years, and it is anticipated that it will play an even more important role in the new curriculum. Some courses (Virology and Clinical Pharmacology) have used WebCT to provide students with electronic lecture handouts, copies of PowerPoint slide lectures, quizzes, and interactions with faculty. Other courses, including Small Animal Medicine and Surgery, have made case materials (photographs and videos) available to students prior to case-based or modified problem-based class discussions. A few case-based CD-ROMs and DVDs have also been developed to supplement lecture-based discussions. In the Department of Small Animal Clinical Sciences
two clinical faculty members (one surgeon and one internist) spent a sabbatical leave at CLIVE developing two interactive DVDs for teaching clinical neurology to veterinary students (Shmon & Taylor, 2003; Taylor & Shmon, 2003). In the Department of Large Animal Clinical Sciences, a series of CAL initiatives began in late 1990s. Results included interactive case simulations using the problem-oriented format: Diseases of Calves and Diseases of Horses (Naylor, 1996) and more recently CD-ROM-based learning modules concentrating on the skills of auscultation, The Art of Equine Auscultation, 2nd edition, (Naylor, 2001) and The Art of Bovine Auscultation (Naylor, 2003), and bovine foot care: Cattle Claw Care (Clark, 2004).

**Provincially Supported Technology-Enhanced Learning Initiatives in Veterinary Curricular Development and Educational Research**

Funding support from the province of Saskatchewan’s Technology Enhanced Learning (TEL) initiative from 2001 to the present has extended the scope of CAL development and evaluation of CAL projects undertaken at the WCVM.

In the Department of Veterinary Microbiology, a Web-based learning resource in veterinary parasitology is being developed. The key element of this resource is a searchable database containing information on the taxonomy, morphology, geographic and host distributions, life cycle, pathology, clinical signs, diagnosis, epidemiology, treatment, control, and public health significance of approximately 100 parasites important in domestic animals in Canada. The text material for each parasite is complemented by a set of images and by animations summarizing the life cycles. For veterinary students, probably the primary users, the database can be accessed through WebCT, which provides opportunities for discussions and quizzes, together with the potential to use the database as an integral component of the students’ learning experiences in parasitology. Practicing veterinarians, animal health technicians, and students in other veterinary programs will also be able to access the database directly through the Web, although it is password protected. To assess whether this WCVM parasitology resource has wider application in veterinary education, parasitologists at the School of Veterinary and Biomedical Sciences at Murdoch University in Western Australia are participating in its development and evaluation. Information and expertise sharing initiatives, such as this parasitology database, provide HCI-based collaboration opportunities for learners, educators, researchers, and practitioners.

In the departments of Small and Large Animal Clinical Sciences, a number of TEL projects have been developed including interactive, self-learning CD-ROMs, and DVDs, developed as alternatives to traditional laboratory manuals and live-animal teaching demonstrations. To date, this resource set includes Passing a Nasogastric Tube in the Horse, Canine and Feline Medical Exercises, Medical Imaging, and Basic Anesthetic and Surgical Principles. Equine Medicine and Canine Orthopedics resources are in development, and a proposal for the creation of a case-based interactive electronic learning environment for bovine disease diagnosis has been funded. In addition to meeting the needs of undergraduate students, the clinical science CAL resources have been designed to support learners enrolled in other veterinary colleges, the veterinary technology program at the Saskatchewan Institute of Applied Science and Technology, for continuing education credit options for practitioners and foreign graduates seeking practicing licenses in Canada, as well for workers in the beef-ranching community. Many of the completed instructional resources have been the focus of educational effectiveness research projects.

A major goal of many of the clinical science CAL projects is to reduce the number of live
animals used in teaching, thus promoting animal welfare, while continuing to provide highly relevant clinical material. To confirm that the approaches to creating and implementing these CAL modules were educationally sound, project members adopted a stance of research-based educational practice. Team members investigated current literature on veterinary education, active learning, and problem-based learning. While problem-based and active learning have become buzzwords in teaching-oriented journals (Hines et al., 2005), the instructional designers and WCVM faculty (Naylor, 2005) specifically employed Dale’s active learning model (see Figure 1).

Learning effectiveness studies suggest that knowledge retention improves with the number of senses stimulated and the degree of active involvement in the learning process (Dale, 1969; Peal & Wilson, 2001). Older methods of teaching often score poorly on the active-passive scale. Traditional lectures, where the professor verbally recites a synopsis of facts that the student copies, stimulate few senses and provoke little mental involvement. The degree of complexity in this task can be increased if the student has to mentally summarize the information before transcribing; however, new technologies make more effective learning methods possible. Computer-based presentations provide a method for accessing and displaying different types of material so that a variety of sensual stimuli can be used to improve retention. In addition, computer-based presentations offer a means of establishing relevance by incorporating actual recorded clinical case material into the presentation. Another benefit of computer-based models is the ability to add specific active learning exercises, which challenge the student, focus the learning, and give immediate feedback.

Accurate characterization of visual, auditory, or tactile phenomena is difficult using purely verbal or text-based descriptions. With paper-based books, this can be partially rectified by inserting annotated diagrams or images, but traditional books cannot reproduce sound or movement. As a result, meaning is lost, and learning may be misdirected. For example, an evaluation of the ability of veterinarians to describe and interpret common equine heart sounds found a lack of a common vocabulary, but not a lack of vocabulary.

**Figure 1. Active learning model (Adapted from Dale, 1969)**

![Active Learning Model Diagram](image-url)
In other words, wide varieties of words were used in an inconsistent and sometimes contradictory fashion (Naylor, Wolker, & Pharr, 2003); in addition, there was a lack of interpretive skills when the clinicians were played recordings of heart sounds from horses with common clinical arrhythmias (Naylor, Yadernuck, Pharr, & Ashburner, 2001).

Text, audio, still photos, medical illustrations, and video demonstrations are incorporated into the clinical science CAL projects. Active learning is stimulated with interactive case simulations or technical problem solving exercises. Veterinary students are asked to work through these materials and complete formative evaluation exercises before performing these techniques on live animals in the teaching hospital. This is regarded as both an example of good learning practice and of attention to animal welfare.

The emergent pedagogical foci on problem-based and active learning were also considered in some modules. This was done by first presenting a clinical case, accompanied by the usual “ill structured” problems, “similar to tasks a student will face in real world” veterinary practice (Schoenfeld-Tacher et al., 2005). Student learning was supported by access to textual and visual information describing the indications and contraindications of a specific technique, as well as demonstrations of common errors and their consequences.

Research-Based CAL Development: Equine

A self-learning computer module, How to pass a nasogastric tube in the horse, was developed by a team of veterinarians, along with instructional designers, and multimedia specialists. The computer-based learning module includes sections on indications for the technique, needed equipment, relevant anatomy, detailed instructions for performing the procedure, and common errors and complications. Each section consists of learning objectives and instructional text, supplemented with a combination of synchronized video clips of endoscopic and external camera views, audio, still photographs, and medical illustrations. The module concludes with an electronically scored student self-test, in which test questions are based upon both text and images (Naylor & Abutarbush, 2004).

The development of this module occurred over a two-year time-period. First, a WCVM faculty member and a resident (clinical graduate student) conducted an extensive literature review and clinical review of anatomy. From this basis, an initial project concept was developed. An exploration of ways to teach nasogastric intubation (NGI) resulted in the selection of synchronous video endoscopy of the internal and external passage of the stomach tube in living horses and dead horses, as well as photography of clinical specimens and medical illustrations.

A clinical resident, with the support of a WCVM faculty member, developed the first draft of the written content for the module. At this point, an instructional designer was added to the team to construct a project blueprint. In collaboration with media specialists, the team expanded the instructional design blueprint into a detailed storyboard, which identified text, visual, audio, and video components and sequences, as well as interactive elements. Illustrations were collaboratively developed by the faculty member, the resident, and a medical illustrator. Instructional objectives were aligned with student performance expectations and evaluation techniques. Media specialists collaborated with the team to select appropriate technologies, add to the overall concept of the project, gather, compile, and edit the video clips, and produce the visual design and navigation of the CAL learning environment. A multimedia programmer used Macromedia Director MX and Macromedia Flash MX to bring each of these elements together in an interactive
Integrating Human Computer Interaction in Veterinary Medicine Curricula

Throughout this process, the instructional designer tracked the overall progress of the project, adjusted the project blueprint and milestones, as required, and distributed updated documentation to group members.

Prior to the release of the CD-ROM for student use, a double blind, monocentric study involving 52 third-year student-participants in the Doctor of Veterinary Medicine program was conducted. The objective of this study was to evaluate the effectiveness of the NGI self-learning computer module compared with the effectiveness of traditional demonstration-based instruction (Abutarbush, Parchoma, Petrie, & Naylor, 2004). Participants were randomly assigned to control (traditional demonstration) and experimental (CAL) groups. Both groups received the same amount of instructional time.

In the NGI study, quantitative and qualitative data were collected and analyzed. Quantitative data were collected via student self-reports on a 5-point Likert scale (5-strong preference for CAL to 1-strong preference for traditional instruction). Twenty-six percent of participants reported either a preference or a strong preference for traditional instruction; 26% reported a preference for CAL; and 48% reported no preference. A comparison of the groups showed that within the control group the mean preference for CAL was slightly lower (2.57) than in the CAL group (3.29). However, the independent samples t-test showed no significant difference in preference between groups.

Learner confidence in mode of instruction received was measured using three questions. The overall quality of instruction was rated as high by 42.6% of all participants and very high by 57.4%. There was a mean rating of 4.6 on the 5-point scale for organization of instruction in the control group and 4.5 in the experimental group. High (46.8%) and very high (57.4%) levels of student-participant confidence in their preparedness to perform the naseogastric intubation procedure were reported. The group means for their level of confidence were 4.39 and 4.67 on the 5-point scale for the control and CAL groups respectively. Again, t-test results showed no significant difference between groups.

Encouragingly, the audio and visual clips on the CD were rated as being significantly better than the live horse demonstration in helping students learn to perform the procedure. Median values were 4 and 5 for the control and CAL groups respectively.

Participant achievement levels were measured by student scores on a knowledge quiz and during practical evaluations of performance of the technique. Each student-participant performance of the technique was videotaped from two camera angles. Two evaluators reviewed the videotapes and assessed student performances. Proficiency of technique performances was measured using an evaluation rubric (see Appendix A). Evaluators had no knowledge of which group individuals had been assigned.

Data collected from the knowledge quiz results and evaluation rubric were analyzed using descriptive statistics, non-parametric tests: the Wilcoxon Rank Sum and Chi-square, with the help of a computerized statistical package, Student Statistix 7 (Abutarbush et al., 2004). Quantitative results showed students in the CAL group performed better on the test of knowledge (median scores out of 10 were 9.67 for the CAL group and 8.1 for traditional demonstration group; analysis of significant difference resulted in P<0.001) (Abutarbush et al., 2004). In the assessment of the students’ practical ability, there was no significant difference in the number of attempts or number of times assistance was required during the performance of the procedure. The number of technical errors between the two groups was found to be consistent by both evaluators. However, the students in the CAL group needed significantly less time to perform the procedure than did the traditionally instructed group (Abutarbush et al., 2004). A reduction in time to complete the
performance of the procedure reduces stress to the horses, and therefore, contributes to improved animal welfare.

Following the experiment, student comments on their experiences in the evaluative study were gathered via conducting two semi-structured focus group debriefing sessions: one for volunteers from the control group, and one for volunteers from the experimental group. The focus groups were facilitated by the instructional designer, rather the faculty from the WCVM in order to ensure students felt able to comment freely, without concern for faculty members’ responses to individual comments.

Focus group transcripts were made anonymous, coded, and analyzed prior to results being shared with faculty members. The results of these focus group sessions contributed to refinements of the NGI CAL module, as well as to subsequent educational research directions.

As a follow-up to the pilot use of the NGI resource, a faculty member who was not yet involved in either the CAL development or the associated research study was interviewed after using the CD-ROM to teach the technique. A summary of the interview follows:

As a new faculty member at WCVM, I had not participated in development of the CAL module and had not taught the laboratory previously. I had reviewed the module prior to teaching the laboratory and compared it to my own experiences with the procedure.

I purposely limited instruction to the students reviewing the CD module without additional verbal instruction or demonstration of the procedure. It was intended to have each student review the CD individually; however, due to technical problems in the computer laboratory, several students had to share computers and review the CD as a group. Following review of the CD, I only provided logistical information, such as how many students were to work on any one horse, and gave instructions pertaining to safety measures. The students then proceeded to pass nasogastric tubes, with instructors present to answer questions and provide help as needed.

The students reviewed the CD module very willingly and completed most of the module in the time given. Most students had not reviewed the CD module prior to the lab. Several students volunteered positive feedback pertaining to the quality of the module. It was interesting to observe students reviewing the module as a group or individually; while students reviewing the module individually tended to complete it step by step, much discussion arose in the groups sharing one module and students explained to each other what was unclear to them and highlighted important points.

During the practical portion of the laboratory, all students were able to pass a nasogastric tube successfully in the time allotted, and no major problems, such as significant bleeding in the teaching horses arose. I was pleasantly surprised by this outcome as I had expected problems and remembered my frustration of not being able to complete the procedure as a veterinary student myself. The students approached the procedure without much hesitation and appeared to recall most of the instructions given on the CD. Help was needed mostly when problems arose with restraint of horses, or to reassure students that they had completed the procedure successfully.

It was again very interesting to observe interactions between students. Five to six students worked on one horse and took turns completing the procedure. Students who had already completed the procedure could overhear recounting their experiences and providing advice to their peers. The quality of their explanations was as good, if not better, than that I could have given myself, especially as students could relate to the initial insecurities much better than a more experienced person. Following the laboratory, several students asked to check out the CD module for additional review.
This was my first experience using a CAL module for student instruction and it was a very positive experience. I have since become involved with development of additional modules to teach equine procedures, and am looking forward to using them in future medical exercises laboratories.

Documentation of the learning benefits of CAL in the NGI study and continuing student and faculty enthusiasm for the use of the NGI resource prompted faculty interest in developing more CAL modules. The Department of Large Animal Clinical Science has undertaken a new and more ambitious project, Techniques in Equine Medicine. This project is slated to include modules on performing a number of diagnostic techniques including transtracheal wash, pleurocentesis, liver biopsy, abdominocentesis, urine collection, and cerebrospinal fluid collection from atlanto-occipital and lumbosacral sites.

The Techniques in Equine Medicine project completion date is projected for 2007. While this project is much greater in scope than the NGI project, the lessons learned in the NGI development, as well as elements, such as the learning environment’s structures, functionalities, and visual design will be reused, thus creating time and cost efficiencies.

Research-Based CAL Development: Canine and Feline

A self-learning computer module, Canine and Feline Medical Exercises, was developed by a veterinarian at the WCVM who was not involved in the NGI module in conjunction with a University of Saskatchewan team of instructional designers and media specialists. The development of this project took place over the course of three years, and an educational study is underway to evaluate the modules. The canine-feline medical exercises CAL modules were structured similarly to the NGI design, but a series of adaptations were made to accommodate multiple exercises. Five systems were identified (respiratory, gastrointestinal, urinary, dermatology, joints), and the important diagnostic and sample collection techniques taught to veterinary students for each system were determined.

Each of the 28 technique modules was designed to include the following components:

- A list of indications and contraindications for performing the technique
- A link to a case description to illustrate where the technique was successful in obtaining a diagnosis or influencing therapy
- A list and photographs of the specialized equipment necessary to perform the technique
- A step-by-step written description of the technique paired with digital photographs (with anatomic landmarks labeled) and/or drawings illustrating each important step of the procedure; the written description was then followed by a narrated videotape of the procedure as it was performed, re-emphasizing the important points already discussed
- A description of appropriate sample handling, submission for analysis, and (where appropriate) interpretation of results
- A list of possible complications of the technique
- Self-tests emphasizing key anatomic landmarks or details of the techniques

A detailed list of the digital still photos and video requirements needed was prepared for each technique. Instructional designers formatted all of this information into a course design map. This map clearly defined the learning objectives, and the content, activities, and media requirements for each objective. The design map was then circulated among the development team for approval.

Following the development of the design map, the faculty member met several times with an in-
structional designer to blueprint each procedure. The blueprint provided the media team with the information it needed to produce the final product. Each screen of the final product was sketched. The media team knew exactly what was required to appear on each screen and the written text to accompany it. The completed blueprints were sent to the media team and the design team.

Video footage and still digital photos were taken during two days of demonstrations of the techniques. Once the raw material had been gathered, the media team began to edit and assemble the pieces. Errors and omissions were discovered and corrected. A multimedia programmer used Macromedia Director MX and Macromedia Flash MX to bring each of these elements together in an interactive learning experience.

Five fourth-year veterinary students and two veterinary technicians, under the guidance of an instructional designer, user-tested the set of two CD-ROMs. User testing resulted in a series of revisions and improvements to the modules. These revisions included additional feedback to learners on their performance in interactive exercises and self-tests.

As an extension of the NGI research study into the educational effectiveness of WCVM’s CAL resources, the research study into the Canine and Feline Medical Exercises modules will investigate student learning styles, student preferences, and module effectiveness as a learning tool. This direction has been taken, in part, because student-participants in the NGI study reported individual learning style as a variable in learner preferences for traditional or CAL-based instruction. A literature review was undertaken, and peer-reviewed articles that support the student reports were identified (Buchanan, Carter, Cowgill, Hurley, Lewis, MacLeod, Melton, Moore, Pessah, Roberson, Robertson, Smith, & Vadenplas, 2005; Dale, Nasir, & Sullivan, 2005; Schoenfeld-Tacher, McConnell, & Schultheiss, 2003). The Canine-Feline study compares traditional versus CAL instruction. In addition, research team members want additional insight into the effect of learning styles on student responses to CAL resources and will attempt to discover if individual learning-style preferences are a significant variable in instructional mode preference or in student achievement.

Fifty-eight third-year veterinary students agreed to participate in the Canine-Feline research study. The research design included quantitative and qualitative research methodologies. The research team assigned all participants numbered codes to insert in the identity portion of the online version of the Felder-Silverman Index of Learning Styles (ILS) measurement instrument, and all student participants completed the ILS questionnaire to establish their learning style. Participants were assigned to experimental (CAL) and control (traditional laboratory manual) groups using block randomization. Participants were divided into four groups based on their learning styles and then randomized within groups. No member of the faculty of Veterinary Medicine knew which students or codes had been assigned to control or experimental groups.

The ILS measurement instrument has been rigorously tested via multiple studies across post-secondary disciplines and institutions for reliability and validity. Reliability and validity results have been published in peer-reviewed, scholarly publications (Litzinger, Lee, Wise, & Felder, 2005). Results of the ILS measurement instrument are only considered valid and reliable when the instrument is used to help instructors “to achieve balanced [learning-style] course instruction” and to “help learners understand their learning strengths and areas for improvement” (Felder & Spurlin, 2005, pp. 110-111). In this study, the researchers will use participant scores on the ILS for the purpose of seeking further information on the comparative effectiveness of traditional and computer-assisted modes of instruction for students with different learning styles as well as evaluating the impact of learning styles on
learning-mode preference. It is anticipated that the results of this study will have an impact on the design and development of future products to support student learning in HCI environments.

Participants were asked to complete a short survey, including mode-of-instruction-preference questions with responses selections on a Likert scale. Likert scale results will be compared to ILS measurement results in order to investigate potential linkages between learning styles and learning mode preferences. The correlation between learning styles and learning mode of instruction preference will be examined using Spearman’s correlation coefficient.

The association between learning styles and achievement will be assessed using regression analysis. Learning styles will be measured along the visual versus verbal continua (Felder & Spurlin, 2005) in order to determine the degree of polarity (or lack of polarity) of individual visual versus verbal learning styles within the participant group. Data analysis will include measures of potential combined effects of self-reported learning preferences and ILS scores. Achievement will be measured using student performance on a standardized practical oral examination.

The question of whether multimodal instruction using the CAL modules results in better achievement in students of particular learning styles will be assessed via regression analysis. The study will specifically examine whether use of the CAL modules or the traditional laboratory manual worked differently for students with different learning styles. Data will be analyzed assessing whether or to what extent instruction modules designed to support individual learning styles might interact with learner achievement.

The results of the Canine and Feline Medical Exercises CAL study will post-date the publication of this chapter. The research team hopes to use the evidence gathered to identify ways to improve future instructional design and development to better meet WCVM learner needs.

CONCLUSION

Given the significant challenges and pressures influencing veterinary colleges, teaching hospitals, and educators, new strategies for providing high quality learning must be considered. CAL is an effective tool that can be used to enhance the veterinary curriculum and provide increased student access to clinical material while reducing the unnecessary use of live animals in teaching. The CAL-based veterinary medical learning resources developed at the WCVM represent a collaborative effort between the veterinary clinicians and researchers who conceived each project and served as content experts and the instructional designers, media specialists, and multimedia programmers who fine-tuned each project as it was developed. The results of educational research performed on the CAL modules as they have been implemented in the curriculum have already directly influenced the development of future projects integrating HCI into the WCVM curriculum and future directions for research focused on these projects. It is hoped these efforts will contribute to the globalization of the veterinary profession through evidence-based approaches to innovation in the use of HCI in veterinary education.

ACKNOWLEDGMENTS

Research and development projects described in this chapter have been supported by the Government of Saskatchewan’s Technology Enhanced Learning (TEL) initiative, and the Association for Media and Technology in Education in Canada (AMTEC) Trust.

Lily McCaig, a WCVM student, contributed to the literature review and the development of the equine medicine CAL modules.

Juliana Deubner, medical illustrator for the WCVM, prepared all medical images for the CAL learning modules, as well as the figure for the chapter.
Frank Bulk, Gabe Ng, and Wayne Giesbrecht, multimedia developers at the University of Saskatchewan, have contributed their talents to many projects described in the chapter.

APPENDIX A: RUBRIC USED FOR EVALUATION OF STUDENT PERFORMANCE OF NASOGASTRIC INTUBATION

Student # ______________
Tape # / Angle ______/______ (overhead / floor views of camera angle and tape number)
Time frame on tape # _____ / _____ /______ to _____ /_____/______ (OH or FL time-stamp: circle your initials)

<table>
<thead>
<tr>
<th>Time taken to complete the procedure</th>
<th>minutes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of times the student asked for assistance (circle one below)</td>
<td>0</td>
</tr>
</tbody>
</table>

1. Technical Errors in NGI procedure
   - Failed to evert the false nostril
   - Occluded the nostril
   - Left the free end of the tube unattended
   - Incorrect restraint
   - Failed to do measurements
   - Failed to lubricate the tube
   - Failed to stimulate swallowing
   - Failed to kink the tube
   - Bleeding occurred with tube passage
   - Failed to flex the neck/left the neck stretched
   - Failure to perform 3 checks of tube position

2. Tube position checking procedures
   - Ensured correct resistance on the tube
   - Checked whether air could be sucked back
   - Checked whether the tube could be seen moving on the outside of the neck
   - Inflated the esophagus
   - Rattled trachea to see if can feel the tube
   - Checked for sound or smell of stomach gas
   - Had an assistant use a stethoscope to listen for stomach sounds
   - Checked whether the tube could be felt moving on the outside of the neck
   - Coughing not elicited

3. Number of times to successful completion

INTRODUCTION

A portal is defined as an entrance point to online content. The portal concept has evolved across a number of markets and applications. Customer portals focus on individual customer and offer a one-stop Internet access. By providing a number of services, such as searches, shopping, e-mail, and games, portals allow individuals to avoid browsing the Web but to in-fact rely and stay at one Web site like a one-stop shop. Accordingly, portals drive eyeballs, and hence create and drive advertising revenue and alliances. The concept of a single public port to given content on the Internet is used as a means of pulling in a large number of users. As an example, America Online (AOL) acts as a portal site to general Web content. It is a specialized portal created by AOL and also has content from partners such as Time Warner (Kleindl, 2003). This article reviews the role of portals in consumer search behavior and certain aspects in marketing.

PORTALS AND PRODUCT CUSTOMISATION

A key function of marketing is to match buyers and sellers, and facilitate transactions; to do this a firm needs to create the proper institutional infrastructure. It has been found that digital information goods, such as news articles, digital images, or music allow perfect copies to be created and distributed almost without cost via the Internet. With the introduction of the Internet as a commercial medium for businesses to conduct their activities, various studies have found that the technology is leading to aggregation. This, in turn, is fast becoming a profitable strategy for marketers, as the marginal production costs are low and consumers are generally homogenous. Several Internet-based technologies assist buyers searching: multimedia, high bandwidth, and rating sites provide more product information. These search engines can be hierarchical directories like Yahoo, generic tools like Alta Vista (in
early 1998) or specialized tools that work best in the context of specific markets like Pricewatch, ComputerESP for computers, or Expedia and Travelocity for travel (Casagranda, Nicholas, & Stevens, 1998).

Customer portals should provide companyspecific information for customers, such as product information, inventory and order tracking, help desk applications, and other services (Kleindl, 2003). Marketers should begin considering portals as the brains of the organization as they can provide employees with vital information for success in hyper-competitive marketplace, in turn can secure the survival of the organization. The method is cost-effective because portal technology uses artificial agents, tiny programs to find and organize information rather than salaried employees.

Clarke, III and Flaherty (2003) suggest that portals are the most valuable land on the Web. According to them, about 90% of Internet traffic goes to 10% of Web sites, among which portals are the largest shareholders of that traffic. The authors have also found that about 15% of all Web page-view traffic goes through the top nine portals. Hence, this heavy traffic flow creates a unique position for portals as part of the overall marketing strategy of all organizations.

Some suggest that with portal technology it is possible for an individual to buy a newspaper at a local newsagent and this newspaper can be tailored to suit the person’s specific information needs. This newspaper can contain a section on industry news, another on company news, and a third on all financial reports, all of this information may be very relevant to the person. If such a newspaper could be economically produced the reader would not need to buy a whole newspaper to read but just a few pages. Such customization can be achieved economically with portal technology because the artificial agents used in portals are programmed to search and index sites containing information the user specifies as relevant (Kotorov, 2001).

Slywotzky (2000) extends this concept of customization of products and services using portal technology to newer heights. According to the author, customers will soon be able to describe exactly what they want, and suppliers will be able to deliver the desired product or service without compromises or delays. This innovation is what the author calls “choiceboard,” this concept includes interactive online systems that allow individual customers to design their own products by choosing from a menu of attributes, components, prices, and delivery options. The role of the customer in this system shifts from passive recipient to active designer. The shift is just the most recent stage in the long-term evolution of the customers’ roles in the economy.

It was further illustrated that with a choiceboard system, marketers will see a major shift of customers becoming product makers rather than product takers. Traditionally, companies create fixed product lines that represent their best guesses about what buyers will want, and buyers make do with what they are offered. There may be some minor tailoring at the point of purchase—a few optional features or add-ons—but by and large the set of choices is fixed by long before customers even begin to shop (Slywotzky, 2006).

The choiceboard concept became an interactive, online system model, allowing individual customers to design their own products by choosing from a menu of attributes, components, prices, and delivery options. The customers’ selections send signals to the supplier’s manufacturing system that set in motion the wheels of procurement, assembly, and delivery. They are already in use for example; customers can design their own computers with Dell’s online configurator. They can create their own dolls with Mattel’s My Design Barbie, assemble their own investment portfolios with Schwab’s mutual fund evaluator, and even design their own golf clubs with Chipshot.com’s PerfectFit system. This Choiceboard is still in its infancy, as it is involved in less than 1% of the $30 billion world economy (Slywotzky, 2006).
By providing a number of services, such as searches, shopping, e-mail, and games, portals allow individuals to avoid browsing different other Web sites, but to stay at one single portal type site. Since the site drives eyeballs, it in turn will drive advertising revenue and alliances. The concept of a single public port to access content is used as a means of pulling in a large number of users (Kliendl, 2003).

CONSUMER BEHAVIOR AT PORTALS

The growth of the Internet and its immense capability of providing consumers with product and service information has empowered the consumer immensely. Consumers are becoming more mature, sophisticated, and intelligent. These days they are seeking a higher levels of product information before making purchasing decisions. The rapid advancements in Web technology have enhanced consumer’s decision-making outcomes. The creation and subsequent growth of software and technological devices such as smart agents that are linked to portals have provided an intelligent interface for the consumer. These computer decision aids improve transactional efficiency by providing merchandising and sales information to consumers, offering sales support, and facilitating sales promotions, while at the same time, enhancing the consistency, availability, and quality of support to consumers.

In a study to test the relationship between the use of these smart agents, or query-based decision aids (QDBA) as they are referred to, and consumers, it was found that the greater the amount of relevant information the decision maker has, the greater is his or her confidence in judgement. The research study developed and tested a general model for understanding the influence of query-based decision aids on consumer decision making in the e-commerce environment. The results showed that the use of a well designed QDBA led to increased satisfaction with the decision process, and increased confidence in judgements. The research subjects who had access to QDBA perceived an increased cost saving and a lower cognitive decision effort associated with the purchase decision. The conclusion proved that subjects who had access to the QDBA, liked the interface, and had more confidence in their judgements in comparison to subjects who did not have access to QDBA (Pereira, 1999).

In their study, Meisel and Sullivan (2000), found that most Web surfers and shoppers want portals to conduct five important functions as follows:

• provide easy, convenient, and organized way for users to use the Internet;
• act as a filter and hence helping in the decision making process of the purchase online;
• assure users of the integrity of the sites for Web transactions;
• provide users access to propriety content and/or communication technologies like Internet telephony and e-mail; and
• finally, to facilitate the electronic equivalent of one-stop shopping for the user.

Studies have indicated that the main reason individual’s use portals is for gathering information, these fall into two categories namely: personal needs, covering leisure (sport, films, games, specific niche hobbies, chat) medical information, news and politics, local community and historical information; and information gathering, which include the gathering of information for business needs, this can cover technical resource information, academic research and company information. Portals support the information search stage of the buying process; research has found that consumers do make use of portals for the decision-making process in consumption behavior (Michael, 2006).

Hanson (2000) found that most Web users start their online activities at one of the main search
or directory portal sites, hence making portals an important source of traffic that can be obtained for free. Managing an organization’s portal presence requires traffic-building efforts that combine strategic and tactical activities. A key strategic initiative to manage ones portal presence is to classifying a site carefully using proper keywords, descriptors, and categories. This is very important especially for directories that group sites into specific classification systems.

Marketers of portals should work with the directory personnel to make sure that the latter correctly locate the company’s site to provide a steady stream of visitors. Hanson (2000) further suggests that there needs to be a continuous tactical attention to effectively leverage the portals, especially search engines. He states that consumers search using a range of methods these could include things like keywords in search engines, meta-tags, and various other links. These variables should then be kept in mind by marketers and be used strategically with search engines to enable it (search engine) to retrieve proper results for the searcher/surfer. A Web site manager must monitor and improve the chances of material being found and retrieved early in the list of results of these pages.

**CONCLUSION**

Portals as the definition suggests are gateways to the Internet, they should be used as strategic tools in the marketing process. Marketers need to keep abreast as to the growth, potential, and changing nature of these sites which play a key introductory role to Web searchers. They are best summed up as very large aggregators that will become more and more of a one-stop shop for consumers. Portals were one of the first pure e-commerce type companies to focus and create online brands, true examples of these are the popularity of brands such as Yahoo!, Alta Vista, Amazon, Travelocity, and the likes.

It has been found that consumers rely on branded names especially in this mire of products and services that is available over the Internet. Research has also proved that if in doubt, consumers are straightaway attracted to the online brands that are become familiar with, little wonder that Amazon is supposedly the most successful pure online company and brand. Portals have matured to become a key trading exchange intermediary between consumers and businesses, and also between business and other businesses. They (portals) recent focus is now on convenience, price, and variety. In their role as business to business exchanges, portals are rapidly taking the form of creating strategic alliances between like minded companies. It now seems rest assured that portals the gateways will be the key in our future cyber journey.

**REFERENCES**

**KEY TERMS**

**Choiceboard**: This concept includes interactive online systems that allow individual customers to design their own products.

**Directory**: The word directory is used in computing and telephony meaning a repository or database of information.

**Marketing**: A function within an organization, of a set of processes for creating, communicating and delivering value to customers, to benefit the organization and its stakeholders.

**Online**: A term used to describe information that is accessible through the Internet.

**Portal**: An entrance point to online content.

**Search Engine**: A search engine or search service is a program designed to help find information stored on a computer system such as the World Wide Web, inside a corporate or proprietary network or a personal computer.

**Web Surfers**: Consumers who go online, the phrase “surfing the Internet” was first popularized in print by librarian Jean Armour Polly in an article called *Surfing the INTERNET*, published in the Wilson Library Bulletin in June, 1992.

Chapter 4.18
Human Factors in the Development of Trend Detection and Tracking Techniques

Chaomei Chen
Drexel University, USA

Kaushal Toprani
Drexel University, USA

Natasha Lobo
Drexel University, USA

INTRODUCTION

Trend detection has been studied by researchers in many fields, such as statistics, economy, finance, information science, and computer science (Basseville & Nikiforov, 1993; Chen, 2004; Del Negro, 2001). Trend detection studies can be divided into two broad categories. At technical levels, the focus is on detecting and tracking emerging trends based on dedicated algorithms; at decision making and management levels, the focus is on the process in which algorithmically identified temporal patterns can be translated into elements of a decision making process. Much of the work is concentrated in the first category, primarily focusing on the efficiency and effectiveness from an algorithmic perspective. In contrast, relatively fewer studies in the literature have addressed the role of human perceptual and cognitive system in interpreting and utilizing algorithmically detected trends and changes in their own working environments. In particular, human factors have not been adequately taken into account; trend detection and tracking, especially in text document processing and more recent emerging application areas, has not been studied as integral part of decision-making and related activities. However, rapidly growing tech-
nology, and research in the field of human-computer interaction has opened vast and, certainly, thought-provoking possibilities for incorporating usability and heuristic design into the areas of trend detection and tracking.

**BACKGROUND**

In this section, we briefly review trend detection and its dependence on time and context, topic detection and tracking, supported by instances of their impact in diverse fields, and the emerging trend detection especially for text data.

**Trend Detection**

A trend is typically defined as a continuous change of a variable over a period of time, for example, unemployment numbers increase as the economy enters a cycle of recession. Trend detection, in general, and topic detection techniques are groups of algorithmic tools designated to identify significant changes of quantitative metrics of underlying phenomena. The goal of detection is to enable users to identify the presence of such trends based on a spectrum of monitored variables. The response time of a detection technique can be measured by the time duration of the available input data and the identifiable trend; it is dependent on specific application domains. For example, anti-terrorism and national security may require highly responsive trend detection and change detection capabilities, whereas geological and astronomical applications require long-range detection tools. Other applications of this technology exist in the fields of business and medicine.

Much research has been done in the field of information retrieval, automatically grouping (clustering) documents, performing automated text summarization, and automatically labeling groups of documents.

Policy makers and investigators are, obviously, eager to know if there are ways that can reliably predict each turn in the economy. Economists have developed a wide variety of techniques to detect and monitor changes in economic activities. The concept of business cycles is defined as fluctuations in the aggregate economic activities of a nation. A business cycle includes a period of expansion, followed by recessions, contractions, and revivals. Three important characteristics are used when identifying a recession: duration, depth, and diffusion — the three Ds. A recession has to be long enough, from a year to 10 years; a recession has to be bad enough, involving a substantial decline in output; and a recession has to be broad enough, affecting several sectors of the economy.

**Topic Detection and Tracking**

*Topic Detection and Tracking* (TDT) is a sub-field primarily rooted in information retrieval. TDT aims to develop and evaluate technologies required to segment, detect, and track topical information in a stream consisting of news stories. TDT has five major task groups: (1) story segmentation, (2) topic detection, (3) topic tracking, (4) first story detection, and (5) story link detection. Topic detection focuses on discovering previously unseen topics, whereas topic tracking focuses on monitoring stories known to a TDT system. First story detection (FSD) aims to detect the first appearance of a new story in a time series of news associated with an event. Roy, Gevry, and Pottinger (2002) presented methodologies for trend detection. Kontostathis, Galitsky, Roy, Pottinger, and Phelps (2003) gave a comprehensive survey of emerging trend detection in textual data mining in terms of four distinct aspects: (1) input data and attributes, (2) learning algorithms, (3) visualization, and (4) evaluation.
TDT projects typically test their systems on TDT data sets, which contain news stories and event descriptors. The assessment of the performance of a TDT algorithm is based on Relevance Judgment, which indicates the relevancy between a story and an event. Take the event descriptor Oklahoma City Bombing as an example. If a matching story is about survivors’ reaction after the bombing, the relevance judgment would be Yes. In contrast, the relevance judgment of the same story and a different event descriptor U.S. Terrorism Response would be No. Swan and Allan (1999) reported their work on extracting significant time varying features from text based on this type of data.

An interesting observation of news stories is that events are often reported in burst. Yang, Pierce, and Carbonell (1998) depicted a daily histogram of story counts over time. News stories about the same event tend to appear within a very narrow time frame. The gap between two bursts can be used to discriminate distinct events.

Kleinberg (2002) developed a burst detection algorithm and applied to the arrivals of e-mail and words used in titles of articles. Kleinberg was motivated by the need to filter his e-mail. He expected that whenever an important event occurs or is about to occur, there should be a sharp increase of certain words that characterize the event. He called such sharp increases bursts. Essentially, Kleinberg’s burst detection algorithm analyzes the rate of increase of word frequencies and identifies the most rapidly growing words. He tested his algorithm on the full text of all the State of the Union addresses since 1790. The burst detection algorithm identified important events occurring at the time of some of the speeches. For example, depression and recovery were bursty words in 1930-1937, fighting and Japanese were bursty in 1942-1945, and atomic was the buzz word in 1947 and 1959.

**EMERGING TREND DETECTION (ETD)**

**ETD for Text Data**

Unlike financial and statistical data typically found in an economist’s trend detection portfolio, ETD in computer science often refers to the detection of trends in textual data, such as a collection of text documents and a stream of news feed. ETD takes a large collection of textual data as input and identifies topic areas that are previously unseen or are growing in importance with in the corpus (Kontostathis et al., 2003). This type of data mining can be instrumental in supporting the discovery of emerging trends within an industry and improving the understanding of large volumes of information maintained by organizations (Aldana, 2000). In the past few years, many companies have been storing their data electronically. As the volume of data grows, it will hold information, which if analyzed in the form of trends and patterns, can be valuable to the company, provided it is appropriately and accurately extracted. By using ETD, companies can extract the meaningful data and use it to gain a competitive advantage (Aldana, 2000). ETD provides a viable way to analyze the evolution of a field. The problem switches from analyzing huge amounts of data to how to analyze huge amounts of data.

**The Role of HCl in ETD**

ETD systems are complicated to make and understand, thus there are many HCI issues that must be considered. First of all, the system should let the user define what an emerging trend is. In general, an emerging trend can be defined as a significant quantitative growth over time. However, what counts as significant should not be entirely determined by computer algorithms.
Many ETD algorithms have different threshold levels to define a topic as an emerging trend. Thus threshold levels should not be fixed and unchangeable for a system. Also, the user should be able to define what documents are in the data corpus. Additionally, the algorithm should be hidden from the user. Ideally, the system would take its inputs and produce the outputs. When the user is given information, pertaining to inputs and outputs, sufficient amounts of user guidance should be provided. The design of an ideal user interface of a computer-based information system should be intuitive and self-explanatory. Users should feel that they are in control and they can understand what is going on. Despite the technical complexity of an underlying algorithm, the user interface should clearly convey the functions to the user (Norman, 1998).

Once a new trend is found, the system should include some mechanisms to define the essence of the new trend. A text summarization algorithm is a possible solution to this problem. Text summarization is capturing the essence of a data set (a single paragraph, document, or cluster) after reviewing the entire data set and producing output that describes the data set.

Once the data corpus is scanned, the user should be provided with feedback about the corpus. The user should be provided with information like the number of documents found, number of topics (or trends) found, number of new trends found, and other related information. For example, the system studied by Masao and Kôiti (2000), produces an entity-relationship (ER) graph showing the relation of topics. This not only shows the user what new trends were found, but also shows how they are related. ETD systems should also support an adaptive search mechanism. Users should have the option of providing keywords to search for emerging trends in specific fields.

Applications

Automatic trend detection has benefited a wide range of applications. An analyst will find emerging trend detection techniques useful in his area of work. The most generic application is to detect a new topic in a field and track its growth and use over time (Roy et al., 2002). Two examples are cited in the following sections.

European Monitoring Center for Drugs and Drug Addiction (EMCDDA)

The EMCDDA was disappointed when it realized that it failed to recognize the emerging trend in the use of the drug ecstasy. “...earlier identification of new drug consumption patterns would allow more time to assess the likely impact of such changes and, therefore, facilitate the earlier development of appropriate responses” (EMCDDA, 1999). With an effective trend detection system, agencies like the EMCDDA can prepare for and prevent the associated problems with a drug epidemic. However, with the number of documents in some databases reaching over 100,000 a manual review of the data is impossible.

XML

The emergence of XML in the 1990s is shown in Figure 1 in terms of the growing number of articles published each year on the second-generation language of the World Wide Web. Market and field analysts will find such knowledge of an emerging trend particularly useful. For instance, a market-analyst watching a biotech firm will want to know about trends in the biotechnology field and how they affect companies in the field (Kontostathis et al., 2003).

Stock market analysts rely on patterns to observe market trends and make predictions. In
The general goal is to identify patterns from a corpus of data. In the past, analysts have relied on the human eye to discover these patterns. In the future, trend and topic tracking systems can take over this role, thus providing a more efficient and reliable method for stock market analysis.

**FUTURE TRENDS**

The future is promising for HCI concepts to be heavily embedded in the analysis and design of emerging trend detection (ETD) systems. Powerful data modeling techniques can make salient patterns clearer and in sharper contrast. Some of the major technical problems are how to make the changes over time easy to understand and how to preserve the overall context in which changes take place.

ThemeRiver is a visualization system that uses the metaphor of a river to depict thematic flows over time in a collection of documents (Havre, Hetzler, Whitney, & Nowell, 2002). The thematic changes are shown along a time line of corresponding external events. A thematic river consists of frequency streams of terms; the changing width of a stream over time indicates the changes of term occurrences. The occurrence of an external event may be followed by sudden changes of thematic strengths. On the one hand, searching for an abruptly widened thematic stream is a much more intuitive task to detect a new story than text-based TDT systems that can only report changes in terms of statistics.

There are many things to keep in mind while developing an HCI-friendly ETD system. The basic usability goals can be used as a guideline to producing a user-friendly ETD system. By striving to make a system learnable, efficient, memorable, keep errors under control, and give the user satisfaction from using the system, the foundation for an HCI friendly system is laid. Table 1 defines each of the usability goals and how they can be applied in an ETD system.
**Human Factors in the Development of Trend Detection and Tracking Techniques**

Table 1. Usability goals and how to apply them to ETD

<td>“How much users like the system” (ROZANSKI &amp; HAAKE 2003)</td>
<td>The users should be able to accomplish their goals without frustration.</td>
</tr>
</tbody>
</table>

A set of usability heuristics, proposed by Jakob Nielson (n.d.), can also pose as a good rule of thumb (see Table 2).

Task analysis is a detailed description of an operator’s task, in terms of its components, to specify the detailed human activities involved, and their functional and temporal relationships (HCI Glossary, 2004). By having users describe their process, step-by-step designers can learn much about the user’s behavior. When conducting task analysis, have the users describe “the steps they would follow, the databases and tools they would use, and the decision points in the process” (Bartlett & Toms, 2003).

**CONCLUSION**

Emerging trend detection is a promising field that holds many applications. However, for ETD systems to reach their full potential, they must be effective, easy to learn, easy to understand, and easy to use. A poorly-designed system will shun users away from this technology. It is important to remember that ETD systems are interactive systems. An ETD system, that just takes a data corpus and scans it, is not an effective one. Users must be able to define and experiment with thresholds, view feedback about the data corpus, and be able to understand new trends.

**Human Factors in the Development of Trend Detection and Tracking Techniques**

**KEY TERMS**

**Burst Detection**: The identification of sharp changes in a time series of values. Examples of bursts include the increasing use of certain words in association with given events.

**Information Visualization**: A field of study aims to utilize human’s perceptual and cognitive abilities to enable and enhance our understanding of patterns and trends in complex and abstract information. Computer-generated 2- and 3-dimensional interactive graphical representations are among the most frequently used forms.
**Intellectual Turning Points:** Scientific work that has fundamentally changed the subsequence development in its field. Identifying intellectual turning points is one of the potentially beneficial areas of applications of trend detection techniques.

**Paradigm Shift:** A widely known model in philosophy of science proposed by Thomas Kuhn. Paradigm shift is regarded as the key mechanism that drives science. The core of science is the domination of a paradigm. Paradigm shift is necessary for a scientific revolution, which is how science advances.

**Topic Detection and Tracking:** A sub-field of information retrieval. The goal is to detect the first appearance of text that differs from a body of previously processed text, or to monitor the behaviour of some identified themes over time.

**Trend:** The continuous growth or decline of a variable over a period of time.

**Trend Detection:** Using quantitative methods to identify the presence of a trend. A number of domain-specific criteria may apply to determine what qualifies as a trend, for example, in terms of duration, diversity, and intensity. Primary quality measures of trend detection include sensitivity and accuracy.

**Turning Point:** A turning point marks the beginning or the end of a trend. For example, the point at which economy turns from recession to growth.
Chapter 4.19
The Internet, Health Information, and Managing Health: An Examination of Boomers and Seniors

Christopher G. Reddick
The University of Texas at San Antonio, USA

ABSTRACT
This article examines the use of the Internet for gathering health information by boomers and seniors. This study attempts to determine whether online health seekers (individuals that have Internet access and have searched for health information online) have changed their behaviors from the information they found online. Essentially, has online health information helped them to manage their health more effectively? This research analyzes the Kaiser Family Foundation e-Health and the Elderly public opinion dataset of access by boomers and seniors to online health information. The major results indicate that boomers marginally use online health information more than seniors for the management of their health. The most significant results indicated that boomers and seniors who are more aware and have positive feelings toward online health information would use it more to manage their health.

INTRODUCTION AND BACKGROUND
For baby boomers, the Internet has become the most important source of health information other than consultation with their family doctor (Kaiser Family Foundation, 2005). The focus of this article is on both baby boomers, those in the age range of 50 to 64, and seniors, or those 65 and older. This study examines the use of online health information by baby boomers and seniors and how they use the information for managing their health. The primary objectives of this article are to examine the differences in behavior between boomers and seniors and to test for the presence of a variety of associations among their characteristics and a number of management of health variables.

This study explores five specific questions. First, are there any differences between boomers and seniors and their access to health informa-
tion for managing health? Second, will healthier boomers and seniors rely less on online health information in order to manage their health because they would have less need? Third, will the presence of boomers and seniors that have more experience and familiarity with the Internet lead to greater use of online health information to manage health? Fourth, will individuals who are in a lower sociodemographic status rely less on online health information because of lack of resources to access this information? Finally, will avid Internet users use online health information more often to manage their health because they would have greater access to and familiarity with the Internet?

The American health care system is different from many Western countries, since it is administered primarily by the private marketplace. The majority of the United States population contracts with a private provider for his or her health insurance coverage. Medicare is a federal health insurance program for people age 65 and older. In addition, Medicaid, a program sponsored by the federal government and administered by states, is intended to provide health care and health-related services to low-income individuals. However, there are millions of Americans who do not fit into either the Medicare or Medicaid plans and, essentially, remain uninsured. Online health information is especially important, given the millions of uninsured Americans trying to get information on their health situation. Individuals can use this online health information to make informed choices on their health care needs. They potentially can use information on the Internet to better manage their health.

Essentially, has online health information influenced the behaviors of boomers and seniors with respect to their health care needs? This influence could be as extensive as visiting a doctor or simply talking to family or friends about health information that a boomer or senior found online.

Access to timely and reliable information on health and health care long has been a goal for seniors, who face a greater number of health conditions and use prescription drugs and health care services at a higher rate than younger adults (Kaiser Family Foundation, 2005). However, the online behavior of seniors has not been studied as closely as that of health information searches of adolescents (Gray, Klein, Noyce, Sesselberg, & Cantrill, 2005), women (Pandey, Hart, & Tiwary, 2003), cancer patients (Eysenbach, 2003; Ziebland, 2004), those affected by the digital divide (Skinner, Biscope, & Poland, 2003), and those that compare online and off-line behavior (Cotton & Gupta, 2004). There is little empirical research that examines whether online health searches affect the management of health (Lueg, Moore, & Warkentin, 2003; Nicholas, Huntington, Williams, & Blackburn, 2001), one of the two objectives of this study. This study measures whether Internet health information changed the self-reporting behavior of boomers and seniors and does not specifically address change in health outcomes.

There are two reasons why this study does a comparison of both boomers and seniors. First, baby boomers represent future seniors, and by examining this age group, this study can provide some indication about what the future holds for the Internet and health information. Second, both boomers and seniors are in the greatest need of health information, since they are more prone to have health problems than other age groups.

This study is different from existing works of Nicholas et al. (2001), Lueg et al. (2003), and Huntington et al. (2004), since it focuses on the use of online health information in the management of health. This study focuses especially on comparing two groups, boomers and seniors, while the existing empirical work examines the entire Internet population. This study is different from studies that conduct a meta-analysis, which combine published results from different sources (Eysenbach, 2003). This research performs a statistical analysis that leads to conclusions that are different from the original dataset (Kaiser
Family Foundation, 2005). The aim of this study is not just to learn about the differences between boomers and seniors and access to online health information; it is to discern the magnitude of differences between these groups and the impact of factors such as awareness and feelings on health management.

In order to accomplish the goal of examining online health information and the management of boomers’ and seniors’ health, this article is divided into several sections. First, this research examines the literature on the use of the Internet as a health information source. Second, this article outlines how the literature can be summarized into hypotheses that model the most probable impacts on management of boomers’ and seniors’ health. Third, this research provides details of the Kaiser Family Foundation’s e-Health and the Elderly dataset that is used to model public opinion data of online health information (Kaiser Family Foundation, 2005). The fourth and fifth sections discuss the models and results of tests on the use of online health information for health care management. The sixth section provides a discussion that outlines how the test results confirm or deny the specified hypotheses and shows the broader significance of this work. The last section provides avenues for future research and presents limitations of this study.

**LITERATURE REVIEW**

The following section outlines the common themes found in the literature on the Internet and health information and the management of health. They can be divided into the factors of differences between age groups, the health of the individual, online proficiency, sociodemographic characteristics, and awareness and feelings about online health information. Existing research shows that little is known about how Internet usage, health status, and sociodemographic characteristics affect health information seeking (Cotton & Gupta, 2004).

Eysenbach (2003) provides a conceptual framework of the possible link between Internet use and cancer. Some of the important factors, according to that author’s meta-analysis, indicate that Internet use is related to communication, community, and content, leading to an impact on cancer outcomes. In a similar line of inquiry, a study by Lueg et al. (2003) provided a conceptual framework of Internet searches for online health information. These authors examine the situations with which individuals find themselves confronted in terms of health needs and frequency of use, predicting access to health information. Eysenbach’s (2003) conceptual framework is different from Lueg et al. (2003), in that the former examines the social

---

Figure 1. Conceptual framework of access to online health information by boomers and seniors
aspects of Internet use and health information, while the latter study focuses on the situation involvement and the frequency of Internet use. The conceptual framework of this study is similar to Eysenbach (2003) and Lueg et al. (2003) but differs, in that it examines boomers and seniors and factors such as frequency and satisfaction having an influence on the management of health (Figure 1).

Online Health Information and Managing Boomers’ and Seniors’ Health

If the Internet can be used to change the behavior of individuals, this is one assessment of the long-term utility of this information resource. If individuals just look at information online and do not use it in any substantial way, it does not make much sense to invest in Internet health resources. The Internet suggests a remarkable change from the traditional doctor-knows-best approach (Eysenbach & Jadad, 2001). The Internet can be seen as challenging hierarchical models of information sharing, in which the provider of the information decides how the information should be delivered (Ziebland, 2004).

For example, existing research in a 2001 survey showed that 44% of online health information seekers said that the information they found online affected a decision about how to treat an illness or to cope with a medical condition (Fox & Rainie, 2002). A majority of respondents to a survey of adolescents and use of Internet health information reported that it helped them to start a conversation with a lay or professional medical person (Gray et al., 2005). Online health information seekers mostly are going online to look for specific answers to targeted questions (Fox & Rainie, 2000). In addition, four out of 10 young people say that they have changed their personal behaviors because of health information that they obtained online (Rideout, 2002). In an Internet survey, more than one-third of the respondents said that their conditions had improved after having visited a Web site, and more than one in four said that the Web information had resulted in a deferred visit or had actually replaced a visit to the doctor (Nicholas et al., 2001). Therefore, the existing research has examined adolescents’ and all age groups’ behavioral changes but has not focused on seniors and their use of the Internet for managing health. There are five factors outlined in the literature, which are differences between boomers and seniors, the health of boomers and seniors, their online proficiency, their sociodemographic characteristics, and awareness and feelings toward online health information that are predicted to have an impact on whether online health information is used.

Boomers’ and Seniors’ Differences

Existing empirical evidence shows that health seekers are proportionately more middle-aged than very young or old, with the highest proportion of usage witnessed in those between the ages of 30 and 64 (Fox & Rainie, 2000). A more recent survey indicates that 70% of baby boomers has gone online in 2004, while only 31% of seniors has gone online (Kaiser Family Foundation, 2005). Boomers will retire shortly, and the amount of online health information for which they will search should increase dramatically compared to what seniors are currently consuming. In order to explore both the present and what the future will hold for online health information and seniors, it is important to compare both age groups. In addition, individuals over the age of 50 may have a greater need for more information on health care than someone much younger because of the greater chance of facing health problems (Brodie et al., 2000).

Health of Boomers and Seniors

The literature also mentions that individuals who are in worse health will want to search more for
online health information. The Internet becomes an additional tool in order for them to search for health information. Empirical evidence shows that there is a link between an individual’s health and his or her need for online health information. Less healthy individuals are more likely to explore different aspects of a Web site and to use more health-related interactive features and, in doing so, improve their well being (Lueg et al., 2003). Individuals who were suffering with an illness were two and half times as likely, compared to respondents without a standing illness, to say that they had used information from the Internet as an alternative to seeing their general practitioner (Nicholas et al., 2001). In many cases, information seekers were acting on behalf of others, such as family and friends. However, access to online health information also should be related to the consumer’s ability to use the Internet, not just on whether they are healthy.

**Online Proficiency**

The ability to use the Internet also should have an impact on whether boomers and seniors use online health information to manage their health. Individuals who use Internet information more to manage their health have broadband Internet access, are frequently online, spend many hours online, and search for information on many different topics. Research shows that individuals using a Web site regularly were more likely to have said that the information was helpful (Nicholas et al., 2001). A survey of adolescents shows that there are issues of the disparity of Internet access and quality of Internet access such as dial-up vs. broadband connection (Skinner et al., 2003).

**Sociodemographic Characteristics of Online Health Seekers**

Another factor explored in the literature that should have an impact on access to online health information is the sociodemographic characteristics of the individual. There is research on the digital divide, between the haves and the have-nots of Internet access. This research predicts that those who have greater access to the Internet would have more resources in society. For instance, those groups of individuals who are more disadvantaged economically in the United States would have less access to the Internet and online health resources. Hispanics, the largest minority group in the United States, traditionally have had less Internet access (Fox & Rainie, 2000). Those with medium to high family incomes should be able to access the Internet more for health information because of greater resources.

Existing research shows that individuals who are older, have lower incomes, are minorities, are less educated, and are males will be less likely to use the Internet for health information seeking (Cotton & Gupta, 2004; Anderson, 2004). In contrast, women increasingly rely on the Internet to supplement health information received from traditional sources (Pandey et al., 2003) and are more likely than men to seek online health information (Fox & Rainie, 2000; Nicholas et al., 2001). Awareness and feelings toward online health information also should have an impact on using this information to manage consumers’ health.

**Awareness and Feelings Toward Online Health Resources**

A final factor that should explain access to Internet health information is the awareness and feelings of the individual toward online health information. If boomers and seniors have more positive feelings about the Internet as a health information resource, they will utilize it more often than someone who harbors more negative feelings toward the Internet. In addition, individuals who go online for health information frequently should use it more to manage their health. If a boomer’s or senior’s doctor or medical professional recommends or uses the Internet as a communication device,
the patient is more likely to use it to manage his or her health. In summary, the prediction is that boomers and seniors who are more aware of online health resources should use these resources more to manage their health. In addition, boomers and seniors who have positive feelings about the benefits of online health information will use this resource more to manage their health.

Empirical evidence shows that there is a relationship between using the Internet more often and accessing health information (Lueg et al., 2003). Those using the Web once a day were twice as likely to report that it helped a lot in terms of being better informed from health information found on the Web (Nicholas et al., 2001). E-mail is still a new medium for obtaining access to consumer health information and also is explored in the research as a way to manage a consumer’s health (Huntington et al., 2004). The literature just outlined can be formally specified with the following hypotheses that demonstrate the relationship between boomers and seniors, the Internet, and the management of health.

**HYPOTHESES**

In order to examine whether online health information has affected the choices that individuals make in managing their health and the differences between boomers and seniors, several hypotheses are tested in this article. These hypotheses are derived from the literature mentioned in the previous section and are divided into five areas:

**Boomers’ and Seniors’ Differences**

**Hypothesis 1:** Online health seekers who are baby boomers are more likely to believe that online health information has helped them to manage their health better compared with seniors.

**Health of Boomers and Seniors**

**Hypothesis 2:** Online health seekers who are healthy or who have family and friends that are healthy will rely less on online health information because of lack of need.

**Online Proficiency**

**Hypothesis 3:** Online health seekers who have broadband Internet access will go online more for health information to manage their health.

**Hypothesis 4:** Online health seekers who go online more often and conduct many online activities will use Internet health information more to manage their health.

**Sociodemographic Status**

**Hypothesis 5:** Boomers and seniors who are females will rely more on online health information.

**Hypothesis 6:** Boomers and seniors who are college educated will rely more on online health information.

**Hypothesis 7:** Boomers and seniors who are Hispanics will go online less for health information.

**Hypothesis 8:** Boomers and seniors who have family income above $75,000 will go online more for health information.

**Awareness and Feelings Toward Online Health Resources**

**Hypothesis 9:** Online health seekers who most of the time and always look to see who provides medical information on the Internet will use
online health information more to manage their health.

**Hypothesis 10:** Online health seekers who access health information online once or twice a month will have a greater likelihood of using online health information to manage their health.

**Hypothesis 11:** If a doctor has recommended a Web site to an online health seeker, he or she is more likely to use health information to manage his or her health.

**Hypothesis 12:** If an online health seeker has communicated with his or her doctor via e-mail, he or she is more likely to use online health information to manage his or her health.

**Hypothesis 13:** Online health seekers that have more positive feelings about looking for health information on the Internet are more likely to use this information to manage their health.

These hypotheses are examined with a dataset that surveyed public opinion of both baby boomers and seniors on their use and acceptance of online health information.

**DATASET AND METHODS**

The e-Health and the Elderly dataset is a nationally representative random digit dial telephone survey of 1,450 adults age 50 and older. Included in this sample were 583 respondents age 65 and older. The survey was designed by Kaiser Family Foundation (KFF) (2005) in consultation with Princeton Survey Research Associates (PSRA), and the survey was administered in the field by PSRA. The survey interviews were conducted between March 5 and April 8, 2004. The entire dataset of 1,450 respondents was first examined to determine the characteristics of boomers and seniors and access to online health information.

Out of the 1,450 responses to the survey, this study also has taken a subsample of 628 respondents, of which there were 464 boomers and 164 seniors surveyed. Therefore, the original dataset was split, and the sample sizes differ for both age groups. The 628 boomers and seniors represent those individuals who are called online health seekers. They both have Internet access and have looked for online health information. This group is of interest, since in this study, there is a comparison of the characteristics of those that actually look up online health information.

In this study, we use a consumer survey to explore the differences between boomers and seniors and their use of online health information to manage health. This research uses both descriptive statistics and logistic regression to explore differences in access to online health information between boomers and seniors.

**DESCRIPTIVE STATISTICS OF BOOMERS AND SENIORS AND ONLINE HEALTH INFORMATION**

In order to model the relationship between seniors and boomers, online health information, and its impact on managing health care needs, this study has specified the following variables that will comprise the models tested.

Table 1 provides information on boomers and seniors who go online for health information. Boomers that go online for health information represent 78.2%, while seniors that go online for health information represent just over 21% of those surveyed in this category. This table generally supports the notion that boomers tend to go online more for health information than seniors. Boomers that do not go online for health
information represent 43%, and seniors that do not go online represent 58% of those surveyed in this category.

Table 2 outlines demographic information of boomers and seniors that go online and do not go online for health information. The digital divide is very evident with the data presented in this table. For instance, 43% of college-educated individuals go online for health information compared with only 15% who are college-educated that do not go online for health information. Among females and Hispanics, there is not much of a difference in the percentage who go online and do not go online for health information. However, boomers and seniors that have a family income above $75,000 in 2003 were more likely to go online for health information. Finally, age seems to have an impact on accessing online health information. The mean age was 61 years for individuals that go online and 69 years for consumers who do not go online for health information. Higher income implies greater use of online health information.

The Internet, Health Information, and Managing Health

and having a college education means a greater likelihood of going online for health information. This finding also indicates that boomers are more likely to go online for health information, since the average age range was just over 61 years old.

Logistic regression is used to test whether sociodemographic variables predict whether boomers or seniors go online for health information. Logistic regression was used, since this study models dependent variables that are binary, represented by either a 1 or 0 (Nicholas et al., 2001; Lueg et al., 2003). The odds ratio can be used to interpret the relative impact of the observance of a 1 in the dependent variable. Table 3 shows that almost all of the sociodemographic variables help to explain whether someone goes online for health information, with the only exception being Hispanic. For instance, having a college education means that a boomer or senior is four times more likely to go online for health information. Having a higher income indicates that boomers and seniors are two times more likely to go online for health information. However, as the age of the respondent increases, this marginally decreases the likelihood of someone going online for health information.

### Dependent Variables

Table 4 provides a list of the dependent and predictor variables and also demonstrates whether there were differences between boomers and seniors in these variables. Perhaps the most important dependent variable is whether “somewhat” or “a lot” of information on the Internet has helped to take care of a senior’s or a boomer’s health. The mean score indicates that 59% of boomers and 46% of seniors believed that the Internet has helped them to take care of their health, demonstrating some impact on the management of their health.

The second dependent variable measures whether online health seekers had a conversation with family or friends about health information that they found online (Table 4). Family and friends who go online for health information may guide someone else as to whether they should see a doctor because of this information (Eysenbach, 2003). The results indicate that 66% of boomers said that they had a conversation with family members or friends, and only 48% of seniors said that they had this conversation about the information they saw online. There were statistically significant differences between seniors and boomers for

Notes: The number of observations are 464 for boomers and 164 for seniors.
this question with the reported F-statistic being significant at the 0.01 level, meaning that boomers were more likely to have a conversation with family and friends about health information that they found online.

The third dependent variable measures whether online health information changed the behavior of boomers and seniors (Table 4). Thirty-six percent of boomers’ behaviors changed as a result of online health information, compared with 25% of seniors. This result also was shown to have a statistically significant difference between boomers and seniors at the 0.01 level. Around one-third of boomers changed their behaviors, which is a good indication that the information that they are finding is affecting their health.

A fourth management of health issue was whether boomers or seniors made a decision on treatment of an illness as a result of the information they found online (Table 4). The results showed that 34% of boomers believed that they made a decision about how to treat an illness because of information they found online, while only 26% of seniors made a decision on treatment. This result also showed a statistically significant difference between the two age groups at the 0.01 level.

Another dependent variable was visiting a doctor as a result of the health information found online (Table 4). Only 16% of boomers visited a doctor as a result of health information they found online, while 13% of seniors visited a doctor. Visiting a doctor was the least utilized change in behavior as a result of online health information.

Referring back to Hypothesis 1 on whether online health information has been used to manage a boomer’s or a senior’s health, this study has found that overall, there were differences between both groups of online health seekers (Table 4). The mean values for all five dependent variables were higher for boomers compared with seniors. In addition, three out of the five dependent variables showed statistically significant differences between boomers and seniors at the 0.01 level. With these dependent variables outlined, this research also should describe the predictor variables and their characteristics.

**Predictor Variables**

The predictor variables used to explain how the Internet has managed the health care of boomers and seniors also are presented in Table 4. Many of the predictor variables are represented in terms of binary numbers in order to capture the specific impacts on the dependent variables. As previously noted, this study has divided the hypotheses into the differences between boomers and seniors, the relative health of the individual, his or her online proficiency, and how active he or she is at seeking online health information. This study discerns the impact that these factors have on the management of the health care of boomers and seniors.

To see all of the predictor variables, refer to Table 4. We will only mention a few of them in this section. For instance, an index was created of the health problems that boomers and seniors or someone they know have faced in the past year. An individual who has more health problems or is concerned with someone else’s health problems would score higher on the index. The health problems index indicates less than four issues that they or someone they know faced, indicated by online health seekers (out of nine possible health problems). The nine possible health problems listed were cancer, heart disease, obesity and weight loss, arthritis, diabetes, Alzheimer’s, high cholesterol, osteoporosis, and mental health.

The online activities index measures the amount of activities that boomers and seniors conduct online, and the average is around two activities (Table 4). The prediction is that health seekers who conduct more online activities have a greater likelihood of using health information to manage their health because of their familiarity and comfort with the Internet. The four
online activities that comprised the index were using instant messaging, reading news, buying a product, and checking the weather.

The online health information predictor variables also show the capacity of the individual to look up health information on the Internet (Table 4). Seniors are more trusting of the health information that they read online, with only 24% of seniors “most of the time” and “always” looking to see who provides medical information on the Internet. On the other hand, 40% of boomers are looking to see who provides the online health information. This difference was also statistically significant at the 0.01 level. In addition, boomers are more frequent consumers of online health information, using it at least once or twice a month, as represented by 38% of the sample. Seniors consume online health information marginally less frequently with 34% doing so.

With regard to overall positive feelings toward the Internet, there was an average score of two on an index scaled from zero to three, indicating that boomers and seniors have overall positive feelings toward the Internet as a source of health information. The index was calculated by adding up the specific responses to whether the online health seeker agreed that online health information gave them information quickly, whether it helped them feel more informed when they go to the doctor, and whether it allows them to get information from a lot of different sources.

On an index of zero being the lowest and two being the highest, less than one was found, indicating that very few online health seekers harbor negative feelings toward the Internet as a source of health information. The index was calculated by adding up the specific responses to whether the online health seeker agreed that online health information gave them information quickly, whether it helped them feel more informed when they go to the doctor, and whether it allows them to get information from a lot of different sources.

Notes: ** significant at the 0.05 level and *** significant at the 0.01 level.
is not that high, given the attention placed on the differences between these age groups (Kaiser Family Foundation, 2005).

In terms of online proficiency, those who had broadband Internet access were less likely to have a conversation with a family member or a friend about what they saw online and less likely to make a decision about how to treat an illness. However, for those online health seekers who are online every day, this had a consistent impact across all five dependent variables, if they used online health information to manage their health. For instance, there was a 1.82 times greater chance that daily online users changed their behavior because of online health information. In addition, individuals who go online every day were 1.41 times more likely to visit a doctor because of information that they found online. In terms of being online more than 10 hours a week, this had a negative likelihood for the dependent variables “somewhat” or “a lot” of information on the Internet helped to take care of their health, but had a positive impact with an odds ratio of 1.46 for making a decision on how to treat an illness. Overall, there was no overwhelming support that being more proficient with the Internet helped to take care of their health, but had a positive impact with an odds ratio of 1.46 for making a decision on how to treat an illness. Overall, there was no overwhelming support that being more proficient with the Internet helped to take care of their health, but had a positive impact with an odds ratio of 1.46 for making a decision on how to treat an illness.

The strongest predictors of using health information to manage health were for the online health information awareness and feelings variables. Frequent consumers of online health information were 3.51 times more likely to use the Internet to take care of their health. It has become a valuable tool for their health care management needs. There was also a 3.11 greater likelihood of someone making a decision about treating an illness to use the Internet more than once a month for health information. In fact, frequently accessing health information registered an impact for all of the dependent variables.

Individuals who had positive feelings about online health information were more likely to use online health information to manage their health. Boomers and seniors who had more negative feelings toward online health information were less likely to use it for health management. This finding was consistently found across all five of the dependent variables. Online health seekers who usually looked to see who provided the health information were more likely to use this to manage their health. For instance, individuals who looked to see who provided the health information were 2.80 times more likely to have a conversation with family or friends about the information that they saw online. If a doctor recommended a health or medical Web site, online health seekers were 2.13 times more likely to make a decision about how to treat an illness because of online health information, and they were 3.68 times more likely to visit a doctor because of information they found online. In addition, individuals who communicated with a doctor or a health care provider via e-mail were 1.95 times more likely to have a conversation with a family member or a friend about health information that they found online. Overall, the logistic regression results indicate the most consistent and highest support for
increased awareness and positive feelings toward online health information as a driver for helping to manage boomers’ and seniors’ health.

CLASSIFICATION TREES ANALYSIS OF TAKING CARE OF BOOMERS’ AND SENIORS’ HEALTH

Another way to examine the relationship between boomers and seniors and online health information is a classification tree analysis. Classification trees are used to predict membership of cases or objects in the classes of a categorical dependent variable from their measurements on one or more predictor variables. Classification tree analysis is a common data mining technique. Figure 2 shows that the taking care of health variable is related to boomers and seniors having positive feelings toward looking for online health information. In addition, having positive feelings about online health information is related to accessing health information online once or twice a month or more. These findings reinforce the logistic regression results that awareness and feeling toward online health information helps in the management of a boomer’s or a senior’s health. How do these findings relate to the hypotheses outlined in the beginning of this article?

DISCUSSION OF RESULTS AND HYPOTHESES

This section will discuss how the empirical results of this study confirm or deny the hypotheses (see Table 6). First, the evidence shows through the difference of means tests that boomers and seniors are different in terms of their use of online health information in the management of their health. The mean values scored higher for boomers in using online health information to take care of their health, having a conversation with a family or a friend about the health information found online, changing their behavior because of online health information, and making a decision about treating an illness because of online health information. There is some evidence that boomers will use more online health information to manage their health, supporting Hypothesis 1. However, there is no overwhelming support for differences between boomers and seniors and using health information to manage their health, with boomers only utilizing this information one and one-half times more than seniors.

The health of the individual, or Hypotheses 2, only predicted the use of online health information to manage a boomer’s and a senior’s health when they had a conversation with a family member or a friend about online health information and when they made a decision about how to treat an illness. In addition, the health variable predicted a boomer’s and a senior’s behavior when he or she talked to his or her doctor about information that he or she found online. Overall, there was not overwhelming support that the health of the boomer or senior had an impact on use of online health information to manage his or her health.

Hypotheses 3 and 4 examine whether being more proficient online means that the online health seeker will use the Internet more to manage his or her health. The results consistently showed that those who go online every day were more likely to use the Internet to manage their health. There was not much support that being more proficient with the Internet meant that boomers and seniors would use it more often for health information, since many of the other independent variables in this category were not statistically significant. This is most likely explained by what these online health seekers are doing on the Internet; they are looking for information, which does not require, for instance, broadband Internet access, since a standard dial-up connection will suffice. Therefore, this research cannot confirm that being more proficient with the Internet means that

online health seekers will use this communication media to manage their health more than those who are not as proficient. However, this could change with greater availability of streaming video health information, which is much more suited to a broadband Internet connection.

Boomers and seniors of higher sociodemographic status use the Internet for health information much more than lower sociodemographic status individuals (Hypotheses 5-8). Therefore, this research confirms that there is a digital divide in access to online health information, and public policy should attempt to address this issue. It should be noted that one-third of the United States adult population has not gone online and, therefore, would not be able to benefit from online health information (Pew Internet & American Life, 2005).

Hypothesis 10 was confirmed in the logistic regression results that those who are frequent patrons of online health information actually will use it more often to manage their health. The results showed that health seekers who are accessing health information online once or twice a month or more will be more likely to actually use this information to manage their health. Therefore, these individuals are not just searching for information; they actually are using some of what they find online. Individuals who have positive feelings about online health information also will use it more often to manage their health, and individuals that harbor more negative feelings will use it less often (Hypothesis 13). Online health seekers who are very aware of who provides the medical information on the Internet are more likely to use this information to manage their health (Hypothesis 9). Finally, where there is communication with their doctor via e-mail or at the doctor’s office about online health information, boomers and seniors are more likely to use online health information to manage their health (Hypothesis 12). Awareness and feelings toward online health information generally were well-supported predictor variables (Hypotheses 9-13), having an impact on a boomer’s or a senior’s use of this information to manage his or her health care needs.

RECOMMENDATIONS, LIMITATIONS, AND FUTURE RESEARCH

This article examined the use of the Internet for accessing health information by boomers (age 50 to 64) and seniors (age 65 and over). Boomers generally use Internet health information to manage their health more than seniors. However, there was no overwhelming differences between boomers and seniors, which is the main difference in the finding from another study (Kaiser Family Foundation, 2005). For instance, boomers are much more likely to talk to a doctor about health information that they saw online. Boomers are around one and one-half times more likely than seniors to use online health information to manage their health. This study found that awareness and feelings toward online health information provided the best explanation of health information for management of boomers’ and seniors’ health.

Since boomers were found to use online health information marginally more than seniors, what are the implications of this observation? Will seniors of tomorrow be similar to seniors of today? Perhaps boomers will continue to seek online health information as they get older. The implication that boomers and seniors may be in the greatest need of health information may not be true in the future with the growing obesity epidemic in the United States, which affects all age groups.

Some policy recommendations should be noted in order to bring more seniors online and to enhance the quality of Internet health resources. Health care professionals should recommend Web sites, promote more effective search and evaluation techniques, and be more involved in developing and promoting uniform standards for
The Internet, Health Information, and Managing Health

health Web sites (Morahan-Martin, 2004). Since only a minority of seniors has ever gone online, this represents a significant digital divide. These findings confirm that for the foreseeable future, the Internet is less likely to be a primary source of information for most seniors, which suggests a need to invest more heavily in education and outreach strategies. This is especially the case for seniors with low or modest incomes, who are least likely to go online for this information. These recommendations could make seniors more aware and could create a positive experience when going online for health information.

In the near future, the Internet will become a decision-making tool for seniors, who will need to make choices about the Medicare prescription drug benefits. They will need to decide which plan has the most attractive premium and to determine whether it will cover the medications they take and will work with the pharmacy they use. Seniors also will need to manage the Internet to make these important decisions. Web site design is part of the solution, since seniors have problems scrolling on Web sites and remembering Web pages (Voelker, 2005).

There are some limitations of this research. With any type of public opinion data, especially when asking subjective questions about sensitive topics of consumers’ health, respondents may not be as forthcoming with information. Another limitation is that of the general applicability of the results, given that the proportion of the sample is different for seniors and boomers. In addition, there is no question that specifically addressed whether there was an improvement in the health outcome, just that people felt better informed. Future research could do a longitudinal follow up of this dataset, which might reveal shifts in the use of Internet health information for managing health with boomers and seniors, looking at other measures to see if there is an impact on change in the person’s health.

Chapter 4.20
The Online Effect: Transitioning from the Legacy Help Desk to the Online Task Management System

Kym Mawson-Lee
University of New South Wales, Australia

ABSTRACT

This case centres on a request management system that was developed and implemented in response to the growing requests to the Information Technology (IT) unit for assistance. Primarily, this assistance was with a core corporate application called WorkDesk, a back office processing system. The request management system, an IT unit initiative, was designed in collaboration with representatives of the organisation’s business units. The initial development project lasted for approximately two months and upon implementation was well received by the organisation. This first implementation turned out to be a proof of concept for a much larger system called the Request System that has been developed and implemented as a single online channel to manage all requests made of the IT unit. The Request System has greatly increased the ability of the IT unit to strategically manage IT and its support across the organisation. The core benefit of this case is the discussion of the successful development of an online task management system and its 10 key functions. This system effectively manages all requests made to the IT unit and introduced accountability for its completion. The system described can be easily repurposed based upon the knowledge demonstrated in this case study for a wide range of task management purposes. The situation described in this case resulted in the organisation’s maturing in terms of IT understanding, an issue with which many organisations are struggling and one that, if understood, will assist students to have a positive impact on similar organisations.

ORGANISATIONAL BACKGROUND

The Office of the Employment Advocate (OEA) was established under the Australian Workplace Relations Act (1996). The Employment Advocate’s role includes providing assistance and advice to employees and employers on workplace legisla-
tion, especially related to Australian workplace agreements (AWAs) and freedom of association, particularly in small businesses (OEA, 2003). The OEA, an agency of the Department of Employment and Workplace Relations (DEWR), is based in Sydney with regional offices in each state and the Northern Territory and consists of 180 staff. For a recent 2004 summary of the OEA, see http://www.oea.gov.au/graphics.asp?showdoc=/corporate/newsletter-sept2004.asp&Page=0 (Accessed 11/26/04).

The OEA’s mission is improving Australian workplaces (OEA 2004). The primary way in which the OEA achieves this mission is through AWAs. AWAs are individual agreements struck between an employer and an employee about the employee’s wages and conditions of employment. AWAs were introduced by the Australian government to give employers and employees flexibility in setting wages and conditions, allowing them to customise arrangements to their workplaces.

In terms of management structure, the OEA is very hierarchical both physically and culturally for an organisation of 180 staff with two layers of management that report to two layers of executive. In order to manage the entire organisation, the OEA has implemented the organisational structure depicted in Figure 1. From this organisational chart, it is possible to see that the IT unit is located at the third level of the hierarchy. The IT unit is a subunit of Corporate, which is an internal organisational enabler considered a supporting business unit of the organisation. The purpose of Corporate is to assist the OEA

---

**Figure 1. OEA organisational chart (OEA, 2004)**

![Diagram](image-url)
The Online Effect

in meeting its business objectives as an internal enabler; the IT unit is considered one component of that. Having this structure has required the National IT Manager to carefully manage the Information Technology Steering Committee (ITSC) as the main channel of communicating with the rest of the executive level of the OEA. The ITSC comprises the National IT Manager (Chairperson), together with the two deputy Employment Advocates, the Corporate Director, and the Director — the Strategic Advice Unit. Outside of the ITSC, high-level strategic actions regarding IT are approved in consultation with the Corporate Director, an otherwise non-IT-related role. The IT unit is based in Sydney as part of the OEA head office and supports regional offices in each state and the Northern Territory supporting a total of 180 staff.

Financially, the OEA is funded via an Australian government budget allocation provided to the OEA through the parent organisation, DEWR. For budgeting purposes, internally all business units are operated as cost centres. The IT unit budget, in particular, is split into two core categories: infrastructure service from DEWR and normal operating costs. The OEA has grown steadily over the last seven years from approximately 30 staff to 180 (a 600% increase with 40% of this growth being in the last two years) this year with 30 roles being filled just in the last 12 months (OEA, 2003). A strategic plan is developed each year in order to meet organisational objectives. The OEA’s strategic plan is a three-year rolling plan, meaning it is updated on a yearly basis to address the next three years.

For further information about the OEA, please refer to www.oea.gov.au.

This case study is about a request system developed by the OEA. Primarily, this case will examine task management and coordination of these tasks within an IT environment, as well as the capture of the information related to these tasks. As an example, these requests currently are broken up into six key areas. The first area is for requesting a modification to a Web page either on the OEA intranet or the OEA Internet site. These requests can be as simple as changing a word to something as complex as developing a new section on the intranet for a new team and all of the related pages that go with it. The next four areas are for requests specific to four different corporate applications that the IT unit support for the OEA, and the final area is for suggestions relating to anything that the IT unit can implement to improve the organisation.

The OEA and the IT unit are approximately seven years old, and until 12 months ago, the IT unit handled most requests as ad hoc issues with no formalised process for handling them. The IT unit was staffed with six individuals whose average tenure was three years, with most of the knowledge being held tacitly (i.e., knowledge that is not explicit and highly personal). Approximately 12 months prior to the writing of this case, two of these key staff left the agency, taking with them the knowledge of how to provide key IT functions. The IT unit supports four core corporate applications as well as an intranet and Internet site. This case describes one of the ways that the IT unit planned to manage this transition in staff.

SETTING THE STAGE

Within the OEA, there are varying levels of IT utilisation from a cutting edge .NET Internet application to an archaic Visual Basic (VB) application. This VB application contains vital organisational data that only a few people can access and that was found to be impossible to migrate to a more accessible system. The management of IT within the agency has a hierarchical approach. Representatives from the many levels attend a monthly ITSC meeting where a range of IT-related strategic issues are discussed, such as new projects and their related business cases. The National IT Manager chairs these discussions and prepares the agenda and minutes. Decisions
are made at the ITSC level and are carried out primarily by IT staff. The other members of the ITSC have varying levels of IT knowledge.

In the past, as an organisation, the OEA has not placed a high priority on IT. Previous experiences of IT projects had left the executive and management teams with a poor view of IT and its utilisation. One example of this is WorkDesk, the OEA’s core corporate application. WorkDesk is both a workflow and content management system that has tailor-made user interfaces, functions, and workflow specifically designed for the purpose of filing, assessing, and approving AWAs. More than half of the organisation’s staff is required to use WorkDesk on a daily basis. This application cost the equivalent of the annual IT budget to build and implement but was found wanting in some of its basic functions, such as searching and retrieving some specific types of AWAs within complex queue arrangements, causing many users to contact the IT unit on a daily basis for assistance to find these AWAs. Another example is the client service system (CSS), which cost approximately 5% of the annual IT budget and was developed in-house. This application is a basic customer management system used by the Client Services Network (CSN) business unit. During its informal development, it suffered massive scope creep, and while the application essentially is successful, some staff felt that the system should have been developed following a more formal process.

This was a difficult situation for the IT unit, as it did not have any allocated budget for the development of new systems; however, as the following scenario will show, there was a definite need.

Twelve months ago (2003), the IT unit of the OEA underwent a major change in staff. One of the key concerns in this situation was the loss of corporate systems support knowledge. After this change of staff occurred, a diverse range of skills was available; however, four of the staff were relatively new and inexperienced. The departure of two key staff at a time when there were few established or documented processes and only moderate application documentation created operational challenges. When the primary WorkDesk administrator left the IT unit, it became clear that there was little understanding about what support the previous administrator was providing. This required a carefully managed transition to the new WorkDesk staff. WorkDesk being an idiosyncratic application required a vast amount of knowledge to be maintained effectively.

In order to manage this transition effectively, a consolidated approach to handling requests was required. The aim was for the IT unit to be able to service the OEA’s business units quickly, effectively, and professionally. It was from these requirements that the Request System was born. With the implementation of this system, the IT unit was able to move from a reactive position to a position of effectively managing their workload. This system is the subject of this case study and is called the Request System.

The main issue confronting the IT unit at this time of staff turnover was that it required an effective way to manage requests for support. The IT unit now services a massive variety of requests, ranging from help-desk requests for WorkDesk and expert system design style requests to requests for designing whole applications such as the CSS. The ongoing management of this variety of requests was quite complex. The Request System was proposed to handle these requests and overcome this complexity.

Initially, the Request System was required to handle the capture, notification, processing, and completion of requests for assistance with WorkDesk. However, very quickly, the system was enhanced to facilitate requests for the following:

- Web modifications to both the Internet and intranet (Webmods);
- AWAonline II, an Internet application;
- AWAMS 1, a legacy application;
- Other organisational applications: COMS, CLOCS, CSS, System Monitor; and
Suggestions relating to AWAonline II, intranet, Internet, online polls, and the ITU Request System itself.

For some months prior to the Request System, requests would come to IT staff in all manner of ways, including e-mail, telephone, hallway chatter, chance meetings, during meetings, mobile phone, and third-hand messages. The before and after of the methods requests for assistance were handled as presented in the diagram presented in Figure 2.

Some of the challenges associated with the Before diagram (Figure 2) and having so many avenues to make requests include:

- No record of the request.
- No centralised archive of those requests that were recoded.
- No way to track the amount of workload currently being experienced by IT staff.
- Little opportunity for management reporting.
- No process documentation; therefore, little opportunity for process improvement.
- No knowledge retention and management.

In the After diagram, the communication flows are marked by the letters $a \rightarrow e$, which signify the task artefact. As an example of the flow of a task artefact, each request for assistance with AWA-
online II is assigned to a staff member, who has the necessary skills to complete a request about AWAonline II. Importantly, once the request is completed, the original requester is notified of its completion.

In summary, the development of the Request System started in May 2003. The impetus for the project was to better manage IT staff turnover and to overcome the ad hoc manner by which requests for assistance were being made to the IT unit, combined with the ad hoc manner by which these requests were handled. There was little reassurance from the staff involved as to whether a task had been completed or whether the business unit was happy with the actions taken to complete the task.

**CASE DESCRIPTION**

In early 2003, the OEA IT unit had found itself in a challenging situation. There was no funding for systems enhancement or development such as the Request System, and staff with important tacit knowledge about handling requests for core corporate applications were about to leave the organisation. The members of the IT unit with support of the National IT Manager worked hard to overcome these challenges. As a starting point, the project manager of the request system development needed to identify what functions were needed and if such a system for managing these task-based requests existed. Two key literature sources — collaborative systems and knowledge management literature — were used, and an action research methodology was adopted. The goal was to identify a way to assist the OEA to facilitate the management of tasks being requested of IT staff. This case will follow the development and implementation of this application, which has centred on the development of an effective e-based task artefact (an electronic instance and record of a task).

Supporting an organisation’s teams in routine and ad hoc tasks is a continual goal of Information System (IS) (Mahling & Craven, 1995). However, for every IS-related solution developed and implemented, there are generally some drawbacks. Influenced by the role of technology in business processes, this case begins to develop a continuous thread, drawing upon collaborative systems theory for current and future e-based information systems development. In particular, the case study reviews the support for facilitating, requesting, documentation, communication, and overall management of tasks.

Considerable literature utilises the concepts of artefact and task artefact; in particular, the fields of Computer Supported Cooperative Work (CSCW), Interorganisational Information Systems (IIS), and Software Engineering (Daneshgar, 2001; Dustdar, 2004; Giaglis, Paul & Doukidis, 1996; Schulz & Milosevic, 2000). However, it appears that very little has been done to combine these disparate uses of the concept into a single holistic thread in order to establish task artefact utilisation as part of task management, a fundamental research component of IS. It is intended that this case will begin to address this issue and form the basis of future work. From initial readings, there seemed to be no unified approach to e-based task management within the literature.

E-based support for task management dates back to the origins of computing machinery (Mahling & Craven 1995) and provides a solid foundation for this case study. As e-business becomes adopted more widely, one of the emergent research areas is the identification of models that are generalizable in order to support the process of e-business (Mukhopadhyay, Smith, & Muniz, 2003). The particular aspect of e-business support that this case covers is that of task management within e-based task management systems in order to support requests for IT support.

This case also begins to evaluate the usefulness of designing a model for e-based task artefacts
in order to facilitate and improve the process of task management within the OEA. Furthermore, in order to support the integration of task management within business processes, e-business task management systems require clarity in the identification of task artefacts and how these artefacts can be used to support OEA processes. As an example, a fairly simple task artefact is provided in Figure 3.

In response to needs of the system requirements identified so far, an action research approach was taken to facilitate the iterative development of the request management system. The action research methodology adopted was based on McKay

and Marshall (2001) with specific attention to their linked spiral model that develops research knowledge based upon the actions being taken. These authors provide an excellent illustrative example of this process, of which a representation is provided in Figure 4. For further information on this model and how it is implemented, please refer to McKay and Marshall (2001).

The Request System needed to handle requests for any type of IT assistance as well as the consolidation and recording of these requests.

![Image](image_url)
A core requirement of the system was the capturing of all of the required information that the IT unit needed in order to service a request within what is called a task artefact. Initially, the scope of the application was to manage and store requests from business units in relation to one specific corporate application, WorkDesk. The scope for the project quickly grew to encompass requests in relation to all corporate applications as well as the OEA intranet and Internet sites. The road map in Figure 5 provides an overall view of the path taken — Stages 1, 2, and 3 correspond to the investigation and analysis sections of the Systems Development Lifecycle (SDLC) and stage 4 to the design and implementation sections. More detail is provided in the Development Process section that follows.

**Development Process**

The OEA already had a corporate intranet. In order to facilitate ease of access for the entire organisation, the request system was to be built into the intranet. The intranet was based on Active Server Page (ASP) technology, which seemed fairly ideal as a development environment, particularly since it was a known technology. The following three phases are the iterative stages in the development of the Request System.

**Phase 1**

While conceptually each of the IT staff had their own idea of what should be developed, it was important to develop a shared understanding...
among IT staff and across the organisational business units. The project team facilitated the following steps:

1. The IT staff work-shopped the following:
   a. Requirements in terms of what information needed to be captured in order to complete a request for assistance for the WorkDesk application; and
   b. Some indicative categories into which requests for assistance with WorkDesk could be broken down.

2. With the guidance of the project team, expert users of WorkDesk work-shopped the following:
   a. The types of questions that they ask regularly;
   b. Those questions that tend to be novel; and
   c. The overall requirements of such a system.

On the basis of these workshops, the first component of the system was developed. It consisted of a limited interface with a corresponding backend database. This component, which also served as the basic prototype for what was to become the Request System, was tested by IT staff and two designated expert users for a period of two weeks. During this time, all information about each request was collected, not only in the task artefact via the Request System but also comments made about the request and additional e-mails that were sent. After two weeks, the collected data were analysed with the goal of facilitating 100% of all requests for WorkDesk assistance through the request system. A series of recommendations was made on how to improve this component, which was then prioritised and developed. This improved component was then made available to those staff that had contributed in the first instance to the requirements specification for further comment.

This is a very brief description of many hours and weeks of work that resulted in the first version of the WorkDesk component of the request system. As this was the first attempt to consolidate the channels for making requests within the organisation, it was important that a clearly defined model for developing the interfaces for each of the other OEA applications be developed in order to make subsequent development easier. The knowledge developed from this process is presented at the end of phase three as well as how other organisations could utilise these aspects far more easily. The finalised interface for inputting the required information for the WorkDesk task artefact is presented in Appendix 1a.

Phase 2

Based upon the knowledge from phase one, phase two commenced soon after the completion of version one of the first component. Phase two was the development of a new component that would facilitate requests for changes to be made to the OEA Internet and intranet sites known as Webmods. This phase was made somewhat easier by the existence of a previous database that was used by the Webmod staff to help them keep track of the requests made. However, this database was not accessible to non-IT staff and essentially involved a lot of copying and pasting from e-mails received. The project team replicated the process from phase 1, identifying the requirements of the staff who carry out the Web modifications and then working with regular requesters of Web modifications to identify their requirements.

From the requesters’ points of view, their requirements were simple: (a) make the requested change to the Web site and (b) let them know when it was completed. The main challenge was making the job of updating Web pages easier and more efficient. The Webmod staff requirements included which page needed changing, whether there were other pages affected by this change,
and when the changes needed to occur? This essentially meant asking the requester to supply considerably more information with the request than normally was provided in the first instance. Once this range of requirements was identified, version one of the Webmod request component was developed. The finalised interface for inputting the required information for the Webmod task artefact is presented in Appendix 1b.

Phase 3

The third phase was to roll out the request system to all OEA employees. The system to this point contained a component for WorkDesk requests and for Webmod requests. A third feature was added to drive further developments of the system; namely, Other Requests. The motivation behind this was to ensure that all requests made to the IT unit could be received via one channel — the request system. It was the role of the project team to process these Other Requests by breaking them down into existing or new request categories and having requirements specified for the development of an appropriate new task artefact interface, if required.

During this third phase, collaborative systems literature, particularly that of Dustdar (2004) and Dustdar and Gall (2003), was employed to take full advantage of previous research work in the area. As this literature was reviewed, key characteristics were identified and recorded into a task artefact characteristics chart. This chart is presented in Appendix 2 to assist readers in identifying the basis of what was built into each task artefact and the system overall. Each of the characteristics was assessed for suitability for inclusion in the request system. The main criterion by which each of the characteristics was assessed was whether its adoption would assist users or administrators to make or complete requests more effectively. Interestingly, many of the characteristics identified in the literature had already been developed into the request system intuitively as part of the requirements identified by members of the IT unit. However, there were also quite a few characteristics, such as notification and status, that enabled a more effective end-to-end process to be established.

Once these three phases were completed, the Request System project team began the process again, although not so formally and not in as much depth. The purpose of the iterations was to calibrate the effectiveness of the system, which is summarised in the following 10-point summary of the key aspects of the Request System. The iteration of all three phases occurred three to four times in varying levels of depth.

The task artefacts provide the basis of the success of the system and much of the knowledge gained. These task artefacts started as a blank file asking high-level questions. As a result of the three-phase iterative action component of the action research approach adopted, the task artefacts now had the following core functionality and contributed to the research component. These ideas can be draw upon for other task support systems:

10 Core Functions for E-Based Task Artefacts

1. Each task artefact is prepopulated with identifying information of the task requester, such as name, contact number, time stamp of the request, IP address, and physical address.
2. The requests are categorised on the basis of the required outcome to facilitate relevant detailed questions being presented automatically to the person requesting the task. This is done in order to capture all of the pertinent information required for completing each task.
3. The requester can set a date by which the request needs to be completed, which is
particularly useful for work prioritisation. A review date is assigned automatically to all Webmods so that all OEA intranet and Internet Web pages will be reviewed on a six-month basis.

4. Prior to submitting selected requests, the requester is presented with a Frequently Asked Questions (FAQ) page that includes explanations of how requesters can complete a common range of requests without IT staff intervention, if, for example, a user receives an unexpected response from an application.

5. The request is given a unique identifier. This request ID is sent immediately to the requester with a copy of the request just made.

6. Each request is assigned automatically to an IT staff member on the basis of the type of request made and the skills it will require to be completed. This ensures that the staff member with the required skill will complete the request. This is managed by a skills matrix, identifying all IT staff and their associated skills. Each IT staff member is able to navigate via the intranet to a page identifying all of the outstanding and completed requests.

7. The staff member who has been assigned the request then can set a status to the request such as analysing, or if more information is required, there is an option to ask for further specific information and then set the request to User Reply Required, at which point the original requester is notified by e-mail that further information is required.

8. Requesters are able to view the status of their requests at any time through a Web interface.

9. When requests are completed, there is an e-mail notification to the requester, advising the requester that the IT unit believes the request is completed, but that if the requester believes it is not completed, the requester is asked to reply to the e-mail with further details of the request.

10. Each of the requests is counted by category and by whether it is completed or not. These counts are fed into a reporting component that is used to assess the IT unit’s performance on a monthly and quarterly basis, facilitating a more strategic approach to IT management.

In terms of the research component of action research, most of the work to date has been related to identifying literature that is of assistance and developing the task artefact characteristics chart provided in Appendix 2.

**Summary of System Outcomes**

The three-phase approach to the development of the Request System has proved to be effective. This effectiveness is demonstrated through the greatly reduced number of follow-up phone calls and e-mails that previously were required to complete the root cause analysis often required to complete tasks. The Request System also assisted the IT unit in identifying opportunities for innovative ways to support the other OEA business units by facilitating the analysis of request patterns and request types. If there is a significant increase in a particular type of request, this now can be managed in a more effective manner. Often, any request, even those that were trivial to complete, required a phone call or an e-mail to identify specific information; however, now, only highly complex requests require further information, which is facilitated by a requester-reply-required status that automatically sends an e-mail to the original requester for further information.

From the reporting module of the Request System, for the last six months, the system has been handling between 300 and 400 requests per month. The system has approximately 40 regular users (more than one request per week) and approximately 100 less regular users. Importantly,
prior to the Request System, it was unknown how many requests for assistance IT staff was handling each month. An unplanned benefit is that the IT unit managers now have concrete evidence of what work the IT unit staff is doing and can ensure consistent responses to requests made. For illustrative purposes, a screen shot of the July 2004 report is available in Appendix 1c.

Key aspects of the request system’s success came from two core business decisions. One consisted of ensuring that the application was designed to effectively handle processes from end to end. This facilitated the second decision: making the system usage mandatory. The decision for mandatory usage created a lot of buy-in from the business units, as their representatives had a vested interest in ensuring that they understood and communicated the needs of their business unit in terms of making requests. The project team was able to make it clear that those requests that had not been clearly specified in terms of the business requirements would not be handled by the request system and, therefore, could not be requested. When combined with the commitment of the developers, this led to the development of a system that has received excellent feedback from users both in terms of ease of use and completeness of how the tasks were handled.

As a result of the Request System, the following three goals were achieved:

1. **Centralised location for self-help information.** The Request System has provided the ideal location for answers to commonly asked questions
2. **Reporting.** Real-time reporting of all requests is made available to all staff. The report provides details ranging from an individual request to a report on the number of requests received in relation to a specific issue.
3. **Correct assignment of requests.** Previously, various requests would be made to staff members who did not have the knowledge to complete the requests. Now, the request is assigned automatically to the correct IT staff member on the basis of skill sets that are contained in the skills matrix component of the system.

### CURRENT CHALLENGES/PROBLEMS FACING THE ORGANISATION

The current stage of the Request System is that of maturing. Business units are starting to leverage the concepts utilised in the system for their own benefit, creating task artefacts for their own use and for requesting tasks of business units other than IT. However, some staff members within the organisation are still only beginning to familiarise themselves with the opportunities that the Request System provides.

Within the organisation, the IT unit holds regular meetings with other business units in order to explore and address issues that arise as a result of requests made in the Request System. Some of the issues experienced so far include the following:

- Some users do not utilise the request system as designed. They use incorrect categories and do not supply the information specified in the user interface.
- Users sometimes do not read information readily available in the system to resolve issues. For example, those requests that are covered in the FAQ would allow users to resolve their own request.
- Some users lodge requests that they could have completed themselves, because they prefer IT staff to complete the task to save their own time.
- Users lodging requests that are not IT tasks. IT staff has to forward such a request to another business unit for completion.
The Online Effect

- Non-IT staff members who have requests assigned to them do not have their performance measured by completion of such requests. As a result, some of the non-IT staff who are trialing the use of the system for their own purposes have many outstanding requests, which reduces the overall perception of the effectiveness of the system.

- There are significant differences in the requests from experienced users and those received from new users of the request system. As an example, there are varying levels of clarity in the request description. This may cause misunderstandings between the IT staff and the requester.

- Despite best efforts in communicating the existence and usage of the system, some staff members are still not sure of its use and tend to use other methods to resolve their requests.

- There is room for more executive involvement in terms of reporting.

While this list provides an understanding of the day-to-day issues facing the OEA, at a strategic level, there is a more complex issue. The Request System has been somewhat evolutionary in its design; as staff members within the organisation become aware of its effectiveness and add their own new task artefacts online, it has become somewhat confusing for some staff to use. The IT unit developed a plan to tackle this by involving the business units in developing a new menu and navigation structure; however, as is often the case in IT development, this has been challenging, since these business units have other tasks that they consider to be a higher priority. Another related issue is the user interface. Due to original design restrictions, the layout and colors are quite bland; however, the original restrictions no longer apply, and a new layout has been designed. The IT unit is ready to release this new design but can’t until it addresses the menu structure.

Key benefits for students and managers include a description of iterative application development using action research, using business requirements driving application development, and drawing upon collaborative systems research when designing a task management system.

*This work was previously published in the Journal of Cases on Information Technology, edited by M. Khosrow-Pour, Volume 8, Issue 1, pp. 79-96, copyright 2006 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).*
This section includes a wide range of research pertaining to the social and organizational impact of human-computer interaction around the world. Chapters introducing this section analyze gender differences in the adoption and reaction to IT, while later contributions offer an extensive analysis of differing social and cultural dimensions of technology adoption. The inquiries and methods presented in this section offer insight into the implications of human-computer interaction at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.
Chapter 5.1
Gender, Race, Social Class and Information Technology

INTRODUCTION

The issue of the underrepresentation of women in the information technology workforce has been the subject of a number of studies and the gender gap was an issue when the digital divide dominated discourse about women’s and minority groups’ use of the Internet. However, a broader view is needed. That perspective would include the relation of women and IT in the communities in which they live as well as the larger society. The information society that has emerged includes the United States and the globalized economy of which it is an integral part.

Women and minorities such as African Americans and Latinos are underrepresented in computer science (CS) and other information technology positions in the United States. In addition, while they are no longer numerically underrepresented in access to computers and the Internet – as of 2000, (Gorski, 2001) - they continue to enjoy fewer benefits available through the medium than white boys and men. The following article explores the diversity within women from the perspectives of race, ethnicity and social class in North America, mainly United States.

The technology gender and racial gap persists in education and in the IT workforce. A broader and deeper look at women’s position in relation to the increasingly techno-centric society reveals that women may have reached equality in access, but not equity in academic study and job opportunities.

BACKGROUND

Linebarger (2003) pointed out three traditional digital divide constructs: ‘family socioeconomic status’, ‘location of access to new technologies’ and ‘gender/race’ for school age children. Inequalities tend to appear along both social class and...
gender lines, with male students and students from high socioeconomic status backgrounds well positioned to outpace female students and students from lower socioeconomic backgrounds in terms of computer skills and knowledge (Lockard, Abrams, & Many, 1987).

**Equality in Access, but No Equity in IT Jobs**

The gender digital divide refers to the gap in access rates between men and women (Gorsky, 2001). Based on this traditional gender digital divide definition, the gender digital divide gap has narrowed to reach “access equality.” In 2002, 83 percent of American family households owned a computer (Corporation for Public Broadcasting, 2004). About the same proportion of adult men and women had access to home computers. The digital connectedness of American families was increased through home computer ownership. In 2001, 59 percent of American people had connections at home. By the end of 2000, women surpassed men to become a majority of the United States online population (Gorski, 2001).

The societal race and gender gaps in the United States as a whole have narrowed in the past 10 years, but in the IT field, the gender gap generally appears to be wider at all levels of employment. Overall growth in these IT occupations was so strong during the decade of the 1990’s that women working in IT continued to increase through the year 1996. According to D’Agostino (2003), in 1996 women were 41 percent in the IT field. The ITAA (2003) recorded a decline to 34.9 percent by 2002.

The situation is worse in highly professional positions such as computer programmers and computer systems analysts, where women tend to lag far behind men. The Table 1 shows how women are overrepresented in lower IT positions while there are few women in professional computer science fields.

However, the potential exists for this situation to change. Kvasny (2003) reports that minority women in low-income communities perceive IT as a means of escaping poverty while highly educated, middle-class and professional women regard IT as offering fewer opportunities for advancement. Kvasny suggests that IT and gender studies recognize the diversity within women.

**Gains in Access, but Loss in Computer Science Major**

The problem of underrepresentation of women in IT starts from the math and science pipeline at school. Through high school, girls are less

(Source: Bureau of Labor Statistics)
Gender, Race, Social Class and Information Technology

likely than boys to enroll in computer science classes, and the disparity increases in programming courses.

The American Association of University Women (AAUW) commissioned early studies on the gender gap in education (1992, 1998). The first study noted the barriers faced by children from lower socioeconomic status. It also pointed out African American girls had fewer interactions with teachers even though they tried to initiate such interactions. By the latter AAUW study, the issue of technology had emerged. The report noted that a gender gap had begun to appear in computer science classes. Girls made up only a small proportion of students in such classes and the gap widen between grades eight and grades eleven. The study reported that boys exhibited a higher degree of self-confidence about computer skills than girls.

According to the National Council for Research on Women (2002), by the eighth grade, Latinas score higher in math than their male peers; and by twelfth grade they do better in science than Latinos, but they are outperformed by their male peers on the Math SATs.

A more alarming situation is the trend of fewer women entering the field of computer science. Between 1985 and 2002, women went from earning 36 percent of the computer science bachelor’s degrees (D’Agostino, 2003) to only 20 percent in 2002 (Taulbee, 2004). Even when women choose computer science as their major, their relative (compared to men) lack of preparation for the coursework and male dominated classroom climate forces them to drop out of the program (Margolis, 2003).

Table 3 shows the distribution of bachelor’s degrees in computer science by the race/ethnicity of the recipients for 2001. Analysis of the figures from a gender perspective reveals some interesting patterns. One is that the gender gap is greater among white women than women from underrepresented minorities. Generally, African American and Native American women and

Table 3. Bachelor’s degrees in computer science degrees by race/ethnicity and sex of recipients. 2001 (Source: Taulbee, 2003)
Latinas earn more than their share of science and bachelor’s degrees than men in their respective groups (National Council on Research for Women, 2002).

White women earned 22 percent of the computer science bachelor’s degrees conferred on white males and females, while underrepresented minority women earned 41 percent of the CS bachelor’s degrees conferred on minority males and females. Among African American CS bachelor’s degree recipients, the numerical gap is almost non-existent, less than 300 out of a total of just under 4100. The gap between Latino/Hispanic males and female bachelor’s recipients is much larger than that among African Americans, 839 out of a total of 2,199. The picture is similar for American Indian CS bachelor’s recipients, with a 29 percent female to 71 percent male ratio.

Why don’t girls’ recent gains in access to technology translation into long-term advancement in college majors and careers? Gurur and Camp (2002) noted that attitudes, computer experience, computer games, mentoring and role models, self-confidence, computing environments, societal influence, teacher and family encouragement, all-female environments, perceived difficulties in balancing work and family are some factors contributing to the problem. The nerd image of the field, the fact that computer games are targeted mostly at boys, the perception of computing careers as boring, and the lack of role models for girls are a few reasons pointed out by Margolis and Fisher (2000).

Cohoon (2001) points out that despite beliefs espoused by some in computer science that women have deeply ingrained traits that suit them less for study and practice of computer science than men, female underrepresentation in computer science could be avoided. Gilbert has observed the importance of support systems for immigrant groups studying computer science and suggested that underrepresented groups in the U.S. could benefit from such practices (Loftus, 2004).

**Technology Access and Social Class/SES**

Here technology access will be discussed from two perspectives. One is computer access and the other is Internet access. Table 4 shows computer usage by 5-17 year-olds, either at home or at school by their parents’ education and by income (NCES, 2003). A large gap exists between children whose parents have the least and the most education. Rates of students using computers at school are fairly even among students from high-income families and those from low-income families, each 75.2 percent and 85.4 percent, respectively. Schools have played a key role in access equality for students of different backgrounds.

According to the National Center for Education Statistics (NCES, 2001), in 1994, 20 percent of

</table>
public schools in low income areas enjoyed Internet access while 35 percent of all public schools had such access. By 2000, the figures were 94 percent and 98 percent, respectively.

Of those who use the Internet, 78 percent access it from home, compared to 68 percent from school. Thirty-five percent of students from families with income of less than $20,000 access the Internet at home, while 52 percent do so at school (NCES, 2001). Again, schools have played an important role in narrowing digital divide by providing equal access to students from different class backgrounds.

When girls are compared to boys in terms of computer access, Internet access, the time spent on computers and Internet and computer activities, they are not much different (National School Boards Foundation, 2000). In fact, Linebarger and Chernin (2003) show that among children between 4 and 8 years old, boys use computers more than girls, but use Internet less than girls do.

What affects girls the most with respect to the digital divide is their SES, similar to the case for boys. There is research on correlations between gender and social class or SES and computer access. Davies, Hancock and Condon (2003) reported that there is little difference in access to home computers and access among families with high SES for boys and girls and but there is about a 10 percentage difference in home computer and Internet access between boys and girls in lower SES families.

Usage of home computers varies by social class or SES. Fifty percent of the children from high-SES families with home computers used word processing, compared with only 24 percent of the children from low SES families with computers at home (NCES, 2001).

Parents’ SES influences students’ attitudes toward computers and eventually contribute to widen the technological gender gap. Shashaani (1994) reported that family SES affected sex differences in attitudes towards computers. In general, gender-differential attitudes are more pronounced in the lower socioeconomic group and SES has a stronger effect on girls than boys. Both girls and boys perceive the gender stereotypes about computing held by their parents, and such attitudes inversely affect girls’ own attitudes.

**FUTURE TRENDS**

From a societal perspective, while girls’ and women’s use of computers and the is on a par with use by boys, it is yet to be seen if the comparable patterns of usage in the future will translate into equitable academic and professional outcomes. The computing environment, starting from the home through elementary, middle, and high schools must be made more encouraging (Cohoon, 2001 & Margolis, 2000). Further research on family SES with gender needs to be done. In addition race and gender interactions have not yet been a central theme among researchers, but research sponsored by the National Science Foundation is altering the research priorities. The findings by researchers such as Kvasny (2003) that working class African American women see opportunities in computer-related or IT careers in contrast to middle class white women’s perceptions of obstacles in the compute science pipeline need to be explored in further research.

**CONCLUSION**

While school provides good access to all students and computer access is theoretically equitable between the sexes, complex social factors serve to limit girls’ participation both in school and at home. Technology is more than physical resources; it is intertwined with social and cultural factors that differentially affect interactions. These include family computer cultures and encouragement, psychological access, social identities and the setting for the technology use, to name a few.
The traditional definition of “digital divide” no longer paints an accurate portrait of technology. The whole picture needs to be evaluated from a broader perspective. As computer prices continue to fall, lower SES families or schools in low SES areas may have greatly narrowed the traditional digital divide, but further gains may be difficult.

Simple class and economic predictions cannot be made, even within the white American segments. The process becomes much more complex as race and ethnic characteristics are included.

**Key Terms**

**Digital Divide:** the condition of unequal access to computer-related resources, varying along the demographic dimensions of age, gender, race and ethnicity, education, income, and nationality.

**Diversity:** in a social and cultural context, the presence in a population of a wide variety of cultures, opinions, ethnic groups, socioeconomic backgrounds, disabilities, and sexual preferences.

**Information Technology (IT):** a term that encompasses all forms of technology used to create, store, exchange, and use information in its various forms. Graduates of computer science majors may seek IT jobs.

**Math/Science Pipeline:** a phenomenon where the number of female students, students with lower socioeconomic status, and students of color in proportion to white males in advanced math and science progressively declines during high school.

**Social Class:** a category of people who have generally similar educational histories, job opportunities, and social standing and who are conscious of their membership in a social group that is ranked in relation to others and is replicated over generations.

**Socioeconomic Status:** the economic, social and physical environments in which individuals live and work, as well as demographic and genetic factors. Measures for SES may include: Income or Income Adequacy, Education, Occupation, or Employment.

**Underrepresentation:** a situation in which members of a group by color, race, sex, or ethnicity (but not all) constitute a lower percentage of the total number of people within the category in the job market, or in schools.

INTRODUCTION

The “shrinking pipeline” of women who ascend through the ranks in computer science education programs and careers is by now a familiar problem. Women drop out at rates faster than men at all levels of educational and professional advancement, resulting in a gender gap especially pronounced at the highest levels of the computing workforce, and that has not narrowed appreciably at any level in more than 20 years (Camp, 1997; ITAA, 2005; Vegso, 2005). Efforts to move more women into the pipeline at lower levels have met with limited success (cf. the Carnegie Mellon experience as reported by Margolis & Fisher, 2002); girls and women still express less interest than boys and men in studying computer science and pursuing information technology (IT) careers (Bentson, 2000; Vegso, 2005).

A reason often cited in the literature is the masculine culture of many computer science programs and IT workplaces, which is perceived by many women as alien and unwelcoming (Bentson, 2000; Spertus, 1991; Turkle, 1988). Even when institutions make efforts to treat women and men equally or accord women special consideration...
in admissions and hiring decisions, attitudes discouraging women from entering computing persist, both within the institutions and in society at large. Sometimes these attitudes are expressed overtly: Underground “hacker” culture is notoriously antagonistic to women (Gilboa, 1996), and even mainstream computer aficionados respond with resistance and sexist jokes to proposals to recruit more girls and women to study computer science (Slashdot.org, 2005). Moreover, there is a widespread perception that computer experts are socially-isolated “geeks” or “nerds” obsessed with technology, a mode of being that women, who tend to be more socially oriented, find unappealing (Margolis & Fisher, 2002; Turkle, 1988).

Fortunately, the situation for computer science does not tell the whole story. In the latter part of the 20th century, the expansion of computing and the Internet fueled the rise of applied IT fields in which technical skills, rather than being developed for their own sake, are increasingly put to use in the service of human needs. Applied fields, such as information science, information systems and instructional technology, have gained strength, and a new interdisciplinary field, informatics, has emerged. At the same time, interest in computer science itself is declining, especially among women (ITAA, 2005; Vegso, 2005). In this article, we explore the possibility that applied IT fields may provide more women-friendly cultures while still focused on technology. The larger question underlying this exploration is: Does applied IT education have the potential to bridge the “gender computing gap”?

BACKGROUND

Previous research has focused primarily on problems faced by women in computer science, especially in undergraduate-level education (Camp, 1997; Cohoon, 2001; Spertus, 1991). Many influences have been cited as contributing to the educational gender gap in computer science, including aspects of institutional culture, such as lack of role models (Pearl, Pollack, Riskin, Thomas, Wolf, & Wu, 1990), mentoring and advising (Whitely, Dougherty, & Dreher, 1991), informal networking (Smith-Lovin & McPherson, 1993) and a sense of belonging and identity (Ely, 1995); work-family conflict (Netemeyer, Boles, & McMurrian, 1996); and teaching styles (Cohoon, 2001; Turkle, 1988).

One of the most often-cited factors that discourage girls and women from studying computer science is the culture of computing itself: Computing is historically and conventionally associated with masculinity, an association that attracts boys to computers who then become role models for other boys, creating environments in which girls feel marginalized (Hacker, 1990; Turkle, 1988). Citing Margolis and Fisher (2002), Read (2002) argues that “women are further alienated by a stifling ‘geek culture’ that celebrates obsessive computing at the expense of broad interests.” Hackers are perceived as keeping exceptionally long hours and late nights, and manifesting “highly focused, almost obsessive behavior” (Frenkel, 1990, p. 38). For many women, this work ethic conflicts with their desire to start a family or, if they are older, their actual family responsibilities. Meanwhile, hackers, who are predominantly male, are seen as being “bright and creative,” while women remain on the periphery. Rasmussen and Hapnes (1991) suggest that this type of culture is important in producing and reproducing male domination in higher education in computer-related fields and that it influences the integration of women and their position within the field of computing.

The abstractness of much computer science instruction exacerbates the gender-biased culture, in that girls are more likely to be interested in real-world problem solving in contexts involving human users than in machines and programming languages (Clarke, 1992). A related deterrent for women is that most introductory computer science courses focus on programming skills rather than concepts of computer science. Girls and
women like IT, the findings suggest, but want to do something with it to improve the world; they are not satisfied with mastering computing skills for their own sake.

Applied fields such as information science, information systems and instructional technology have an a priori advantage over computer science when it comes to attracting future female professionals. They are grounded in the disciplines of real-world problems; for example, business, education and information management. Indeed, while women are significantly underrepresented in the IT workforce overall (ITAA, 2005), especially in computer science (Bryant & Vardi, 2002), applied careers, such as education and library and information science, attract higher proportions of women (e.g., Maata, 2003). However, research on the status of women in these professions shows mixed outcomes. On the one hand, women in applied disciplines are more likely to achieve professional parity or near parity with men (Quint, 1999; Wolverton, 1999). On the other hand, even in female-predominant applied professions such as education and library science, most high-ranking administrators are men (Growe & Montgomery, 2000; McDermott, 1998). Moreover, men tend to be disproportionately represented in IT work in these fields, which also tends to be more highly paid and more prestigious (e.g., Harris, 2000 for library and information science).

Little has been written about what leads women (or men) to choose applied IT careers, or what kinds of disciplinary cultures they encounter when they decide to study an applied IT domain. That is, there is no body of literature directly comparable to that available for computer science on which to base predictions about the long-term effects of the growth of applied IT fields on the gender computing gap. To address this research gap, we initiated the Information Technology Workforce (ITWF) project.

**INFORMATION TECHNOLOGY WORKFORCE PROJECT**

The ITWF project, funded by the National Science Foundation, has been collecting and analyzing data on the experiences, attitudes and outcomes of women and men in IT programs at five large public universities in the United States (U.S.) since September 2003. The focus is on students at all levels majoring in applied IT disciplines, specifically: information systems (IS), instructional systems technology (IST), informatics (I) and library and information science/studies (LIS).

We expected to find differences among these fields and between applied fields and computer science (CS); more generally, we expected that more female-oriented (“women-friendly”) disciplinary cultures would produce more successful outcomes (Jones, 1990), where success is defined both in terms of the quantity of women who enter IT-related educational programs and the quality of their educational experiences (Ahuja, Herring, Ogan, & Robinson, 2004).

Data collection for the project as a whole is via Web-based surveys, telephone interviews and face-to-face interviews with students, faculty and staff in the IT programs. In this article, we focus on findings from an initial Web survey of all IT student majors in the five universities (from the four applied IT fields plus computer science) that took place in spring 2004. The survey asked 100 questions about students’ experience, behaviors and attitudes regarding computers; their parents’ occupations and attitudes toward gender roles; student demographic information; and information about mentoring, stress and burnout in their academic environment.

**SELECTED FINDINGS**

The results of the survey were revealing of the attitudes and experiences that influence students in their selection of an IT career. Three distinct
patterns emerged, showing variation according to gender, IT discipline and the interaction between gender and discipline.

**Gender-Based Variation**

For some survey questions, men and women tended to answer differently, regardless of their program of IT study. For example, one question asked students to assess the relative importance they place on their career and their personal life. While most people answered that the two are equally important, females were more likely to choose the balanced response, while males were more likely to say that their careers are more important. This is consistent with previous observations that men in IT are more focused on their work, while women seek a more balanced lifestyle (Frenkel, 1990; Margolis & Fisher, 2002).

Another series of questions asked about work/life balance as a potential cause of stress. Most students answered “occasionally” or “seldom” to questions about whether schoolwork interferes with personal life and vice versa. However, women were more likely to say that school strain affects their personal life all the time, and men were more likely to respond that it never does. This could be a reflection of female students having greater domestic responsibilities (Netemeyer et al., 1996); more of the female than male survey respondents said they were married and/or had children at home.

Unsurprisingly, most of the IT students reported that they feel very comfortable using computers. However, here, too, a gender pattern is evident. Males in all majors were more likely to answer that they are very comfortable, whereas females gave most of the “somewhat comfortable” or “not at all comfortable” responses; this includes women in CS. Women also reported learning to use computers later than men, and playing fewer computer games when they were children.

These results support previous findings on gender differences in early computer experience and in computer self-efficacy (Durndell & Haag, 2002; Fromme, 2003), suggesting that some manifestations of the gender computing gap persist in applied IT disciplines.

**Discipline-Based Variation**

Differences are also evident within the IT disciplines, independent of respondent gender. A common tendency was for responses for LIS and IST to pattern together, in contrast to responses for CS and IS, with informatics falling in between. For example, when asked to weigh the relative importance of their career vs. their personal life, students in IS and CS were more likely to indicate that career was more important, and students in LIS and IST were more likely to say that their personal lives mattered more. Perhaps not coincidentally, students in IST and LIS also expressed greater satisfaction with their majors than did the IS and CS students.

Conversely, when asked what attracted them to their IT career choice, students in IS singled out earning a good living, and students in CS cited the challenge inherent in the subject matter. These considerations were rated less important by students in IST and LIS, for whom helping others was the highest consideration.

Disciplinary differences were also found with regard to students’ backgrounds and childhood experiences. CS and IS students were more likely to have had a father and/or mother who worked in an IT-related profession. CS, IS and informatics students clustered together in terms of where and when they first started using computers (at home, before or during their elementary school years) and the amount they played computer games as children (“very frequently” or “frequently”). Of those who answered that they did not learn to use a computer until high school or college, and played games “rarely” or “never,” most were from IST and LIS.

When asked what kind of job they expected to find after graduation, a majority of the re-
respondents, with the exception of IST students, answered “scientific or technical.” In addition, CS students preferentially indicated “university teaching and research,” and IS students indicated “administrative/managerial,” “consulting” and “sales.” IST students responded “consulting” and “K-12 teaching,” and LIS students indicated “administrative/managerial,” “clerical” and “other.” It is hardly surprising that different disciplines target different careers; however, the students’ career expectations in CS and IS (e.g., industry researcher, professor) tend to be higher status and better paid than those in IST and LIS (e.g., K-12 teaching, clerical). Computer science and business are traditionally “masculine” fields, whereas education and library science are traditionally considered “feminine” professions.

**Gender and Discipline Variation**

In the third pattern of survey results, gender and IT discipline interact. Specifically, males in traditionally masculine disciplines tend to pattern together with females in traditionally feminine disciplines, and females in traditionally masculine disciplines pattern together with males in traditionally feminine disciplines. These results suggest a natural mapping between the gender of the student and the traditional gender associations of the discipline.

For example, the survey asked students to indicate their degree of satisfaction with their major. While most answered “very satisfied,” CS men and IST/LIS women were overrepresented on that response. The inverse pattern was found for the less-enthusiastic response “somewhat satisfied”: CS women and IST/LIS men were overrepresented. In particular, women in IST and LIS selected “very satisfied” much more often than did women in CS, consistent with our expectations that IST and LIS are more “women-friendly” cultures (Jones, 1990).

Or consider another set of results, in response to the question, “How similar are your values to those of your field?” IS males and IST/LIS females were most likely to answer “very similar,” and informatics females and IST/LIS males were most likely to answer “not at all similar.” If we consider informatics to be part of the CS/IS cluster, this instantiates the same pattern.

Students’ confidence about finding a job after graduation displays a similar cross-distribution. Males in CS and females in IST/LIS were most likely to answer that it will be “very easy” to find a job; LIS males and male students in CS and informatics were most likely to answer “very hard,” and women in CS and informatics were overrepresented in the “don’t know” category. There seem to be two types of male CS student; those who are very confident and those who are more pessimistic about their job prospects. Apart from this, these results also fit the tendency for confidence and satisfaction to accompany a mapping of student gender onto IT discipline.

**DISCUSSION**

The results of a Web-based survey of students in different IT programs in five U.S. universities reveal gender differences among students, differences among IT disciplines and a mapping of gender onto disciplinary cultures, all of which potentially affect students’ choice of and satisfaction with an IT career. Rather than clustering together in contrast to CS, the responses of students in applied IT programs tended to fall out along gender and disciplinary lines, with CS and IS clustering at one end, and LIS and IST at the other; informatics, the new discipline, mostly fell in between.

Somewhat discouragingly, the women in the applied IT programs, like the women in computer science, report having less early computer experience and less confidence in their computing abilities than their male peers (Ogan, Ahuja, Robinson, & Herring, in press). At the same time, the female students’ reported preference for a
balanced lifestyle may help to explain why more women choose applied IT majors than CS. The most popular IT majors among women in our study are those that are traditionally feminine, in which there are more women peers and role models, and which value using technology to help people. Fewer women choose IT majors where the focus is on technology for its own sake (in the case of CS) or making money (in the case of IS), although the women who choose those majors appear to do so for those reasons, similar to men. Most intriguingly, both genders report greater satisfaction with and optimism about their career choices in IT disciplines that mirror the gendered cultures found in society at large.

**FUTURE TRENDS**

These findings are simultaneously encouraging and problematic. On the one hand, they suggest that the rise of applied IT fields does indeed open the door to more women studying and working in IT. Specifically, the findings indicate that IT programs located in traditionally “women-friendly” contexts may be more accessible and appealing to women, and by extension, that other IT contexts might evolve to become more women-friendly as well. Informatics is an example of a discipline whose culture has not yet become fixed; in this study, it tended to pattern weakly with CS and IS, but that tendency could shift.

At the same time, the survey findings are problematic in that they re-inscribe cultural stereotypes about gender roles and interests in the IT domain. Moreover, a positive interpretation of the results assumes an equivalence between the various IT fields that is more illusory than real. “Feminized” professions such as instructional design and librarianship still have less status and are lower paid, even when they incorporate IT (Lorenzen, 2002). Moreover, the computing technology involved is typically less rigorous than in computer science (e.g., it may not require practitioners to know how to program a computer). Does women’s greater satisfaction with applied IT programs help to bridge the gender IT gap, or does it reproduce a larger societal status quo, of women as less technology- and career-oriented?

Ideally, IT study should be equally accessible and rewarding for women interested in hard-core computing and men interested in human applications as it is for men interested in, for example, grid structures, or women interested in information management or educational applications. Again, informatics may help to bridge the gap if a culture can be forged in which technical rigor is balanced with a focus on computing applications that benefit people.

**CONCLUSION**

This study has raised a previously unasked question about the potential of applied IT fields to close the gender computing gap. The question remains, for the most part, unanswered; further research needs to be done, for example, to compare the IT content of applied IT programs, and to take national culture (in addition to disciplinary culture) into account in assessing the appeal and outcomes of different approaches to IT. In the meantime, enrollments in CS are declining in U.S. universities (Vegso, 2005) and the IT workforce is aging (ITAA, 2005), but society’s need for IT expertise remains high. In the future, it is likely that career seekers of both genders will turn increasingly to applied IT and to the new interdisciplinary paradigms emerging from combinations of computing, information studies and other fields (Berghel & Sallach, 2004). It is important to understand the social dynamics and implications of these trends, in the hope that we may be able to shape them into gender-equitable configurations.

INTRODUCTION

While traditional face-to-face (FtF) forms of interaction have proven disadvantageous to females in mixed-sex settings, computer-mediated communication (CMC) holds the promise of helping to level the playing field between the sexes, at least in terms of equitable communication between genders. However, evidence from recent research shows that gender inequalities persist. The objective of this article is to shed light on why the promise of gender equalization in CMC is not evidenced.

BACKGROUND

The equalization phenomenon of CMC is attributed to the reduction in social cues associated with an online virtual environment (Dubrovsky, Kiesler, & Sethna, 1991; Kiesler, Siegel, & McGuire, 1984; Kiesler, Zubrow, Moses, & Geller, 1985; Siegel, Dubrovsky, Kiesler, & McGuire, 1986). In this comparatively lean mode of interaction, it is argued, status cues are filtered out, which leaves people feeling more anonymous and less individual. This “deindividuation” lowers self-awareness and self-regulation, resulting in less evaluation apprehension and overall reduced social inhibitions. According to Kiesler et al., the relative distance and anonymity afforded by CMC decreases the salience of status, resulting in the increased participation of lower status members. The emphasis shifts from message contributor to message content, thus serving to equalize the influence of high-status individuals.

Indeed, a repeated finding in the early research in this area is that both participation in group discussion as well as influence over group outcome is more equal under conditions of asynchronous CMC compared to traditional FtF interaction (Clapper, McLean, & Watson, 1991; George, Easton, Nunamaker, & Northcraft, 1990; Hiltz, Johnson, & Turoff, 1986; McLeod, 1992;
Gender Equalization in Computer-Mediated Communication

Rice, 1984; Zigurs, Poole, & DeSanctis, 1988). Females, being of lower status than males (in most cultures), are thus expected to fair better in a CMC context as compared to a traditional FtF context. However, as pointed out by Postmes and Spears (2002), many studies of electronic media use have not found evidence to support the equalization hypothesis (Adrianson & Hjelmquist, 1991; Berdahl & Craig, 1996; Hollingshead, 1996; Matheson, 1991; Saunders, Robey, & Vaverek, 1994; Straus, 1996; Weisband, 1994; Weisband, Schneider, & Connolly, 1995).

REVIEW OF LITERATURE

The article begins by reviewing literature on status, particularly as it relates to gender differences in traditional FtF communication environments before moving into CMC environments. The focus of the review concerns mixed-sex, task-oriented work situations.

Sociological-Based Theories

Sociological-based theories pertaining to status include status-characteristics theory (SCT) and social-role theory. SCT is concerned with the effects on face-to-face interaction of differences in individuals’ status. A central tenet of SCT is that status hierarchies influence interaction in groups (see Wagner & Berger, 1993, 1997, for summaries). Findings indicate that high-status members contribute more opinions and enjoy increased influence in groups. Regarding gender, males are accorded a higher status than females and are believed to have more expertise overall (e.g., Eagly & Carli, 1981; Kent & Moss, 1994; Wood & Karten, 1986). Thus, both sexes expect higher task performance from males, independent of whether gender is relevant to the group’s task at hand (Berger, Rosenholtz, & Zelditch, 1980). In mixed-sex groups, females contribute less task-relevant content due to the expectation of superior male performance. As pointed out by Johnson et al. (1998), these findings are consistently supported (Anderson & Blanchard, 1982; Dovidio, Brown, Heltman, Ellyson, & Keating, 1988; Lockheed & Hall, 1976; Piliavin & Martin, 1978; Strodbeck & Mann, 1956; Woody & Karten, 1986).

The SCT research considers traditional FtF interaction. In an attempt to tease out the effect of differing degrees of FtF interaction on the effects of status, Mueller et al. (2002) found that the predictions from SCT are more likely to be supported when “women and men regularly interact face-to-face” (p. 178). Thus, they conclude that the amount of face-to-face interaction best predicts whether SCT’s claims on gender inequalities will be supported.

Social-role theory (Eagly, 1987) asserts that males and females are socialized differently such that each sex learns dissimilar (i.e., gender-appropriate) behavioral patterns. Females are socialized to respect and defer to males and to exhibit relative docile behavior (Seibert & Grunfeld, 1992). Males, on the other hand, are socialized to be more assertive, competitive, and aggressive (Eagly & Steffen, 1984; Powell, 1988).

These socialization processes result in individuals exhibiting stereotypical traits and behavior associated with their gender, which is reflected within the interaction of participants in mixed-sex groups (Broverman et al., 1972; Eagly & Steffen, 1984; Strodbeck & Mann, 1956). This body of research generally finds that males participate more and are more influential in mixed-group settings than their female counterparts (e.g., Eagly & Carli, 1981; Williams, 1992). Males also emerge more frequently as group leaders (Eagly, 1987). These findings hold regardless of the sexual composition of the group (see below). Although social roles have become less rigid over the years, gender stereotypes continue to persist (Biernart & Wortman, 1991; Diekma & Eagly, 2000; Steil, 1997).
Structural Theory

The theory of proportional representation (Kanter 1977a, 1977b) provides a structural approach for accounting for within-group behavior due to status differences. It posits that the numerical representation of a status category (e.g., race, sex) influences intragroup interaction. A group member from the numerical minority experiences feelings of isolation and powerlessness. This leads to behavior by the numerical minority that tends toward passive and inhibited conduct. As a means of lessening the feelings of isolation and powerlessness and to fit in, the numerical minority may adopt the behavioral characteristics of the numerical majority. These behaviors are evident in “tilted” groups, where group members account for between 15% to 35% of the minority status, but are more prevalent in “skewed” groups, where they represent less than 15% of group membership. Polarization occurs as the numerical majority alienates the numerical minority by discounting contributions of the minority.

In terms of mixed-gender groups, proportional-representation theory suggests that the numerical representation of men and women directly influences behavior rather than the sex or socialized-gender roles of the individuals themselves. Research suggests that the results of proportional representation are quite direct. For example, Johnson and Schulman (1989) found that solo female members engaged in task activities significantly below the group average. However, there is evidence that men and women are differentially affected by underrepresentation. That is, when females are in the majority and there is a lone male group member, the solo male may dominate (e.g., Crocker & McGraw, 1984; Williams, 1992).

Linguistic Differences in Communication of Men and Women

Researchers within the area of sociolinguistics have uncovered numerous differences in the way males and females use language to communicate and interact. These differences occur to such an extent that sex-specific patterns of communication are evident in discourse (Coates, 1986; Preisler, 1987). Men’s discourse is more competitive and involves preserving their independence, while women’s is supportive, consensus seeking, and socially oriented (Coates; Preisler; Rhodes & Wood, 1990). Women express more agreement and seek the opinions of others to a greater extent than men (Eakins & Eakins, 1978).

In both mixed and homogeneous groups, men contribute more task communication (e.g., Bartol & Butterfield, 1976; Ellis & McCallister, 1980; Hare, 1976; Nemeth, Endicott, & Wachtler, 1976; Strodbeck & Mann, 1956; Sturm, 1989). Women, however, contribute more to statements relating to group maintenance (e.g., Bartol & Butterfield; Ellis & McCallister, 1980; Strodbeck & Mann; Sturm). While both task and group-maintenance communication is necessary for effective group functioning (Bales, 1950), leadership is consistently attributed to those who contribute task, rather than maintenance, input (e.g., Hare; Nemeth et al.; Strodbeck, James, & Hawkins, 1957).

Specific linguistic features are also associated with each sex. Females use more expressive and emotional language, and their language incorporates a variety of markers that males do not tend to use (Lakoff, 1975). These markers include hedges (e.g., “I’m not sure, but...”), (very) polite forms (e.g., “I’d really appreciate it if...”), tag questions (e.g., “You’re leaving now, aren’t you?”), direct quotes (men paraphrase more often), and apologies (e.g., “I’m sorry, but I feel that...”). Women also speak less frequently than men in mixed-sex settings.
Gender-EQUALIZATION Studies in Asynchronous CMC

While there is a body of research pertaining to equalization and status in CMC (see above), the number of studies specifically relating to gender equality in CMC is quite sparse. Studies purporting the status-equalizing effects of CMC do so based on non-gender-related status markers (e.g., occupation, Saunders et al., 1994; education, Weisband et al., 1995). By and large, CMC research has not studied gender equalization or controlled for gender effects. Below, I review CMC studies relating to gender equalization.

Selfe and Meyer (1991), in one of the earliest studies to report on gender in CMC, found that males and other high-status members dominated online interaction under normal as well as anonymous conditions. Herring has conducted a series of studies on gender in CMC. In a particularly telling study, Herring (1992, 1993) conducted a 5-month-long analysis of two academic Listservs. In her study of their discourse, she identified linguistic features associated with each gender. These features comprised significant sex-based differences, such that they formed a style recognizable as woman’s language and men’s language. The features of women’s language included explicit justifications, questions, apologies, personal orientation, and support of others. In contrast, men’s language included strong assertions, self-promotion, rhetorical questions, authoritative orientation, humor, and sarcasm. These findings are similar to the aforementioned linguistic differences noted in traditional FtF interaction.

Furthermore, in terms of participation, Herring (1993) found that a minority of men dominated the discourse for both the amount and content of contributions. She notes that “the most striking sex-based disparity is the extent to which men participate more than women” (p. 4). Although women constituted between 36% and 42% of the membership on the Listservs, their communication rate was significantly less than what would correspond to their numerical presence. Herring goes on to relay that when women attempted to participate on a more equal basis, they were actively censored by men who either ignored their contributions or attempted to delegitimize their postings. Herring observes that because women are conditioned to avoid conflict, they avoided participating. She concludes that

[r]ather than being democratic, academic CMC is power-based and hierarchical. This state of affairs cannot however be attributed to the influence of computer communication technology; rather, it continues pre-existing patterns of hierarchy and male dominance in academia more generally, and in society as a whole. (p. 11)

Recently, Postmes and Spears (2002) conducted a series of laboratory studies on equalization in groups communicating via CMC by looking at dominance, the antithesis of equalization. All teams consisted of four undergraduate students and were balanced in terms of sex (i.e., two females, two males). They analyzed dominance in terms of the content of contribution, and also counted the number of words and postings of the participants. While their studies did not show evidence of male dominance in terms of word or statement counts, males were found to dominate team discussions in terms of linguistic style. Males used forceful, independent, confident, and assertive language in order to dominate. Furthermore, under conditions of supposed anonymity, gender differences were more salient. They attribute this to the inability to be truly anonymous when communicating. Due to patterned differences in the discourse of men and women, it is thus likely that gender can be determined even under anonymous conditions where gender is hidden.

Postmes and Spears (2002) conclude that the prior mixed findings regarding equalization can be attributed, at least in part, to employing an inappropriate measure based on a numerical count. Their focus on measuring content differs from
previously cited studies that found equalization in CMC, which relied on measures of equalization based on the numeric count of words and postings. Postmes and Spears warn that researchers must consider the content of the contributions to determine a true measure of the equality of participation and influence.

FUTURE TRENDS

There is certainly room for more gender studies in CMC. While studies by linguists (Herring in particular) have informed our understanding of gender differences in CMC in terms of discourse, these field studies have largely been conducted using discussion boards. While other studies of status and equalization have been conducted using task-oriented teams, most have not looked at gender. And while there are some studies of gender on teams interacting via CMC, these do not consider status and equalization. Finally, there are no studies that focus on the gender composition of teams as an independent variable.

CONCLUSION

What can be concluded from the limited research is that CMC does not promote gender equalization. Many of the conditions leading to gender inequality in traditional FtF interaction find their way into the context of CMC. As described by sociological theories as well as structural theories, status effects relating to gender appear to carry over into CMC. However, significant gaps in gender research in CMC remain.

**KEY TERMS**

**Computer-Mediated Communication (CMC):** Electronic communication using a computer.

**Deindividuation:** The loss of individual identity and a gaining of the social identity of a group.

**Equalization Phenomenon:** The salience of status is decreased by interacting in a CMC environment; it is a hypothetical result.

**Expectation-States Theory:** Argues that power and prestige differences within a group arise from differing performance expectations that members hold for themselves and others.

**Heterogeneous Group:** Mixed-sex group (i.e., male and female group members).

**Homogeneous Group:** Same-sex group (i.e., all female or all male).

**Lean Mode of Interaction:** Due to the reduction in social cues, CMC is considered lean compared to face-to-face interaction.

**Social-Role Theory:** Asserts that males and females are socialized differently such that each sex learns dissimilar (i.e., gender-appropriate) behavioral patterns.

**Status-Characteristics Theory (SCT):** Is concerned with the effects on face-to-face interaction of differences in individuals’ status; a central tenet of SCT is that status hierarchies influence interaction in groups.

**Theory of Proportional Representation:** Provides a structural approach for accounting for within-group behavior due to status differences; it posits that the numerical representation of a status category (e.g., race, sex) influences intragroup interaction.
Chapter 5.4
The Cross-Cultural Dimension of Gender and Information Technology

Haiyan Huang
The Pennsylvania State University, USA

INTRODUCTION

The underrepresentation of women in the information technology (IT) sector has been widely studied in the contexts of western countries such as North American and Western European countries. These studies indicate that the underrepresentation of women in the IT sector is unveiled in multiple perspectives, including IT access, the development, adoption and use of IT, IT education, and the IT workforce in general and within the IT workforce structure itself (e.g., different levels of IT positions) (Cooper & Weaver, 2003; Gürer & Camp, 2002; Hartzel, 2003; Klein, Jiang & Tesch, 2002; Margolis & Fisher, 2002; Rommes, 2002; Trauth, 2002; von Hellens, Neilsen, & Beekhuizen, 2001; Webster, 1996).

Why is it important to study issues related to gender and information technology? First, it is argued that the information technology sector should value and leverage all kinds of diversity (including gender diversity as one dimension) to enhance productivity, to facilitate IT innovation, and to develop IT for a wide variety of people (Avgerou, 2002; Roberts, 2003; Trauth, Huang, Morgan, Quesenberry, & Yeo, 2006). Second, it is also argued that women’s underrepresentation in and exclusion from information technology can be attributed to power and socio-cultural reproduction of inequality through technology development and use, and the historically social-construction of technology fields as “masculine” domains, which result in a gendered digital divide (Cockburn, 1985; Kvasny & Trauth, 2002; Kvasny & Truex, 2001; Wajcman, 1991, 2004; Woodfield, 2000). Ignorance or failure to address issues related to gender and IT will further marginalize women’s participation in future economic and social development, and will endanger social equality and social welfare in general (Kvasny & Trauth, 2002).

A significant trend of the contemporary information technology industry is towards globalization, which is manifested through a
variety of established practices such as IT offshore outsourcing, global software development, and innovation through global R&D (research & design) collaboration (Sahay, Nicholson, & Krishna, 2003; Walsham, 2000, 2001, 2002). Such a globalization trend of the IT industry and market has put forward new challenges to gender and IT research, to incorporate the cross-cultural dimension. Similar to the rationale for studying gender and IT in developed countries (leveraging diversity and improving social inclusion), Hafkin and Taggart (2001) argued that it is imperative to examine the cultural factors while studying gender and IT in developing countries.

Although the research on the cross-cultural dimension of gender relations with information technology is limited, Galpin (2002) pointed out that the underrepresentation of women in IT seems to be a worldwide phenomenon indicated by statistics. Galpin (2002) also pointed out that there is a wide range of participation in IT by women, which is influenced by complex cultural and societal factors that are different from country to country. Models related to gender relations to IT developed in certain socio-cultural contexts may not be applicable to others (Clarke & Teague, 1994a; El Louadi & Everard, 2005; Mukhopadhyay, 1996, 2004).

In addition to the importance of studying gender and IT within a specific cultural context, there is another perspective of the cross-cultural dimension of gender and IT: the increasingly diversified global IT workforce as a result of the IT skill shortage, global IT outsourcing, and other global IT collaborations. For example, under the pressure of the skill shortage of the IT workforce in America, the IT institutions and industry turn to the global intellectual pool for recruiting talented international students and skilled IT workers through F-1 and H1-B visas (National Research Council, 2001). According to the 2005 ITAA (Information Technology Association of America) report, the representation of Asian IT workers in the IT workforce doubled the number of Asian worker in the overall workforce in America (ITAA, 2005). Globally, an increasing number of countries have a maturing IT sector, which enables them to enter the global IT outsourcing market or to engage in globally distributed collaborative software work through virtual environment (Trauth et al., 2005). The mobility and cultural diversity of the global IT workforce will add more complexity to articulate their gender relations to IT since individuals may have different cultural backgrounds and experiences.

Therefore, it is important for scholars and practitioners to explore the cross-cultural dimension of gender and IT to understand how the nuances of different cultural influences shape women’s relations with IT, to build knowledge with respect to the plural perspective of gender and IT research, and to prepare future global IT workforce. In this article, I first articulate the theoretical underpinnings of cross-cultural dimension of gender and IT research, then review some current studies related to this research area, and finally discuss some future research agendas.

BACKGROUND

The theoretical explanations about why women are underrepresented in IT education and the workforce are complex in nature (Adam, Howcroft, & Richardson, 2002, 2004; Webster, 1996). Those theories attempt to articulate the gender IT gap from either the technology perspective (including the IT sector environment) or the people perspective (e.g., women). From the technology perspective, there are two theoretical orientations: technology determinism and social shaping of technology. From the people perspective, there are three theoretical orientations: essentialist theory, social construction theory, and Individual Difference Theory of Gender and IT (Trauth, Quesenberry, & Morgan, 2004).

Technology determinism views technology as a value-free artifact without any biases, and the
The Cross-Cultural Dimension of Gender and Information Technology

impacts of technology on society are self-directed and universal. It neglects the influences of socio-cultural contexts in which the technology is created and used. Social shaping of technology, on the other hand, views technology as a product of socio-cultural and power relations and the impacts of technology on society are shaped by the socio-cultural beliefs embedded within the technology and the societal attitude towards the technology. For example, Kvasny and Truex (2000) argued that power relations and controls are embedded in technology and in society’s attitudes towards technology, and hence new technology tends to “reify the dominant relations in the existing social order.” The embeddedness of social order in technology will privilege certain groups while disempowering others (Kvasny & Trauth, 2002). Technology related educational disciplines and industrial sectors have been historically dominated by men and hence are embedded with belief systems that are engendered with “masculinity,” which may be exclusive of women’s participation (Cockburn, 1985; von Hellens et al., 2004; Wajcman, 1991, 2004). Driven by this theoretical orientation, researchers recommend bringing IT closer to women: changing technology development methods, increasing women’s participation in system development and implementation, modifying the “masculine” culture of IT at various levels from societies, to industries, and to organizations and educational institutions.

The essentialist theory argues that men and women are differentiated by their biological differences; such differences are inherent and fixed and thus act as main causes to determine their different relationships with IT (Adam et al., 2004; Trauth et al., 2004). Similar to the technology determinism, the essentialist theory only emphasizes the intrinsic internal differences between men and women and overlooks the influences of social contexts in which both technology and people are embedded. Social construction theory views gender identity and gender relationship with IT as on-going negotiation processes in social interactions, in which the influences of various factors are relevant and important (Trauth et al., 2004; von Hellens et al., 2004; Wajcman, 1991; Webster, 1996). Driven by this theoretical orientation, researchers recommend bringing women closer to IT, which include setting up mentoring programs, providing convenient child-care facilities, and developing initiatives to facilitate work-life balance of female IT workers.

Trauth (2002) pointed out that social construction theory of gender and IT tends to separate men and women as two separate socio-cultural groups, which mainly focuses on the differences between the gender groups while overlooks the differences within the gender group. Within the gender group, differences such as ethnicity background, family, social class, individual life experiences, age, individual personality and attitude also play important roles in shaping one’s relationship with IT (Kvasny, 2003; Trauth et al., 2004). Trauth argued for focusing on individual level of analysis and developing Individual Difference Theory of Gender and IT (Trauth, 2002; Trauth et al., 2004).

MAIN THRUST OF THE ARTICLE

Theoretical Underpinnings of Cross-Cultural Dimension of Gender and IT

In his research on cross-cultural information systems production, use, and management, Walsham (2001, 2002) emphasized the importance of examining the cultural diversity and argued that the existing local socio-cultural context is a critical factor in mediating the globalization process in a specific context and, in turn, will have an impact on the complexity of globalization. Similarly, to study the cross-cultural dimension of gender and IT, the underlying theories should be sensitive to and account for the dynamics of cultural diversity. Evidences show that cultural diversity and its influences on gender and IT is connected to
three theoretical perspectives: social construction of gender relationship with IT, social shaping of technology, and Individual Difference Theory of Gender and IT.

El Louadi and Everard (2005) examined current labor force condition of Arab countries, and more particularly Arab women. They pointed out that because of the Arab cultural influences, the future opportunity of engaging Arab women in IT work may lie in telework, which can bring work and information technology into the home where Arab women can be professionals and care for the family at the same time. This is an example of the distinct Arab socio-cultural influence on women’s relationship with IT.

Nielsen et al. (1998) studied non-Asian and Asian female students enrolled in IT disciplines in Australia and the differences among their perceptions of IT educations and careers. Their study showed that both non-Asian and Asian females had similar views about the IT professions. However, Asian female students were more inclined to choose IT related subjects despite their negative perceptions of IT professions because of the future prospects of employment opportunities (Nielsen, von Hellens, Greenhill & Pringle, 1998; Nielsen, von Hellens, Pringle & Greenhill, 1999). Such a choice is influenced by collectivist characteristic of Asian culture and is based on practical consideration, as compared to the “free-choice” decision making in most Western cultures. The research by Geary on comparing children’s mathematic achievements in different countries also supports this argument (Geary, 1996; Geary, Bow-Thomas, Liu & Siegler, 1996): Asian culture emphasizes practical reason (e.g., usefulness) in decision-making while Western culture emphasizes free choice. The studies by Nielsen et al. (1998, 1999) indicate that although the perceptions of IT professions might be similar between Asian and non-Asian women (e.g., the social shaping of technology is similar), their relationships with IT are different because of the cultural influences. Also their studies are situated in one national context, Australia, which implies that researchers should pay close attention to the differences within gender groups (in this case, Asian and non-Asian Australian female IT students). It also implies that cross-cultural influence is an important dimension in studying the Individual Difference Theory of Gender and IT.

An early study by Clarke and Teague (1994a, b) is also about the Australian context. Based on interview data, their study shows that Asian female CSE (Computer Sciences and Engineering) students did not see computing as a male domain and they also received direct encouragement from family to pursue computing related secondary studies. This is an example of cultural influences on both social shaping of IT and social construction of gender relationship with IT. Clarke and Teague (1994b) pointed out that “the differences within gender groups are greater than the differences between gender groups” (p. 259), which indicates the relevance and important in studying the individual difference of gender and IT.

The study by Mukhopadhyay (1996, 2004) also strongly supports considering a cross-cultural dimension in studying gender and science (although IT is not a central subject in this study, it is closely relevant). Mukhopadhyay (1996, 2004) challenged both the essentialist theory and those American theories of gendered science that embodied long-standing American cultural models to other socio-cultural contexts. She pointed out that it is the Indian cultural model of family, gender, and science that influences the Indian women’s academic decision-making process, and hence results in a predominantly male scientific community in India. Mukhopadhyay (2004) also stressed that:

“We need to explore the processes through which individuals internalize and utilize what Strauss and Quinn (1997) call “public culture” as it relates to gender, schooling, academic subjects (mathematics, science, etc.), family, kinship, and marriage. We need to understand more about how...
and why some messages have more motivational force than others, for some girls more than others, and how they mediate math and science attitudes, achievements, and choices. (p. 487)

**Current Research on Cross-Cultural Dimension of Gender and IT**

A comprehensive review of current research on cross-cultural dimension of gender and IT is beyond the scope of this article. Here, I would like to provide a brief overview. Current research on cross-cultural dimension of gender and IT can be classified into two categories. One category consists of comparison studies that investigate how and why the women's participations in IT are different in different countries. The study by Galpin (2002) provided a good summary and references for this type of study. Another example is the study by Hafkin and Taggart (2001), which focuses on studying the developing countries. The primary objectives of those studies are: to understand the nuances of different socio-cultural influences on gender and IT in different countries; to come up with solutions to improve women's participation in IT that fit with a specific socio-cultural context; and to see whether or not some practices and experiences can be transferred from one country to another country.

Another type is to situate the cross-cultural dimension of gender and IT within a specific societal context while studying how the diverse cultural backgrounds of different women may influence their relationships with IT. The studies by Clarke and Teague (1994a), Nielsen et al. (1998, 1999), and by Mukhopadhyay (1996, 2004) are the examples. The primary objectives of these studies are to critically address the cultural influences on women's relationships with IT within gender groups, and to leverage the influences of cultural diversity on IT to a great extent. The number of this type of study is limited compared to previous types. However, the importance of this type of research is increasing due to the globalization of the IT market and industry and the mobility of IT professions.

**FUTURE TRENDS AND CONCLUSION**

In this article, I argue that it is important to investigate the cross-cultural dimension of gender and IT because of the contemporary globalization phenomena. From the theoretical perspective, I discuss how the cross-cultural dimension can be incorporated into the social shaping of technology, social construction of gender and IT, and individual differences perspective on gender and IT. However, the number of studies in cross-cultural dimension of gender and IT is limited.

Therefore, one of the future research agenda items is to have more studies in this area to address the influences of cultural diversity. Another future research agenda item is to further incorporate the cross-cultural dimension into the theoretical developments of gender and IT. To do so, we need to encourage interdisciplinary discourse among different disciplines, and also global collaborations in gender and IT research.

**REFERENCES**

**KEY TERMS**

**Essentialism:** The assertion of fixed, unified and opposed female and male natures (Wajcman, 1991, p. 9). This theoretical perspective is used to explain the underrepresentation of women in the information technology field by arguing the existence of “essential differences” between males and females with respect to engagement with information technology.

**Individual Differences Theory of Gender and IT:** A social theory developed by Trauth (Trauth, 2002; Trauth et al., 2004) that focuses on within-group rather than between-group differences to explain differences in male and female relationships with information technology and IT careers. This theory posits that the underrepresentation of women in IT can best be explained by considering individual characteristics and individual influences that result in individual and varied responses to generalized environmental influences on women.

**Social Construction:** A theoretical perspective articulated by Peter Berger and Thomas Luckmann (1967) that focuses on social processes and interactions in the shaping of actors. This theoretical perspective is used to explain the underrepresentation of women in the information technology field by arguing that technology—socially constructed as a masculine domain—is in conflict with socially constructed feminine identity.

INTRODUCTION

Prior to the Internet, forms of social expression, communication, and collaborative behavior are known to be sensitive to cultural nuances. According to researcher Geert Hofstede (1991), a widely used definition of culture is proposed where “Every person carries within him or herself patterns of thinking, feeling, and potential acting which were learned through their lifetime” (p. 4). Hofstede referred to such patterns as mental programs or “software of the mind.” It is expected that such mental programming related to cultural differences will affect perceptions of the electronic medium as well (Raman & Watson, 1994). Related to the topic of this volume, culture has a place in the consideration of e-collaboration when individuals come together to work toward a common goal using electronic technologies. This may include various domains including e-business, e-learning, distributed project management, working in virtual teams of various forms, to name a few.

While there is little work to date on the explicit topic of culture and e-collaboration, there is evidence that creating culturally appropriate user interfaces (Cyr & Trevor-Smith, 2004) contributes to a better perception of the interface (Kondratova & Goldfarb, 2005), and indeed to enhanced levels of Web site trust and satisfaction (Cyr, 2006). In e-commerce settings, Web sites that are perceived as appropriate to the user have also resulted in greater commitment (Oliver, 1999). In this article, and building on previous work in related areas, it is argued that the development of culturally appropriate electronic interfaces can enhance user involvement, ultimately resulting in enhanced e-collaboration.

In the following sections, culture as a context for e-collaboration is outlined followed by considerations of the Web used as a communication tool, and how trust and satisfaction are related to
the online collaborative process. The article ends with concluding remarks.

**CULTURE AS CONTEXT**

Over the decades sociologists have proposed that socially shared meanings are culture specific. These shared meanings are grounded in language, geographical proximity, and history as shared by members of nations or those who have lived within the same social environment (Hofstede, 1980). In both commercial and noncommercial settings, culture has been found to have implications for information systems research. More specifically, culture is proposed to affect online trust (Jarvenpaa, Knoll, & Leidner 1999), Web site development (Sun, 2001), use of group support systems (Reining & Mejias, 2003), predisposition for type of electronic communication media (Straub, 1994), among other topics.

Related to how individuals operate together in groups, mental schemas for knowledge construction (Kock, 2004) influence the impact of e-collaboration technologies on the individuals involved. Schemas can be socially constructed, causing groups to interpret information in specified ways (Lee, 1994)—thus influencing perception and interaction. As Kock (2004) elaborates, the degree to which members of a task group share similar schemas, then less cognitive effort is required to successfully accomplish the task. Members of the same cultural group are more likely to share similar mental maps or schemas than with members of external groups.

In decision making, Tseng and Stern (1996) found significant differences in the information gathering behavior between Asians and North Americans. Different online communication strategies were uncovered in a study that included Japan, Spain, and the United States (Okayazaki & Rivas, 2002). Further, cultural differences exist in instant messaging between Asia and North America (Kayan, Fussell, & Setlock, 2006). For example, North Americans reported significantly less multiparty chat and rated emoticons lower in importance than Asians. Ethnicity has been established as a factor in electronic brainstorming (Tan, Wei, Watson, Clapper, & McLean, 1998). Based on the foregoing, it is a natural extension that culture influences e-collaboration behavior.

**THE WEB AS A COMMUNICATION MEDIUM**

Bordia claims that “computers and electronic networks have revolutionized communication” (1997, p. 99). Although it is not always clear that the electronic medium has enhanced the communication process since nonverbal cues that form a significant portion of the transmitted message are mostly missing. In fact, research has demonstrated that an absence of nonverbal cues that serve to “embellish meaning or social context regarding gender, age or status” can potentially hamper communication efficiency (Bordia, 1997, p. 9). Alternately, new capabilities for communicating content and collaborating using the Web are created (Tsao & Lin, 2001).

Simon (2001) used media richness theory (from Daft & Lengel, 1986) to examine how information richness might enhance user perceptions of the interface. Various design characteristics of Web sites were considered such as shapes, colors, language, site layout, and quality of information. It was expected that information rich Web sites would reduce user ambiguity, increase trust, reduce perception of risk, and encourage users to utilize the site. Significant differences between cultural groups in the study were uncovered, with Asians registering higher levels of trust with information across all Web sites in the study than European and North American groups. This finding suggests that not only is creating information rich interfaces useful generally, but that across cultures different preferences for the user interface prevail.
In studies on graphical user interfaces (GUI) in group support systems (GSS), benefits of using icons over text have been established, although this research does not explore aesthetics or usability of the system (Sia, Tan, & Wei, 1997). One would expect that computer supported, interactive, visual representations contribute to a user’s assessment of the medium as more effective, and may vary across cultures. As already noted, in one study on instant messaging differences in perceptions of emoticons across cultures were discovered. In other work, German users were found to value hierarchy and verbal components of a Web page, while Asia users prefer visuals (Sun, 2001). Color connotes different cultural meaning (Barber & Badre, 2001; Cyr & Trevor-Smith, 2004). Red means happiness in China but danger in the United States. In a study that compared Canadian, American, German and Japanese users, Japanese favored a more visual and “emotional” approach to user interface design (Cyr et al., 2005).

Related to the preceding, and in the context of e-collaboration, it is expected that if user interfaces are culturally appropriate then users are more likely to become engaged in the communication process, and with one another. This would be the case whether cross-cultural collaboration occurs in e-business, e-learning, or distributed work settings.

**TRUST AND E-COLLABORATION**

The use of computer-mediated and Web-based communication technologies has created new virtual environments in which trust plays a significant role. Online trust between collaborating parties is more difficult to elicit than trust in traditional settings since users have fewer cues than in a face-to-face or brick-and-mortar context. The primary communication interface for the user is an information technology artifact rather than a person.

Despite the complexity involved in studying online trust, in recent years a body of knowledge has been developed around this topic. David Gefen (2000, 2003) has contributed significantly in this area and identifies trust as a combination of: (1) beliefs about integrity, benevolence of another party; (2) general belief that another can be trusted; (3) feelings of confidence and security in the response of another; or (4) a combination of these various characteristics. Further, Corritore et al. (2003, p. 740) provide a definition of online trust that includes cognitive and emotional elements. They suggest that trust encompasses “an attitude of confident expectation in an online situation or risk that one’s vulnerabilities will not be exploited”. In e-collaboration, the user ideally seeks confidence in the computer mediated experience and that over time a trusting relationships with other users can be established.

There is a growing reservoir of research on the role of trust in computer-mediated communication (CMC) including virtual collaborations and long-distance communications in instant messaging, blogs, e-mail, teleconferencing, video conferencing, or virtual teams (Bos et al., 2002; Jarvenpaa et al., 1998; Walther, 1992). Trust research in these contexts has focused on interpersonal relationships as they pertain to collaborative work (Hossain & Wigand, 2004). More specifically, how initial trust develops is important to understanding how long distance relationships are developed and nurtured (McKnight et al., 1998). Taken collectively, it is expected that if Web based technologies are able to elicit trust in users, then communication as in GSS and other forms of e-collaboration will be enhanced.

Alternately, it has been proposed that CMC can potentially delay trust formation related to a slower rate at which clues about a partner can be gathered in a virtual setting (Walther, 1992). One might expect trust formation to be especially difficult in a CMC context that transgresses cultural boundaries. Not only is there difficulty in obtaining cues about a partner due to spatial distance, but
due to cultural distance or unfamiliarity as well. Little work has been undertaken on cross-cultural effects and online trust, and studies completed in this area have generally yielded inconclusive results. For instance, trust in e-commerce was examined between American and Taiwanese participants and systematic differences were found concerning privacy, but no differences were evident related to culture (Lui et al., 2004). In another study on culture and trust, differences existed between American, Canadians, and Germans with Japanese (Cyr et al., 2005).

In sum, trust formation is important in virtual relationship building just as it is in face-to-face encounters. In settings where visual cues are absent, and when cultural differences prevail, e-collaboration is likely to be more challenging. Once again, it is expected that cultural sensitivity to user values and expectations is a precursor to the development of successful working relationships using technology. In some instances face-to-face encounters prior to virtual collaboration may be useful both within and between cultures.

SATISFACTION AND E-COLLABORATION

For decades satisfaction has been important to the information systems research agenda, and has frequently been used as a facsimile for success. If users are satisfied, then they have positive attributions to the system, service, or user encounter. Numerous determinants of satisfaction have been proposed and confirmed including system quality and information quality (Doll & Torkzadeh, 1988). With the advent of the Internet many other studies have considered the user interface as a potential contributor to online satisfaction. This has included the “ambience associated with the site itself and how it functions” (Szymanski & Hise, 2000, p. 313).

Disconfirmation theory has applicability to e-collaboration. This theory stipulates that satisfaction is determined by a comparison between the perception of performance and a cognitive standard (Oliver & DeSarbo, 1988). In other words, does the object meet a user’s expectations? Marketing studies have a history of using disconfirmation theory to explain or predict satisfaction in the context of products or services. The theory has also been used to measure manager satisfaction with group decision support systems (DeSanctis & Gallupe, 1987). In this instance, user satisfaction is broadly defined as the “multidimensional attitude towards various aspects of MIS such as output quality, man-machine interface, EDP staff and services, and various user constructs such as feelings of participation and understanding” (Khalifa & Lui, 2004, p. 39).

In other work, Mahmood et al. (2000) compiled studies on user satisfaction over a ten year period and determined that satisfaction is mainly affected by user background, perceived benefits, and organizational support. User background is determined by user experience, user skills, and user involvement in the system development process. Perceived benefits are measured by user expectations, ease of use, and perceived usefulness of the system or object. Organizational support is driven by user attitudes toward information systems, organizational encouragement, and perceived attitude of senior management. Expectations about the system are thus related to disconfirmation theory and are shaped by personal experience and environmental factors (Khalifa & Lui, 2004). It is anticipated that the above determinants of satisfaction are tempered by culture, and the user experience of in-country system characteristics and support.

Taken collectively, it is feasible that culture factors into the satisfaction equation and is based on different values that prevail across cultural groups (Hofstede, 1980). As one example, Hofstede outlines different levels of uncertainty avoidance in diverse cultures, when members of a group seek to reduce personal risk. Such risk aversion occurs in traditional settings, but could
be extrapolated to online encounters as well. Also part of Hofstede's framework, certain cultures such as those in North America prefer to operate more independently, while Asian cultures tend to operate in groups and collectively. While these are cultural generalizations, in the context of e-collaboration there are indications that different expectations regarding online interactions are likely. If a discrepancy exists between cultural values and the collaborative format, then user satisfaction is less likely to occur.

Pulling together the threads of research as it affects various forms of e-collaboration, it appears that user values and expectations including those that are culturally based will influence perceptions of user satisfaction. User values, norms, and experience are likely to have an impact on reactions to technologies used for computer mediated communication.

CONCLUSION

The introduction and use of e-collaboration technologies has met with mixed levels of success (DeSanctis et al., 1993; Kock, 2004). In this article, it has been argued that culture is important to better understanding how e-collaboration operates. It is an area that has been largely overlooked to date. However culturally sensitive user interface design is described to potentially increase user trust and satisfaction, therefore enhancing the user e-collaborative experience.

In the future it is expected that designers of e-collaboration tools or interfaces will factor in cultural characteristics to the technology system. As one example there is growing evidence that culturally appropriate user interfaces are important for educational courseware (Pfremmer, 2004). Cultural acknowledgement can impact user impressions of usability, accessibility and acceptability of software and will influence factors such as ease of learning, efficiency of use, memory ability, error frequency and severity, and subjective satisfaction (Kondratova & Glodfär, 2005). Also related to e-learning, collaboration and learning can be hindered by teaching style differences, problems related to different educational values, or diverse language and semantics (McLoughlin, 1999).

Similarly, cultural characteristics should be considered as they relate to effective functioning of project management teams, group support systems, and other forms of e-collaboration. A challenge for researchers is how to best adapt various technologies for diverse cultures. In an area ripe for future enquiry, investigations might focus on how trust and satisfaction are enhanced in e-collaboration, and factors that influence this process.

Chapter 5.6
Cultural Barriers of Human–Computer Interaction

Deborah Sater Carstens
Florida Institute of Technology, USA

INTRODUCTION

Information and Communication Technology (ICT) researchers and practitioners are well aware of the cultural challenges brought on by a global market (Smith, 2004; Smith, Dunckley, French, Minocha, & Chang, 2004). However, there are many unresolved problems concerning the extent to which culture influences ICT usability. Businesses use ICT in the form of databases to house customer information, Web sites enabling customers to place orders, information systems for management or suppliers, training systems, and as products sold to customers. Internet growth enables businesses to expand their customer base to international markets. Thus, businesses benefit from the explosion of Internet usage but may be challenged by how to best meet the needs of their multi-cultural customers, suppliers, and employees. There is a need to develop a model of cultural barriers to human-computer interaction (HCI). With all of the technology in use today, along with the different cultures that interact with ICT, it is important to identify a model of ICT and the HCI barriers produced by it to better help designers of ICT avoid these technology pitfalls. Figure 1 displays how the incorporation of technology, people, and culture into businesses must be carefully positioned together to optimize the success of all involved.

This article examines cultural barriers to HCI and outlines a model to help designers of ICT avoid these barriers so as to enhance a company’s ability to conduct business internally and with international businesses and customers. The article addresses topics of interest to ICT practitioners and researchers alike. Current services available to businesses that support effective international HCI are discussed. Current research and future research opportunities in the field of international HCI in ICT are also examined.

BACKGROUND

It is important to define HCI as the study of human behavior in interacting with any computer-based device such as a Web page, information system,
or other technology. Through the study of HCI, researchers optimize interactions between the human and technology through better design of the ICT. Traditional ways of conducting business seldom exist in a society experiencing growth in the Internet, globalization of trade, and digital integration internal and external to a company. The role of ICT including e-commerce and information systems has become more complex as businesses continue expansions into global markets (Laudon & Laudon, 2004). With businesses having multi-cultural customers, suppliers, and employers, there are demands for businesses to utilize ICT that adequately meets the needs of cultural groups that interact with the technology. This section discusses how international HCI is an important aspect of ICT. In fact, there are businesses that specialize only in servicing other businesses in providing multi-cultural aspects to ICT. Furthermore, current research in the field of HCI is addressed to uncover cultural barriers to HCI that potentially produce ineffective ICT for specific user communities.

Today, HCI is in the spotlight as companies outsource software development or Web sites, operate e-commerce businesses, and extend their services to international customers. The globalization of business has pushed industry into finding ways to incorporate international HCI. Usability is a topic under the umbrella of HCI that is important to design into any ICT, especially systems utilized by a multitude of international users. Zwick and Dholakia (2004) suggest that adoption of any ICT brings about multiple issues to consider regarding social, political, economic, and cultural implications. ICT such as Web sites are generally adopted to solve a business need, but this article also suggests that with the introduction of technology, businesses may inherit new challenges before achieving full resolution of their business need. With the globalization of businesses, cultural barriers must be identified and
corrected in ICT-enabling companies to continue relationships with different cultural groups within their customers, employees, and suppliers.

There are ICT practitioners dedicated to servicing businesses to support effective international HCI. Current services available to support multi-cultural HCI business needs consist of companies that provide written translations, verbal interpretations, multilingual desktop publishing, audiovisuals, Web site localization, globalization consulting, language services, global branding support, content development, end-user experience designs, translation of business correspondence, international user research, usability testing, etc. Aplomb Translations (2004) is an example of a company that specializes in providing multi-cultural language services. Aplomb focuses on audio and video transcription, subtitling, voice-overs, and Web site translation. Another company, ABC Translations (2004), focuses on services such as Web site and software localization. Web site localization assists a company with services such as providing multilingual online marketing strategies to globalization-friendly sites. Software localization uses in-country specialists to create localized versions of software applications to serve specific cultural user communities. Crosscultural (2004) provides global online marketing, helping companies expand their Internet presence into different cultural communities. The expansion into global markets creates open doors for practitioners and researchers providing services and solutions that help businesses to better meet the demands of multi-cultural customers, suppliers, and employees through effective international HCI in ICT.

Research has been performed in the field of HCI and the subtopic of international HCI has increasing popularity with the globalization of business. Cultural barriers to verbal communication between individuals from even different English-speaking countries can be difficult (Norman, 1999). Barriers to international HCI are therefore concerned with not only language but also other factors as well. Heldal, Sjøvold, and Heldal (2004) suggest that a user’s perception of a Web site will vary from culture to culture and is influenced by every aspect of a site, even beyond content and language. This experiment focused on evaluating Web sites using subjects from Norway and South-Europe. Aspects of a site such as site organization, frustration and innovation were rated differently by the Norwegian participants than the South-European participants. These findings suggest that differences in perceptions or impressions of a site can be related more to culture than the actual design of a site. An experiment conducted by Siala, O’Keefe, and Hone (2004) indicates that individual religious backgrounds may also affect online trust towards electronic commerce. They found that people and communities of people sharing common values and personality traits from different cultural groups can build in-group trust (Siala et al., 2004). The study compared individual responses based on their religious affiliation (Christian, Muslim, etc.), gender, and ethnicity. The study measured the extent to which religion and possibly in-group trust affects a participant’s buying habits and inclinations to buy online from within a religious group. Findings indicate that religious backgrounds did make a difference as some participants appeared to be more consumer religio-centric. Trust and attitude in a Web-based retailer varies within cultural groups and increases the importance of businesses identifying with different cultural groups where trust and attitude affect buyer behavior (Siala et al., 2004). Another study by Cannon and Perrault (1999) suggests that satisfaction is important in relationship marketing, which is also linked to communicating proper and distinctive impressions. There are also interrelated aspects of these cultural barriers, as Heldal et al. (2004) suggest that poor usability of a site may give a customer a bad impression of the company and its products. These studies serve to demonstrate that international HCI is important in the design of effective ICT.
The term “usability” refers to the capacity of software to easily and quickly perform the tasks that users seek (Dumas & Redish, 1999). Nielsen (1993) further classifies usability as either practical or social acceptability. For the purposes of this article practical acceptability examines the usefulness of the ICT being able to carry out needed user functions. For example, if a person from England uses the search feature on an American Web site to find the term “organisation,” the site should accommodate the language of the user even if it is not in the language of the designer of the site (i.e., Americans spell the term using a “z” instead of a “s” as in “organization”). Social acceptability refers to whether the technology is considered ethical within the purpose of the technology. This area is obviously complex and important since different cultures may have different impressions of ethics. Companies obviously should be interested in the effect of how pleasant a customer’s online shopping experience is on sales. Furthermore, it is important that employees have very usable ICT systems because employees using difficult systems may spend longer performing set tasks and this could also impact morale and subsequently productivity.

Wickens (1992) developed a human-information-processing model that addresses the internal and external information processing that a human goes through in performing an information task. The model is useful in the application of ICT design of HCI issues as culture impacts the perception and interpretation of information. For example, if the language conversion feature on an online purchasing site is worded in English instead of having pictorial language indicators (such as flags), many users will have difficulty in understanding the site. More recent work by Te’eni and Sani-Kuperberg (2004) performed research extending the human-information-processing theory into the identification of Levels of Abstraction (LoA). LoA refers to the process of users getting lost in the details of information search. When users shift focus to reading the online help feature, they are switching from one level of abstraction to another. LoA research is a detailed task analysis of a user operating technology. If LoA can be generalized for specific cultural communities, it may also be useful in designing ICT for multi-cultural information processing and thus extend previous information processing research.

CULTURAL BARRIERS TO HCI

ICT was earlier described to include any computer-based device. For businesses, common ICT consists of customer relationship management databases, computer-supported collaboration, management information systems, Web sites, training tools, supply chain management systems, and technology produced or used by a company. The literature asserts that cultural barriers to adoption and effective use do exist and greatly vary from culture to culture (Heldal et al., 2004; Siala et al., 2004; Smith, 2004; Smith et al., 2004; Zwick & Dholakia, 2004). The literature suggests that some of the common barriers that exist include poor organization, hard-to-use features (not user-friendly), frustration, confusion, non-usable features, trust, religion, ethics, and lack of satisfaction (Cannon & Perrault, 1999; Heldal et al., 2004; Nielsen, 1993; Norman, 1999; Siala et al., 2004). If Nielsen’s (1993) earlier work is considered, new barriers not previously identified include religion, trust, and ethics. Figure 2 displays a model that shows the impact that cultural barriers have on ICT for a business. The negative consequences of the barriers that impact customers, businesses, employees, and suppliers are extracted from the literature and include poor impressions of a business, decline in sales, and company efficiency and productivity (Lazar, 2001; Heldal et al., 2004; Cannon & Perrault, 1999; Siala et al., 2004). In a world where businesses are under constant pressure and competition to attract customers, to maintain dedicated employees, and to develop innovative products, it is challenging for companies...
to devote the necessary time and attention that HCI demands in meeting multi-cultural needs to adequately optimize businesses, technology, and people. The model presented in Figure 2 aids designers of ICT in considering cultural barriers to HCI and its impact on businesses, employees, customers, and suppliers.

**FUTURE TRENDS**

Future research opportunities for ICT practitioners and researchers are discussed in this section. The current implications are that ICT will continue to grow and eventually pulse through every aspect of an individual’s environment and the emerging field is in the social appropriation of ICT. The social appropriation of ICT brings with it an increasing need to view adoption from a users perspective in an environment of almost infinite choice. In such circumstances HCI will continue to be a significant part of the new and changing adaptations of ICT.

Obviously this will require increased effort on behalf of researchers and designers to define and mitigate barriers to ICT usability. Culture has been identified as a significant issue in the increasingly globalized world and follow-on research is required to validate the cultural barriers to the HCI model proposed. The next steps include the identification of guidelines that could be developed to design out cultural barriers to HCI addressing how to design ICT that is considered easy to use.

Luckin (2003) identified a checklist to help learners use multimedia. The checklist includes identification of the goal for using the technology, reminders of the goal, guide to sub-goals, and a model answer, thus providing feedback to the user for future use of the media. Given the increasing importance of social appropriation, research should be expanded to identify a checklist for use by designers of ICT to design out cultural barriers to HCI.

There is a need for research addressing the influence of animations on interaction with Web
Cultural Barriers of Human-Computer Interaction

pages to measure the effectiveness of these interface enhancements (Schaik and Ling, 2004; Lee & Benbasat, 2003). This also presents an opportunity to identify the cultural preferences of such features. As Intranets also utilize such animations, research could be conducted to determine if productivity of employees is enhanced when such features are active. Furthermore, design teams could be studied to determine the successful incorporation of international HCI in ICT. Therefore, the effectiveness of multi-cultural design teams should be studied. Several researchers have explored international usability testing and have found challenges in the cost of operation across cultures as well as difficulty in communications between the usability professionals and users of different cultures (Dray, 2001; Murphy, 2001; Yeo, 2000, 2001).

As the world continues to push technology into global markets, a gap analysis effort could be performed to identify current and potential future needs of businesses versus current available services in terms of effective HCI in ICT.

CONCLUSION

The world has been revolutionized by the abundance of ICT that greatly transforms the way businesses and individuals communicate and operate. International HCI looks at ways that information displayed through ICT can be enhanced to optimize use in multi-cultural environments. While there is increasing recognition of the importance of the impact of culture on effective use of ICT in a rapidly globalized world, there is not a substantial body of research or practice that matches the expanding use of ICT. As ICT favours increasing economies of scale, business (both large and small) will drive the demand for answers to the impacts of culture on the social appropriation of ICT. This is of vital importance to regional business as it seeks to build interactions with particular regions across the world.

Cultural Barriers of Human-Computer Interaction

**KEY TERMS**

**Barriers to Human-Computer Interaction:** Anything that poses as a challenge to a human interacting with technology. Examples include poor organization of a Web site and language conversion issues.

**Consumer Religio-Centrism:** Individuals who are so strongly committed to their specific religious group (Christian, Muslim, etc.) that their buying preferences consist of purchases from companies owned or operated by individuals with their same religious beliefs.

**Customer Relationship Management:** Technology in a business that houses information on customers. The information systems give businesses an integrated view of each customer that may consist of demographic data, buying trends, and financial data.

**Enterprise Functions:** Enterprise functions are composed of typical functions of a business such as human resources, marketing and sales, manufacturing, accounting and finance.

**Human-Computer Interaction (HCI):** Study of human behavior in interacting with any computer-based device. HCI is concerned with
identifying ways to optimize such as through the design of technology and the relationship between humans and computers.

**In-Group Trust:** Communities of people that have similar beliefs, values, and personality traits induced by cultural forces and are more willing to identify members inside their group as trustworthy. Individuals within these communities obtain role models and opinion leaders within their group that influence individual’s beliefs and behavior to include buying decision processes.

**Information Processing:** Study of how humans interact within their environment while interpreting information to identify a decision. Humans are a unique form of a machine and must process information in order to formulate a decision.

**Management Information Systems:** Systems utilized by management-level employees to seek information pertaining to the operations of their business. The information gives management insight into potential market or financial trends as well as the productivity and efficiency of their employees and equipment.

**Supply Chain Management:** Automates the relationship between businesses and their suppliers to optimize shared processes. An example of this relationship is suppliers through the Internet viewing supply levels of a company and responding automatically through sending more supplies without the company directing the supplier to do so.

**Usability:** Study of the usefulness of technology as it relates to an individual being able to successfully perform their task with ease. Usability is measured through the ability of the technology to do the right job and to do the job right.

Chapter 5.7
Technology and Culture: Indian Experiences

Ramesh C. Sharma
Indira Gandhi National Open University, India

Sanjaya Mishra
Indira Gandhi National Open University, India

ABSTRACT
This chapter discusses the deployment of e-learning technologies in the context of how they are helping towards preserving and disseminating knowledge on Indian cultural heritage. An analysis has also been offered as regards how the technologies like e-learning initiatives have their impact on sociocultural settings within Indian context. This chapter attempts to understand and frame Indian culture and experiences through ICT and e-learning practices, and how the differentiated learning needs of multicultural society can be addressed.

INTRODUCTION
Culture has been important, perhaps one of the most important concepts, of anthropology. A surviving culture is always dynamic in nature; it evolves over time and, at the same time, maintains its identity. Matsumoto (1996, p. 16) defined culture as, “the set of attitudes, values, beliefs, and behaviours shared by a group of people, but different for each individual, communicated from one generation to the next.” It is these values and beliefs which make a culture that can survive against all odds.

Indian civilization is one of the oldest civilizations of the world (dates back to more than 5,000 years). In spite of various foreign invasions and dominations, visits by scholars in search of knowledge, India’s cultural own identity has been maintained. It has adopted the good from them while rejecting those that might have destroyed its unique unity in diversity feature. This nation has witnessed many social, economic, political, and technological changes. Here, science and spirituality both exist. Indian architecture, festivals, dance forms, painting, sculptures, cuisine, literature, and teacher-taught relations, all have
different dimensions of extraordinary variety. This cultural heritage has been passed onto from generation to generation by appropriately preserving, promoting, and disseminating modes be it oral, written, or now electronic.

INFORMATION COMMUNICATION TECHNOLOGY (ICT) IN INDIA

The government of India has accorded high priority to the deployment of ICT for social and community development. Since early 1970s, India has witnessed constant growth in the area of telephone density, Internet penetration, establishment of radio and television stations, broadband connections, and affordable computers and peripherals. These have become within easy reach of the educational institutions, businesses, and individuals and so forth.

Starting with nearly a thousand Internet users in 1992, over 5 million users were enjoying Internet in 2000 (GOI, 2003). TRAI (Telecom Regulatory Authority of India, 2005) reported that there were 105,000 Internet cafes in India; telephone density was 0.6% in 1991, which increased to 11.7% in 2006.

Telephone, radio, and television has been widely used in educational settings in India (Sharma, 2002; Vyas, Sharma, & Kumar, 2002a, 2002b). One-way-video two-way-audio teleconferencing is quite effective for content presentation, learner-expert interactions, and learner-supported activities (Mishra, 1999). In addition satellites have also been considered to be useful in catering to the educational needs of the society. For example, EDUSAT is the first Indian satellite designed and developed exclusively to meet the demand for an interactive satellite-based distance education system for the country (Sharma, 2006). All these different instruments of ICT, like radio, television, teleconference, satellite, Internet, have contributed to the community development under various schemes of the government.

ICT FOR CULTURAL HERITAGE

Different measures for the preservation, transmission, and advancement of languages and culture have been adopted by the communities. With the physical expansion of the world, different cultures and languages have realized the increasing importance of having dynamic and vibrant mechanisms that can help them maintain their identity and foster progress in a multicultural learning environment. Odasz (n.d.) states, “The world’s diverse cultures jointly represent the full cultural genome of humankind’s search for individual and group identity and meaning” and exert pressure to record this important “shared story of humankind.” The sooner actions are taken to save the cultural knowledge of our ancestors, the better will be, as it is feared that nearly half of the world’s 6,000 languages may disappear in one lifetime. Odasz (n.d.) recommends, “The vast cultural knowledge of our elders must be recorded via multimedia storytelling for preservation while they (our elders) are still with us.”

The use of ICT to the cause of culture has been best exemplified through different kinds of technological tools (radio, television, Internet, etc.) being heavily used by Indian communities to maintain or to create new relations. The social networking tools, like MySpace (http://www.myspace.com); Ning (http://www.ning.com); Second Life (http://www.secondlife.com) or Orkut, are connecting people across different cultural and social backgrounds. Cellular phones have become an integral part of common people, due to slashing of rates prompted by the entry of many players and due to the Government of India’s intention to reach to the masses through telephone network. SMS poll is nowadays a common phenomenon in case of any national event where the viewpoint of masses has a say. This is becoming a cultural bonding technology even in some cultural events when the contestants request the people to vote for them through SMS like reality shows on television. Cole and Crawford (2007) consider ICT tools as
an effective means of enhancing communication among communities, building peace and facilitating better understanding of each other. A culture is what we think, what understanding we have for others, and how we behave. Manjul (2005) reported an "alternate media," in the form of a rural newsletter that was initially launched as a communication channel among the women themselves, but by the impact it had on the sociocultural issues, it evolved into a mechanism whereby it addresses the community as a whole, and a great tool for women empowerment.

TECHNOLOGICAL INITIATIVES AND CULTURE

ICT applications in India have been used for educational, economic, and social development of Scheduled Castes, other Backward Classes, and minorities, as well as protection of rights and opportunities for the welfare of disabled persons, children in distress, victims of drug addiction, and the senior citizens. Establishing a telephone help line for disabled persons in Mumbai has been a significant achievement. Similarly, a toll-free telephone service, “Childline,” provides help to children in distress or by adults on behalf of such children. This facility was significantly beneficial to Tsunami affected areas during 2005, like Kanyakumari, Nagapattinam, Kanchipuram, Cuddalore, Kollam, and Port Blair and so forth.

Although many religious communities in India possess strong, gender-related norms, situation is comparatively serious in Muslim community. Girls are not encouraged to leave home without a veil, education is low priority, early child marriage is common. Sharma and Maindiratta (2005) reported an interesting case, where the effort by Datamation Foundation Trust to establish an ICT centre at Babool-Uloom Madrasa (a religious residential school providing learning opportunities to boys from poor families) in a densely populated and low income area of New Delhi initially met with cold response. The Trust wanted to set an ICT centre to address urban poverty and increase women empowerment, and the project was initiated, keeping in view local cultural values. Internet was also used (using eNRICH, a local Web-based browser) to encourage local talent and cultural heritage. Cross-cultural experiences were made available to them to learn about the communities in other countries. Slowly, the results showed their effects and the centre started gaining popularity. This was most conspicuous during the month of Ramadan, when the center was to be closed for the month. The girls convinced the concerned authorities successfully to let the centre remain open for some time. That was unimaginable before, as the girls are not allowed to have such a dialogue. This clearly establishes the impact of the ICT on the cultural values.

Governmental Agencies in India and Projects

In India, technological mechanisms are being used for maintenance and conservation of the country’s heritage, ancient monuments, and historic sites; promotion of literary, visual, and performing arts; administration of libraries, museums, and institutions of anthropology; maintenance, preservation, and conservation of archival records and archival libraries; research and development in the conservation of cultural property; and promotion of institutional and individual initiatives in the field of art and culture. Technology is helping out in generating cultural awareness at the grassroots level to promote cultural exchanges at an international level. Detailed information is also made available on Indian history, literature, philosophy, religions, Sufism, art, architecture, astronomy, astrology, mathematics, medicines, and physical sciences.

Some of the important organizations and agencies in India dealing with preservation, conservation, and spreading awareness of culture are:
Cultural Informatics Laboratory

Cultural Informatics Laboratory (CIL) establishes a synergy between the disciplines of art and information technology leading to usage, development, and demonstration of new technology and cultural documentation.

Kalasampada

The project is sponsored by Ministry of Communications and Information Technology, Govt. of India, (MCIT) under digital library initiative (DLI) – India. The prime focus of this project is to develop a databank of cultural heritage housing over 4.5 million pages of manuscripts, 4,000 photographs, and 200 hours of audio and video.

Content Creation and IT Localisation – Network (COIL-NET)

Sponsored by the Ministry of Communications and Information Technology, Govt. of India, a Web site on “Cultural Heritage Digital Library” has been developed in Hindi with special focus on Hindi Speaking region mainly states of Uttar Pradesh, Uttarakhand, Madhya Pradesh, Chhattisgarh, Bihar, Jharkhand, and Rajasthan.

Manuscripts Digitization Projects

The digitization of rare manuscripts written in archaic languages and scripts such as Arabic, Persian, Sanskrit, Hindi, Urdu, Turkish, and Pashto, and so forth, is an important step towards preservation of Indian cultural heritage.

Ajanta - In-house CD-ROM Project

This CD-ROM project provides wide-ranging knowledge and visual experience (in the form of 1,500 illustrated images, articles from eminent authorities, Bibliography, Glossary, etc.) on Ajanta, a major heritage site of India, included in the UNESCO’s list of World Heritage monuments.

Eternal Gandhi – Multimedia Exhibition

The Eternal Gandhi is state-of-the-art digital multimedia exhibition, which deals with information on the historical events of the life and message of Mahatma Gandhi. The exhibition also presents a wide spectrum of information technology visions inspired by the thought and teachings of Mahatma Gandhi.

National Multimedia Resource Centre (NMRC) project

The National Multimedia Resource Centre (NMRC) project (launched in 1998 and sponsored by the Department of Information Technology, Ministry of Communications & Information Technology, Government of India) identifies and disseminates cost-effective applications of multimedia among the masses.
Indian Heritage Portal

The Indian Heritage Portal developed by C-DAC (Centre for the Development of Advanced Computing) provides information on Indian scriptures like the Vedas, Bhagavad-Gita, Mahabharata, and Dhyaneswari and so forth.

E-LEARNING FOR CULTURAL ISSUES

E-learning is increasingly considered as a means of greater access to education and development (Mishra & Sharma, 2005). Such projects have their impact on rural, illiterate, or women populations, the upliftment of whom is of prime importance. These have greater impact on the cultural issues also. E-learning practices have been found to be an important tool in preserving, promoting, and advancing cultural heritage. The initiatives taken by Kerala Government through its e-tourism have generated a world wide interest. Another successful example is Tamil Virtual University (http://www.tamilvu.org/) established as an Internet-based resource that provides details on the history, art, literature, and culture of the Tamils. This project is very popular among those Tamils who have settled in various parts of world, and interested in knowing about the cultural heritage of Tamil community. Indian Tobacco Company (ITC) is one of India’s leading private companies, and has initiated an e-Choupal effort (http://www.echoupal.com/) that places computers with Internet access in rural farming villages (http://www.digitaldividend.org/case/case_echoupal.htm ). A “Choupal” is a local village gathering place where the villagers gather and discuss their problems or issues.

Culture and Language Instructional Context

Many cultures (like rural folk in Gujarat and Rajasthan State in India) use narration and storytelling as a way of passing on the information from past to the present generation. Narration enables the learners to participate in the process and becomes the core of experiential and contextual approach to learning.

FUTURE TRENDS

Different technologies have different characteristics and thus, impact differently on the cultures (Idrus & Sharma, 2007). A radio or a television may impact differently than Internet. It depends on the nature of technology, that is, be it one-way or two-way/synchronous or asynchronous, how the cultural issues are going to be affected by it. It would be significant to understand in what way innovative ICT approaches can maximize the impact of different technologies by integrating them (Girard, 2005; Mathison, 2005). For example, in the Kothmale Community Radio Internet Project in SriLanka (http://www.kothmale.org) Internet is used to search the information and radio to disseminate it. Also, the listeners can send the questions to the radio station either by post or calling through telephone. Then the team at Radio Station uses Internet to search for needed information, translates it in local language, and broadcasts the answer.

Further, the research on measuring the impact of ICT on community development is still in its infancy in India. There is a strong need to undertake microdata analysis to identify the extent to which ICT changes the performance of small and medium enterprises in developing countries.
FUTURE RESEARCH DIRECTIONS

Future research directions must address the issues like how do the technology programmes deal with different communities and different cultures and languages? Which interventions need to be customized? To what extent is a programme effective in a specific community? Is there any supportive culture for using ICT for bringing out community development?

CONCLUSION

India is a vast country covering wide geographic area, divided into numerous cultures and languages. Over 700 million Indians live in rural areas. Of these, around 190 million live below poverty line. India has perhaps the largest number of poor people in the world. The situation further aggravates, as 84% of our illiterates live in villages. The diversity and magnitude of these problems create huge challenges for the ICT channels, which appear to be disorganized and with little effectiveness for communication and resource sharing. We need to have an in-built feedback mechanism and supporting research studies to showcase the indigenization of culture through ICT.

Culture of a place is reflected through group behaviour, social norms, how the group thinks, behaves, reacts, and responds to a situation. ICT can be an effective tool by encouraging cross-cultural exchanges, while at the same time bringing out positive social changes, by developing mutual respect for each other's culture, sharing of opinion. Proper networking of different agencies in a planned way would tackle sociocultural issues. The public-private partnership involving government would create innovative solution for society’s need. The invention of the simputer in India is an example.

Issues that may arise while developing culturally sensitive instructional material are values and attitudes, ethical perspectives diversity within groups, historical perspectives, socioeconomic perspectives, social roles, social networks, learner expectations, learning styles, and opportunities for interactions (Collis 1999; Dunn & Griggs, 1995; McLoughlin, 1999; Powell, 1997; Reeves, 1997and). Gjedde (2005, p. 104) suggested that issues, such as social and cultural backgrounds and gender-specific interests, must be considered when developing meaningful content and creating narrative e-learning environments. Singh (2003, p. 100) suggested steps to deal with problems faced during the development of e-learning in India viz. the diversified geographical spread; the use of different languages in different states and regions; the communication infrastructure; and the illiteracy. The language problem is being tackled on many fronts. The Microsoft XP desktop operating system has the ability to support nine Indian languages. Modular Infotech Pvt. Ltd., a Pune (Maharashtra)-based company, is actively working on the language front. It has partnered with Microsoft to develop various keyboard handlers for Indian languages.

The Government of India has urged upon private-sector companies to make a commitment to rural areas. India is looking forward to establishing a “Universal Service Fund” to service the rural IT plan. The Government of India has reduced telephone call rates to promote the use of the Internet and make the Internet and telephone services affordable to the general public. The Ministry of IT holds regular meetings to promote the concept of e-learning. The fast developments in information technology and products have revolutionized the ways of teaching and learning across different cultures. The content generated with IT applications acts as a vehicle for knowledge that is well-suited to many cultures and languages across the globe. The Internet tools in the form of Web-logs or pod-casting provide great opportunities for the preservation, expression, strengthening, and dissemination of cultural identities and languages (Mishra & Sharma, 2004).

Chapter 5.8  
Intercultural  
Computer–Mediated  
Communication Between  
Chinese and U.S. College  
Students

Yun Xia  
Rider University, USA

ABSTRACT

This study incorporates the effects of culture and computer-mediated communication (CMC) in the investigation of Chinese college students’ use of English in communication with U. S. college students. Ethnography of communication was used as the method to uncover four language patterns in Chinese college students’ use of English: others-oriented talk, mentor-mentee talk with limited relationship development, adoption of others’ talk, and icebreaker talk. Chinese cultural values showed a strong effect on Chinese college students’ use of English in CMC. Chinese cultural values included Chinese significance of personal relationships, Chinese collectivism, Chinese understanding of authority, and Chinese use of CMC. The characteristics of CMC showed minimal effect as either a constraint or a way of encouragement in the four language patterns.

INTRODUCTION

Although English is a global language in intercultural computer-mediated communication (CMC), patterns, rules, and premises of English use vary across different cultures. Decades ago, Hymes (1968) proposed assumptions regarding speech and language in a cultural group. First, speech and language of a group constitutes a system. Second, speech and language vary cross-culturally in function. Third, speech and language activity of a community should be the primary object of attention. Thus, the study of particular use of English language in a cultural group in CMC should be
the focus that can uncover the resources of different communication contexts. The interpretation of meanings of those resources should provide guidelines for intercultural CMC in return. In this chapter, ethnography of communication was used as the research method to describe, analyze, and interpret Chinese college students’ English language activities and Chinese cultural resources regarding language activities that constructed a distinctive intercultural communication between Chinese and U.S. college students.

BACKGROUND
CMC and Intercultural Communication

In the literature of intercultural computer-mediated communication, there are two major perspectives. On the one hand, the focus on communicative effects of CMC argues that CMC with its unique characteristics can facilitate and contribute to intercultural communication. On the other hand, the evaluation of cultural factors in communication leads to the conclusion that communicative styles in CMC as well as attitudes and perceptions toward CMC are subject to cultural effects. However, few studies in the literature have incorporated both CMC characteristics and cultural effects in the examination of intercultural CMC. The current study adopts both perspectives in the evaluation of Chinese cultural effects and CMC’s effects on Chinese college students’ English communication with U.S. college students.

CMC includes different formats: e-mail, chatgroups, virtual worlds, and the World Wide Web. Across different formats, CMC is primarily in the form of written language. Compared with face-to-face communication, the written communication in CMC is “leaner” because the social context cues in face-to-face communication are missing (Kiesler & Sproull, 1992; Walther & Parks, 2002). The missing social context cues include people’s race, gender, social class, and accent (Sproull & Kiesler, 1991). The direct communicative effect of this characteristic is CMC’s potential for fostering flagrant and hostile language known as “flaming” (O’Sullivan & Flanagin, 2003). CMC is also ranked as low in media richness with less immediate feedback and limited personalization (Daft & Lengel, 1986; Trevino, Lengel, & Daft, 1987). Media with low richness communicate low social presence. In CMC, users may pay less attention to others’ presence. As a result, CMC makes communication more task oriented (Walther & Burgoon, 1992). Empirical studies (Jonassen & Kwon, 2001; Mazur, 2004) report that during group problem-solving activities, CMC participants produce fewer, but more task-oriented, messages than do face-to-face communication participants.

In intercultural communication, these characteristics of CMC encourage more participation from people who may normally feel intimidated in face-to-face interaction. As Warschauer and De Florio-Hansen (2003) stated, people in CMC do not know whether others are a dog, Black or White, male or female, or rich or poor. Thus, people who are less outspoken in face-to-face situations may contribute more in CMC with anonymity or less exposure (Simons, 1998; Tella & Mononen-Aaltonen, 1998). In some cultures, people take a passive rather than an active role in interaction. With low social presence, CMC’s task-oriented communication characteristic offers people an opportunity to make more contributions (Warschauer, 2000; Warschauer & De Florio-Hansen, 2003). CMC’s absence of nonverbal cues such as frowning and hesitating also makes interactions less intimidating and thus allows people in cultures that are less dominant to play a more active role in intercultural communication (Warschauer, 2000; Warschauer & De Florio-Hansen, 2003).

On the other hand, CMC as well as other media is subject to cultural influences (Leonardi, 2003;
Studies show that the differences between individualistic and collectivistic cultures affect the levels of satisfaction with e-mail (Chung, 1992; Scollon & Scollon, 1995; Simons, 1998). With social relationships constructed in language, an individualistic culture allows people to be more satisfied with task-oriented, short, and straightforward e-mail that has minimal context cues. With special forms of discourse that carefully preserve the boundaries between those who are inside members of the group and all others who are not members of the group, a collectivistic culture may require more context information for a successful communication in e-mail (Chen, 1998; Gunawardena et al., 2001).

The differences between high- and low-context culture also affect the use of CMC as well as other communication technologies (Chen, 1998; Chung, 1992; Leonardi, 2003; Xia, 2006). A high-context culture has most of the information in communication implicit (Hall, 1976). The meanings are to be inferred from the context or internalized in communicators themselves. A low-context culture has information explicit in the transmission of verbal messages. In a low-context culture, people tend to use verbal expressions explicitly, value self-expression and eloquent speech, and express their opinions directly. Studies (Chen, 1998; Chung, 1992) suggest that high-context cultures will be less satisfied with relationship building and feelings expressed in CMC. Low-context cultures, on the other hand, are likely to find CMC useful for expressing specifics in a short and straightforward style.

The differences between monochronic and polychronic culture also impact intercultural communication in CMC (O’Dowd, 2001). Monochronic cultures, such as the U.S. and northern European countries, are task oriented with emphasis on scheduling activities according to deadlines. Polychronic cultures, such as countries from the Mediterranean and the Middle East, prefer to combine activities and consider deadlines as objectives rather than as anything certain (Taylor, 2000). Communication between the two cultures can break down if people in a polychronic culture do not answer e-mails on time or do not work on a timetable for a synchronous CMC interaction (O’Dowd, 2001). Meanwhile, people from a monochronic culture may appear to be demanding to polychronic people when they try to get things done as fast as possible (O’Dowd, 2001).

**Language Analysis in Intercultural CMC**

Because CMC is primarily text based, the analysis of language use becomes critical to understand the nature of CMC and the relationship between language and social practice in a culture (Herring, 2001). However, the literature is particularly sparse on how particular language behaviors function in intercultural CMC. Only a few studies have explored unique cultural experience through language interaction in CMC. O’Dowd (2003) investigated intercultural experience in CMC and identified key characteristics of e-mail exchange that helped develop intercultural communicative competence. Choi and Danowski (2002) studied power-play negotiations of dominant and minority cultures in CMC through the analysis of structural patterns of online communication flow. In a study of how linguistic interaction patterns changed over time among a geographically and ethnically diverse group of young people, Cassell and Tversky (2005) uncovered the ways in which people from different cultural backgrounds constituted a community, spoke in a collective voice, and formed a unique culture. Through the analysis of written reports and interview notes, Ma (1996) analyzed the recurring themes in CMC between East Asian and U.S. students. After proposing and testing five propositions about intercultural CMC, Ma found that both East Asian and U.S. students were more direct in CMC than in face-to-face communication.
In the study of culture through language analysis in CMC, Herring and her colleagues played a significant role. According to Herring (1996), individual electronic messages are internally organized text, and texts’ distinctive schematic organization can be uncovered through language analysis. After studying one female-dominated and one male-dominated listserv, Herring found that messages posted by women were more interactive and contained more information while men tended to express their views critically. With the discovery of distinctive schematic text organization, Panyametheekul and Herring (2003) studied language use and culture in turn-taking of a Thai chat room. They found that Thai females had more frequent participation than males. This finding broke cultural expectations about the roles of women in Thai society and the role of women online.

From the intersection of the reviewed bodies of literature, the following are three research questions about Chinese college students’ use of English in intercultural CMC with the U.S. college students. With the three research questions, the study attempts to examine the effect of Chinese culture and characteristics of CMC on Chinese students’ use of English in CMC.

**RQ1:** What are the distinctive language patterns in Chinese college students’ use of English in intercultural CMC with U.S. college students?

**RQ2:** How does Chinese culture affect Chinese college students’ use of English in intercultural CMC with U.S. college students?

**RQ3:** How do the characteristics of CMC affect Chinese college students’ use of English in intercultural CMC with U.S. college students?

**MAIN FOCUS OF THE CHAPTER**

**Method**

In the study of this chapter, ethnography of communication was used as the research method. Ethnography of communication fills the gap between ethnography and linguistics. There is a widespread relationship between a language and a culture. The actual uses and patterns of use of language in different cultural groups need ethnographic description. The focus of ethnography of communication is on the way that communication in a cultural group is patterned and organized as systems of communicative events. An ethnographer of communication is “a naturalist, who watches, listens, and records communicative conduct, in its natural setting” (Philipsen, 1992, p. 7). With non-participant observation of intercultural CMC scripts and in-depth interviews in ethnography of communication, the researcher is able to describe, analyze, and interpret Chinese college students’ language activities that construct distinctive communication patterns.

The international exchange program in a private university of the U.S. was used as the research field. In this exchange program, a group of Chinese students come to the university and study business administration for a year each spring. In the fall before they come to the U.S., the university recruits U.S. students as Chinese students’ mentors. Still in China, each Chinese student communicates with his or her mentor through e-mail and other formats of CMC about culture, classes, campus housing, food, and weather. In this study, a group of 12 Chinese students was solicited as the participants. The participants were contacted and asked to keep their CMC scripts. After the participants arrived in the U.S., CMC scripts were collected and in-depth interviews were conducted. The researcher audiotaped all interviews, and all tapes were transcribed. All interviews were conducted in English.
In the analysis, elements of Carbaugh’s study (1989) about different cultural terms for talk were used. The messages from the terms for talk could be about communication, sociality, and personhood. Those elements enabled the researcher to start with the metacommunicative vocabulary in the interview transcripts that might indicate the way the participants chose to communicate with their U.S. mentors and about how they related to the U.S. mentors. With the metacommunicative vocabulary as the guideline, the researcher read and reread the transcripts of all recorded tapes and collected CMC scripts. During reading, patterns in the participants’ language behaviors were identified. After that, the transcripts and scripts were reassembled and reorganized according to the patterns. Examples and stories in Chinese participants’ communication were used to explain how their language behaviors were affected by Chinese culture and CMC characteristics.

Findings

In the analysis, four patterns that constituted Chinese participants’ English language use in CMC with their U.S. mentors emerged: others-oriented talk, mentor-mentee talk with limited relationship development, adoption of others’ talk, and icebreaker talk. For each of the four patterns, exemplars were used to illustrate Chinese participants’ use of English language. Some uses were experienced by individuals, but others were more universal.

Others-Oriented Talk

In Chinese participants’ communication, there was a clear pattern that showed much consideration of others. Some participants termed this pattern as “others-oriented talk.” The “others-oriented talk” was illustrated by Chinese participants’ extreme politeness, consideration of others as the priority, and talk about others in communication.

Although Chinese participants were more direct in CMC than in face-to-face communication, Chinese participants showed extreme politeness in CMC. The politeness markers, such as “please,” “thank you very much,” and “I appreciate,” appeared in Chinese participants’ e-mails and texts of instant messaging all the time. For example, one Chinese participant asked about the weather in the U.S.: “If it is not too much trouble, would you please tell me whether it is very cold in winter or very hot in summer there.” Sometimes, the U.S. students were even annoyed by the extreme politeness. One Chinese participant spent two paragraphs explaining why she did not e-mail back for two weeks. Her U.S. mentor started the response: “It is OK. You are not ignoring me. It is a waste of time explaining too much. Everyone is busy. I understand. Let’s talk about some serious stuff.” In the interview, Chinese participants explained that being polite showed their consideration of others because they were seeking help from their U.S. mentors.

Others-oriented talk was also about how Chinese participants talked about others rather than themselves. The talk about others could be a perfect example of Ma’s (1996) finding about East Asians’ indirect online communication that directed around another person other than himself or herself. Most Chinese participants loved to talk about their families, friends, and classmates. One Chinese participant mentioned in e-mail that she would bring a laptop to access the Internet. She could keep close contact with her parents and friends. With a computer camera, she could even see her parents as if she was around them everyday. On the other hand, most U.S students engaged in individual talk that was featured by personal plans and personal interests. One U.S. mentor talked about her trip to Puerto Rico and the Virgin Islands in the summer. She also talked about her love of dancing: “Dancing is my life. I’m actually the vice president of the dance team at the university and choreographer. So I like to go out...
to clubs and also we perform also at Basketball games and things like that.”

Others-oriented talk was directly related to the consideration of others as the priority in communication. Chinese participants tended to yield convenience to others and incorporate others’ feelings in CMC. One participant showed her consideration of others in the e-mail: “As your holiday break is coming, you must be extremely busy with your courses these days. I will be embarrassed to bother you with my questions. I will wait until you have all the tests pass.” After several weeks of e-mail communication, some of the participants started to talk about using synchronous CMC, such as MSN or AOL instant messaging systems. The major problem of using synchronous CMC was the time difference. Chinese participants always took the first step to offer the adjustment. One participant said in the e-mail: “Well, since you are busy with class work, I can stay late until 11 o’clock or midnight. It will be your 10 or 11 o’clock in the morning. It is easier for you.”

In the interview, Chinese participants used Chinese culture about the significance of others in a person’s life to explain others-oriented talk. In one participant’s words, others were an integral part of personal life: “I don’t even realize I talk about others a lot in the e-mails to my mentor. Well, for me, without others I will be like a leaf without branches and trunks. I will dry and die.”

In Chinese culture, the significance of others is closely related to Chinese values about smooth and harmonious personal relationships (Yang, 1994). Personal relationships are often encountered when seeking to establish friendships or even business partnerships in China. The way to establish personal relationships is to develop networks of mutual dependence. Personal relationships depend on the creation of obligation and indebtedness to each other. Thus, all participants thought that their questions and queries might add “extra burden” for their U.S. mentors. They all felt “indebted” to others whenever they sent questions to their mentors.

As for the effect of CMC characteristics on others-oriented talk, Chinese participants regarded e-mail as well as other formats of CMC as a constraint for their indirect way of communication. In one participant’s words, e-mail was “direct and formal” communication. E-mail did not work well as a way of communication for Chinese indirect communication. Since Chinese participants still engaged in an indirect way of communication, the characteristics of CMC as a constraint made Chinese participants uncomfortable. Interestingly enough, one participant talked about his changed attitude toward e-mail after coming to the U.S.: “I feel much more comfortable to use e-mail here. I think I am adopting the U.S. direct, straightforward way of communication. E-mail offers me the way to engage in direct communication.”

**Mentor-Mentee Talk with Limited Relationship Development**

Chinese participants used the term “mentor-mentee talk” to summarize the intercultural CMC between them and their U.S. mentors. Chinese participants always remembered their role as a mentee and the U.S. mentors’ role as a mentor. The role as a mentee defined what a Chinese participant could talk about and in what way a Chinese participant could talk.

First, mentor-mentee talk was illustrated by the topics that Chinese participants chose in CMC. In summary, there were six categories of topics that Chinese participants used: weather, schoolwork, textbooks, family, clothes, and campus housing. These topics were “safe for a mentee.” In the interview, Chinese participants explained that they never met their mentors and all they could talk about were the “general stuff in life they need to know.” Second, mentor-mentee talk was also about the way that Chinese participants chose to communicate with their mentors. Chinese participants’ extreme politeness also emerged in mentor-mentee talk. For example, one Chinese participant expressed his appreciation for the
answer about campus housing: “It is very kind of you to take such trouble to give me such a detailed explanation.” In the end of his e-mail, he expressed his appreciation again: “Please accept my gratefulness. Thank you very much.” In the interview, Chinese participants explained that they felt honored and grateful to have the U.S. students as their mentors. They should show great respect for their mentors in communication.

On the other hand, the U.S. students never treated Chinese participants as their mentees. They tried to make friends with Chinese participants. Thus, the U.S. students engaged in a different way of talk. Chinese participants termed their U.S. mentors’ talk as “friendship talk.” In their first e-mail, the U.S. mentors introduced themselves and always concluded with their willingness to be friends of Chinese participants: “Please feel free to contact me with any questions or concerns you may have about coming to the U.S. When you arrive in January, I will be ready and waiting to give you a tour of campus and help you get acquainted with the U.S. Think of me as a friend, you can approach me with anything.”

When one Chinese participant expressed the worry that she might bother her mentor too much, the U.S. mentor e-mailed back: “You are not bothering me. Do not worry. We are friends.”

In terms of the effect of CMC on mentor-mentee talk, Chinese participants had a limited relationship development that was encouraged by the characteristics of CMC. The limited relationship development between Chinese participants and their U.S. mentors was reflected in the way addressing each other evolved from formal to casual and no addressing at all. At the beginning, both Chinese participants and their U.S. mentors addressed each other very formally. One U.S. mentor initiated the contact in the first e-mail with “Dear Christina Yi Zhang” and concluded the e-mail with “Yours, Laurie Smith.” The Chinese participant also answered with “Dear Laurie Smith” and concluded with the term “sincerely” and her full name. After the second week, the U.S. mentor started to address her Chinese mentee with “Hey, Chris” and ended with only “L.” After the fifth week, the U.S. mentor used “Hey, hey” and sometimes started e-mails without addressing. The Chinese participant also switched to “hi” as the start and concluded with “c” in the end. In the interview, the Chinese participant acknowledged that she used formal addressing because she did not know her mentor. After more communication, she “accumulated enough information” in CMC and felt a little bit closer to her mentor. She could use a casual way of addressing.

However, the relationship development in CMC was limited by Chinese participants’ mentor-mentee talk. In one Chinese participant’s words, the relationship was “on the surface,” activated by the need to be as casual and comfortable as possible in communication. With mentor-mentee talk, the relationship could never be developed to “friendship” because of the unequal status. One Chinese participant explained about the limited relationship development: “Do we feel closer to each other after dozens of e-mails? Yes, but I still don’t feel he is my friend. I am asking too much and giving too little. It is not equal. We can’t be friends.”
Adoption of Others’ Talk

In intercultural CMC, Chinese participants adopted their U.S. mentors’ talk when they learned the unique online discourse, native English expressions, and U.S. culture. The adoption was encouraged by Chinese participants’ need to learn native language, and Chinese culture underlining solidarity and integration with others. Text-based CMC provided the context that made the adoption possible.

Chinese participants were often confused by the unique English discourse in CMC. After learning the discourse, Chinese participants adopted them in return. In one Chinese participant’s e-mail, she asked about the meaning of “ill talk to ya soon.” In the response, the U.S. mentor explained: “it is … kind of like a simple way to say goodbye online … keep in touch … ill speak with you in the near future … things like that … and ‘ya’ just is slang for ‘you’. ‘ill’ is a abbreviation for ‘I’ll.’ In online talk, you use lower case letters as much as possible.” Interestingly enough, in the next e-mail, this Chinese participant concluded the e-mail with “ill take [talk] to ya soon.” All participants mentioned that they learned to use “live English” through CMC. One participant said that he learned to conclude e-mails with “If you have questions, feel free to ask me.” Whenever he answered his mentor’s questions, he always concluded with this sentence.

In the communication, Chinese participants also learned to adapt to the U.S. culture. When Chinese participants asked about the weather, they had to use degrees. There was confusion between metric and English system. Chinese participants used Celsius and the U.S. mentors used Fahrenheit. One U.S. mentor asked for the conversion to Fahrenheit when a Chinese participant used Celsius: “What is –2 Celsius? Can you tell me what’s in Fahrenheit? Is it cold like –2 Fahrenheit?” The Chinese participant answered back: “–2 Celsius is like 30 degrees Fahrenheit. It is cold. But is not like deadly cold. I think 0 Celsius is about 32 Fahrenheit and 10 Celsius is about 50 Fahrenheit. I will use Fahrenheit from now on. It is easy for me to do the conversion. I got to be ready for the system anyway.”

In interviews, Chinese participants explained their adoption of some English expressions as helping them to learn native English. Such adoption happens in interacting between people of a second language and native speakers. The adoption can be explained by behavioral adjustments people make during communication. It matches communication accommodation that results in favorable social attractiveness, communication effectiveness, and cooperativeness (Giles, Coupland, & Coupland, 1991). On the other hand, Chinese participants also used Chinese collectivism culture to explain their adoption of the U.S. mentors’ talk. As an essential theme in the literature of Chinese use of CMC, Chinese culture has been used widely to explain Chinese communication behaviors (Chen, 1998; Chung, 1992; Giese, 2003; Weber, 2002). Chinese collectivism culture emphasizes solidarity and integration with others, and prioritizes the needs of the group over the needs of the self. Being collectivistic, Chinese people emphasize in-group belonging, personal interdependence, and social harmony with others (Cheng, 1987; Lu, 1997). In one participant’s words, their adoption of the U.S. mentors’ talk led to similarity instead of dissimilarity that was “good for both sides.”

In addition, CMC characteristics allowed Chinese participants to adopt others’ talk. With text-based communication, CMC did not have “intimidating factors,” such as body movements, vocal tones, and facial expressions. With only text in communication, Chinese participants would be free to ask questions about language, learn U.S. culture, and improve their English. One participant said: “In a face-to-face interaction, I would be embarrassed to ask my mentor to explain the meaning of a English word. But in e-mail, I don’t have to care about how my mentor thinks.” In addition, text-based CMC provided the context for Chinese participants to read, reread, and reflect
on the U.S. mentors’ talk before their adoption. Some Chinese participants admitted that in an oral communication, their mentors’ talk would slip away and they would have nothing to learn in the adoption.

**Icebreaker Talk**

Chinese participants were always careful about what they should talk about in CMC with the U.S. mentors. They tended to stay with “general topics” that were safe for both sides. Some participants termed this talk as “icebreaker talk.” Chinese participants defined “icebreaker talk” as “talk about the surface,” “talk as contact,” and “talk without specifics.” In an icebreaker talk, Chinese participants picked up general topics and never went into specifics. For example, one Chinese participant asked about textbooks: “Would you like to tell me where I buy textbooks? Are they expensive?” In the interview, the participant explained that she did not want to ask for specifics, such as textbooks in her major, exact prices for textbooks, required textbooks, and optional textbooks. She did not expect specifics over CMC. She said that the question functioned more as a way to initiate and maintain the communication with her mentor.

Chinese participants attributed their icebreaker talk to different cultural understandings of CMC. In the U.S. culture, e-mail as well as other formats of CMC become one part of routine communication practice. However, in China, e-mail and other formats of CMC are not popular as ways of communication. Guo (2005), along with other colleagues in the Chinese Academy of Social Sciences, conducted a survey tracking Internet use in five major Chinese cities. According to the survey, over two-thirds of people never or seldom use e-mail, instant messaging, online discussion, and chat groups as ways of communication. Close to 40% of the survey participants check e-mail once or less than once a week. Most survey participants (about two-thirds) use CMC on the Internet for news, especially entertainment-related news and online games. Not surprisingly, Chinese participants in this study mentioned that they would prefer face-to-face interaction to CMC as a way of communication. One Chinese participant offered an example about a typical communication event in China: “If you have questions or problems, you need meet people. Sit down with a couple of tea. Take it easy. Negotiate back and forth.” All participants thought that different formats of CMC functioned as a good way to initiate a contact, but face-to-face interaction was the best for further communication.

Chinese participants also talked about the effect of CMC characteristics on their icebreaker talk. All participants agreed that e-mail or instant messaging functioned well at the beginning between them and their mentors. In one participant’s words, e-mail served as an icebreaker. Without context information, it was easy for Chinese participants to begin the communication with their U.S. mentors. After the beginning, e-mail turned out to be a constraint between them and their mentors. Most participants wished that they could have face-to-face interaction after a few weeks of e-mail exchange.

**FUTURE TRENDS**

**Summary of the Study**

In this study, there were four language patterns in CMC between Chinese participants and their U.S. mentors: others-oriented talk, mentor-mentee talk with limited relationship development, adoption of others’ talk, and icebreaker talk. The four language patterns were affected by both cultural and CMC effects. First, in others-oriented talk, Chinese participants showed extreme politeness, considered others as the priority, and talked about others in communication. Chinese culture about the significance of personal relationships formulated others-oriented talk. CMC constrained
others-oriented talk with its directness and written formality. Second, in mentor-mentee talk, Chinese participants talked according to their role as mentees. Chinese participants respected their mentors because of the Chinese meaning of “mentor” as “teacher” or “consultant.” CMC only allowed a limited relationship development between Chinese participants and their U.S. mentors. Third, in the adoption of others’ talk, Chinese participants learned the unique online discourse, native English expressions, and the U.S. culture. Both Chinese participants’ need to learn native language and Chinese collectivism culture encouraged Chinese participants to accommodate to others’ talk. With its text-based communication, CMC allowed Chinese participants’ learning and adoption of their U.S. mentors’ talk. Fourth, Chinese participants regarded CMC as a good icebreaker in intercultural communication. The lack of context cues made CMC appropriate for icebreaker talk and at the same time constrained further communication.

**Discussion of Implications of Research for Current Situations**

In each of the four language patterns of Chinese participants’ communication, cultural values and effects play a significant role. For others-oriented talk, it is Chinese culture about the significance of personal relationships. For mentor-mentee talk with limited relationship development, it is Chinese understanding of the term “mentor” as “teacher” or “consultant.” For adoption of others’ talk, it is Chinese participants’ need to learn the native language and Chinese collectivism culture that encourage communication accommodation. For icebreaker talk, it is CMC’s unpopularity as a way of communication in China and Chinese preference for face-to-face communication.

Chinese culture that is under the strong Confucian influence becomes essential to explain Chinese use of CMC on the Internet. When Bockover (2003) evaluated the impact of Confucian values, she argued that traditional Chinese values are still strong in Chinese use of CMC. Critical to Confucian values is the concept of a person that is always an essential part of a larger social group, and “personal agency” is always socially defined (Bockover, 2003, p. 164). Thus, in China, the main moral goal has been harmonious interdependence in personal relationships. Bockover argued that the Internet with its autonomy, independence, and free trading of information could be at odds with Chinese cultural values. In the study of the dynamics and political function of the transnational Chinese cultural sphere on the Internet, Yang (2003) argued that cultural repertoire with Chinese values and traditions regulates communications and actions of Chinese participants from mainland China, Hong Kong, Taiwan, and North America. In the study of Chinese policy making and implementation on the Internet, Weber (2002) defined Chinese culture as “diffuseness culture” that emphasizes relationship closeness and harmony in social structure, as opposed to Western individualistic “specificity culture.” These cultural differences lead to interpretation problems of the Internet policies in China. Adding to the literature, the findings of the study offer empirical evidence for the impact of culture on intercultural CMC.

On the other hand, the characteristics of CMC function as either a constraint or a way of encouragement in this study. The supplemental effect of CMC characteristics contradicts the findings about CMC’s determining effect on intercultural CMC (Ma, 1996; Tella & Mononen-Aaltonen, 1998). For example, among Ma’s (1996) widely cited five propositions about intercultural CMC, two propositions are directly derived from CMC’s determining effect. First, East Asians tend to show greater self-disclosure in CMC conversations than in face-to-face conversations. Second, status difference is unnoticeable in intercultural CMC. In the current study, Chinese participants’ icebreaker talk about “safe” and “general” topics is contradictory to the proposition about more
Intercultural Computer-Mediated Communication Between Chinese and U.S. College Students

self-disclosure in CMC. Chinese participants’ talk from the mentor-mentee relationship does not match the proposition about unnoticeable status difference in intercultural CMC. One explanation is the situational use of CMC that varies from culture to culture, context to context, and people to people (Warschauer, 2000). Another explanation may be about Ma’s study sample that consists of Chinese students attending U.S. universities and Taiwan universities. Under the U.S. cultural impact, Chinese students attending U.S. universities may not incorporate much Chinese culture in intercultural CMC. Even Chinese students attending Taiwan universities may not incorporate much Chinese culture in CMC because of strong globalization in Taiwan. In the current study, Chinese participants have never communicated with native speakers in such a scope before. These Chinese participants showed much more cultural effect on their language patterns in CMC.

Chinese culture underlines the patterns of communication that Chinese students have with their U.S. mentors. The patterns can be explained by Philipsen’s (1992) theory of two codes in speaking: a code of honor and a code of dignity. Chinese participants communicate with their U.S. mentors from a code of honor. In a code of honor, “the individual is conceived a role or character, a persona” (Philipsen, 1992, p. 109). In the communication with the U.S. mentors, Chinese participants kept the roles of mentees and perceived their U.S. counterparts in the roles of mentors. In a code of honor, society along with others exists before an individual. In this study, Chinese participants had others-oriented talk and adopted others’ talk for similarity and integration with others. On the virtual stage of intercultural CMC, Chinese participants used the talk in CMC as an icebreaker contact instead of actual communication. In a code of honor, Chinese participants viewed their talk as fulfilling their role as a mentee in the social order with their U.S. mentors.

On the other hand, the U.S. mentors communicate with Chinese participants from a code of dignity. In U.S. culture, a code of dignity is “concerned with the person qua person, as someone who is made up of unique feelings, ideas, and attitudes” (Philipsen, 1992, p. 113). In a code of dignity, communication functions to express individual intent and will. The U.S. mentors engaged in individual talk that featured personal hobbies, personal interests, and personal plans. The U.S. mentors also engaged in friendship talk, treating Chinese participants as equal individuals in intercultural CMC.

Implications of Research for Future Situations

The findings in the study call attention to social constructivism in future studies of communication technologies. In literature about communication technologies, social constructivism advocates that people in a particular culture shape social behavioral patterns regarding technology use (Fischer, 1992; Fulk, 1993; Fulk & Boyd, 1991). Through negotiations and struggles among people, the meanings in people’s use of technologies are internally constructed and redefined in changing cultural contexts (Barley, 1990; Leonard, 2003; Xia, 2006). The application of social constructivism ideas calls for more analysis of technology use for a particular culture in future studies. The findings about the determining cultural effect on Chinese participants’ use of English in CMC with their U.S. mentors offer an example of cultural analysis of technology fit from a social constructivism perspective. In the current study, the four language patterns of Chinese participants’ communication call for the evaluation of a particular culture as a part of social construction process.

Suggestions for Future Applications of the Findings

It is interesting to consider the U.S. students’ responses in discussing this chapter’s future applications of to intercultural CMC. Some U.S.
students felt strange with Chinese participants’ talk about families, friends, and classmates. Some U.S. students felt annoyed by Chinese participants’ paragraphs of apology. Some U.S. students did not understand Chinese participants’ “touch and run” talk. These reactions can be explained by the discrepancy in self-perceptions between the East Asian and U.S. students. Even if the East Asians thought of themselves as direct in CMC, the U.S. students still found them extremely polite, reserved, and indirect (Ma, 1996). How to change this misunderstanding should be the focus of future studies.

The findings in the current study uncover the importance of understanding cultural resources regarding language activities in intercultural CMC. The assumed relation between one language and one culture explains significant meanings in Chinese participants’ communication with the U.S. students. Although Chinese participants use English in CMC, the rules and meanings regarding language come from their native culture. As Hymes (1968) proposed in the assumption about speaking in a cultural group, Chinese participants’ use of English language in CMC consists of a unique system, and their actual language activities should be the focus of study. Knowledge of cultural resources about language activities is the key to mutual understanding. The findings in the current study about Chinese culture in Chinese participants’ others-oriented talk, mentor-mentee talk, adoption of others’ talk, and icebreaker talk can help their U.S partners as well as people from other cultures understand diverse cultural resources in the future intercultural communication over CMC.

**Suggestions for Future Studies**

With the fast development and diffusion of CMC technology as well as cultural globalization, interaction in CMC across different cultures is becoming more and more common. English as a global language is the key for intercultural CMC. As Cassell and Tverksy (2005) reviewed, studies of the particular use of online English in different cultures are sparse. The future research of intercultural CMC should focus more on the particular rules, patterns, and meanings of English language use in different cultures and uncover cultural resources regarding English language activities in CMC.

In the study, there are 12 Chinese participants. Although small samples are common for in-depth qualitative studies, the generalization of the findings to other Chinese students is unknown. The relation between cultural resources and language use in CMC may not be generalized to other groups of people. Further examination with large samples is needed for other groups. Discussing different language patterns in CMC individually helps to describe themes, patterns, and ideas clearly. However, it does not represent the interconnections among them. Apparently, Chinese participants’ others-oriented talk can affect their adoption of others’ talk. More research is needed to unpack these interconnections among different language patterns in Chinese use of English in CMC.

**CONCLUSION**

The study incorporated both cultural effects and CMC characteristics in the investigation of Chinese college students’ use of English in communication with U.S. college students. Ethnography of communication was used as the method to uncover four language patterns in Chinese college students’ use of English: others-oriented talk, mentor-mentee talk with limited relationship development, adoption of others’ talk, and icebreaker talk. Chinese cultural values showed strong effect on Chinese college students’ use of English in CMC. Chinese cultural values included Chinese significance of personal relationships, Chinese collectivism, Chinese understanding of authority, and Chinese use of CMC. The characteristics of CMC showed minimal or supplemental
effect as either a constraint or encouragement in the four language patterns.

ABSTRACT

In this chapter, we discuss how culture influences computer mediated communication (CMC). We use an Input-Process-Output (I-P-O) model as a theoretical framework to analyze relationships between culture and CMC. We describe three dimensions of cultural variability—individualism/collectivism, low vs. high context of communication, and task- vs. relationship-orientation—and describe how these dimensions influence people’s reliance on features of CMC. A review of the literature to date suggests that cultural factors do indeed shape how people use CMC. More specifically, auditory and visual cues appear to have more importance for members of collectivistic, high-context, relationship-oriented cultures than they do for members of individualistic, low-context, task-oriented cultures. However, further research is needed to clarify relationships between cultural dimensions and CMC, to understand the role of moderating variables such as gender of participants, task, and group composition, and to provide design guidelines for new tools to support intercultural communication and CMC in developing regions.

INTRODUCTION

One of the great benefits of the CMC tools covered in this volume is that they allow people to converse across space and time. Today, people connect with others from around the world by participating in chatrooms and discussion lists, by joining global game communities and virtual worlds, by authoring and reading blogs with an international scope, and by a variety of other
Global Culture and Computer Mediated Communication

means. In the work domain, firms are increasingly taking advantage of CMC tools to establish global teams with members from a diverse set of nations (e.g., Carmel, 1999; Churchill & Bly, 2000; Olson et al., 1998). Bridging nations via technology does not, however, guarantee that the cultures of the nations involved are similarly bridged (Olson & Olson, 2000). Mismatches in social conventions, work styles, power relationships and conversational norms can lead to misunderstandings that negatively affect the interaction. For example, an individual from a task-oriented culture such as the United States or Canada may focus exclusively on getting things done, overlooking the social niceties expected by his/her conversational partner from a relationship-focused culture such as China, Japan or Latin America. Similarly, an individual from a low-context communication culture, who relies primarily on verbal language to express his or her thoughts, may ignore facial expressions or tones of voice that are intended to be communicative by his/her partner from a high-context culture.

As the examples above suggest, features of different CMC tools (e.g., e-mail, Instant Messaging [IM], teleconferencing, video conferencing) may make it easier or harder for people to bridge their cultural differences by providing or failing to provide auditory, visual and other sources of information. But how can we characterize these differences between CMC tools and use them to decide what tools will work best for a given set of people performing a given set of tasks? For members of Western cultures, years of research have led to a number of well-developed theories that can be used to motivate such decisions (e.g., Clark & Brennan, 1991; Daft & Lengel, 1984; Postmes, Spears, & Lea, 2002; Short, Williams, & Christie, 1976; Daft & Lengel, 1984, Clark & Brennan, 1991; Walther, 1992, 1995; Postmes, Spears & Lea, 2002). Much less is known about CMC in intracultural (culturally homogenous) groups from non-Western cultures or in intercultural (culturally heterogeneous) groups, making it harder to predict the suitability of different media for different purposes or to design new CMC technologies to facilitate intercultural collaboration.

There are reasons to believe that what we know from research using Western participants will not generalize straightforwardly to other cultures. Cultures vary along a number of dimensions that may impact group processes and outcomes, such as individualism vs. collectivism (the extent to which people prioritize their personal benefit vs. that of the larger group; e.g., Hofstede, 1983; Triandis, 1995), low- vs. high context of communication, (how much contextual information is required for communication; Hall, 1976), and task vs. relationship orientation (whether people focus on getting work done or on establishing rapport with their partners; e.g., Triandis, 1995). These and other cultural dimensions may interact with features of media to create different effects on group processes and outcomes than have been found in studies using Western participants. For example, if expressions and intonation are important parts of communication in high context cultures, standard IM, which doesn’t support seeing or hearing one’s partner, should be less suitable for communication than it is in low context cultures. Consistent with this argument, recent research does in fact suggest that people’s cultural background affects CMC (e.g., Anderson & Hiltz, 2001, Kayan, Fussell, & Setlock, 2006, Reinig & Mejias, 2003, 2004; Setlock, Fussel, & Neuwirth, 2004; Setlock, Quinones, & Fussell, 2007; Zhang, Olson, & Olson, 2004; Zhang, Sun, Chintakovid, Ge, Shi, & Zhang, 2006). Although these studies vary widely in terms of what technologies and cultures are studied and what research methods are used, we can use the results to begin piecing together a theoretical framework for understanding relationships between culture and CMC.

The objectives of the chapter are to provide an overview of research in the area of culture and CMC to date. We first present a conceptual framework for understanding how culture and
CMC shape communication processes and task outcomes. Then, we review research on each component of this framework, highlighting findings that with broad implications for research in CMC. We conclude with some directions we think are especially important for future research.

BACKGROUND

The theoretical framework we use to examine relationships between culture and CMC is an Input-Process-Output (I-P-O) model (e.g., Hackman, 1987), shown in Figure 1. Here, culture and media are inputs that people bring to collaboration. These inputs, both alone and in interaction, influence communication processes and, in turn, subjective and objective outcomes. There are also a number of moderating variables that may influence relationships between inputs and processes and between processes and outcomes. Although the I-P-O framework is a simplification, it can help us conceptualize how culture and CMC interact by explicating relationships between input, process, outputs and moderating variables.

Dimensions of Cultural Variability

The first input to our model is the cultural values of the communicators. For the purposes of this chapter, we define culture as a set of norms, roles and values emphasized by a culture and adopted, to greater or lesser degrees, by members of that culture through such processes as imitation and teaching. Although researchers agree that cultures differ in many ways, they have debated how culture should be defined and the specific dimensions upon which cultures vary (e.g., Hofstede, 1983; Oyserman, Coon, & Kemmelmeier, 2002; Schwartz, 1992; Triandis, 1995). We focus our discussion on three cultural dimensions—individualism vs. collectivism, high vs. low context of communication, and task vs. relationship focus—that are especially important to CMC.

Individualism vs. collectivism. Many culture theories distinguish between individualistic and collectivistic cultures. In individualistic cultures, people tend to identify themselves first and foremost as individuals, with the primary goal of personal (or perhaps familial) gain. In collectivistic cultures, people tend to identify themselves as a member of a larger collective and focus on the betterment of that collective (e.g., Hofstede, 2001; Triandis, 1995). Whether someone is from an individualistic or collectivistic cultural background has far-reaching effects, influencing his or her cognitive processes (Nisbett, 2003) and his/her self-concept as either independent of or interdependent with other individuals (Markus...

& Kitayama, 1991). In addition, Hofstede’s (2001) analyses of survey responses from IBM employees around the world show that cultural tendencies toward individualism vs. collectivism are associated with many aspects of daily life, including business practices, child-raising, and educational techniques.

High- vs. low-context of communication. Another way that cultures have been argued to differ is in the strategies they use to communicate. Hall (1976) distinguished between low context communication, which is verbally explicit, to the point, with relatively little attempt to mask one’s feeling and high context communication, which is indirect, often ambiguous, and sensitive to the specific situational context (e.g., the relationship between speaker and addressee, nuances of facial expressions or tone of voice). For example, low context communicators are likely to disagree outright with their conversational partners, whereas high context communicators may use silence or indirect speech to indicate disagreement. Although people in all cultures use both communication styles, research suggests that low-context communication is preferred in individualistic societies such as the U.S. and Canada and high context communication is preferred in collectivistic societies, particularly Asian cultures (Gudykunst & Ting-Toomey, 1988; Gudykunst et al., 1996).

Task vs. relationship focus. A third way that cultures have been argued to differ is in the orientation they take toward the task at hand (e.g., Triandis, 1995). Task-oriented cultures focus on getting work done, whereas relationship-oriented cultures focus on establishing rapport with one’s partners. As we noted earlier, these differences in orientation may lead to misunderstandings and misattributions in collaborative work. When individuals from task-oriented cultures fail to attend to relationship factors, they may be perceived as rude by their teammates from relationship-oriented cultures; when individuals from relationship-oriented cultures fail to focus on the task, they may be perceived as undedicated by their teammates from task-oriented cultures. The task vs. relationship focus is only quasi-independent of the other dimensions. Individualistic cultures such as the U.S., Canada, and Australia tend to use low-context communication styles and have a task orientation. Collectivistic cultures such as Japan and China tend to use high-context communication styles and to have a relationship orientation.

Although dimensions like individualism-collectivism are often applied at the national level (e.g., Hofstede, 1983, 2001; Triandis, 1989), we almost must consider how these national values are reflected in individuals’ personal values (e.g., Schwartz, 1992) and their construals of themselves as interdependent vs. independent (e.g., Markus & Kitayama, 1991; Singelis & Brown 1995). Both individual values and individuals’ self-concepts are influenced by national cultural but not entirely determined by it. Gudykunst et al. (1996) and Oetzel (1998), among others, have
shown that national values, individual values, and self-concepts all influence the ways people communicate.

**Affordances of Media**

The second input to our model is the medium used for communication. More specifically, we are interested in how features of CMC tools might interact with culture to shape communication processes and task outcomes. We draw on Clark and Brennan’s (1991) influential theory of *media affordances* as a framework for understanding differences among media (see Table 1). For example, telephone calls and video conferencing provide audibility, and thus afford the use of vocal speech production, whereas IM does not. In this framework, features of media alter the costs or difficulty of producing messages, receiving and understanding messages, changing speakers, and repairing misunderstandings.

**APPLYING THE FRAMEWORK TO COMMUNICATION AND TASK OUTCOMES**

Starting from Clark and Brennan’s model, our goal is to understand how cultural dimensions may alter the perceived importance of audibility, visibility, copresence and other media affordances. For example, Gudykunst and Kim (1997) suggest that nonverbal cues such as gestures and facial expressions may be more important for communication in high-context cultures. Thus, we might anticipate that visibility will be more important for members of high-context cultures than for members of low-context cultures. In this section we examine how culture and media influence conversational processes and team outcomes.

**Communication Processes**

Culture may, alone or in interaction with features of media, influence group processes, particularly processes of communication. We see two aspects of communication as especially relevant for CMC: conversational grounding and relational communication. In this section we review prior work on the ways in which culture and media affect these two communication processes.

**Conversational Grounding**

*Conversational grounding* refers to the way people interact to ensure that they understand one another’s messages (Clark & Brennan, 1991; Clark & Wilkes-Gibbs, 1986). Speakers and listeners ask each other questions, provide clarifications, rephrase one another’s messages, and so forth. The purpose of these activities is to ensure that messages are understood as intended. Grounding is easier, and conversation more efficient, when collaborators share common ground, mutual knowledge, beliefs, and so forth (Clark & Marshall, 1981). This common ground can arise from comembership in social groups (e.g., Fussell & Krauss, 1992; Isaacs & Clark, 1987), through the process of exchanging messages (*linguistic copresence*), or by sharing a physical setting (*physical copresence*).

![Figure 2. Mean speaking turns per task by culture group and medium (AA = American only, AC = Mixed American Chinese, CC = Chinese only)](attachment:image)
Affordances of media influence the strategies people use to ground their utterances (Clark & Brennan, 1991; Fussell et al., 2004; Gergle, Kraut & Fussell, 2004; Kirk & Stanton-Fraser, 2006; Kraut, Fussell, & Siegel, 2003). For example, face-to-face settings afford visibility and physical copresence, so speakers can use gestures and deictic expressions such as *this one* to refer efficiently to objects and people in the environment (e.g., Bekker, Olson, & Olson, 1995; Clark & Krych, 2004). On the telephone or over IM, media that lack visibility and physical copresence, speakers must use lengthier verbal descriptions of the same objects (e.g., Doherty-Sneddon et al., 1997; Kraut et al., 2003).

Of particular interest for building theories of culture and CMC is the idea that cultures vary in their strategies for grounding conversations (e.g., Li, 1999a, 1999b). Hall (1976) proposed that audibility and visibility were more important for grounding in high-context cultures than in low-context cultures, because awareness of how others are reacting to one’s messages is an important aspect of high-context communication. This notion is supported indirectly by Veinott, Olson, Olson, and Fu (1999), who found that nonnative English speakers, many of whom were Asian, benefited from video over audio conferencing, whereas native English speakers did not. Veinott and colleagues suggest that the richer cues to mutual understanding provided by visibility (e.g., quizzical looks, raised eyebrows) were especially valuable for nonnative speakers, but it is equally plausible that video was important because these participants were from high-context cultures.

Our own prior studies suggest a less clear-cut relationship between the availability of auditory and visual cues and conversational grounding in low- vs. high-context cultures. In our first study (Setlock et al., 2004), we compared American, Chinese, and mixed American-Chinese dyads performing a negotiation task face-to-face or via IM. We hypothesized that the lack of social/contextual cues in IM would make it poorly suited for communication among members of high-context cultures, whereas it should have minimal or no effect on communication among members of low-context cultures. Consistent with this hypothesis, we found no difference between media in terms of how much grounding American pairs required to complete the task, but a large culture by medium interaction such that Chinese pairs spoke much more face-to-face (Figure 2).

Face-to-face interaction has many affordances not present in IM, including audibility and visibility. To determine which of these two affordances was more important, we (Setlock et al., 2007) compared the same cultural groups interacting via audio or video conferencing. In this case, however, we found no main effect of culture, nor a culture by medium interaction. Thus, audibility seems to be important for Chinese dyads, but adding visual cues via video conferencing did not provide additional benefit. These results conflict with those of Veinott et al. (1999), reported above, and suggest the need for a more detailed examination of factors that differed across the two studies (e.g., tasks, specific cultural backgrounds of participants).

Relational Communication

Relational aspects of communication are concerned not with *what* information is conveyed but with *how* that information is conveyed and what this indicates about the relationship between speaker and addressee(s). For example, nonverbal cues such as eye gaze (e.g., Argyle & Cook, 1976), facial expressions (e.g., Ekman, 1982), and posture (e.g., Mehrabian, 1967) can be used to express intimacy, trust, and attraction. In addition, the verbal content of messages can be crafted in different ways to establish, maintain, or build closeness with (or to maintain or increase distance from) a partner. Speakers’ decisions about forms of address, informal vs. formal language, use of swear words, and so forth, can all have implications for their relationships with their addressees. In Table

</tbody>
</table>

2, we list some of the ways that nonverbal, paralinguistic and verbal cues can add socio-affective meaning to people’s messages.

Which features a medium possesses affects people’s relational communication (e.g., Herring, 1994; Kiesler, Siegel, & McGuire, 1988; see Whittaker, 2003 for a review). For example, some studies have found that when audibility and visibility are absent, as in IM, people are more likely to “flame” their partners (e.g., Kiesler et al., 1988). Kiesler and colleagues attributed this finding to the lack of social context cues in text communication: it is easier to be insulting when you can’t see others’ reactions to the insult. Other investigators have argued that it might instead take more effort to produce the extra words needed to be polite (e.g., sort of, would you mind?) in typed discourse (e.g., Brennan & Ohaeri, 1999), resulting in speakers eliminating those seemingly nonessential words in the interest of efficiency. Other studies have found more relational communication in face-to-face settings than over the phone (Rutter, 1987; Stephenson, Aylng, & Rutter, 1976) or in text communication (e.g., Hiltz & Turoff, 1978). Less research has compared relational communication in audio vs. video conferencing, although many media theories (e.g., Daft & Lengel, 1984; Short et al., 1976) suggest that video will better support relational communication.

The cultural theories discussed earlier suggest that high-context, relationship-oriented cultures place more emphasis on relational communication than do low-context, task-oriented cultures (Ting-Toomey et al., 1991). One area in which this hypothesis has been tested is that of conversational indirectness. People can ask others to do things in a variety of ways, including direct commands (e.g., take out the trash), indirect requests (e.g., would you mind terribly taking out the trash?), and off-record statements (e.g., it’s terribly messy in here). In general, the less direct the request, the more polite it is (Brown & Levinson, 1987). Cross-cultural studies of conversational indirectness have shown that speakers from high-context cultures such as China and Korea use more indirectness than those from low-context cultures such as the United States (Ambady, Koo, Less, & Rosenthal, 1996; Holtgraves, 1997). Chinese speakers are also more likely than American speakers to use language that promotes relationship-building, such as “we” pronouns and social language, both face-to-face and via IM (Setlock et al., 2004). Cross-cultural research on negotiation, in which people work to resolve disagreements, has shown that relational strategies (e.g., compromising) are favored by high-context negotiators whereas informational strategies (e.g., dominating the conversation) are favored by low-context cultures (e.g., Adair & Brett, 2005; Adair, Okumura, & Brett, 2001; Ting-Toomey et al., 1991). Such differences have been attributed to cultural variation in concern for one’s own face vs. the other person’s face (Ting-Toomey, 1988).

Based on these considerations, we would expect a person’s cultural background to interact with the features of a communication medium to influence the production of relational communication. For low-context communicators, a medium such as IM that requires verbal substitutes for relational features such as facial expressions, tone of voice, and gestures may be perfectly suitable. For high-context communicators, who rely more heavily on nonverbal communication, media that are lacking auditory and visual cues may disrupt important aspects of social interaction.
Outcome Measures

In our I-P-O model in Figure 1, inputs (culture and features of technology) impact communication processes such as conversational grounding and relational communication. These communication processes in turn impact a range of outcome measures. Here, we touch briefly on several outcomes that are especially important in intercultural teamwork: perception and subjective evaluations of one’s partners, persuasion, trust, and objective task performance.

Perception of partners. Features of media affect collaborators’ impressions of each other’s personality, intelligence, physical attractiveness, and so forth. For example, people like others more when they can see them as well as hear them (Short et al., 1976; Williams, 1977). Hancock and Dunham (2001) suggest that the lack of social cues in text CMC creates ambiguity. Is a partner being rude, or just a bad typist? Does a lack of response mean that a partner is being rudely dismissive or that his/her computer crashed? Cramton (2001) has shown that when people know less about a remote collaborator’s immediate experiences, they are more likely to attribute problems to internal, dispositional factors (e.g., a partner’s rudeness) than to external causes such as computer problems (Cramton, 2001). Such effects may be especially strong in intercultural interaction, in which people share less initial background knowledge. In our own studies (Setlock et al., 2004, 2007), we found that members of intercultural dyads rated each other more negatively than members of homogenous American or Chinese dyads. However, the tendency to attribute behavior to dispositional factors is in part culturally-specific: East Asians are more likely to consider situational explanations for behaviors than Westerners (e.g., Choi, Nisbett, & Norenzayan, 1999; Morris & Peng, 1994). As a result, we would predict that media lacking visual and auditory cues would have a greater impact on partner perceptions in high-context than low-context cultures. A study currently underway in our laboratory is testing this hypothesis.

Persuasion. Persuasion refers to the extent to which a person can convince others that his or her viewpoint is correct. Early studies indicated that persuasion varied as a function of medium (e.g., Chaiken & Eagly, 1976; Guadagno & Cialdini, 2002; Heim, Asting, & Schliemann, 2002; Morley & Stephenson, 1977), but many of these studies used artificial role-playing paradigms in which conversational grounding and relational communication could not be measured. Other studies have compared how much consensus groups reach using text-based group decision support systems (GDSS) and found less consensus after GDSS than after face-to-face negotiations (Reinig & Mejias, 2003; Watson, Ho, & Raman, 1994). There is little agreement as to whether cultural differences in negotiation styles influence persuasion, either alone or in interaction with features of technology. Some studies (e.g., Reinig & Mejias, 2003; Watson et al., 1994) have found that both culture and medium affect persuasion but no interaction between the two. Others (e.g., Setlock et al., 2004) have found effects of culture but no effects of medium. Adair et al. (2001) suggest that persuasion may be reduced when there are mismatches in negotiators’ styles, although they did not investigate interactions with medium. That there is still much to learn about culture and CMC is suggested by a study by Anderson and Hiltz (2001), in which they found—in contrast to the other studies we’ve reviewed—that face-to-face culturally heterogeneous groups showed the most consensus and asynchronous culturally-homogeneous groups showed the least consensus after group discussion.

Trust. Trust refers to a person’s confidence in the goodwill of others and his/her expectation that others will reciprocate if he or she cooperates (e.g., Ring & Van de Ven, 1994). McAllister (1995) differentiates two broad foundations for trust: cognitive and affective. Cognitive trust is built on respect for others’ intelligence, competence and reliability, whereas affective trust is built on emotional bonding and relationship-building. We
would expect affective trust to be weighted more heavily in high-context, relationship-oriented cultures and cognitive trust to be weighted more heavily in low-context, task-oriented cultures.

Establishing trust is more difficult over CMC than face-to-face, and more difficult with leaner media like IM than with richer media like audio or video conferencing (Bos et al., 2002). To some extent, however, the problems establishing trust via CMC can be reduced when people start with an initial face-to-face interaction before working at a distance (Rocco, 1998; Jensen, Farnham, Drucker, & Kollock, 2000). For high-context cultures, characteristics of the communication medium may be especially important for establishing affective trust. Zhang, Olson, and Olson (2004) found that Chinese pairs showed higher affective trust when negotiating by video conferencing than by audio conferencing, whereas American pairs showed no differences on either affective or cognitive trust between media.

Objective performance. Lastly, the success with which people communicate is predicted to influence how well they perform collaborative tasks. This performance can be measured in a variety of ways, such as task completion times, numbers of errors, or quality ratings. Because the time it takes to do a communication-based task is correlated with how much talking is required, media that support efficient communication through spoken language and gesture typically lead to faster performance times (e.g., Gergle, Kraut, & Fussell, 2004; Kraut, Fussell, & Siegel, 2003). When performance is measured in other ways, however, the effects of media are less clear. For example, Doherty-Sneddon et al. (1997) found no differences in the accuracy of map routes described in video vs. audio conferencing; Jackson, Anderson, McEwan, and Mullin (2000) found no differences in the quality of poster designs created with high vs. low video frame rates; and Straus and McGrath (1994) found no differences in performance on idea generation, intellective, or judgment tasks between text-based and face-to-face interaction. It has been argued that tasks involving negotiation and persuasion will suffer more from a lack of visual and auditory cues than tasks requiring less interpersonal finesse (e.g., Daft et al., 1987; Short et al., 1976), although support for this proposition has been mixed (see Whittaker & O’Conaill, 1997, for a review). A few studies have looked at the influence of culture on performance quality. Li (1999a, 1999b) found no differences in accuracy of information transmission in Canadian and Chinese dyads, but significantly poorer transmission in mixed Canadian-Chinese dyads. Adair and colleagues (2001) likewise found that intercultural teams performed more poorly on negotiation tasks. Neither study examined interactions between culture and CMC, however. As with the other outcome measures we have discussed, more research is clearly needed in order to understand how culture and CMC influence task performance.

FUTURE TRENDS

The research reviewed above provides some initial insights into how culture and CMC might interact to shape group processes and performance, but as is clear from our review, there are many gaps in the literature. In this section, we briefly describe four areas for future work that we believe are crucial for moving research in this area forward: theory development, research on the effects of moderating variables, development of tools for intercultural collaboration, and designing CMC for developing regions.

Theory Development

As we have noted, prior work presents an incomplete picture of how culture and technology interact to affect teamwork. Some studies show interactions between culture and medium that are consistent with the cultural dimensions of individualism vs. collectivism, high vs. low
context of communication, and task vs. relationship focus; others show main effects of culture or medium but no interaction between them. In part, differences among studies may be due to the wide variety of tasks, cultures, media, and measures they have used. An important goal for future research is the development of a conceptual framework that explicates the existing pattern of findings. In addition, the cultures examined in CMC research must be broadened. Research to date has focused predominantly on only a handful of Asian cultures. The extent to which these results will generalize to others such as Thailand, the Philippines, Vietnam, and so forth, remains to be seen. In addition, we must move beyond the current emphasis on Asian/Western dichotomy to understand how culture interacts with CMC in other areas of the world.

Effects of Moderating Variables

As shown in the I-P-O framework in Figure 1, there is a range of factors that may moderate how culture and technology interact to influence communication and outcomes. For example, how do individual characteristics such as gender and age influence the relationship between culture and media? Are cultural differences more pronounced for certain types of tasks, or in certain contexts (e.g., home, education, or work)? Are they enhanced or diminished when teams interact over extended periods of time? Prior studies have varied widely in terms of participants’ individual characteristics, tasks and time periods of interaction, making it impossible to identify the impact of any single factor. If we are to develop a theoretical framework for understanding how culture and CMC interact, we must isolate the impacts of each of these factors.

Tools for Intercultural Collaboration

Several studies of culture and CMC have found especially poor communication and outcomes for intercultural teams (e.g., Adair et al., 2001; Setlock et al., 2004). These effects may stem in part from a lack of fit between the needs of intercultural teams and the tools available to support them. Thus, an important focus for future research is the development of new tools that can enhance intercultural teamwork. For example, a new CMC tool might automatically modify messages to be more appropriate for the recipient’s cultural background, similar to real-time translation software (e.g., Yamashita & Ishida, 2006). Alternatively, CMC tools might seek to educate users about one another’s cultural norms, for example, by informing the sender of a message as to why it might be inappropriate given the recipient’s culture.

CMC for Developing Regions

A related domain for future research is the investigation of needs for CMC tools in developing regions, in which information technology infrastructure may be weak and in which local customs may be quite different from those in more developed nations (Brewer et al., 2006). An interesting example of work in this area is the Combadge project (Fankel & Bronberg, 2005). Combadge is a voice communication device that addresses a lack of continuous telephone connectivity and low literacy rates in rural India by storing messages in a queue on the Combadge device until the person enters the range of a transmitter tower, at which point the stored messages are sent on to their intended recipients. The design and evaluation of CMC tools for developing regions is likely to be one of the most exciting yet challenging directions for future research.

CONCLUSION

In this chapter we have presented an Input-Process-Output framework for understanding how culture influences CMC. We described three dimensions of cultural variability—individualism
Global Culture and Computer Mediated Communication

vs. collectivism, high vs. low context of communication, and task vs. relationships-orientation—and discussed how these dimensions may interact with features of CMC tools to influence group communication and team outcomes. A review of the literature to date suggests that cultural factors do indeed shape how people use technology to communicate. More specifically, people from cultures that emphasize nonverbal and contextual aspects of communication are more affected by the visual and auditory affordances of CMC tools than are people from cultures that emphasize the verbal aspects of communication. Future research is needed to flesh out the I-P-O model, to understand how moderating variables influence culture and CMC, and to provide design guidelines for new tools to support intercultural communication and CMC in developing regions.

Watson, R. T., Ho, T. H., & Raman, K. S. (1994). Culture: A fourth dimension of group support
Global Culture and Computer Mediated Communication

**KEY TERMS**

**Conversational Grounding:** The activities by which speakers and listeners work together to ensure that messages are understood as intended.

**Individualism-Collectivism:** The extent to which members of a culture identify themselves as individuals and focus on their personal gain vs. identify themselves as members of a collective and focus on group gains.

**Input-Process-Output Models:** Models of teamwork that examine relationships between variables people bring with them to an interaction (inputs), the interaction among people (process), and the subjective and objective outcomes of this interaction (output).

**Low- vs. High-Context of Communication:** The extent to which communication in a culture is verbally explicit vs. ambiguous and sensitive to the context in which it occurs.

**Media Affordances:** The properties of CMC tools that permit people to use different communication strategies such as speech vs. typing.

**Relational Communication:** Verbal and nonverbal aspects of how messages are conveyed that provide information about the relationship between speaker and addressee(s).

**Task vs. Relationship Focus:** The extent to which members of a culture orient themselves toward getting work done vs. building good relationships with their colleagues.

Chapter 5.10
Linguistics of Computer-Mediated Communication: Approaching the Metaphor

Rosanna Tarsiero
Gionnethics, Italy

ABSTRACT
This chapter introduces the embodied metaphor as a means of studying the multifaceted relationship between computer-mediated communication (CMC) and culture. It argues that the embodied metaphor offers a more reliable framework, as opposed to both deterministic and dispositional perspectives, in that it provides a way to understand, explain, and frame the user’s adaptive response to CMC. Furthermore, it also argues that culture has the potential to shape interactions by influencing the way metaphors are enacted. The author hopes that the aforementioned approach will provide a new understanding of the interplay between CMC and culture, informing future study design and bridging the existing gap between qualitative and quantitative research through action science.

INTRODUCTION
Since its inception, the study of language has been one of the most fascinating disciplines, combining neurophysiology, anthropology, social psychology, and sociology. In recent years, linguistics has been challenged by the advent of the “new media” whose sensory channel permutations are so high and whose sociological and psychological characteristics are so complicated and intertwined that they stress the very concept of “media discourse.”

With the diffusion of the Internet for civil usage, people who had become familiar with using computers for computational, educational, and leisurely purposes also started engaging in human-to-human interactions through machines. Its remarkable simplicity, customization possibility, and flexibility quickly led e-mail to be the killer
application of the Internet all over the world (ITU, 2001; Pew Internet and American Life Project, 2003). More recently with the birth of the Web 2.0 paradigm, the blending of old media into “new” hybrid spin-offs accelerated remarkably. Even text-written computer-mediated communication now has its sub-genres.

The spreading of the Internet and computer-mediated communication (CMC) also generated interest in computer science and social psychology researchers, who tried to make sense of it. However, in the attempt to provide an explanation, several technical, psychological, and social paradigms blossomed, yet none of them explicitly addressed the increasingly higher proportion of cross-cultural exchanges that had started happening after the Internet spread beyond where it was invented. Despite the diffusion of the Internet and CMC, the raising distributed location of their users, the increasing use of e-mail as a collaborative tool in distributed teams, and the amount of studies and information already collected, laymen and scholars alike neglect the role and weight culture has in shaping e-mail exchanges, and assume unrealistic stands that range from extreme determinism to extreme subjectivism.

The purpose of this chapter is to unfold the relationship between CMC and culture through language by exploring the metaphors behind CMC and how they are enacted in different cultural settings. In doing so, the author openly acknowledges and espouses Lakoff and Johnson’s (2003) view of metaphors as cognitive schemes, and relativism as the interplay between subjectivism and objectivism.

In the “Background” section, the literature on CMC, on CMC linguistics, and on cross-cultural studies will spot some reasons of methodological concern. In the “Main Thrust of the Chapter” section, I will explore the metaphors behind CMC and look at them through the lenses of the literature in order to build a model of how culture affects spontaneously occurring computer-mediated exchanges. Finally, in the “Future Trends” section, I will discuss future scenarios and the limitation of the model, suggesting areas for possible refinement of the model and focus of future research.

BACKGROUND

Computer-mediated communication (CMC) and its linguistics were not specifically investigated with regard to how culture impacts them and their interplay. Therefore, this section is composed of three literature reviews: (a) works on CMC, (b) studies on CMC linguistics, and (c) cross-cultural research.

Computer-Mediated Communication

CMC has been extensively studied from psychological, sociological, and technological perspectives. Quantitative approaches outnumbered qualitative ones (Liu, 2002) and suffered with several methodological issues (Culnan & Markus, 1987; Garton & Wellman, 1995; Lamerichs & Molder, 2003; Walther, 1992, 2002). They focused on short-term interactions in artificially constituted groups whose members participated in the research project due to extrinsic rewards (such as higher course grade, extra-credit, money, etc.) or top-down imposition (such as work-related mandated task, workplace or coursework assignment completion, etc.), therefore the research design often became a confounding factor (Walther, 2002). In many of the aforementioned studies, participants were also asked to evaluate the effects of CMC within close categories (Lamerichs & Molder, 2003), pigeon-holing data range, participant experiences, and interpretative schemes in the name of a strong bias in favor of “objectivity.” Often, computer literacy went unaddressed/unassessed, even though it is known to adversely affect interaction outcome (Walther, 2002). Finally, in most quantitative works neither the culture of researchers nor participants was assessed and/or
planned for in the design of the study. Despite all of these biases, the findings of these studies were surprisingly generalized to represent something “intrinsic to the brain” and CMC to be “clearly” inferior and devoid of advantages. Characteristically, quantitative research negative findings are attributed to negative characteristics of either the communication medium (technological determinism, epitomized by Daft & Lengel, 1984; Short, Williams, & Christie, 1976; Sproull & Kiesler, 1991), the task (task determinism), or the social group mechanisms (sociological determinism, Harasim, 1993; Postmes, Spears, & Lea, 1998; Postmes, Spears, Sakhel, & de Groot, 2001; Riva, 2002; Short et al., 1976; Spears & Lea, 1992; Suler, 1996; Turoff, 1978).

Qualitative studies focused on the hermeneutics of CMC. Most of them came to conclusions that drastically differ from their quantitative counterparts, and depicted online interactions as warm and meaningful (for a meta-analysis see Walther, Anderson, & Park, 1994). The growing body of case studies (Hiltz, 1985) and ethnographies (Baym, 1993, 1998, 2000; Hine, 2000; Turkle, 1995, 1997) usually does not suffer from heavy methodological limitations, and many scholars attribute research findings to participant preferences and choices. Nevertheless, they very rarely factor the participants’ culture into the picture.

In tune with the most recent literature on online learning (Muleinburg & Berge, 2005; Mungania, 2003), Rice and Love (1987), Walther (1992, 1996), Herring (2001), and more recently Wood and Smith (2005) take a dispositional stand toward online exchange outcomes, according to which individuals adapt to a “lean” medium in order to build meaningful relationships. Again from online learning literature we know that three constructs are pivotal to engaging in online activities: (a) perceived control over one’s behavior (locus of control, Rotter, 1966); (b) belief in one’s capabilities to organize and execute the actions required to attain a goal (self-efficacy, Bandura, 1977); and (c) ability of having motivation from within (intrinsic motivation, Deci, 1975). These constructs are proven to be impacted by culture (Earley, Gibson, & Chen, 1999; Iyengar & Lepper, 1999; Santiago & Tarantino, 2002).

Despite the number of studies on CMC, neither the deterministic nor the dispositional stand fully account for how CMC determinants intertwine (Herring, 2001). Furthermore, neither addresses the impact of culture on CMC, while quantitative studies openly espouse determinism. However, if we postulate disposition to play a role in CMC production, no matter how small the role, the impact of culture on CMC can no longer be ignored.

**Linguistics and Semiotic of CMC**

Although the linguistic approach to e-mails provides a way to quantify spontaneous exchanges on an objective basis and can potentially bridge the gap between quantitative and qualitative findings (and their diverging interpretations), it has rarely been used (Lamerichs & Molder, 2003). Simplistically, social scientists and psychologists conceptualized e-mail as a form of written communication, which makes portability of findings into linguistics problematic (Herring, 2001). Even though linguistic scholars have repeatedly called e-mail a new genre (Ferrara, Brunner, & Whittemore, 1991) similar to what a transcript is to an oral exchange (Baron, 1998; Bordia, 1996; Lee, 1996; Herring, 1992, 2004), most studies involved caption and analysis of de-contextualized logs because the model of context is inadequate for e-mails (Herring, 1992, 2004; Jones, 2002).

In CMC, verbal cues are very strong. Communicators using a powerful language style are perceived as attractive, credible, and persuasive (Adkins & Brashers, 1995), and style is often more important than the actual exchange content (Pennebaker, Mehl, & Niederhoffer, 2003). Individuals tend to progressively match each other’s style and fine tune prepositions, articles, and other function words, regardless of the mutual liking or perceived quality of interaction (Niederhoffer &
Pronouns, words describing emotions, prepositions, and conjunctions have been associated with and can be used to predict a number of different outcomes (Newman, Pennebaker, Berry, & Richards, 2003). However, it is not known if these findings are also valid outside of North America.

CMC linguistics and discourse are unique because humans adapt to “lean” technologies by inventing paralinguistic expressions to reduce uncertainty and foster relationship formation (Herring, 2001; Walther, 1996; Walther & Tidwell, 1995), such as unconventional orthography to represent auditory information related to non-language sounds (MacKinnon, 1995), quotes from previous conversation to give the illusion of “taking turns” (Herring, 2001), emoticons to convey facial expressions (Herring, 2001; Rezabeck & Cochenour, 1994; Utz, 2000; Walther & D’Addario, 2001), and textual representations of physical actions to help contextualizing the conversation (Gumperz, 1982).

Counter-intuitively and despite the popularity of the “cues filtered out” approach, a number of non-verbal cues are available through CMC, such as chronemics (Hesse, Werner, & Altman, 1988; Liu & Ginther, 1999; Walther & Tidwell, 1995), which play a major role in impression formation (Liu, Ginther, & Zelhart, 2001; Walther, 1993), and relationship development (Hesse et al., 1988; Walther, 2002; Walther & Tidwell, 1995). Walther and Tidwell (1995) discovered that chronemics are contingent to e-mail orientation (i.e., task vs. social content). If task-oriented messages are sent at night, they are perceived as more dominant and “inherently” less social; the inverse is true for social messages. Also, quick replies to task-oriented messages and slow replies to social-oriented messages were rated more affectionate (Walther et al., 1994). This property can have a major impact on people living in different time zones.

Since the use and meaning of traditional verbal and nonverbal cues as well as paralanguage is modified by gender (Herring, 1992; Yates, 1993) and culture (Matsumoto, 2006), we can expect this to apply to e-mails as well.

Cross-Cultural Studies

There is no consensus on the definition of “culture,” because its meaning varies with context (Chase, Macfadyen, Reeder, & Roche, 2002). Early attempts conceptualized it as a set of acquired dispositions uncritically mutated from a homogeneous group (see Table 1 [Hofstede, 1983, 1991]; Table 2 [Hall, 1959, 1976]). More recently, Spencer-Oatey (2000) introduced an interpretive dimension according to which culture also influences interpretations of the meaning of others’ behaviors.

The main objection of Hofstede’s and Hall’s frameworks is the passiveness of both the individual toward the group and the group toward collective brainwashing. Furthermore, such a group is also homogenous and often restricted to ethnicity or nationality. Since both Hofstede’s and Hall’s works are based on data collected in managerial settings decades ago, they might no longer be valid (i.e., cultural “shift”), be valid only in business-related settings, or a combination of the two. Representing culture-related concepts in binary pairs may also miss the importance of cultural nuances, at least with regard to some constructs (Abdelnour-Nocera, 2002). Finally, other authors question en-bloc the idea of culture as a group phenomenon, operationalizing it as social negotiation of meaning (Scollon & Wong-Scollon, 1995). However, these objections might, in turn, just be a cultural reaction of researchers from an individualistic society who experience difficulty in accepting the power of social group conditioning on the individual.

Most studies on “culture” spanned three main thematic areas: (a) verbalizations of situations, feelings, values, norms, and thought patterns (Maletzke, 1996); (b) culturally sanctioned behaviors (Hall, 1960, 1966); and (c) interpretations of situations, such as conflict and collaboration.

(Hofstede, 1983). Concepts like degree of context expressed through communication (Hall, 1976), time (Hall, 1976), tasks/relationships focus (Laurent, 1983; Trompenaars & Hampden-Turner, 1997), attitudes toward authority, adherence to “traditional” gender roles, group/individual focus (Hofstede, 1991), universalism/particularism pair (Trompenaars & Hampden-Turner, 1997), ways to deal with conflict, decision making, and collaboration (Kim & Bonk, 2002; Trompenaars & Hampden-Turner, 1997) still hold validity, even in limited contexts and even in CMC settings (Ess & Sudweeks, 2005).

Interestingly, in a study of 39 languages, the ones from less individualistic cultures allowed for pronouns to be dropped from sentences (Kashima & Kashima, 1998), while Hinkel (1995) discovered that the use of modal verbs between native-speaker undergraduates and ESL students differs, and such differences do not change with linguistic proficiency and exposure to other socio-cultural constructs. These results are grounds to think that different metaphors stand behind different languages and are expressed differentially according to cultures.

Though cross-cultural studies suffer with conceptual and methodological limitations, intercultural studies have leapfrogged the cultural issue by switching from not considering culture to speaking of “intercultural communication through the Internet” without deepening the concept, validity, reliability of “intercultural” dimension, and its measurements (Chase et al., 2002; Macfadyen, Roche, & Doff, 2004; Scollon & Wong-Scollon, 1995). For this reason, old intuitions can still be used to build more rigorous frameworks.

If the adaptation to CMC is even partially dispositional, culture can influence our motivation in e-mail interaction engagement. If language and paralanguage are differentially shaped by culture, culture will also shape CMC. If our knowledge derives from a given set of mental schemes (i.e., metaphors), culture will also modulate how we enact those metaphors.

**MAIN FOCUS OF THE CHAPTER**

Different cultures adopt different metaphors within their languages, each one denoting what is important in the *weltanschauung* of that specific culture. Because every culture symbolizes its world in a different way, if we want to understand how metaphors are used and what we can do “with” them, we are left to make sense of metaphors. In this section I will first explore which metaphors are used in computer-related language. I will then build a model that puts such metaphors in relation to literature from the previous section and, finally, define a list of e-mail indicators to be used when testing the impact of culture in e-mail exchanges.

**Issues, Controversies, Problems**

Lakoff and Johnson (2003) adopted an interesting perspective about the role and impact metaphors have in structuring and shaping our comprehension of phenomena around us. They claim that humans understand and experience all experiences through the use of previous physical and social knowledge. The connection between previous knowledge and present topic resides in the embodied *metaphor*, rooted in physical experience without which there would be no abstract reasoning. Since we build thoughts and actions through metaphors, by analyzing which metaphors humans use for a given topic, we can understand which cognitive schemes their minds use in representing, framing, and understanding the phenomenon, its consequences on the representation itself, and possible “actions” around that metaphor.

Possible claims against Lakoff and Johnson’s theory focus on two concepts: (a) thought is complex and unconscious for the most part, and (b) abstract concepts are mostly metaphorical. Murphy (1996, 1997) explained technical (psycholinguistics) objections, while Gibbs summarized his stand in favor of the embodied metaphor concept (2003). From a behavioral perspective, it can be
argued that we learn language from the environment, as a response to stimuli, and therefore it does not represent a complex unconscious scheme but just an adaptive reaction. Such reaction would however fail to explain why different metaphors are generated by the same person in a given situation. Alternatively, we could argue with Gumperz (1982) that metaphors are expressions of culture rather than manifestations of cognitive schemes. Such objection, however, would not explain why similar metaphors originate in different situations, environments, or cultures. Finally, a constructivist would object that objective meaning does not exist per se, but only as a negotiation process, therefore analyzing language from a metaphorical perspective de-contextualizes it.

The nouns commonly used when referring to the Internet refer to it as a “space” with boundaries, simultaneously away from where we are (“virtual”) yet earthly present (“world”). Such space is partitioned into smaller ones (“chat rooms,” “channels,” “message boards”) which mirror, in name and behavioral conventions, their “real” counterparts (greeting other participants when joining, introducing oneself, saying “bye” while leaving). Members already present in such space but unwilling to engage in a dialogue (lurkers) exist unobserved at its margins and posts, and messages are held together through “threads,” which implicitly suggest: (a) the presence of discrete separators within public spaces, and (b) the virtual community to be a spatial object with a definite dimensionality brought about by the degree of willingness with which its members interact. Microsoft espoused this metaphor and gave it an adventurous gist through names such as “Explorer,” “Windows,” and “Outlook,” inviting the user to “come out” into a broader space and “take a look.”

Verbs describing Internet activities configure the “Internet is an informal journey” metaphor. Users “go to” one page from another, meanwhile they casually “chat” with whom they meet, superfluously “browsing” information and “surfing” Web content.

The metaphors behind computers and their usage and communication in general go against the “negative” view of computers and CMC that emerged from the quantitative literature review. Schwartz (as cited in Lakoff, 2006) noted how the metaphor behind general machine functioning is “machines are people,” in which the degree of functioning expresses their health while the computational power is seen as “thinking.” Interestingly, the interaction between people and their computers also follows a human-to-human metaphor (Nass & Steuer, 1993). In the case of computer applications, they “go crazy,” “freeze,” and have to be “killed,” “terminated,” or “shut down.” They do not just have a “life,” but computer difficulties in handling the user’s requests are seen as emotional trouble. This last trait conflicts with the metaphor of computers and their parts as working aids for their owners.

Espenson (as cited in Lakoff, 2006) noted how the metaphor behind communication is “communication is linguistic communication.” Text-based or spoken communication features are considered more meaningful than nonverbal cues (“His eyes said yes.” “His look spoke volumes.” “I can read him like a book.” “His gestures underlined what he was saying.”).

Because some have advocated language as the source of cyberspace (Cicognani, 1998), and CMC has been represented in different cultures and languages through a relatively uniform set of metaphors, exploring these very same metaphors may teach us which tools to use when studying the correlations between culture and CMC.

Solutions and Recommendations

If the cognitive schemes applying to CMC result from the interplay of these metaphors, we can expect them to be critically enacted depending on the cultural framework of the interaction participants.
that is, depending on the relative importance and acceptance each metaphor has in a given culture. Since both face-to-face (Kramsch & Anderson, 1999) and online communication patterns (Chase et al., 2002) do vary among cultures, variations in qualitative CMC characteristics might also exist.

The Internet is a space. Proxemics are not limited to physical ones (Riva & Galimberti, 1998) and hold validity also for avatars in virtual environments (Jeffrey & Mark, 1998). For these reasons, some behaviors enacted through e-mails and some specific characteristics of the e-mail can be perceived as an intrusion into the receiver's space and be accepted (or condoned) in situations that vary with cultures. I therefore posit that initiating an unsolicited exchange, the e-mail length, and the e-mail rate are space domain indicators (see Table 3). These indicators might characterize cultures in which a hard work ethic is paramount, and which either value privacy, time, and wide individual spaces (such as North America) or shyness, social order, and conformity (such as China and Japan).

The Internet is informal. Culture affects conversation shape and content, as well as degree of technology adoption (Buragga, 2002; Phillips, Calantone, & Lee, 1994). Novelty-seeking, innovative behaviors and authority and rule-probing/questioning through e-mails could be equally culturally sensitive. For these reasons, I posit the formality domain indicators (see Table 4) to be dependent on culturally sanctioned behaviors with regard to public expression of emotional content and to encompass: (a) e-mail orientation (social/task-related content), (b) number of emoticons

per e-mail, (c) number of other paralinguistic cues (such as emoting, quoting, unconventional orthography, and textual representation of physical actions), and (d) degree of self-disclosure. Other such indicators reflect important culture-related attitudes toward (e) hierarchies and (f) traditions, while (g) e-mail linearity (defined as logical, low-context, step-by-step string of thoughts), and (h) e-mail length reflect the attitude toward reflexivity and extroversion, respectively. Such indicators might be particularly descriptive of cultures that value emotional self-disclosure, extroversion, multi-tasking, traditions, and hierarchies (such as the Mediterranean cultures).

The Internet is a journey. In monochronic cultures, time is compartmentalized, while in low-context ones, competition and order are highly valued. In monochronic low-context cultures, work is conceptualized as a “serious” activity during which no derailments and few distractions are allowed, while journeys are meaningful if they have a goal. I posit that journey and working domain indicators (see Table 5) are: (a) daily differences in e-mail orientation (either polychronic switching/multi-tasking between emotional and task-related e-mails, or monochronic string of work-related e-mails interspersed with occasional personal e-mails or remarks), (b) e-mail linearity

(attitude toward context), (c) e-mail rate (number of tasks and kind of topics the sender has been engaged in daily), (d) e-mail length (extraversion and/or low-context culture), and (e) Walther and Tidwell’s chronemics (to be analyzed together with e-mail orientation). This list of indicators could be useful in exploring polychronic low-context cultures, such as Australia.

Communication is linguistic communication. Low-context cultures rely more on written information, are more verbally explicit and less emotional, and ask for details whenever they do not possess all the information they desire to have (Gill, 1998). When looking at data from Europe on the differential use of text-based CMC, studies reveal higher e-mail usage in northern (low-context) countries and higher chat room usage in southern (high-context) nations (Greenspan, 2002). This can be explained by positing that in high-context cultures, e-mail is less frequent because asynchronous communication is perceived as de facto unable to convey “all the context” or not fast enough. For these reasons I posit that (a) requests for clarifications, (b) e-mail orientation, and (c) e-mail linearity are text domain indicators (see Table 6). This indicator cluster might be an excellent fit to explore the low-context/high-context dimension.

Machines are people. Cultures that value long-term relationships and high-context cultures encourage people to behave traditionally and collaboratively toward the group (Kim & Bonk, 2002), and attend to long-term relationships. In individualistic cultures, abstract nouns and adjectives predominate, as opposed to interpersonal concrete verbs within collectivist cultures (Semin, Gorts, Nandram, & Semin-Goossens, 2002). Furthermore, collectivist cultures approach online decision making with different values (Rahmati, 2000; Thanasankit & Corbitt, 2000), while individualistic cultures have a higher rate of critical exchange (Reining & Mejias, 2004). For these reasons, I posit that (a) the attitude toward collaboration, (b) traditions, and (c) individuals, as well as (d) the emotional e-mail lexicon type (abstract nouns/adjectives vs. interpersonal concrete verbs), (e) the existence of long-term exchanges with one or more in-groups, and (f) the number of critical exchanges, are people domain indicators (see Table 7). These indicators can explore the individual/group dimension.

Looking at possible e-mail cultural aspects through the lenses of the five metaphors identified in the previous section allowed the author to identify 22 putative indicators to be put through validation in further studies.

FUTURE TRENDS

Possible Scenarios

Knowing how different cultures perceive e-mails and their characteristics will be a useful tool in various settings. For-profit and non-profit corporate managers alike could use these findings to align e-mail content, format, and policy to their organizational values, and informally manage enculturation, employee loyalty, and adherence to corporate culture. Human resource development managers and online educators could foster cross-cultural understandings and proper management of distant colleagues/partners, while also increasing knowledge sharing and collaboration whenever desired by tailoring their CMC to the audience’s culture, motivation, and desired workplace or educational outcomes. Senior managers and supervisors could facilitate the social component of merging and outsourcing, by planning online hiring procedures and online job assignments, as well as disseminating electronic memos, news, and training manuals in a culturally sensitive way. Online trainers and educators could exploit online social learning by tailoring the format and content of e-mail exercises and interactions, which would allow them to differentially involve students in full respect with their cultural requirements, while still targeting desired learning objectives and outcomes. Professionals like health providers, academics, knowledge managers, and software developers would benefit worldwide from a blueprint for culturally sensitive interactions with peers for informal training, knowledge generation, and referral. Finally, job hunters and potential students could learn how to write personal electronic materials (i.e., electronic college applications, electronic curriculum vitae, cover e-mails) designed to appeal to like-minded individuals.

Limitations

The embodied metaphor’s perspective main problem is that culture can influence CMC prior to the moment in which a metaphor is enacted or interpreted, since the attitude toward using technology is related to specific cultural aspects (Buragga, 2002; Gill, 1998; Hermeking, 2005; Van Belle & Stander, 2002). However, when analyzing spontaneously occurring e-mail exchanges, this objection seems less poignant because CMC users either belong to a technology-friendly culture or have already overcome their own cultural bias toward technology. The objection is still valid whenever e-mail usage is mandated, and is a serious pitfall of some research study designs if unaddressed. It remains to be assessed if spontaneous e-mail usage is an indicator of relative easiness in overcoming cultural biases in general.

The cross-cultural perspective per se is another possible limitation. Language on the Web “becomes” culture (Kramisch & Anderson, 1999), so CMC might benefit from an inter-cultural perspective instead (Bennet, 1993; Chase et al., 2002; Ma, 1996; Macfadyen et al., 2004). On the other hand, to the newcomer to the Internet and to individuals who have not yet criticized their culture, intercultural perspectives may paradoxically foster cultural insensitivity. The Internet itself may also generate glocalization in dealing with cultural aspects of CMC, especially in public fora where adherence to norms is strongly encouraged.

Although all five domains are developed (see Figure 1) and possess both unique and shared indicators, many indicators are not specific to a category, presenting significant overlapping.

That might reflect a poor metaphor choice as well as nuanced interconnections among metaphor dimensions, or frank interdependence. The best characterized domains are “People” (six indicators, four unique) and “Formality” (nine

indicators, three unique). The latter appears to be the mainstay of the model, also allowing for use as indicator subset for gross model validation. The 22 indicators are evenly split between methodological categories (11 quantitative, 11 qualitative—see Table 8).

Testing of the Model

In order to build an objective theory that matches sample accuracy, it is mandatory to match the complexity of the data set with the one of the model. Among available methods, action science (see Argyris, Putnam, & Smith, 1985) appears to be the most fit because it explores events that: (a) occur spontaneously, (b) are composed of (or can be subdivided into) discrete quantifiable measurements, and (c) are not adequately explorable by an artificial reproduction of their core conditions. The paucity of studies on CMC in “natural” settings and the impossibility to fake or eliminate “culture” point toward the use of observation of “spontaneous” interactions.

Previous studies on CMC belonged to either the positivistic model, where the researcher’s epistemology and ontology are both objective, or the postmodern framework, in which the researcher’s epistemology and ontology are both subjective. Because of the conditions in which both CMC and “culture” occur, the objective ontology and subjective epistemology of action science offer a fresh perspective. Action science also offers excellent guarantees about being the least biased method in these settings, since it does not make a priori hypotheses and does not embed interaction design into the study.

Finally, action science also shares its ontology with Lakoff and Johnson’s (2003) model. The parallel between Argyris’ cycle (observation, model building, testing, and action; Argyris et al., 1985) and metaphors as products of the interplay between objectivism and subjectivism is very strong. Metaphors can act as common ground between one cycle stage and the next one, or between cycles.

Researchers bring into the study their culturally susceptible biases, behaviors, and interpretations (Cray & Mallory, 1998), so a great deal of attention should be paid to study design criteria. Viable strategies are: (a) choosing an intercultural study design, and/or (b) employing multiple teams from different cultures observing, analyzing, and interpreting the same set of data so to either shrink the “cultural divide” or make it apparent.

Data selection has to be carefully done. Researchers should collect spontaneously occurring exchanges before enrolling participants-to-be, to prevent a change in their spontaneous motivation to participate into the exchange from affecting the linguistic of the data under study. Data can be gathered from public fora, Yahoogroups, Google groups, message boards, and listserves, as well as from any person of legal age and capacity to read, understand, and sign an informed consent privacy disclaimer describing type and scope of information data collection. Researchers should then contact and test participants via a standardized test, exploring as many independent cultural dimensions as possible, to determine which values participants do individually espouse. Researchers should code and analyze data before formal participant enrollment or testing, and in any case, without knowing the writer score while coding, scoring, or analyzing the message, so to avoid a source of interpretive bias. The obtained data could undergo a cluster analysis to see if taxonomy similar to the original model is produced.

Future Research

Even after successful testing of this framework, there will be further questions to address design and content of future research studies.

Among the contents to be addressed, a first big bulk of questions to explore relate to the difference between CMC in dyads and in groups,
and the interplay between these differences and culture. These questions correspond to the study of possible intersections between the people and text domains (see Figure 1). How does the presence of more than two persons (group) change the dynamics of CMC exchanges? Are cultural expectations related to participation in group conversations? Are there other norms regarding public interactions that change with culture (for example, is the concept of “face” valid online as well)?

Another big set of questions to research lies in the interplay between constructs such as motivation, self-efficacy, and locus of control, with CMC via the cultural and cognitive metaphors applied to those constructs themselves. These questions would explore possible intersections between the journey/working and people domains (see Figure 1). Are motivation, self-efficacy, and locus of control linked to any specific cultural dimension? How does it impact on technology adaptation? How does it impact on the tendency to transcend one’s culture?

Finally, a further set of questions explores the feedback that CMC may have on culture, which would refine the relationship between the people and formality domains (see Figure 1). Which kind of context is available in different cultures as far as e-mail exchanges are concerned? When, why, and how does the perception of cultural norms about e-mail change how different cultures “do e-mails”? What is the impact that signatures and pseudonyms have on CMC exchanges?

This chapter could provide for a set of CMC metrics that could quantify the impact culture has on CMC, thereby changing the current approach to CMC. Cultural inclusiveness, embedding a representation into the interaction, is not customizable enough for the needs of users, even if it claims to be so. It has to be pointed out how “cultural inclusiveness” is a concept germane to political correctness, which in turn is deeply rooted into the American culture and would therefore be yet another “symptom” of cultural imperialism.

Intercultural sensitivity, on the other hand, recognizes and acknowledges different cultures in a framework in which one’s culture is examined critically, while the other person is evaluated from within his/her culture (Bennett, 1993).

If this paradigm will be validated, it might really impact CMC research. The use of metaphors to make sense of CMC has never been attempted before and could be extended toward other forms of CMC such as IM. Findings from these studies could change the policies on the usage of CMC, with particular attention to workplace settings, and that in turn could change people’s behavior and perceptions about CMC.

CONCLUSION

Despite the increasing use of asynchronous text-based CMC in cross-cultural settings, most of what we know about it comes from studies that did not take culture into any account. As a general rule, CMC research has either opted for “laboratory” conditions in the attempt to quantify measurable behavior, or used qualitative methods in the attempt to capture the complexity of field conditions, but results have been channeled into determinism of some sort. The approach this chapter illustrates is a promising one because it refuses to take “absolute” sides, yet addresses qualitative and quantitative issues in the attempt to match complexity of the problem with complexity of the method of study.

The way culture has been conceptualized and studied has shown to be outdated not merely because it dates back to the 1960s: methodological concerns arise toward the generalization of findings from special populations to the whole humankind. However, some of those concepts and findings can still be used to frame actual research. This chapter uses those findings as categories, in a way as “tags” to start from for classifying events and their properties, and then reframe them to explain everyday phenomena.
Building a model based on the metaphors that most frequently are associated with CMC and looking at those metaphors through frameworks accounting for cultural differences allows the author to find a list of qualitative and quantitative behavioral and linguistic metrics (see Table 8) potentially able to depict how culture impacts on CMC exchanges, going beyond the stands that have dominated the field so far. In fact, such metrics cut along disciplines and are related to one another in a way that also allows predictions about their change depending on starting conditions and changes that can occur in them.

This chapter mixes those overlapping disciplines that have most frequently studied CMC into a consistent framework that traces the path for future research. Action science is described as a way to conjugate metrics grounded in an interdisciplinary framework, while implementation details about future research suggest area of improvement.

Chapter 5.11
Impression Formation in Computer-Mediated Communication and Making a Good (Virtual) Impression

Jamie S. Switzer
Colorado State University, USA

ABSTRACT
In face-to-face interactions, people generally form impressions by focusing on a variety of nonverbal cues. Increasingly, however, people are communicating virtually and forming impressions based on mediated interactions. In an online environment, the range of nonverbal cues that normally aid in impression formation is drastically narrowed. In the absence of these nonverbal cues, forming impressions via computer-mediated communication places a greater emphasis on verbal (text-based) and linguistic cues. This chapter offers strategies to ensure virtual workers make a good impression on their clients and colleagues when interacting online.

INTRODUCTION
As the saying goes, you never get a second chance to make a good first impression. This is especially true when working virtually, where impressions are formed via computer-mediated communication (CMC). As Wallace observes, “Increasingly…the online persona is playing a larger role in first impressions as people rely on email, websites, and discussion forums more for the first contact, and the phone call, letter, or face-to-face meetings less” (1999, p. 14).

The varieties of nonverbal cues that normally aid in impression formation do not exist in an online environment. In the absence of these nonverbal cues, forming impressions via CMC places a greater emphasis on verbal (text-based) and linguistic cues, as well as depending more
Impression formation in Computer-Mediated Communication and Making a Good (Virtual) Impression

upon social cues such as shared schema, context, and stereotypes. Indeed, as Tannis and Postmes observe, “communications over the Internet are all but free from influences of the social, the cognitive, and the physical” (2003, p. 692).

It is critical, then, that people working virtually understand how impressions are formed in an online environment and what types of cues aid in forming those impressions, so virtual workers can manage their own online behavior in such a manner that allows others to form an accurate impression.

BACKGROUND

Impression formation is a significant characteristic of communication and a fundamental social-psychological process (Walther, 1993; Liu, Ginther, & Zelhart, 2002). Asch (1946) and Goffman (1959) are generally associated with the earliest scholarly research into impression formation. Regardless of the nature of an interpersonal interaction, as humans “we seem to exit most of our social encounters with some general impression of the other person’s characteristics and dispositions” (Hancock & Dunham, 2001, p. 325). It is simply human nature to form impressions of those around us with whom we communicate in a variety of ways and with differing motivations and goals.

Early scholarship into impression formation emphasized how traditional cues and sources of information identified as important in face-to-face interactions were reduced or eliminated in a CMC environment (Short, Williams & Christie, 1976; Kiesler, Siegel & McGuire, 1984; Sproull & Kiesler, 1986). These theories, collectively termed the “cues filtered out” approach (Culnan & Markus, 1987), concluded that a lack of nonverbal cues prevented people from forming impressions in CMC.

However, a growing body of empirical research has since contested the findings of the cues filtered out theories, and instead has shown that people compensate for the lack of nonverbal cues in a variety of ways and do indeed form well-developed impressions in mediated environments (see Sherman, 2001, p. 54). One of the more recent theoretical models that is key to understanding impression formation in CMC is social information processing theory (SIP).

SIP (Walther, 1992) posits that in the absence of nonverbal cues, people adapt. They are motivated to use whatever information they have available in a particular medium to provide cues to assist in impression formation. According to SIP, while certain nonverbal cues are missing in CMC, other cues needed to form impressions are still exchanged during an interaction. Because of the nature of CMC, the process takes more time and impressions are formed over a more extended period than in face-to-face interactions.

IMPRESSION FORMATION CUES IN CMC

As predicted by SIP, human beings rely on specific types of cues inherent in CMC to form impressions. Categories, stereotypes, schemas, cultural background and preconceived biases all influence the formation of impressions. Studies have shown that the impact of these social cues is considerable in impression formation (Tanis & Postmes, 2003). In CMC, the number of social cues is reduced, but that “does not point to a reduction in the social context of the CMC” (Spears & Lea, 1992, p. 324).

Social stereotypes and exemplars are types of metonymic models (models in which one member of a category is used to understand the membership as a whole) that are commonly utilized when forming impressions in an online environment (Jacobson, 1999). A stereotype is a model where a society or culture recognizes characteristics of an individual or group of people as representing an entire category. For example, some athletes often make headlines by engaging in unruly
and unlawful behavior. Thus athletes are often categorized as being rowdy and uncontrollable, which is more likely the exception instead of the rule. There are many, many athletes who devote their time, energy, and money to charitable causes, who are dedicated to their families, and who do not break the law. However, athletes as a whole are often stereotyped according to this commonly held belief that athletes are unmanageable.

An exemplar is a specific individual that a person has encountered, who is then taken as a representative of others who are thought to be in that same category. However, different people have different experiences with different people who serve as exemplars. Using the previous example of athletes, if someone met an athlete at a charity function who was talking and interacting with the crowd, happily signing autographs and taking photos with children, the inference might be that this particular athlete was a nice person. Based on this one encounter, that athlete is an exemplar for all athletes, who must therefore all be nice people. That is certainly not the case, particularly in a few specific sports.

Impression formation in CMC, as in face-to-face interactions, is extremely dependent upon social cues such as stereotypes, along with the context of the communication and shared schema. People tend to fill in their gaps of knowledge about another person with typifications based on stereotypes and exemplars, a concept defined as “idealization” (Goffman, 1959). Within that framework, people need to seek as much information as possible to form an impression.

Impression formation refers to the “interpersonal processes by which people employ all available information and make general judgments of others’ personality characteristics” (Liu, Ginther, & Zelhart, 2002, p. 73). In a face-to-face environment, people rely on nonverbal cues like vocal patterns (such as tone or accent), linguistic markers (such as vocabulary and grammar), body posture, gestures and eye contact to glean information. The words that are actually spoken are not as influential when forming an impression (Wallace, 1999). But those nonverbal cues are missing when working virtually—the range of cues available to participants in the interaction is narrowed in mediated interactions (Lyon, 2002).

In an online environment the impressions people form and the judgments they make are based solely on the information available to them. People create a perception of others to the extent that they extensively process available information (Leyens & Corneille, 1999) within the context of their own biases and culture. However, in an online environment, that information is extremely limited and is usually conveyed mainly via keystrokes, making the keyboard an “unfamiliar and awkward impression-making device” (Wallace, 1999, p. 28). Yet there are many ways—some subtle, some obvious—that information is communicated in CMC.

E-mail addresses and domains can convey a considerable amount of information about someone’s personality, character, and status. “John. Smith@mycompany.com” gives the impression of professionalism; “beachluvr@hotmail.com” does not. An e-mail coming from a “dot edu” domain indicates that the person is in some way involved in education, which implies a more intellectual status than a “dot com” domain. However, there is ambiguity within a message received from a “dot edu” domain. Is the sender a teacher or professor? A student? An athletic coach? A maintenance worker? To form an accurate impression of the sender of the message, the receiver must rely on additional textual and linguistic cues.

Linguistic style in discourse has a significant impact on impression formation. Users of powerful language styles are perceived as competent, credible, attractive, and persuasive (Adkins & Brashers, 1995). Likewise, in CMC, additional cues such as language use, word choice, vocabulary, sentence structure, and spelling also provide information about a person.

For instance, in the previous “dot edu” example, if an e-mail included a number of references to a
complicated scientific process and long, unpronounceable words, one may conclude the sender was a professor. If the message contained words such as “dude” and “awesome” within short, incomplete sentences with informal or even incorrect spelling (such as “kewl” or “howRU”), the impression is that the sender is an undergraduate student.

Obviously there can be ambiguity within language styles. A professor might very well use the word “awesome” and an undergraduate be well versed in the language of science. In general, however, our shared social schemas lead to forming those particular impressions. According to the stereotype, people believe professors use large words when communicating, and stereotypical undergraduate students use slang.

Likewise, the presence of spelling errors in an online interaction can have multiple meanings. Was the sender just in a hurry and did not closely proofread the e-mail? The impression one might form is that the sender is too busy to be bothered with proper spelling, meaning perhaps it will be difficult to collaborate virtually with this person because they are overworked. Does the sender truly not know how to spell? The impression then might be that the sender would not be a viable partner in a virtual business collaboration.

Vocabulary, word choice, and spelling can also provide information about nationality and/or geographic location. If one of the participants in an online interaction used the word “boot” when referring to the back end of a car, the impression is that the person is from England and not the U.S. (where the term would be “trunk”). Likewise with spelling: the word is spelled “color” in the U.S. and “colour” in England.

Even within countries, linguistic cues can provide geographic information. The term “y’all” is typically associated with the southern region of the U.S. If a message is received containing that term, the impression is that the sender is from the South, which in turn conjures up a host of other stereotypical impressions (usually unflattering) of people who live in the southern U.S.

Information can be communicated in CMC using paralinguistic cues, which can also assist with impression formation. Typographical marks and other textual features such as exclamation points (excitement), ellipses (trailing thought), emoticons (smiley faces), and use of capital letters (SHOUTING) have no lexical meaning per se. The meaning of paralinguistic cues is “dependent on the group or individual context that is pre-established for the communication” (Lea & Spears, 1992, p. 321); to understand them, the meanings must be socially shared among all participants in the interaction. Based on the context, impressions formed using paralinguistic cues can be positive or negative.

Another nonverbal cue utilized when forming impressions in CMC is the use of time, known as chronemics (Walther & Tidwell, 1995). The timing of message sending and receiving, as well as the frequency and duration of online interactions (Liu, Ginther, & Zelhart, 2002), influences impression development in CMC and provides information that can be interpreted in a variety of ways, particularly in the context of a work environment. For example, if a person sends an e-mail late at night, the impression may be that sender is a hard worker who spends many long hours at the computer. If a receiver waits a long time to respond to a message, it may signify superiority of the receiver or a perceived lack of status on the part of the sender. An immediate response implies priority and importance.

However, like all other nonverbal or paralinguistic cues, chronemic cues have their greatest influence in the context of other cues and relationships (Walther & Tidwell, 1995). It may be that the late-night e-mailer works from home and is most productive at night and sleeps during normal business hours. Therefore, the impression of the person as a hard worker may not be correct and other cues are needed to form an accurate impression.
Impression management is the process by which individuals attempt to control others’ perceptions of them, motivated by the desire for social acceptance and relationship development and maintenance (Becker & Stamp, 2005). People spend a great deal of time on impression management, working to regulate what information is known and not known by others about oneself in order to manage the impressions others have of them (O’Sullivan, 2000). Impression management theory posits people are motivated to control the impressions they make on others (Schlenker, 1980), regardless of whether or not the interaction occurs face-to-face or virtually.

Studies by Asch (1946) showed long ago that people tend to leap to conclusions very fast, with few cues to guide them, when forming first impressions. First impressions, however, are “notoriously susceptible to misperception” (Wallace, 1999, p. 15) because people base their impressions on minimal cues and all other assumptions flow from that initial conclusion, regardless of its accuracy.

Additionally, initial impressions often lead people to behave toward another person in certain ways (Sherman, 2001). Sherman gives the example of perceiving someone to be friendly and therefore interacting with him or her in an open and welcoming manner; the other person, then, may respond in a manner even more friendly than perhaps they would normally. This is referred to as the “snowball effect” (Gilbert, 1995), in which a first impression can initiate interactions that gather momentum and become harder to alter and correct if they are indeed inaccurate. First impressions are important because people do not like to admit mistakes. This can lead to confirmation bias, where people ignore evidence that may contradict their first impressions and even actively seek information to confirm the original impression, even though it was incorrect (Wallace, 1999).

Self-presentation is a technique used in impression management. Senders of messages can take advantage of the nature of CMC to carefully craft messages and deliberately enhance the representation of themselves by optimizing self-presentation (Walther, 1996). By engaging in selective self-presentation, people can control what information is revealed during an interaction, thereby influencing what cues are available for the receivers of the message to form impressions.

In some ways, impression management is easier to control in CMC because there are no accidental or unintended nonverbal behaviors or physical cues (Walther, Slovacek, & Tidwell, 2001). Additionally, visual cues may not be present, so there is no preconceived stereotypical perception that can prejudice the interaction.

In other ways, however, impression management in CMC is more difficult than in a face-to-face environment. Research has shown that physical appearance is extremely important in the formation of first impressions (Hatfield & Sprecher, 1986); in most cases that cue is absent in CMC. Words can be construed with different meanings than originally intended in the absence of nonverbal cues. Text-based communications can be wholly misinterpreted by the receiver of the message because there are no additional social cues present to aid in understanding the message more accurately. It is important, then, that virtual workers manage their online behavior in such a manner that others have the information they need to form an accurate impression.
STRATEGIES FOR MANAGING IMPRESSIONS IN CMC

“The desire to form impressions of other people and to manage our own impressions in social settings...does not disappear just because we now do these things on the Internet” (Wallace, 1999, p. 36). Virtual workers must be acutely aware of the nature of CMC in order to make a good virtual impression on their clients and colleagues when interacting online. As predicted by SIP, people form impressions based upon one’s online behavior, conveyed using verbal (text-based) and linguistic cues in the context of cultural background and personal biases. In the absence of any “reality checks” (Jacobson, 1999) such as nonverbal cues or visuals, virtual workers must employ a variety of strategies to carefully manage their interactions to gain social acceptance as well as develop and maintain viable relationships.

CMC users employ a variety of uncertainty reduction cues to “give and gain impressions of one another” (Walther, Loh, & Granka, 2005, p. 40). According to Uncertainty Reduction Theory (URT), the exchange and collection of information allows people to predict the attitudes and behaviors of others (Berger & Calabrese, 1975). The more information that is gathered about a person, the more uncertainty toward that person is reduced (Tidwell & Walther, 2002).

URT posits that individuals utilize three different information-gathering strategies as a means of reducing uncertainty: passive, active, and interactive (Tidwell & Walther, 2002). Passive strategies involve the unobtrusive observation of a person to garner information. Active strategies involve targeted efforts to collect information about someone, but without that person’s knowledge. Interactive strategies for reducing uncertainty entail direct exchanges among the people involved.

As predicted by URT, people are going to be actively seeking information with which to form an impression of others. In CMC, it is difficult to “observe” a person’s behavior, but it is very easy to seek information about someone either actively (by Googling them, for example) or interactively via direct dialogue. Therefore, virtual workers must manage their own behavior in such a way that allows others to form an accurate impression of them in a mediated environment. Below are some strategies to ensure that virtual workers make a good impression on their clients and colleagues when interacting online. While these uncertainty reduction strategies may seem relatively simplistic and straightforward, they are the most accessible and effective to employ in CMC.

Full Disclosure

One way to reduce uncertainty and prevent idealization of senders and receivers of messages is to voluntarily disclose as much relevant information as necessary in the context of the virtual workplace and the task at hand. The sharing and acquisition of information is a proactive strategy that can significantly reduce any uncertainty present due to the lack of nonverbal cues in CMC (Tidwell & Walther, 2002).

Writing self-descriptions is one way to share information. Introducing oneself to virtual colleagues and customers, providing biographical details relevant to the establishment and development of the relationship (such as years of experience in the field), is an excellent strategy for managing impression formation. People have a tendency to increase the amount of information shared (self-disclosure) when interacting via CMC (Joinson, 2001), thus providing additional cues to aid in impression formation. Research has shown that even minimal cues, such as a few biographical details, can have a drastic impact on the quality of impressions people form of one another (Tanis & Postmes, 2003).

Be Honest

There is considerable uncertainty about the accuracy of information in CMC, particularly with
Impression Formation in Computer-Mediated Communication and Making a Good (Virtual) Impression

respect to self-presentation and how closely that matches how people really are (Walther & Parks, 2002). Honesty is critical when interacting virtually. It can be tempting when managing impressions to not be absolutely forthright, particularly if there is no chance the virtual working relationship will ever move to a face-to-face environment.

People employ a variety of information-seeking strategies beyond direct online interaction, such as acquiring information from third party sources without the other person’s knowledge or using search engines to discover information that is available on the Internet (Ramirez, Walther, Burgoon, & Sunnafrank, 2002). So it is likely that if a person is not honest when communicating virtually, that deception will be discovered. Likewise if an initial impression is inaccurate when it is articulated, if left uncorrected, the “snowball effect” discussed previously can occur.

Research suggests, however, that people do not actively deceive others when trying to form relationships and manage the impression others develop in an online interaction (Albright, 2001). Even “to reveal oneself as clearly and honestly as possible requires individuals to select from a repertoire of self-presentational activities to convey themselves accurately,” suggesting that self-presentation is not necessarily manipulative or deceptive, but “should be viewed as a broader concept that includes efforts to present oneself accurately” (O’Sullivan, 2000, p. 406).

Additionally, people who know that the virtual relationship will eventually lead to a face-to-face meeting tend to be more open and honest in the self-disclosure process (Gibbs, Ellison, & Heino, 2006). When that face-to-face meeting does occur and the reality does not match the impression formed from the online interaction, it is usually the result of the participants “filling in the blanks” incorrectly (Goffman’s concept of idealization), not because they were mislead or lied to (Albright, 2001). People who meet and interact in a text-based environment are often wildly mistaken when they imagine one another’s off-line appearances (Jacobson, 1999), partially because of the impact of cultural stereotypes and personal schema on impression formation.

Ask Questions

Anticipated future face-to-face interaction also strongly impacts CMC participants and promotes the asking of more personal and intimate questions (Tidwell & Walther, 2002). Asking questions aids in self-disclosure and information gathering. If the available information is ambiguous, simply asking for clarification will ensure that accurate impressions are formed without jumping to incorrect conclusions. Asking questions can also reduce the possibility of the snowball effect or idealization occurring.

Precise Use of Language

The precise use of language is essential to managing impressions in CMC, to ensure that the expression equals the intention (Adkins & Brashers, 1995). Communications in a text-based environment can be extremely ambiguous, particularly because of the absence of nonverbal cues. For example, delivering the words “I hate you” with a smile, a wink, and an embrace make the actual intention of the message clear; paying attention to only the words used in the communication gives an inaccurate impression. Therefore, it is important to take advantage of the nature of CMC by taking the time to construct messages and craft them in the clearest and most comprehensible manner to avoid any misunderstanding.

Be Aware of Cues

Being aware of the verbal (text-based), linguistic, and paralinguistic cues present in CMC is the most important detail to pay attention to when working virtually. As discussed previously, the absence of nonverbal cues in CMC requires participants to use other content and linguistic strategies to gather
Impression Formation in Computer-Mediated Communication and Making a Good (Virtual) Impression

information that assists in impression formation. Virtual workers must guard against jumping to conclusions based on minimal cues as a guide.

Be aware of the subtle cues communicated by e-mail addresses; a virtual worker’s e-mail address should project professionalism. Think about the subtle meanings conveyed by linguistic style when interacting via CMC. Pay attention to details such as language intensity, lexical diversity, and spelling. Be aware of the impact chronemics can have upon impression formation. Paralinguistic cues can also communicate information that is used in impression formation, but only if the virtual workers involved in the interaction share the same framework for assigning meaning to the indicator.

Impression development is significantly dependent upon schema, context, and stereotypes, particularly if they are shared. Participants in a virtual interaction must have the same social context in which to work so communication is clear and understandable. For example, knowing the term “y’all” is associated with people from the southern part of the U.S. If that concept is not shared, the term is meaningless and provides no information that can contribute to impression formation. Impressions are based on the cues provided, in addition to cognitive models and conceptual categories as well as the context in which messages are viewed (Jacobson, 1999). Understanding how those verbal (text-based), linguistic, and paralinguistic cues can be interpreted in light of an individual’s cultural stereotypes and personal schema is key to managing impression formation when working virtually.

FUTURE TRENDS

The majority of research on impression formation in CMC has been conducted in text-based environments such as e-mail, bulletin boards and chat rooms. Newer technologies, however, allow for mediated interaction beyond mere text. Virtual workers can now communicate online using a variety of media and channels that permit the exchange of nonverbal cues.

Web cameras and videoconferencing allow real-time mediated face-to-face interaction where people can actually see each other as they engage in a dialogue. They can see the facial expressions, body posture, ethnicity and gender of someone as well as hear the inflections in a person’s voice. Digital photographs cannot provide real-time cues, but they still convey information such as the ethnicity, gender, and overall “look” (such as perceived attractiveness, hair color, manner of dress) of a person. Voice over Internet protocol (VoIP) allows people to talk to each other using a computer, where they can also discern accents, linguistic style and voice inflection.

Each of these “richer” (Daft & Lengel, 1986) communication technologies permits the transmission of nonverbal cues that reduce uncertainty. Common sense dictates that the use of these technologies will facilitate the formation of impressions in CMC. There is scant research into this area, but what little has been conducted has found otherwise.

Studies have shown that seeing a photograph of someone or interacting via videoconferencing does not facilitate and may actually hinder impression formation (Walther, Slovacek, & Tidwell, 2001; Fullwood, 2007), possibly because nonverbal cues may be distorted in a mediated environment, or those cues simply do not have the same impact in CMC versus face-to-face. Additionally, other nonverbal cues tend to be overemphasized in a mediated environment. A photograph may evoke a stereotypical impression, whereas the lack of a picture eliminates that possibility. Indeed, the loss of certain information can have positive consequences (Gilbert & Krull, 1988).

Even though richer communication technologies permit the transmission of nonverbal cues, they may not assist in impression formation. Therefore, virtual workers should still employ the strategies discussed previously to ensure
they make a good impression on their clients and colleagues when interacting using newer technologies.

**CONCLUSION**

Early research suggested a lack of nonverbal cues made CMC feel impersonal and would therefore hinder impression formation. Theories based on further research such as SIP and URT, however, indicate that people interacting via CMC can indeed form well-developed impressions (Sherman, 2001) by simply adapting and using other content and linguistic strategies to aid in impression formation. As Tidwell and Walther observe, “When people want to get to know one another, they overcome the limitations of the medium and do so” (2002, p. 341). Research has also shown that impressions formed in an online environment tend to be less detailed but more intense than those formed in a face-to-face interaction (Hancock & Dunham, 2001), but that impressions formed via CMC become more developed over time (Walther, Loh, & Granka, 2005). As uncertainty about a person is reduced, people form impressions and create mental models that help to understand the environment around them (Srull & Wyer, 1989).

People tend to believe they give the same impression to others regardless of whether the interaction is online or offline (Sherman, End, Kraan, Cole, Campbell, Klausner, & Birchmeier, 2001). As this chapter has demonstrated, that is clearly not the case. The absence of nonverbal cues that normally aid in impression formation drastically impacts how people form impressions in CMC. For virtual workers to gain social acceptance and develop and maintain viable relationships, they must employ specific strategies to carefully manage their online interactions:

- Disclose everything
- Be honest
- Ask questions
- Use precise language
- Be acutely aware of cues

“The impact of CMC on society is still evolving and our understanding of its social, psychological, political, and economic implications is far from complete” (Sherman, 2001, p. 69). As the workplace becomes increasingly virtual and the nature of business practices begins to change, the Internet is transforming how people interact and communicate. While the eventual societal impact of working virtually via CMC is still uncertain, one thing will always remain true: you never get a second chance to make a good first impression.

Impression Formation in Computer-Mediated Communication and Making a Good (Virtual) Impression

Impression Formation in Computer-Mediated Communication and Making a Good (Virtual) Impression

KEY TERMS

**Computer-Mediated Communication**: Interaction that takes place through or is facilitated by mediating technologies, such as a computer.

**Exemplar**: A specific individual that a person has encountered, who is then taken as a representative of others who are thought to be in that same category.

**Impression Formation**: Creating an opinion or mental image of somebody or something.

**Impression Management**: The process by which individuals attempt to control others’ perceptions of them, motivated by the desire for social acceptance and relationship development and maintenance.

**Linguistic Communication**: Interacting and gleaning information using language, both verbal and textual.

**Nonverbal Communication**: Interacting and gleaning information not using words but by using cues taken from actions such as vocal patterns, linguistic markers, body posture, gestures, and eye contact.

**Paralinguistic Cues**: Typographical marks and other textual features that have no lexical meaning per se, but the meanings are dependent on group or individual contexts.

**Stereotype**: Where a society or culture recognizes characteristics of an individual or group of people as representing an entire category.

**Working Virtually**: Interacting and communicating to achieve set goals or tasks using information and communication technologies, not in a face-to-face manner.
Chapter 5.12
Group Decision Making in Computer-Mediated Communication as Networked Communication: Understanding the Technology and Implications

Bolanle A. Olaniran
Texas Tech University, USA

ABSTRACT

Networked communication is proliferating our world. The fact that global information communication technologies (ICTs) are becoming increasingly available is facilitating human computer interaction, which permeates the use of computer-mediated communication (CMC) in various organizations, groups, and interpersonal contexts. As a result, the issue facing today’s organizations is not whether to use global information technologies (GITs) in networked communication, but rather how to use them for effective functioning and as efficient coordination tool; especially how to incorporate GITs into the decision-making process. Consequently, this chapter examines the issues in designing CMC into group interactions and decision-making processes.

INTRODUCTION

The shift toward globalization in organizations necessitates increase reliance on information communication technologies (ICTs). However, the nature of ICTs required is not the stand alone, but rather networked ICTs. The growth in networked ICTs such as e-mail, computer conferencing, desktop conferencing, and videoconferencing emanates from the need for speed in decision
Group Decision Making in Computer-Mediated Communication as Networked Communication

Making and the general ability to coordinate activities of geographically dispersed workers, or to facilitate learning beyond certain geographical boundaries. The networked communication process and the accompanying decision-making processes are made possible by the Internet.

**BACKGROUND**

Many organizations and business executives continue to realize the role of employee participation in the decision-making process and organizational productivity for survival. Thus, organizations continue to develop ways to actively engage their members in teams either in co-located or distributed virtual groups. Networked global information technologies (GITs) especially benefit geographically dispersed groups to engage in decision-making process virtually. However, the literature addressing GITs and computer-mediated communication (CMC) focus on comparative features of the technologies over face-to-face (FtF) or traditional communication media instead of looking at the decision-making process occurring over these media as instances of networked communication. There is a potential benefit in examining decision making as networked communication. This approach allows one to ask questions about what technology to use, or why use a particular technology, and when to use a given communication technology? Therefore, the goal of this chapter is to offer insights about the decision-making process in ICTs by looking at some key factors that must be addressed, while offering some recommendations regarding the effective decision-making process when using GITs. First, however, the next section identifies and discusses factors in networked communication decision making as a way to address issues and problems in the networked communication.

**ISSUES, CONTROVERSIES, AND PROBLEMS**

Although the group decision-making process is made possible in networked communication, the tendency to succeed or fail hinges on attention to some key issues. For instance, there is a greater need to adapt communication technology and communicative behaviors to accommodate the decision-making process across different geographical boundaries and social contexts (Olaniran, 2004). The decision-making process where group members are located across different geographical boundaries and time zones necessitates the need to attend to culture. Attending to different cultural needs is not only necessary, but also is increasingly essential for an effective decision-making process to occur. It has been suggested, that success in organizations at large has less to do with market forces than it does with the cultures and the values existing within cultures (Alas & Vadi, 2003; Cameron & Quinn, 1999). There are specific instances of the culture factor in networked communication and the decision-making process. A case study identified that the East Asian culture and its social structure showed cultural differences through the suppression of e-mail use when subordinates are interacting with superiors. More specifically, subordinates are reported to refrain from the use of e-mail with superiors. This is not an isolated incident, as a similar difference was found with the Dutch who showed greater preferences for a more structured decision-making process than their American counterparts (Kiser, 1999; Gezo, Oliverson, & Zick, 2000).
Attention to the issue of culture is important in networked communication for two reasons. One, culture preferences may affect the choice of GIT or communication medium for interaction. Two, the need to realize that technology (i.e., networked ICTs) may not necessarily overcome some deeply held traditional beliefs that underlie how individuals communicate.

Culture is also important in networked communication because it interferes with interactions of groups in organizational decision-making processes. For instance, people in co-located groups have greater access to multiple communication media and, thus, have the benefit of using multiple channels, which in turn permits a broader range of messages, cues, and feedback immediacy (Olaniran, 2004). This is not the case in networked group decision-making processes. Even when individuals have access to other communication media, their usage may be impossible due to geographical distance, and thus, clarification that facilitates message comprehension may be hindered with delayed feedback (Olaniran, 1995). For example, Armstrong and Cole (2002) found that remote sites in virtual teams often fell off radar screens and usually were ignored during telephone and videoconferences. In addition, in videoconferencing, unless the system has cascading capacity, the most visible locations participants are able to see are restricted to two (i.e., picture in picture). Furthermore, time zone differences also create some sense of psychological distance along with the problem of finding a time that works for all group members.

Similarly, the temporary nature and short history of many geographically dispersed teams has become the center of attention in development and sustenance of the relationship among members in CMC decision-making groups (Poole & DeSanctis, 1992). For example, consensus building is one such area in decision making. It is argued, that when mediated group members in dispersed groups have limited time, they often fail to seek adequate social and contextual information to support their attributions (Crampton, 2002; Olaniran, 1994; Walther, 2002). This may result in dire consequences for participants in maintaining relationships or developing cohesion in dispersed CMC groups. Without a shared frame of reference that is developed through frequent and previous interactions, participants encounter problems in decision-making groups. Accuracy in interpreting group members’ messages becomes difficult (Olaniran, 2004). The problem is expected to occur in unitary organizations operating under the same cultural norms, while it is expected to be heightened or exacerbated in distributed networks and in organizations that are geographically dispersed (Kelly & Jones, 2001; Olaniran, 2004).

It is important to examine some of the reasons why decision making over GITs is attractive to organizations that are committed to it and why others are clamoring to explore it. The next section looks at the key benefits of computer-mediated communication and other GITs.

**Some Key Benefits of CMC**

**Freedom to Participate**

CMC has been touted as the means to bring about freedom of participation and increased interaction in groups (McComb, 1994; Olaniran, Stalcup, & Jensen, 2000). CMC discussions offer greater freedom and opportunities to participate than face-to-face (FtF) meetings (Phillips & Santoro, 1989; Olaniran, 2004). In general, the greater participation in CMC (e.g., e-mail or computer conferencing) is attributed to the concurrency of the communication medium. Concurrency is the ability of a communication medium to allow different individuals to simultaneously contribute to the decision process in network communication (Valacich, Paranka, George, & Nunamaker, 2004).
In other words, group participants do not have to wait until a group member completes a thought or yields the floor before they can add their comments. Thus, participants can input their comments at the same time without interfering with other members’ messages especially in synchronous interaction. In an asynchronous interaction, the technology still allows members to participate in the decision process at their convenience by allowing individuals to work around different schedules and time zone differences. This is not the case with FtF. Participation in the decision process through FtF occurs with the requirement that all group members be in attendance to contribute their ideas. Also, FtF interaction requires members to take turns in order to have meaningful interactions.

Equalized/Democratic Participation

Another benefit of the freedom to participate or increased participation enhanced by CMC is the possible equalized or democratic participation. Some scholars have argued that CMC increases the democratic decision-making process (Dubrovsky, Kiesler, & Sethna, 1991; Phillips & Santoro, 1989). This is the area where characteristics and features (tools) designed into different GITs come into play. For instance, certain decision-making tools, such as voting and analyses tools, are offered in some decision support systems that allow groups to reach consensus on decisions (Poole & DeSanctis, 1992). In addition, videoconferencing, through the ability to see co-communicators improves participation and interpersonal interaction as a whole (Badenhorst & Axmann, 2002). However, one must not forget the fact that it is the choices that people make about GIT features regarding their appropriation or use that will determine the final outcomes such as facilitating democratic decision-making process or equalized participation. For example, Poole and DeSanctis (1992) found that the choices people make in using CMC systems often counter the intent of the system designer. In other words, CMC features are designed to accomplish the spirit, which is a particular purpose, but those features, are applied in unintended ways. More specifically, groups appropriate systems from, not only the structural features of the technology but also from other relevant institutions, such as the environment and from group characteristics (Poole & DeSanctis, 1992). Furthermore, user knowledge affects the way tasks are approached in CMC. For example, it has been shown that inexperienced users are more interested in task accomplishment, while more experienced users are interested in efficient application of ICTs (Trumbly, Arnett, & Johnson, 1994). The former stressed learning the minimum requirements for task performance, while the latter put greater emphasis on comprehension of technological features. Consequently, the resulting outcomes in one group over another may vary to a certain degree. The next section will address conditions for which to use ICTs and how to use them successfully.

SOLUTIONS AND RECOMMENDATIONS

Given some of the possible contextual variations in decision making and communication outcomes in networked communication, it is useful to address conditions when certain GITs can be used to foster effectiveness and efficiency. First, effectiveness, in a general sense refers to the idea of process or usage leading to accomplishment of group goals. Second, effectiveness, in a specific sense, refers to the opportunity that GIT offers to improve what is possible under the traditional method (e.g., FtF). Efficiency, on the other hand, focuses on factors such as the speed or cost at which access to information is attainable. Therefore, deciding what technology to use and when to use it is possible by focusing on these two factors.
In light of contextual variations in technology use, there are certain conditions under which equality may result from CMC interactions. For instance, it should be noted that anonymity usually neutralizes any status effect and, thus, allows participants to contribute freely to discussion. Individual identity is protected, and participants do not have to worry about how their messages will be received (i.e., evaluative apprehension) by other participants (Olaniran, 1994). However, the challenge with anonymity is that even when organizations attempt to safeguard members’ anonymity in the decision-making process within CMC, users still may be apprehensive about their contributions. Furthermore, while anonymity is available under experimental conditions, most organizational use of CMC is devoid of anonymity. Yet, a certain degree of equal participation still may be achieved in such settings. For instance, when the communication setting surrounding the problem solving and decision making is informal (e.g., when participants, organizational, and group members are on a first-name basis), interactions that overlook status are possible, enhancing freedom to voice opinions and increase the level of attention paid to opinions and suggestions. In other words, organizations should pay attention to developing open communication climates that would carry over into interaction over technology communication networks.

The need to facilitate an open communication climate and increase participation in group interactions also involves attention to the social norms that guide communication, the structure, and rules, or organizational cultures that guide acceptable communicative behaviors. This argument is in line with the finding that when GIT is used in conditions where group norms are salient, members tend to exhibit behaviors that conform to accepted group norms (Lea & Spears, 1992). Thus, it is necessary to note how social contexts like rules and norms may take precedence over medium effects.

Furthermore, unlike dyadic relationships, group interaction focuses attention away from independent users (i.e., sender and receiver of messages) toward interdependent relationships. Therefore, if a group member selectively discards someone’s message in CMC, others can re-introduce the message during the discussion. This is something that might be too threatening in FtF, especially when the decision process involves interaction between high- and low-status individuals. In essence, CMC has the capacity to mask cues attributable to power and status differences, and therefore, increases the freedom to exchange information (Siegel, Dubrovsky, Kiesler, & McGuire, 1986).

Consequently, CMC holds an advantage over traditional FtF interaction in reducing negative impacts of selective message processing or redistributing power among group members. This argument is consistent with the network paradigm presented by Rice (1990), which emphasizes principles of convergence, where attention is redirected from individuals as independent senders and receivers to one where an individual is an actor in a network characterized by interdependent relationships in social settings. To this end, Kelly and Jones (2001) contend that managers and organizational decision makers pay as much attention to the underlying development and the social communication structure as they do to GIT infrastructure.

The role that social cues play in decision making and communication interaction needs to be addressed. The degree with which GITs allow social cues in interaction differs depending on the type. A general criticism of text-based GIT is that it is lacking in nonverbal cues. For instance, research on relational communication argues that nonverbal codes are relationally warm and fulfilling while arguing that verbal codes are best at satisfying the content or task function (Walther, 2002). Notwithstanding, the lack of nonverbal cues in certain technologies, GITs, have been shown to
encourage participation by masking status effect that is likely in FtF discussion. Furthermore, the lack of nonverbal cues in CMC does not equate an absence of social cues from the communication process. For example, different forms of social cues have been found in CMC: Paralinguistic cues that involve textual manipulation to add context and considerable socio-emotional content to messages (Lea & Spears, 1992; Rice & Love, 1987). Others consist of lexical surrogates and icons used to produce codes or symbols that convey expressions similar to nonverbal facial expressions such as the smiley. More recent examples include sophisticated emotions with audio capability like the ones employed in the Yahoo instant messengers and other computer conferencing. Furthermore, paralinguistic codes such as capitalization, parenthetical notes, and exclamation marks are used to express emotion and meaning (Lea & Spears, 1992).

There also is empirical evidence that confirms text-based CMC groups demonstrate socio-emotional tone from the moment of initial interaction (Walther, 1997). At the same time, advances in computing capability, graphical emoticons are improving how social information is conveyed in CMC.

Making Networked Communication Work

The choice and selection of GITs must be based on the overarching goal of the group. The two-stage model of the group decision-making process may be used to offer some guide (Olaniran, 1994, 2004). The two-stage model consists of the idea generation and idea evaluation. The idea generation stage involves groups attempt to analyze problem, determine goals, and generate possible solutions for a given task. The idea evaluation, on the other hand, focuses on developing criteria for evaluating possible solutions, and discussions of implications of possible decisions and the eventual consensus on selection of solution to the task.

The need for member creativity is particularly important during the idea generation stage of the decision-making process. In order to accommodate creativity, interaction procedures that maximize participants’ participation as alluded to earlier are important (Olaniran, 1994, 1995). Consequently, GITs that nurture individual creativity while reducing evaluation apprehension would be the most productive. It would appear that any GIT would do, provided the organizational culture and interaction norms stress informality. However, when, this is not the case, organizations and groups should strive to use text-based CMC with special attention to protect participants’ anonymity. In this case, networked communication that utilizes central bulletin board or discussion list where ideas are less likely to be traced back to individual contributors. This way, group members are able to participate without fear of reprisals. Furthermore, they will not be participating as in FtF where nonverbal cues can negatively influence group member’s level of participation. Specifically, Olaniran (1994) found that anonymous CMC groups generated more than three times as many ideas as FtF groups and almost two times as many ideas than other CMC groups when group members do not have to worry about their identity being revealed.

The decision to select either synchronous or asynchronous CMC should be determined by the amount of lead time a group has to complete the task, as it would seem to have no effect on the idea generation stage. However, the need to offer anonymous participation holds certain implications for the degree to which e-mail, intra-organizational instant messengers, teleconferencing and videoconferencing can be used in the idea generation stage of the decision model. These communication media clearly reveal the user’s identity in networked communication. The way around this problem, it seems, is to have in place organizational and group climate that stresses informal structure.
The idea evaluation stage, contrary to the idea generation stage, focuses on the role of critical thinking in the process of enhancing decision quality. Thus, the need for group members to freely discuss the pros and cons of each possible solution is crucial. At the same time, the need to develop social interaction and bond (i.e., cohesion) with other group members is important and best nurtured during the idea evaluation stage.

Therefore, communication media that can facilitate critical analyses of ideas while helping in addressing relational and social needs of group members are needed during idea evaluation stage. The development of a lasting relationship while reaching high quality decision making is best accomplished in a group when the social structure such as breaking down cultural barriers, removal of perceived distance, and utilization of GIT media that can appeal to different senses are in place. For example, Waldir Arevoedo (a research analyst at Gartner Inc.) argues that the more CMC interactions involve multiple media that can support cues such as voice, text, and audio, the more the barriers of time, distance, and culture can be overcome (Solomon, 2001). Therefore, ICTs such as videoconferencing and audio teleconferencing offer the most cues for accomplishing relational goals in the decision-making process and networked communication.

An alternative, is to provide multiple communication media or ICTs that allows participants to take control of how they choose to participate in the decision-making process. Thus, when group members need social relations they can select the medium that best accomplishes the desired goal. However, at times, these communication media are not accessible (Olaniran, 2004). When access to multiple communication media, or those providing nonverbal cues, are not the case, attempts must be made to manipulate text-based CMC to meet the need of group members. One method offered for developing social relations is to allow members to work in ongoing groups where group members are able to continue to negotiate and renegotiate their relationships over different tasks (Olaniran, 2004). This suggestion may also help foster critical thinking needed in idea evaluation of the decision making by allowing members to refrain from free riding or lurking activity.

As in the idea generation stage, the decision to use synchronous or asynchronous networked communication should depend on the amount of time a group has. Notwithstanding, synchronous networked communication fosters increased immediacy and feedback, such that clarification of ideas and answers to group member concerns are instantaneous. Similarly, synchronous networked communication allows the decision-making process to flow more smoothly than in asynchronous interactions. On the other hand, idea evaluation in asynchronous networked communication offers group members more time to reflect over ideas before composing a response. 

**FUTURE TRENDS**

One of the major hindrances to adoption and usage of global information systems in organizations’ decision-making processes around the globe, involves the propensity to transfer and use communication technology. The propensity to transfer and use communication technology involves the degree to which global and multinational corporations are willing to allow their technologies to become accessible to their joint venture partners in another country or world region. The problem with propensity to transfer and use technologies has even far greater consequences for the less economically developed countries (LEDCs) where infrastructure and cultural values are different. In essence, the propensity to use global information systems begins with access to technology and the willingness to use it. For the most part, the lack of adequate access to certain global information systems, creates a digital divide between individu-
als from economically developed and those from the less economically developed countries.

Bozeman (2000) argues that technology transfer is based on cost and benefits, and usually the transfer exists only when benefits outweigh the cost. This is significant in the race to use GIT and in bridging the digital divide between economically developed countries (EDCs) and LEDCs. Major information technology advances occur in developed countries, to the detriment of LEDCs, such that affordability becomes a critical issue. Along the same line of reasoning, Ya’u (2004) argues that LEDCs are primarily consumers of global information systems and technologies. As consumers of GITs, LEDCs face knowledge deficiency that also could affect creative use of technologies. Furthermore, there is different motivation regarding the propensity to transfer technologies. While the United Nation’s Commission on Science and Technology for Development wants to use ICT to bridge the digital divide by creating human development initiatives in LEDCs, World Trade Organizations (WTO) and traditional organizations are in it for profit motives in what has been described as another attempt to re-colonize LEDCs in the new global order (Ya’u, 2004). Consequently, the motivation to transfer technologies is not aimed at bridging the digital divide, but, instead, it is driven by conglomerates’ needs to access other markets in response to their home markets, which are increasingly inadequate for sustaining required corporate growth due to saturation of the developed countries’ markets (Ya’u, 2004).

Furthermore, Ishemo (2004) claims that new information and communication technologies are invented in the framework of capitalism development. Consequently, foreign direct investment and critical technology transfer goes to profitable markets rather than markets where there is the need to promote universal access by subsidizing access to global information systems. These strategies perpetuate the divide rather than actually bridging it. For instance, it was found that international firm, large host country, and recently established affiliates correlate highly with technology transfer. Grosse (1996) stresses the profit motive behind technology transfer when indicating that technology transfer is greater when the cost of carrying out the transfer is low and when the resulting benefits of technology transfer were higher. Similarly, host countries’ local government regulations that govern partnerships and joint venture programs and political instability in LEDCs creates additional risks for technology transfer, which some companies are not willing take. Organizations fear that, unless the revenue potential is substantial in a given market, their investment in the country may be short-lived.

At the same time, when technology is available, the propensity or motivation to use it is an internal one. There has to be a willingness or motivation on the part of potential users to want to try or use them (Storck & Hill, 2000). The motivation to use a particular technology is linked to the cultural norms in place. Some cultures resist technology or adopt technology only as long as it does not conflict with their cultural norms (e.g., Heaton, 2001). The example of Cuba’s application of the Internet illustrates this point. Also, older generations have the tendency to resist new technology because of complacency with old ways of doing things (Wheeler, 2001). At a specific level of culture is the issue of language, where over 87% of Internet content is in English (Wilborn, 1999; Van Dam & Rogers, 2003). Non-English-speaking individuals may feel that technology has nothing to offer them. It stands to reason that people in poor nations or rural communities would be motivated to learn and use technology when it helps them access information tailored to their specific needs (see Sassi, 2005).

Certainly, realization of benefits offered by any global information system, depends on the ability of the users to explore and experience proposed benefits on their own. Forced usage would result
in resistance and rejection of the technology as a whole and, more specifically, it would create failure to achieve successful incorporation into the decision-making process.

**Implications and Recommendations**

The driving factor in decision-making processes (networked or otherwise) is the need to attain a level of trust that is essential for group members to reach consensus and effectively make a decision. Schein (1992) argues that decision makers must value and develop relationships that would facilitate joint problem solving and solution implementation. The goal in decision-making groups is to foster adaptability, creativity, and flexibility in group interactions, which have direct impact on organization learning. In connection with learning, it has been suggested that a focused task-oriented culture is crucial to cope with the external environment, while a relational-oriented culture is crucial for accomplishing internal integration (Alas & Vadi, 2003). However, developing organizational learning also demands the ability to work together as teams (Alas & Vadi, 2003; Senge, 1997). Thus, a sense of common identity is developed when each group member serves as reference point for one another. Group participants’ dependence on one another for socio-emotional, as well as task support, enhances relational development that indirectly influences commitment and overcomes barriers to learning.

The information provided in this chapter suggests that the issue facing modern organizations is not whether to use ICT or CMC in the decision-making process. Rather, the challenge is how to adapt communication technology in group collaboration and the decision-making process effectively and in a way that fosters task and relational goals respectively. In order to accomplish such a complex task, attention must be paid to certain environmental factors. First, organizations embarking on implementing networked communication in its group decision-making process would need to realize that there are social obstacles that technology or CMC is unable to overcome. For instance, technology can be used to facilitate relationships within organizations provided individuals seek out such relations. Otherwise, technology in and of itself would not create trust, creativity, and adaptability needed for success in group decision-making processes. Second, the decision to use GIT in a group process need not be based on the idea of “everyone is using it,” rather, it must be evaluated based on the fact that its deployment will help accomplish goals that are central to organizations’ core practices. Third, the social context in which GITs are being deployed is just as important as the task for which they are deployed to accomplish. Differences in outcomes from research in GIT and group decision processes are significantly influenced by how individuals adapt technology, which is often different than GIT designers’ intent.

Organizations’ need to recognize that GIT and other groupware provides a part of the overall communication environment (Kelly & Jones, 2001). It is important to understand that GIT and other decision support are available to supplement face-to-face and other traditional media and not replace them. It is also recommended that software designers need to help organizations overcome some of the challenges in GIT. One is the issue of bandwidth, which prevents against implementing more sophisticated GIT applications, such as those allowing audio and video channel cues, the likes of computer videoconferencing and IPTV. Along the same line, designers need to create third-party software that offers multiple cues that are easy to deploy in the context of group decision making, and are easy to access across the globe.

Networked communication media designers are encouraged to keep in mind criteria involved in the decision-making process by paying attention to the stages, goals, and social needs of organizations and users. One way to bring
this about is to create GIT architecture in a way that adheres to the “analytic hierarchy process” (AHP) of decision making at the minimum. The AHP involves decision-making communication protocols that conform to real-world problems (Ghinea, Magoulas, & Siamitros, 2005; Saaty, 1980). The AHP approach is similar to the two-stage model of decision making by emphasizing that a networked communication media allows users to be able to generate sets of alternatives, prioritize those alternatives, address issues of resource allocations, and predict possible outcomes while resolving conflicts. The capacity to address subjective criteria in the decision-making process also is considered as paramount in any systems design. The AHP should be taken as minimum criteria upon which other features can be incorporated into GITs.

Along the same line, Olaniran (2004) recommends a combined media in virtual or networked groups. He suggests that the combination of both FtF and CMC media in decision making offers an approach that gradually introduces group members to GITs and also creates an approach where GIT users do not feel like they are completely giving up face-to-face interaction for electronically mediated communication. Finally, the need to address the needs of GIT users is important to the decision-making process as much as the decision outcomes from the use of these technologies.

**FUTURE RESEARCH DIRECTION**

Future research on global information technology (GIT) must begin to explore communication technologies not as “either or” when compared with traditional FtF medium. Rather the unique characteristics of each communication technologies should be assessed and then effort should be made to identify how these characteristics can complement established and effective communication interaction and decision-making processes. Furthermore, it is essential that new research focuses on cultural implications of communication technologies. For instance, questions such as: How different communication technologies reinforce or disrupt clearly established cultural patterns of communication across the globe? What effects do dimensions of cultural variability have on organizations’ struggles with communication media selection and usage? These questions are essential in the globalization age where product and service standardization along with market differentiation (i.e., globalization) is the norm.

Along a similar trail of thought is the need for researchers to explore how best to use new and modern CITs to reinforce existing organization culture. It has been found that CITs do not excel when used to change organizational cultures, but instead, they help promote existing cultural norms (e.g., Canessa & Riolo, 2006).

Future research also needs to focus on the use of certain CITs (e.g., videoconferencing and synchronous CMCs). While these CITs are purported to add immediacy and in a videoconferencing case, geographical distances in terms of different international datelines may render them useless. Similarly, it would help to examine the impacts of these synchronous CITs on actual member participation in the decision-making process and as communication media of choice by organizational members. The issue of anonymity or perception of anonymity makes using asynchronous CITs attractive to people for participation in the decision-making process. Thus, there is the need for future research to explore implications of synchronous interactions over CITs when anonymity is removed especially within different cultures.

Taken together, addressing these areas would add significant information to the body of literature in GIT. At the same time, it will help researchers on theory development. As for organizations and their members, the information would be invaluable in identifying what works and how to effectively incorporate CITs into the decision-making process.
CONCLUSION

Finally it is essential that as executives in their respective organizations attempt to deploy or incorporate GITs into their decision-making processes, it would help for them to pay attention to how users in different cultures react to these technologies. Additional impetus could come from researchers who would be able to evaluate meaningfully the role of different cultures in GIT deployment. For instance, while the idea of democratic participation and freedom to contribute in the decision-making process is welcome in the Western culture; would individuals in power distant culture (where status is cherished as the cultural norm) welcome this approach? In other words, there are several cultural factors, including the exercise of power, in terms of who has it, and how they guard it, that may hinder effective implementation of global information technologies in decision-making processes that are beyond the scope of this chapter. However, this chapter offers a potentially successful platform for executives to adapt and modify as situations demand.

Group Decision Making in Computer-Mediated Communication as Networked Communication

**ADDITIONAL READING**

This work was previously published in the Handbook of Research on Global Information Technology Management in the Digital Economy, edited by M. Raisinghani, pp. 243-256, copyright 2008 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).
The purpose of this study was to answer the question: Is the level of achievement of working adult students in an online class directly related to the method of computer-mediated communication used by faculty? The study examined the relationship between the methods of computer-mediated communication utilized, the independent variable; and student outcomes, the dependent variable, among working adult students in online courses. Through an examination of course communication records and student final exam grades, the researcher developed course-based measures of the methods of computer-mediated communication and student outcomes. These measures were used to conduct statistically appropriate tests to determine if there was a statistically significant difference in the student final exam scores between classes that used only basic methods of computer-mediated communication as opposed to courses that employed both basic and advanced methods.

With businesses continuing to increase their expenditures for employee education, there is progressively more focus on maximizing employees’ educational outcomes to effectively leverage corporations’ investment. Dunn (2000) predicts that large corporations will develop their own approval systems for higher education programs similar to the current regional accreditation process.

Bradburn and Zimbler (2002) make the point that the 1999 National Study of Postsecondary Faculty lacked detailed questions about modes of technology, training and instructional practices in individual distance education courses and affirm that further studies in faculty participation in distance education are needed. Northrup (2002) confirms this opinion by stating that future studies should consider variables that may affect the individual learner, the learning environment and instructional strategies that may be most appropriate for specific learning outcomes. Quilter and Chester (2001) emphasize that few formal
Effects of Computer-Mediated Communication

research studies have been conducted to examine the relationships between online communication technologies and teaching and learning, and reaffirm that research employing empirical documentation of communication technologies is lacking.

The method of computer-mediated communication is important since different technology-supported methods of interaction (e.g., two-way interactive TV, text-based chat, e-mail) have different characteristics in regard to immediacy of feedback, student-student and student-faculty interaction, realism and student user control (Smith & Dillon, 1999). Kearsley (1995) reinforces the belief that the method of computer-mediated communication used is critical to the learning process, as it affects the provision of feedback to the student. Distance learning environments that support synchronous communication can provide immediate feedback to the learners and rapid interaction between learners, a feature that may motivate some learners. In contrast, distance learning environments that support asynchronous communication can provide the student with more control over where and when communication occurs as well as more time to reflect on and respond to course content and communications (Moore & Kearsley, 1995). The modality of communication employed in the course is a significant factor in determining the nature of the learning community that is formed in the course.

Duffy and Kirkley (2004) state that most higher education research relies on survey data; that is, class ratings and specialized surveys like the National Survey of Student Engagement (Kuh, 2001), to infer, based on student report, that learning has occurred. It is this researcher’s opinion that one of the main reasons for a lack of prior studies using quantitative data collected directly from course records has been the difficulty inherent in obtaining such data in an online, distributed learning environment.

THE RESEARCH PROJECT

The research project consisted of a combination of three individual studies covering a total of 116 courses and approximately 1,700 students that, taken together, provide a detailed analysis of the question. The first study of 16 courses provided a proof of concept to test the instruments and measures developed and to identify any significant issues. The main research effort involved a large sample of 80 courses that was built upon the results of the preliminary study. The third and final study of 20 courses was a validation study to further evaluate the repeatability of the results and assure the reliability of the instruments and measures.

For purposes of this project, computer-mediated communication was defined as: computer-mediated communication between instructor and student or between students, which discussed some aspect of course content, assignments or student progress in an online course. The study examined outcomes of courses that were supported by both synchronous (simultaneous) and asynchronous (delayed) methods of computer-mediated communication.

Data collected from course management software administration statistics included: (a) methods of computer-mediated communication employed and (b) student final exam grades. Data analysis was performed using appropriate statistical techniques, including the use of an index to represent study variables. The use of an index allowed for statistical analysis and comparison of the aggregated levels of activity. The following index was created: per course combined student final exam grade index (STUFIN).

STUFIN was defined as the arithmetic mean of the student raw percentage scores achieved on the final exam for a specific course. It is the average score received by students on the final exam on a scale of 0-100%, with 100% being a perfect score.
Software features provided by the course management software and used by new online faculty were divided into two categories; basic methods of computer-mediated communication and advanced methods of computer-mediated communication. The methods were grouped as either basic or advanced based on the complexity of the method, multi-media aspects of the method and the method of utilization of the specific method in delivering the online course (Table 1). Courses designated as utilizing basic methods of computer-mediated communication employed only those items listed as basic methods in Table 1. However, courses designated as utilizing advanced methods of computer-mediated communication employed both basic and at least some advanced methods of computer-mediated communication.

The final exam process was designed so that final exams were administered consistently and included comprehensive coverage of the entire course. The consistent nature of the final exam structure and process throughout the university and the wide range of disciplines and number of classes included in the study served to increase internal validity.

RESULTS

In each of the studies comprising this project there was a statistically significant difference in the average final exam score achieved for students in courses utilizing both basic and advanced methods of computer-mediated communication vs. the average final exam score achieved for students in courses utilizing only basic methods of computer-mediated communication. The statistical analysis was done in two stages: first using a student’s t-test for comparison of the group means of the STUFIN index, and then using ANOVA to compare the group means. In each of the studies the results of both types of analysis were significant at the .01 level, indicating that there was a statistically significant difference. The advanced methods courses always returned higher average final exam scores. The average values for the STUFIN index are shown in Table 2. The t scores, ANOVA F scores and related significance levels for the comparison of the group mean values for STUFIN in each study are shown in Table 3.

Smith and Dillon (1999) refer to the media/method confound, a concept stating that the technology alone does not cause the effect; rather, it is the combination of the technology and the way the technology is employed that impacts student outcomes. The act of utilizing advanced features in a course indicated that the faculty member was attempting to actively employ technology to provide a better learning experience for the students. It should be noted that the mere presence of advanced software features was not sufficient to affect a change in student outcomes. Those courses that employed only basic methods of communication had all of the advanced features and functionality available, though were not utilized. The presence of more sophisticated technology does not translate to more effective results unless that technology is employed in an effective manner.

The results indicate that as a group, students achieved higher final exam scores in courses in which the faculty member made an effort to employ the advanced technology in the course.

The effectiveness and manner in which a given faculty member employed the more advanced software features may have contributed to the amount of improvement in student outcomes realized in a given course.

**LIMITATIONS OF THE STUDY**

The primary limitations of the study included the experience level of the faculty member with technology and specifically with online educational technology, a factor that may have potentially impacted the internal validity of the study results. This factor was mitigated by limiting the faculty group to new online faculty. All new online faculty participating in the study received (a) identical on-site training in the use of the software toolset, (b) identical Internet-based training in the use of the software toolset, and (c) individual ongoing mentoring throughout the initial course.

The experience level of the student with technology and specifically with online educational technology also may have impacted the internal validity of the results. Students with significant experience and comfort using online educational tools may participate in a course to a greater degree than less experienced students. Incorporating a wide mixture of courses ranging from beginning to advanced levels served to mitigate this effect.

There may be a number of indirect relationships, supported by multiple factors, impacting outcomes in online classes, including (a) student perceptions and attitudes or (b) institutional requirements, such as the required minimum level of participation in class. The analysis of these indirect relationships was outside the scope of the proposed study. The relative effectiveness of different advanced methods of computer-mediated communication or of an individual instructor’s ability to employ the software was also outside the scope of the study.

**CONCLUSION AND FUTURE TRENDS**

As course management systems become increasingly sophisticated, the associated acquisition, licensing and maintenance costs will also tend to increase. Both of these trends—the increasing sophistication of the course management software and the increasing cost of that software—appear to be ongoing.
The study results suggest that the investment in these software systems is, in spite of the cost, a proper decision that can be of value for both the university and the student. The difference in student final exam results is a clear indicator that this ongoing evolution is a positive factor that can contribute to the success of online education programs.

Garrison and Shale (1990) state that the quality and effectiveness of education at a distance is directly attributable to the kind of communication between teacher and student. The value that advanced software features provide is in their ability to offer faculty more options and creative alternatives in communicating with the student and delivering the course material.

Future research regarding reasons for the preference of a specific method of software-facilitated communication or a specific software feature may assist in developing future enhancements to functionality in course management software. The inclusion of all interested parties in the ongoing software development process should assure that the needs of business, students and educators are all being addressed.

This study was conducted with working adult students enrolled in an accredited university. A research area that merits further study is the relationship between methods of software facilitated communication and student outcomes in online programs with different demographic profiles. Additional research might also be conducted into the relationship between the method of computer-mediated communication employed and student retention in online programs.

NOTE

An earlier version of this paper material has been published in the Journal of Educators Online, Volume 1, Number 1, Summer 2004.

Effects of Computer-Mediated Communication

KEY TERMS

Advanced Methods of Software Facilitated Communication: For purposes of this study, advanced methods of software facilitated communication were defined as including features such as interactive chat rooms, whiteboards (live interactive chats), group teleconferences, customized course calendars, interactive simulations and virtual project labs.

Asynchronous Communication: A delayed time communication, typically in text format, between the learner and instructor or among learners.

Basic Methods of Computer-Mediated Communication: For purposes of this study, basic methods of computer mediated communication included such tools as threaded discussions, grade-books, class announcements and lecture notes.

Computer-Mediated Communication: Communication between instructor and student or between students, which discusses some aspect of course content, assignment or student progress in an online course, utilizing the online computing environment for the communication.

Course Management System: A software-based system for managing the development and delivery of online courses and programs and managing student progress over the Internet.

Final Exam Grade: For purposes of this study, final exam grade is defined as a student’s percentage score (0-100%) awarded on the last, comprehensive exam, which covers course material of the entire online course.

Methods of Computer-Mediated Communication: The communications options made available to the faculty and students by the software features of the online course management system (eCollege™ used by the university, which was the subject in the study.

Student Outcome: For purposes of this study, student outcome is defined as the level of participation of students in online courses and the final exam grades awarded to students upon completion of an online course.

Synchronous Communication: Online interactive or real-time communication between the student and instructor or among students.

Threaded Discussion: Asynchronous communication between students and instructor or among students, where participants post text-based messages.

Chapter 5.14
Exploring “Events” as an Information Systems Research Methodology

Anita Greenhill
The University of Manchester, UK

Gordon Fletcher
University of Salford, UK

ABSTRACT

In this article we build upon existing research and commentary from a variety of disciplinary sources, including information systems, organisational and management studies, and the social sciences that focus upon the meaning, significance and impact of “events” in the information technology, organisational and social context. Our aim is to define how the examination of the event is an appropriate, viable and useful information systems methodology. The line of argument we pursue is that by focusing on the “event” the researcher is able to more clearly observe and capture the complexity, multiplicity and mundaneity of everyday lived experience. An inherent danger of existing traditional “event” focused studies and “virtual” ethnographic approaches is the micromanagement of the research process. Using the notion of “event” has the potential to reduce methodological dilemmas such as this without effacing context (Peterson, 1998, p. 19). Similarly, in this article we address the overemphasis upon managerialist, structured and time-fixated praxis that is currently symptomatic of information systems research. All of these concerns are pivotal points of critique found within event-oriented literature regarding organisations (Gergen & Thatchenkery, 2004; Peterson, 1998).

INTRODUCTION

An examination of event-related theory within interpretative disciplines directs our focus toward the more specific realm of the “event scene.” The notion of the “event scene” originated in the action based (and antiacademy) imperatives of the
situationists and emerged in an academic sense as critical situational analysis. Event scenes are a focus for contemporary critical theory where they are utilised as a means of representing theoried inquiry in order to loosen the restrictions that historical and temporally bound analysis imposes upon most interpretative approaches. The use of event scenes as the framework for critiquing established conceptual assumptions is exemplified by their use in *CTheory*. In this journal’s version and articulation of the event-scene poetry, commentary, multivocal narrative and other techniques are legitimated as academic forms. These various forms of multidimensional and multivocal expression are drawn upon to enrich the understandings of the “event” to extricate its meaning and to provide a sense of the moment from which the point of analysis stems.

The objective of this paper is to advocate how information systems research can (or should) utilise an event scene oriented methodology. The paper is organised as follows: we begin by presenting the theoretical background and definitions of “event scenes” and the “event.” We do this as a means of illustrating how events capture multidimensional and multivocal forms of expression. The significance of this method is that it is a nonlineal and less time focused approach that has the potential to challenge the managerialist, structured and time-fixated praxis that is currently dominating information systems research and development. In the next section we illustrate why and how event oriented methods advocate including elements of illogical asemiosis of experience that eschews the application of management process and articulates arhythmic patterns of life, including political and cultural experience. We then argue there is a need to utilise consumption based approaches in information systems research away from traditional production-based systems understandings. Finally and most importantly, utilising an event-based focus in information systems can challenge existing constructs that perpetuate mainstream regimes of power by widening the boundary of what we understand as “the system.”

**WHAT ARE EVENTS AND EVENT SCENES?**

*The whole life of those societies in which modern conditions of production prevail presents itself as an immense accumulation of spectacles. All that once was directly lived has become mere representation.* (Debord, 1994, Thesis 1)

In this paper we present a sample of literature concerning event-oriented approaches, especially those inspired by the situationists, in order to consider the more specific representational issues found in the specific praxis of the “event scene.” We build upon Peterson’s (1998) literature review that offers a taxonomy of organisational events to develop a critical debate regarding the relationships of events to organisations. The event scene is the direct descendant to the situationism’s act of détournement, in which significant and insignificant elements of observations are isolated and inserted into new and unexpected contexts. Détournement is most readily explained with examples such as found art and the work of artists such as Tracey Emin that includes her Curriculum Vita (CV) presented as a framed piece and more recently an abusive text message sent to a fan. A majority of Emin’s work places the mundane in a formal environment in unexpected ways, forcing the viewer to (hopefully) reconsider their position and view the subject of the works in new ways. As a necessarily obtuse explanation of this tactic, Debord and Wolman (1956) describe détournement as being “less effective the more it approaches a rational reply” to the cultural situation it critiques. The situationist’s invocation for obscurity is a political resistance to the likelihood of mainstream recuperation — of being made ir-
Exploring “Events” as an Information Systems Research Methodology

relevant by becoming commodified. Event scenes are a mechanism utilised by contemporary critical theory in order to loosen the restrictions of historical and temporally bound analysis that are a consequence of most interpretive methods.

Our emphasis is primarily interpretative and contrasts with the growing use of Complex Event Processing (Mohamed, 2006; Niblett & Graham 2005). This theorisation of the event has developed from a computer science and processual perspective. While the founding rationale for this approach could arguably be seen as similar to our own, its implementation and general focus of attention differs significantly.

The general theoretical orientation of this work is drawn from the situationism of Debord’s (1994) Society of the Spectacle (Albright, 2003), de Certeau (1988), Lefebvre (1992) and a cautious reading of Baudrillard’s work (1988, 1998) regarding simulation and hyperreality. We acknowledge that this selection is a somewhat distorted representation of a situationist work. Debord and Baudrillard, for example, have been claimed as being at odds with one another intellectually at various points in their careers, as well as with the general development of situationism (Albright, 2003). Debord’s (1994) identification of the spectacle informs the meaning of the event scene used in this paper and assists in justifying our position that it is a legitimate approach to researching contemporary cultural and organisational phenomena. Baudrillard’s (1993) argument regarding the balance between the mundanity of everyday life and moments of tension also positions the observation of event-driven culture.

In contemporary culture, even for the Frankfurt School of Critical Studies two generations ago, “diversion, distraction, and amusement had become the norm.” (Hoover & Stokes, 1998). Attention to the minuscule of everyday life is both the norm of everyday life as well as being the representational tactic employed within the event scene (Peterson, 1998, p. 20).

The focal point of the event could be claimed as a complex potlatch; it is no coincidence that Potlatch was a key journal that inspired original situationist thought. The event is the mundane, the integrative blending of moments that constitute everyday life, the nonlinearity of experience, the illogic of expectations, the indeterminate acceleration and deceleration of personal temporality and the moments of the unexpected or unforeseen (Albright, 2003; Debord, 1994; Gergen & Thatchenkery, 2004; Peterson, 1998, p. 24; Plant, 1997, p. 236). The researcher is politically obliged within this framework to represent the event (any event) as an event scene — the excised moment of observation and experience captured and individually emphasised by them (Peterson, 1998, p. 20). Representing human experiences in the context of the “immediate” supports our claim that research methods that are less dependent upon historical and temporal references have the potential to reveal alternative and important understandings of information systems development and use.

EVENTS AND COLLECTIVE MEANING

Collectively considered together, “events” are the combination of situations and occurrences that have persistent significance to a social group as shared meaning-making and identity-making constructions (Urry, 2002). The examination and

In the face of the threats of a total weightlessness, an unbearable lightness of being, a universal promiscuity and a linearity of processes liable to plunge us into the void, the sudden whirlpools that we dub catastrophes are really the thing that saves us from catastrophe. Anomalies and aberrations of this kind recreate zones of gravity and density that counter dispersion. (Baudrillard, 1993, p. 69)
Exploring “Events” as an Information Systems Research Methodology

intermediate of events and their representation as event scenes is not a new research enterprise. Its foundations lie in classical historical analysis, including the documentation of significant moments of humanities’ progress through time (see Burke’s 1978 mainstream détournement). As Burke (1978) acknowledges through his own somewhat unconventional view of history, an event offers different meaning to different social groups that reflect divergent genealogies of events. Within information systems research, attention to structure and process produces a lack of sensitivity to the everyday and constant interplay of events. Plant (1997, p. 12) also provides an indefinite definitional basis for the spectacle when she identifies it as the “materialisation of ideology.” In the broadest sociological sense, contemporary events include reality television programmes, sports fixtures and annual festivals. All of these have been made the focus of theoried examination through a variety of methodological lenses. In an information systems context events exist in a variety of forms, including version change, system failure (in its many well-documented permutations), new personnel and new cohorts of “users” (such as the annual induction of higher education students to virtual learning environments). Events in this way are imprecisely situated within a historical, temporal, political and locational morass. The logic of information systems events is more clearly defined and understood by their shifting interrelationship to one another rather than their position on a Gantt chart, in a timeline, physical location or particular management regime.

It is those events that are shared and recalled (although not necessarily in any linear or logical fashion) as significant referents that engender cultural dynamism and contribute to the perpetuation of social structures. It has been argued by Urry (2002) that events such as wars, inventions, rituals, ceremonies, births and deaths are the core elements in the construction of shared meaning and are vital for the establishment of individual as well as social identity. The documentation of past events — or, alternatively, written histories — are significant cultural artefacts that retain collective consciousness in a tangible and objectified manner. Similarly, the documentation of future events in procedures and system designs embed historical, temporal, political and locational bias and assumptions that are effaced (or at least obscured) by the internal “logic” of documentation practice and the “structure” of a system’s design. These realisations are implied as central concerns for the situationists with their criticism of contemporary art and visual representation (Plant, 1997). Situationist thought, which by implication informs the event-driven perspective more generally, understands that the indirect experience of the event encapsulates a hidden but mediating representation that contributes to the obfuscation of the influences that the holders of “real” power have in contemporary society (Albright, 2003). The mechanism by which events or other units of enquiry are represented and labeled through a seemingly neutral “methodology” is consequently recognised as a powerful (and empowering) aspect of the research process. The embedded political relations found in research-based representations of events also contributes to a wider agenda that preserves the existing structures of mainstream power, whether this be political, gendered, ethnic or economic. De Certeau (1988, p. xvii) expresses this concern as the marginality of the majority:

Marginality is today no longer limited to minority, but is rather massive and pervasive: this cultural activity of the non-producers of culture, an activity that is unsigned, unreadable and unsymbolized, remains the only one possible for all those who nevertheless buy and pay for the showy products through which a productivist economy articulates itself.

The event that was the attack on New York in September 2001 and its later evolution into the media-driven event scenes of “9/11” a year later is one indication that the representation of
Exploring “Events” as an Information Systems Research Methodology

Events is a powerful political tool. The difficulty with representational strategies is that they can be used equally by situationists and critics of contemporary culture as well as by the holders of existing power (Albright, 2003; Plant, 1997). Realisation that the political motivations of situationism had itself been recuperated by the mainstream as “witty” ads and ironic play was a pivotal cause in the fracturing and dissolution of the movement. The Sex Pistols are one example of this tension. As their manager manipulated mainstream sensibilities to commercial success, the band’s own initial political and social commentary became increasingly questionable. We advocate, in the largely conservative environment of organisational studies, a critical re-examination of what methodology “does” but do not ad hoc reject all existing methodological paradigms (Gergen & Thatchenkery, 2004, p. 235). The issue being critiqued here is the current practice within information system’s research for continuous, but empty, justification and reiteration of “its” methods. Modernist desire for self-legitimation obscures recognition of the continuous sequence of interrelated events that is the information system in order to emphasise the research activity itself and to legitimate its utility (Gergen & Thatchenkery, 2004, p. 240). More significantly, debate concerning methodological appropriateness, if we apply the concerns of situationism, obscures examination of the real power holders who benefit from the events that are represented.

A VIEW OF THE EVERYDAY

To dérive was to notice the way in which certain areas, streets, or buildings resonate with states of mind, inclinations, and desires, and to seek out reasons for movement other than those for which an environment was designed. (Plant, 1997)

At first glance the effort to dérive (to become a derivite, to drift) appears to be the opposite political action called for by the desire to represent, recognise, and respond to the complacency of mundanity. However, the act of dérive is better viewed as the political and methodological act of looking beyond the veil of hegemonic expectations in order to see the actuality of use in places and with things. In an information systems context this could be (merely) seen as looking beyond the managerialist and structuralist views of a system (Peterson, 1998). The contemporary seminal example of the act of dérive are the unfocused, random and personal actions of the “Web surfer” (Andersen, 1998; Hartmann, 2003). Observation and participation within a system is contextual within a continuous sequence of interrelated events that captures what is actually done on a day to day basis rather than what is expected of individuals.

The role of the everyday within information systems research is, however, only marginally articulated or acknowledged in the majority of seminal information systems literature. Such a paucity of material is despite the significant impact that information systems themselves have upon daily life, both in a workplace context and increasingly in the domestic environment. However, the discussion of everyday life and its critical debates are well covered elsewhere (in other disciplinary contexts) by writers such as de Certeau (1988) and Lefebvre (1992). Both of these authors had also recognised association with situationist thought. De Certeau (1988, p. xviii) in discussing the personal interrelationships of everyday life claims that statistical investigation remains virtually ignorant of these trajectories, since it is satisfied with classifying, calculating and putting into tables the “lexical” units which compose them but to which they cannot be reduced, and with doing this in reference to its own categories and taxonomies.

These claims can be rightly construed as a critique of quantitative and positivist praxis.
The implication in a critique of this type is that these approaches produce their own internal logic that obscures external influences of power upon those people and “things” being tabulated, and who are ultimately affected. De Certeau (1988) argues for the significance of the interrelatedness of everyday life when he claims that “the analysis of the images broadcast by television and of the time spent watching television should be complemented by a study of what the cultural consumer ‘makes’ or ‘does’ during this time and with these images.” Basden (2005), in examining the works of Dooyeweerd, also claims that

though we cannot theorize scientifically about everyday life, we can understand it philosophically as an integration of the aspects of our experience. In the everyday, all aspects play their proper place to a greater or lesser extent. This is why, for example, it has an important social aspect and a religious (pistic) aspect, as well as a sensory aspect. But it also means that everyday living is not devoid of analytical activity (which is akin to theoretical thinking), though this takes the form of an analytical subject-object relationship rather than a theoretical Gegenstand-relation. This provides a useful foundation for analysing the richness of everyday life, everyday engaged attitudes and tacit knowledge.

The situationist view of the everyday is not, however, celebratory. Situationist association of everyday life with people’s oppression and disempowerment largely prohibits this perspective, at least directly. De Certeau’s general observations regarding everyday life also reflect this political hesitation.

As the indivisible stage of experience, everyday life is the venue for the construction and articulation of events (Peterson, 1998, p. 20). Understanding information systems in this context places them in the realm of everyday life, where they cease to exist in any systematic or singular sense. Information systems (whatever these may be) as an experience of everyday life become (perhaps merely) a surfeit of received information so that “today, the population is subjected to a continuous bombardment of damned stupidities that are not in the least dependent on the mass media” (Debord, 2002, p. 130). Debord (2002, p. 130) sustains this critique by claiming that “information theory straightaway ignores the chief power of language which lies on its poetic level; to compete and supercede.” Information does not have inherent power solely as a consequence of the scale of individual collections (with the Internet being the uber example) but in conjunction with the manner that information is read and reinterpreted; in short, how it is presented and represented.

THE MULTIPLICITY OF EXPERIENCE

The event-based approach is a rejection of the linearity of practice that is assumed within predominant “systems” based approaches. Methods that seek to understand “the system” commence with a series of assumptions that include the belief in an a priori presence of a system “merely” because the concentrated accumulation and representations of information is labeled as such.
Belief in the systemic nature of everyday life is an agreement of coherence and semiosis that is not borne out by experience. An event-oriented method, in contrast, integrates and recognises the illogical asemiosis of experience that eschews the application of management process and articulates arhythmic patterns of life (Peterson, 1998). For example, organisational studies of university management would attend to the application of documented policy, the process of committee based decision making and the general hierarchy of authority within a university. An event-oriented approach applied to the same environment may focus on the “hidden” flows of e-mails between colleagues, the use of “chair’s action” for decision making and the day to day solving of problems that contradict documented policy.

Critical and contemporary social studies no longer unwittingly accept the dominant historical accounts of events as the only “truth.” Nor do these perspectives blindly accept the unseen influences of power in the constitution of social phenomena or even identity. Writers such as Baudrillard (1998), Bergson (1910) and Game (1996) have all challenged the linearity of history and have gone so far as to argue for, at least in some cases, the death of history. In this rethinking of history the temporally cemented event — fixed, reified and glorified — is challenged. Raising doubt regarding the “certainty” of specifically identified events is particularly true in relation to the role that history plays as the central parameter of cultural understanding. The exploration of notions of time and space and their philosophical relationships is a central focus in contemporary studies of the social. Time, Bergson argues, has philosophically become spatialised (1910). That is, when time is spatialised it is understood as being able to be touched, seen as having discrete elements or presence and, most significantly, it can be presumed to be represented in this way (Game, 1996). As Game states “the common conception of time is that it is abstract, linear, and homogenous; homogenous empty time” (Game, 1996, p. 95). It is Bergson’s notion of multiplicity, however, that positions — even anchors — the construction of event scenes and the representation of everyday life experiences. The method of multiplicity, outlined by Bergson, employs dislocation by taking any object and disassociating its different moments, or its different ways of meaning (Game, 1996, p. 92). Bergson’s multiplicity mirrors the political strategy and research method of détournement (the disentanglement of cultural products to present new and oppositional meanings). Pulling apart the normality of everyday life plays with the meanings (and understandings) of the single instance and multiple events (their interlocking relationships) (Debord & Wolman, 1956). Bergson is critical of the approach and idea that “the present contains nothing more than the past, and what is found in the effect was already the cause” (Bergson, 1910, p. 15). The influences of historical materialism is readily identified within both qualitative ethnographic works and quantitative longitudinal studies (two methodological approaches that currently find favour within information systems research). Historical materialism presumes that what has preceded is the key relationship and source of understanding. However, for the contemporary moment it is an under theorised enquiry.

**CAPTURING THE EVENT WITHIN THE RESEARCH PROCESS**

The diverse approaches to systems thinking utilised in the field of information systems necessitates critical engagement with the question of the research position as the actual site of analysis and point of observation of the event. Systems theory methodologies require a boundary to be placed at the site of analysis (Heylighen, 1998). Encapsulating the subject under examination reduces the endless combinations and interactions of complex systems — the wide range of
Exploring “Events” as an Information Systems Research Methodology

events — that can be observed. It is at the nexus between advocacy for the need for boundaries and alternatively their permeability that debates regarding the meaning and purpose of information systems research exists. General systems theory applies boundaries in order to present a minimalised but holistic position of analysis (Heylighen, 1998). The bounded conceptualisation of a system exists within the broader continuum of system theory approaches and has been utilised across the information systems field, which ranges from the “hard system/cybernetic” approaches to “soft systems” (see Checkland & Howell, 1998 for a history of systems thinking in information systems development).

Systems operating within organisations are usually considered open in that there is recognition of the dynamic interaction of the system with the surrounding environment (Robbins & Barnwell, 1994). The system’s boundary serves to enclose internal operational elements from those external to the system and environmental conditions which may impact upon the system as a whole. However, the system’s boundary is permeable (Greenhill, 2002). Within the system, information is processually transformed from input to the output stage. Systems developers expect and plan for information taken into a system to be altered in predictable systematic ways up to the final point of output, of release from the system. Bundled with this initial assumption, the meanings and purposes associated with specific information are also fixed. Baskerville and Pries-Heje’s (1998) study on the management of knowledge capability and maturity in a small to medium size software development organisation is a pertinent example of the expectations of the systems developers in developing and maintaining fixed meanings within systems. The company Baskerville and Pries-Heje studied experienced difficulties developing organisational and Web-based systems. Assessment of the company’s situation was carried out primarily in managerial terms, rather than as a sequence of events, as the employees themselves claim.

I realise that all documents needed to support this, namely customer contract, project presentation, budget and requirements specification, were nowhere, and there were a thousand different meanings within Proventum about how they should look... Today we have as many different contracts as we have employees, because we don’t have a template to work from. (Jan in Baskerville and Pries-Heje, 1998, p. 183)

We need to be better at exploiting the knowledge from previous projects, much better, so we don’t make the same things again and again and again. (Henrik in Baskerville and Pries-Heje, 1998, p. 183)

Many systems designs rely on the fact that there can be no unsystematic, nonprocessual or unexpected alterations to the meaning of information (no unforeseen events). The experience of the system is not regarded as a varied combination of interconnected events but a continuous timeline of neatly packaged and logical actions. In the case of this often cited example, information was seen in management terms to remain static and continuously available to enable its exploitation in the future. However, from an event-based perspective the purpose and use of the information within a planned system does not necessitate or provide any singular or fixed accumulation of meanings. In place of uniform certainty is an array of interrelated meanings that the user may variously interpret from a system and its usage. It is only the genealogy and association crafted through organisational culture that produces mutually shared understanding of the system. As Wittgenstein observed, there can be no “private language.” Understanding and mutual comprehensibility is a joint-action (Gergen & Thatchenkery, 2004).

The interpretive position offered by Orlikowski & Gash (1994) and Feldman & March (1981) are
two examples of the influence of situationism on information systems research. The assertion that information always holds multiple meanings challenges any methodological assumption surrounding the construction and representation of meaning that presumes a linear monodimensional process (Baudrillard, 1994). An event-oriented perspective enables the identification of many taken-for-granted positions to be found in current methodological frameworks through the act of détournement, and reveals rather than obscures the political environment around which information is manipulated (Baskerville, Travis, & Truex, 1992). The foundational model for information systems was developed within a modernist context and utilises static and linear understanding to the meaning of information. It is only now that we, as participants within a postmodern cultural condition, are able to critique and question the appropriateness of static models of systems models usage.

Generally, analysis of systems operations and information systems utilise the modernist tradition, which emphasises and restricts understanding through the processes of production (see Alter, 1996; Hirscheim, Klein & Lyytinen, 1995). The information system is represented and understood as a Fordist information “factory.” For example, the system Baskerville and Pries-Heje (1998) explore is a knowledge management system that requires the system output – knowledge – to be managed. The input into the system is garnered from knowledge obtained from new and existing employees on the software programming team. More specifically, new knowledge, meanings and hence inputs that the individuals have in relation to database technology, Internet technology and Web technology are inserted into the system (Baskerville & Pries-Heje, 1998). The management of this knowledge within the monolithic managerial perspective requires information at the input stage to remain deterministically static in order to be both predictable and reusable. The application of this knowledge may be required at a later date (as systemic output). Therefore, it must be controlled in terms similar to those of a factory process. The system is valued purely in terms of this restrictive and narrow, but tangible, output. Processual approaches restrict the understanding of a system to an examination of data, its utilisation and manipulation. The goal or objective of the system is reached by asking whether the end product or output is effective and achieves the desired outcomes. Outcomes are generally assessed from a managerial perspective, simultaneously reducing the day-to-day user to a component of the system. Mechanistic positions reflect much of the contemporary information systems thinking (see Alter, 1996; Achterberg, van Es & Heng, 1991; Hirscheim, Klein & Lyytinen, 1995; Morgan & Smircich, 1980). Incorporating the event into systems analysis challenges production driven theorisations by shifting analysis away from production and the privilege of the manager. Consideration of events and the role of less privileged users reduces the dominance of hierarchical and managerial views of the system. Ultimately, the political aim of this perspective is to reposition those who contribute to events in the system as owners of that system.

**METHODS FOR REVEALING AND REPRESENTING THE EVENT**

Much of the methodological challenge that is taken up by event based analysis has been described ad hoc under the rubric – “the postmodern turn” (Brown, 1990, p. 196). Although this “turn” is yet to be fully articulated within the studies of organisations, commentaries such as that of Gergen and Thatchenkery (2004) do justify the turn for further critical work. Although postmodernism has been posited as antithetical to the modernist project, the relationship is not simply a structuralist dichotomy (Lagopoulos, 1993). Foster (1983, p. xi) suggests that the task of postmodernism is to extend the project of modernism by opening
Exploring “Events” as an Information Systems Research Methodology

“its closed systems to the heterogeneity of texts.” The politically confining aspects of modernist methodology are alternately accentuated, ignored or rejected in the various “postmodern” approaches (Huysen, 1992; Jencks, 1992.). Klotz (1988), in his attempt at reaching a definition of architectural postmodernism — itself a potentially modernist task — provides the basic framework for critical social research. He cites ten defining characteristics of the postmodern experience, ranging from geographic specificity and poetic cultural constructions to a need for relativism. Recognition of these cultural conditions irrevocably alters the justification of modernist methodology. The recognisable traits of postmodernism all emphasise the irrevocably altered nature of social relations in advanced mainstream capitalism, including what we claim is a surfeit of events. Among other qualities found in Klotz’s (1988) definition of postmodernism are the use of fiction in conjunction with function, the ironic “use” of history, the plurality of style, and a movement away from the perceived inevitability of technological progress. Capturing this complex social environment is more readily done through the gaze of the dérive — looking at the world of everyday life from the outside — and engaging in détournement — tearing down the supposed stability of systems.

The urban form, the visual, a celebration of the mundane, the embodiment of readable messages within material culture items and, obliquely, the increasing importance of entertainment in daily life are all elements of a critical methodology that attempts to understand contemporary social life. The movement away from modernist method and its quantifying concerns has been paralleled with an interest in the study of the popular and — to its extreme manifestation — kitsch (Jameson, 1983). What had been previously dismissed as not worthy of study or as being simply ugly have acquired undiscovered qualities, bringing them into the framework of theoried examination. The academic study of the products in the everyday life of mainstream capitalism, such as tourist’s souvenirs and the car, is compatible with the attitudes of the dérive.

Examining the mundane “things” of everyday life and their relationship to other “things” also emphasises a shift in focus from production-based analysis to more consumption-orientated approaches. This is a view which is confirmed by Shields (1992, p. 2), who believes that “in general, the modernist separation of economy and culture has left little room for serious engagement with consumption practices.” Consumption-based methods provide a degree of flexibility and encompass a significant part of an individual’s social life. Being “out” in the public sphere is to be consuming, not just foodstuffs and fuels, but more intangible items, including events and information. The practice of consuming in advanced capitalist social life has become synonymous with social participation (Derrida, 1978). People’s ability to remain social participants is determined by their consumption practices. In this sense consuming events and gazing upon objects are important aspects of everyday life, and by implication the research methodologies concerned with human experience. Consumption encompasses a significant proportion of social life when the supposedly “ordinary” can be viewed both as spectacle and as the parody of spectacle — the unspectacular event.

Within the context of everyday life the consumption of events is sublimated into the realm of the ordinary slipping from political consciousness to reinforce existing power structures. The situationists provide two methodological tactics that support their underlying theoretical and political standpoint: dérive and détournement. A third methodological tactic was identified by the situationists as the position and action that must be resisted, that of recuperation (being subsumed into the mainstream). Much of the obscurity, complexity and incoherence of the original situationist works was incorporated as a defense mechanism against this counter-tactic.
Criticism of later works with a situationist heritage could also be understood through the realisation of this tactic and proactive resistance. Writings such as Baudrillard’s (1998) “postmodernism” and Derrida’s (1978) “poststructuralism” are two immediately obvious examples. There is a tendency to isolate an individual tactic of situationism and celebrate its relevance. Of the three methods this response is most commonly found with the dérive and the Web (Andersen, 1998; Hartmann, 2003). However, this methodological isolation is a disservice to the original intent of the situationists. The *Internationale Situationiste* (1958) claim for détournement, as “the integration of past or present artistic production into a superior construction of a milieu,” continues to have relevance in relation to information systems as an inter-related combination of events that are not constrained by the arbitrary boundary of a documented system. Setting the information system free of unfounded delineation requires the act of the dérive. To drift and discern the location of these relevant but distanciated events requires the attitude that mirrors Baudelaire’s *flâneur* who is not constrained by the conventions that the recuperated information system seeks to sustain and perpetuate upon its hierarchically labeled and systemically controlled users.

Existing examples of event-oriented critiques of information systems are not readily found as printed documents. However, the increasing domestication of information technology acts as an enabling mechanism that brings event-based critique to the Web. These are generally visual and visualisation projects. The *Digital Landfill* project ([www.potatoland.org/landfill](http://www.potatoland.org/landfill)) takes images and texts from randomly selected Web sites and détournes them into a single image that seems to be “almost” meaningful. Similarly, the home page of [spaceless.com](http://spaceless.com) generates a random selection of images gathered from everyday life that appears to be a coherent collection. The semiotic obscurity of the resultant combination of images resists recuperation while standing as a critique of the vast asemiotic information system that is the Web. A more focused use of situationist tactics to develop a critique of an e-commerce system was the ongoing dispute between *etoys.com* and *etoys.com* (Stallabrass, 2003). *Etoy.com* became the vehicle from which “toy war” was launched. This “war” parodied the techniques of online business to détourn the meaning of e-commerce. The final result of this political engagement was the corporate failure and bankruptcy of *etoys.com*.

However, some Internet art projects reach beyond détournement and this is explained by Debord and Wolman’s definition of the tactic. “The distortions introduced in the détourned elements must be as simplified as possible, since the main impact of a détournement is directly related to the conscious or semiconscious recollection of the original contexts of the elements” (Debord & Wolman, 1956). This tactic is consequently not an anarchic free for all, but rather a considered and theoried technique that specifically endeavours to produce a political response to the observed world and status quo.

### THE DEATH OF HISTORY (OR THE DEATH OF CRITICAL INFORMATION SYSTEMS RESEARCH)

This article has presented the definitions of event scenes and the theoretical background regarding events. We provide an overview of existing research and commentary that focus upon the meaning, significance and impact of “events” in the information technology, organisational and social contexts. Peterson’s (1998) literature review provides initial guidance in revealing the possibilities for a taxonomy of organisational events. In this way, we have developed the foundations for a critical debate regarding the relationships of events to organisations.

The argument presented here has demonstrated how the “event” as a method can capture multi-
dimensional and multivocal forms of expression. We have shown how the examination of the event can form the basis for an appropriate, viable and useful information systems methodology. By focusing on the “event” the researcher or system designer can observe and capture the complexity, multiplicity and mundane of everyday lived experience. By utilising an “event” focus in IS research, we argue for the potential to reconstitute the mundane, the integrative blend of moments that constitute everyday life, the nonlinearity of experience, the illogic of expectations, the indeterminate acceleration and deceleration of personal temporality and the moments of the unexpected or unforeseen (Albright, 2003; Debord, 1994; Gergen & Thatchenkery, 2004; Peterson, 1998; Plant, 1997).

We have argued that utilising the event-oriented method, including elements of illogical asemiosis of experience, eschews the application of management process and articulates arhythmic patterns of life. The significance of the event-based approach to information systems development and research is that a nonlineal method challenges managerialist, structured and time-fixated praxis that currently dominate information systems research and development. The implication of our critique is that these existing popular approaches produce their own internal logic that obscures the influences of power on people and “things” located and ordered within the system. The influences of historical materialism can readily be identified in the preference for current research approaches. Historical materialism presumes that what has preceded is the key relationship and source of understanding — the event, in contrast, is currently an under theorised enquiry. Such theoretical foundation means that systems developers expect and plan for information taken into a system to be altered in predictable systematic ways up to the final point of output, where they are released from the control of the system. However, from an event-based perspective, the purpose and use of the information within a planned system does not necessitate or provide any singular or fixed accumulation of meanings. Consideration of events and the role of less privileged users reduces the dominance of hierarchical and managerial views of the system. Ultimately, the political aim of an event-oriented perspective is to make those in the system the owners of that system.

Finally, what is being presented in the event and the event-scene is not a metamethod for information systems research but an attempt to incorporate the complexities of everyday life and the subtleties of political meaning into the sterility of systemic systems thinking. Event-oriented perspectives in information systems offer the opportunity to engage in détournement for the purpose of both understanding existing environments and contributing to the development of future systems’ “architecture.” The active engagement in re-engineering echoes the situationist’s own town planning and architectural experiments (Sadler, 1998). Rebuilding the component parts found in the détournement produces new, unexpected and politically challenging approaches to the mundane of everyday life. Information systems research, in contrast, has been recuperated from its inception. Its methods, philosophy and advocacy continuously return to questions of business efficiency, process improvement and time management. As information systems become increasingly domesticated, the continuous and automatic reiteration of these perspectives without debate or critique will merely serve to perpetuate existing mainstream regimes of power.

ABSTRACT

The horizontal and vertical dimensions of individualism and collectivism are an important characteristic of cultures. These dimensions have many implications for the ways in which individual learners use and respond to interactive technologies. This article reports on a study that investigated the impact of culture, specifically horizontal individualism (HI), vertical individualism (VI), horizontal collectivism (HC), and vertical collectivism (VC) on the effectiveness of technology mediated learning. Results indicate that the four dimensional patterns have differing effects on the use of TML communication capabilities, feelings of sense of community, satisfaction with the TML experience, perceived learning, and declarative knowledge acquisition.

INTRODUCTION

Culture is emerging as an important variable in the investigation of Technology Mediated Learning (TML) (Anakwe, Kessler, & Christensen, 1999; Collis, 1999; Gunawardena, Nolla, Wilson, Lopez-Islas, Ramirez-Angel, & Megchun-Alpizar, 2001; Salvatore, 2002). TML has been defined as “an environment in which the learner’s interactions with learning materials (e.g., readings, assignments, exercises), peers, and/or instructors are mediated through advanced information technologies” (Alavi & Leidner, 2001, p. 2). This
Culture's Impact on Technology Mediated Learning

This article extends the current examination of cultural influences on the effectiveness of TML by investigating the impact of one cultural dimension: individualism-collectivism at the individual level of analysis. This level of analysis is best conceptualized as “fluctuating pressures or tendencies” (Singelis, Triandis, Bhawuk, & Gelfand, 1995, p. 243), rather than as a distinguishing attribute (used in categorizing nations (Hofstede, 1980).

This research emphasizes the analysis of culture in a single learning setting, as opposed to cross-cultural studies that focus on the impact of culture across different settings (usually multiple geographic locations). One of the major differences in using a single learning setting and examining culture from an individual level of analysis is that the cultural dimensions being studied are not necessarily viewed as bipolar opposites (Triandis, 2004b). Rather, individuals can attribute characteristics of each dimension to themselves. That is, they can be bicultural, having both individualistic and collectivistic traits (Yamada & Singelis, 1995).

Calling for more holistic investigations of how TML can be used to improve the efficiency of delivery and effectiveness of learning outcomes, Alavi and Leidner (2001) stressed the importance of considering underlying psychological processes that are affected by TML. In their suggested framework, however, individual characteristics known to influence these learning processes were conspicuously absent. As Triandis (2003a) states, “cultural psychologists think of culture ‘in’ the person … there is no psychological process that is not shaped, to some extent, by culture” (p. 30). Therefore, from the perspective of individuals, learning in a TML environment should be influenced by their cultural inclination. Of the myriad cultural dimensions that have been identified (see, for example, Myers & Tan, 2002; Straub, Loch, Evaristo, Karahanna, & Srite, 2002), Individualism–collectivism has received the most attention (Triandis, 2004b), at both national (i.e., cross-cultural) and individual levels. We believe this dimension of culture is a critical factor in determining the perceived importance of various TML characteristics (asynchronous vs. synchronous communication tools), the perception of the TML environment itself (i.e., its social context), and as a predictor of learning outcomes. The following sections will expand upon the TML model developed by Alavi and Leidner (2001), and discuss the implications of the individualism/collectivism dimension in order to build support for this study’s hypotheses. This will be followed by a presentation of the study setting, methodology, results and discussion.

RESEARCH MODEL

Alavi and Leidner (2001) contend that to best examine the effectiveness of TML, the “mutual influence” of a constellation of variables need examination. They propose that instructional technique, coupled with the learning environment will impact underlying psychological learning processes of individual learners, which in turn will impact learning outcomes (satisfaction, perceived learning, and actual learning).

It is our belief that, beyond the characteristics described by Alavi and Leidner (2001), the TML ecosystem consists of idiosyncratic predilections of individuals participating in the learning context (e.g., individualistic and collectivistic traits), and use of the training technology (e.g., asynchronous and synchronous) communication capabilities. In addition, it is our contention that while TML may occur in isolation (e.g., computer-based training), learning outcomes improve from exposure to a social learning context in which learners interact with each other (Richardson & Swan, 2003), the instructor (Arbaugh, 2001; Picciano, 2002), and course content (Swan, Shea, Fredericksen, Pickett, Pelz, & Maher, 2000). Thus, our research model (see Figure 1) indicates that the individualistic-collectivistic dimension of culture affects the use of the Web-based communication technology in addition to perceptions of social presence (the
feeling of closeness with other learners), sense of community, and learning outcomes (learner satisfaction, perceived learning performance, and actual learning performance). The next section will provide a general description of online TML to establish the context in which culture is to be examined in this research.

**TML LEARNING CONTEXT**

Within a TML environment, interaction between learner, content, peers, and the instructor are vital to learning effectiveness (Moore, 2002). The mutual responses and social interaction enabled by TML have been suggested as the most natural way for people to learn (Hiltz, 1994). Recent research has found support for the critical role of each of these forms of interaction in creating an effective learning environment for both individuals and groups (Arbaugh, 2001; Gunawardena & Zittle, 1997; Hiltz, Zhang, & Turoff, forthcoming; Schmidt & Ford, 2003; Yi & Davis, 2003). However, the learning environment is not created by the technologies used, but instead within the environment enabled through the technology. That is, it is through ongoing interactions within a shared social context, that students will feel they are part of a learning community (Rovai, 2002b), rather than isolated individuals completing a course concurrently. This connectedness can only occur as a result of multiple interactions and active engagement within the learning environment (Gunawardena, 1995; Walther, 1995).

For TML, though, the key to these interactions is that learners choose to begin the process by actively seeking to interact through this medium. When focusing on how to design effective TML initiatives, it is critical that we better understand the impact that learners’ cultural beliefs have on the use of these communication technologies. Thus the remainder of this section will focus on the impact of individualism and collectivisms on the processes and outcomes of TML.

**ELEMENTS OF THE MODEL**

**Individualism-Collectivism**

Individualism implies that social behavior is established by personal goals and does not overlie the goals of the collective, while collectivism implies that the group is more important than the individual and the people in the group are inclined or ready to cooperate. It has been suggested that
a student’s “predisposition toward learning is systematically influenced by the individualistic or collectivistic values that dominate in a learner’s culture” (Chang & Lim, 2002 p. 88).

From the process perspective of TML, with its reliance on interaction, collaboration, and a social learning context for effective TML, individualistic tendencies that favor personal goals over the collective, self-sufficiency (Hofstede, 1980), and task orientation and focus (Trumbull, Rothstein-Fisch, & Greeneld, 2000) can create barriers to use of the communication capabilities of a TML environment and thus reduce students’ ability to take part in the creation of a social learning context. On the other hand, individualistic characteristics that rely more on words to interpret meaning (Hall, 1976), a greater competence for earning group membership (Triandis & Suh, 2002), and ability to establish non intimate, short-term relationships (Triandis & Suh, 2002), factor positively into forming the needed interactions in a TML. In the end, the individualistic tendency to have calculated interpersonal relationships, entering into a relationship if they have something to gain (Triandis, 2004a), may be the determining factor in using the capabilities of a TML to form a community of learners and receive the greatest benefit from the learning experience.

Likewise, collectivist characteristics can be seen to have both positive and negative influences on a learner’s approach to TML. The importance of group identity over individual identity (Chang & Lim, 2002), a focus on social obligations (Triandis, 1995), and acceptance of communal interpersonal relations (Triandis, 2004a), all provide support for the collaborative interactions necessary in a TML environment. However, for the collectivist, reliance on gestures, timing and facial expressions (Francesco & Gold, 1998), lack of skills for entering into new groups (Triandis & Suh, 2002), and a focus on more intimate and long-term relationships (Triandis & Suh, 2002) can also create barriers to the effective use of TML environments.

From the above summary, one could come to the conclusion that individualistic tendencies, due to emphasis on “task,” should ceteris paribus be positively associated with perceived and actual learning outcomes. However, the same tendencies that provide for the adequate attention and motivation necessary for positive learning outcomes may conflict with content delivery in an online TML environment. Therefore, it is hypothesized that these individualistic tendencies should in general be negatively associated with social presence, sense of community and satisfaction. A similar hypothesis is suggested with respect to the collectivistic findings. Certain collectivistic traits should increase the use of TML capabilities and the creation of a social learning context while others can hamper a person’s ultimate goal of effective learning. Thus, we propose to use the horizontal and vertical dimensions of individualism and collectivism (Triandis, 1995, p. 40) to further our analysis of this cultural dimension, with the expectation that the more specific analysis (or microanalysis) will help to refine our understanding of the impact of individualism-collectivism on TML.

Triandis (1995) argued that individualism and collectivism are multidimensional or polythetic constructs (Triandis & Gelfand, 1998), and recommended that the conceptualization of both individualism and collectivism be modified based on the additional attribute of the horizontal or vertical nature of a population. The horizontal aspect emphasizes the equality or similarity of people, whereas the vertical aspect accepts inequality among individuals and views differences among people positively. The horizontal-vertical distinction parallels Hofstede’s (1980) notion of power distance that is based on one’s level of acceptance of unequal power distribution; individuals aligned with the vertical dimension tend to be more accepting of this difference than those who are aligned more along the horizontal dimension. Support for the distinctiveness of these dimensions has been reported in the lit-
erature (Abraham, 1997; Chiou, 2001; Singelis et al., 1995; Soh & Leong, 2002; Thomas & Au, 2002; Triandis, 1995; Triandis & Gelfand, 1998). According to Triandis, “given the viability of the constructs, future researchers should focus on incorporating these dimensions into theory and research in social and organizational psychology” (Triandis & Gelfand, 1998, p. 125)

Research on differences among the four patterns of Horizontal Collectivist (HC), Horizontal Individualist (HI), Vertical Collectivist (VC), and Vertical Individualist (VI) has found:

Horizontal collectivists merge with in-groups (e.g., family, tribe, coworkers, nation); the well-being of their in-groups is important to them. However, they do not feel subordinate to their in-groups. In contrast, vertical collectivists submit to the norms of their in-groups and are even willing to sacrifice their personal identities for their in-groups. Horizontal individualists are characterized by seeking individuality rather than distinctiveness, that is, they tend to “do their own thing” and not to compare themselves with others. Lastly, vertical individualists are especially concerned with comparing themselves with others. They believe that competition is the law of nature, and they desire to win in all kinds of competitions. (Chiou, 2001, p. 668)

In addition to these generalized characteristics, research findings indicate that certain values are associated with the horizontal and vertical aspects of individualism and collectivism (Oishi, Schimmack, Diener, & Suh, 1998; Schwartz, 1994; Soh & Leong, 2002). These findings indicate that of Schwartz’s 10 values, power and achievement are associated with VI, self-direction with HI, benevolence with HC, and conformity and tradition with VC (Oishi et al., 1998).

Using this framework, we propose that the cultural-specific patterns of HI, VI, HC, and VC will affect TML in different ways (see Table 2). For each component of the research model, Table 2 indicates the effect of each pattern (HI, VI, HC, and VC) on that aspect of the model. For example,

Table 2. Proposed effects of HI, VI, HC, VC on research model
HI, VI, and VC are all expected to be negatively related to social presence, while HC is expected to be positively associated with social presence. Overall, the table indicates that while there are positive aspects of all four cultural patterns, the tendencies of HC individuals are best suited for the TML environment.

**HYPOTHESIS DEVELOPMENT**

**Use of Communication**

Because HI is associated with self-direction, we expect this to have a barrier-like effect on the use of TML communication. Self-directed learning would best be achieved in a CBT environment where interactions are between the learner and the content, with occasional interactions with an instructor. In the TML environment of our research setting, the learning process and outcomes are predicated on the interactions with content and instructors, but importantly, also among other learners. Thus, the need to achieve for VI will lead to the use of the communication capabilities when they form the foundation of the learning environment. With VC, we believe that their nature to conform will have them participating and interacting based on the structure of TML. Finally, we believe that HC benevolence and ability to merge with groups will allow them to quickly form group bonds, leading to early and repeated interactions using the only means available in TML, the communication tools. Therefore, we propose the following hypotheses:

H1: Cultural attributes of HI, VI, HC, and VC are associated with the use of TML communication capabilities.
H1a: HI will be negatively associated with use of communication.
H1b: VI, HC, and VC will be positively associated with use of communication

**Social Presence**

Social Presence (SP) is defined as a reflection of “the degree of salience of the other person in the interaction and the consequent salience of the interpersonal relationships” (Short, Williams & Christie, 1976, p. 65). Social presence is not a manifestation of static media characteristics; rather, social presence is a reflection of user perceptions that emerge over multiple interactions (Burke & Chidambaram, 1999; Walther, 1995). SP has been shown to be an important factor in the effectiveness of TML (Richardson & Swan, 2003; Shin, 2003; Youngjin & Alavi, 2001). Tu (2000), linking social presence theory with social learning theories, states that social presence “is required to enhance and foster online social interaction, which is the major vehicle of social learning” (p. 27). Past research has demonstrated the importance of cultural differences influencing perceptions of social presence (e.g., Gefen & Straub, 1997). There is additional evidence that social group membership influences the extent to which one perceives social presence (Bhappu, Griffith, & Northcraft, 1997). Recently, cultural differences (power distance and individualism-collectivism) were found to have a differential effect on the perceptions of website appropriateness, including that of social presence (Simon, 2001), and Gefen and Straub (2004) found social presence has an influence on trusting in e-commerce, especially with regards to feelings of benevolence. Taking direction from these studies, we argue that the cultural dimensions examined here will also have differential effects on perceptions of social presence.

**HV/INDIVIDUALISM — HV/COLLECTIVISM AND SOCIAL PRESENCE**

Social presence is in part contingent on the salience of others. Therefore, it is expected that an
individualistic perspective that values the self over others, coupled with a focus on tasks rather than people, will result in lower perceived social presence. In contrast, collectivist tendencies, which focus on people rather than tasks, would be expected to be associated with increases in perceived social presence. In the TML environment in which others are not seen but experienced via asynchronous text messages, it can be difficult to recognize the learners behind the messages while remaining focused on the task at hand. That is, individualism can lead to the view that asynchronous text messages read seriatim are akin to additional supportive material such as lecture notes, rather than as evidence of salient others. However, the predisposition toward group identity, focus on social obligations, and communal relationships of collectivism makes it more likely that collectivist learners will perceive the salience of the other behind the text message, leading to greater perceptions of social presence. Likewise, we expect that horizontal tendencies will lead to more positive perceptions of social presence. In contrast, those with vertical tendencies will describe fewer instances of social presence.

In the TML environment, feelings of equality and benevolence (HC) will allow for freer expression of ideas and thus foster more interactions among learners. As these interactions proliferate, opportunities to perceive the salience of the others in the conversation will also expand, thus increasing perceptions of social presence. On the other hand, emphasizing differences and self-direction (HI), power and achievement (VI), and conformity and tradition (VC) among learners can lead toward lurking or the withholding of viewpoints, with the effect of reducing interactions among learners and thus reduced perceptions of social presence. Taken together, this analysis suggests that HC should perceive higher levels of SP and the remaining groups will display lower levels of SP. Thus, the following hypotheses are stated:

H2: Cultural attributes of HI, VI, HC, and VC are associated with individuals’ perceptions of social presence.
H2a: HC will be positively associated with sense of social presence.
H2b: HI, VC, and VI will be negatively associated with sense of social presence.

**SENSE OF COMMUNITY**

McMillan and Chavis (1986, p. 9) define community as “a feeling that members have of belonging, a feeling that members matter to one another and to the group, and a shared faith that members’ needs will be met through their commitment to be together.” An important element in the formation of community within the context of distance education is interaction (Rheingold, 2000; Rovai, 2002b), and the inability to generate interactions among learners may create less effective online TML environments (Karuppam & Karuppum, 1999; Ueltschy, 2001). Rovai (2000) defined classroom community as consisting of four components: spirit, trust, interaction, and learning. Of particular importance with regard to the cultural dimensions being studied is spirit which denotes “recognition of membership in a community and the feelings of friendship and cohesion” (p. 287), characteristics associated with collectivism. We expect, then, that similar to perceptions of social presence, sense of community will also be impacted by the horizontal and vertical aspects of individualism-collectivism.

Belenky, Clinchy, Goldberger, and Tarule (1986) theorized that patterns in textual communication can enhance or inhibit the formation of classroom community. They conjectured that text which is viewed as separate, autonomous, or independent will inhibit community formation whereas text viewed as being relational and connected enables community formation. In their
theory they classify these distinctive voices as being respectively, male and female dominated. Research by Herring (1996) and Blum (1999) supports this claim. Similarly, we propose that the distinction between individualism and collectivism can also be expected to influence text voice, and thus impact the sense of community.

**HV/INDIVIDUALISM — HV/COLLECTIVISM AND SENSE OF COMMUNITY**

Similar to social presence, a key factor in building a sense of community among learners is interaction. It seems apparent, based on the definition of sense of community given by McMillan and Chavis (1986), that the attributes associated with collectivism — importance of the group and relationships within the group — are more conducive to contributing to a sense of community within the learning context. Indeed, if the individualistic attribute of autonomy becomes dominant, a sense of community may not develop leading to a less effective online TML environment. Likewise, we expect that those persons with horizontal tendencies, emphasizing equality of people, will have more positive perceptions of sense of community than would be associated with vertical tendencies, with its emphasis on differences among people. We contend that the properties of benevolence (HC) and conformity (VC) will lead to a positive sense of community within the TML environment. Alternatively, emphasis on power and achievement (VI) and self-direction (HI) will lead to a negative sense of community. Thus, the following hypotheses are stated:

**H3:** Cultural attributes of HI, VI, HC, and VC are associated with individuals’ perceptions of sense of community.

**H3a:** HI and VI will be positively associated with sense of community.

**H3b:** HI and VI will be negatively associated with sense of community.

**HV/INDIVIDUALISM — HV/COLLECTIVISM AND LEARNING OUTCOMES**

Chang and Lim (2002), using social interdependence theory (Johnson & Johnson, 1989), found that an individualist’s focus on task helps to promote the reasoning process, whereas the collectivist’s focus on relationships facilitates the social and response process of learning. Since learning in a TML environment necessitates group participation and communication, it is expected that collectivism will be positively associated with satisfaction. However, since individualists are less concerned about group harmony and success, they will be less satisfied by the need to interact with the group in the social and response process of learning. With its focus on task and achievement, it is also expected that individualism will be positively associated with the perceived and actual learning outcomes. With its focus on the group, and the importance of relationships, collectivism should be positively associated with perceived and actual learning, but only to the extent that the social and response process improve an individual’s ability to learn the material. Further, we expect that horizontal tendencies will be associated with greater satisfaction with the process of learning in a TML environment, compared to vertical tendencies. Likewise, the vertical tendency to view people as different may create disadvantages in a TML environment by creating instances where individual knowledge becomes subservient to the group; in this case, circumstances of perceived learning and actual learning might be expected to be lower than in the horizontal dimension. Thus, we believe that aspects of HI, VI, and HC can be expected to have a positive effect on learning outcomes (both perceived and actual). However,
we believe VC’s tendency to submit to the norms of their in-groups coupled with a willingness to sacrifice their personal identities will negatively influence learning outcomes. Thus, the following hypotheses are stated:

H4: Cultural attributes of HI, VI, HC, and VC are associated with individuals’ learning outcomes (satisfaction, perceived learning, and actual learning).
H4a: HI and HC will be positively associated with all learning outcomes.
H4b: VI will be negatively associated with satisfaction but positively associated with perceived and actual learning.
H4c: VC will be positively associated with satisfaction but negatively associated with perceived and actual learning.

We believe that as learners’ awareness of social presence and sense of community increase, the learning environment becomes akin to a community of practice. In such a community of practice, robust knowledge and understandings are socially constructed through talk, activity, and interaction around meaningful problems and tools (Vygotsky, 1978). In other words, a culture of learning develops. In this community of practice, within the context of an online TML environment, students distribute their intellectual activity so that the burden of managing the process does not fall to any one individual and learning effectiveness is enhanced (Bransford, Brown, & Cocking, 1999). A review of the literature on social interaction in a computer supported environment (Kreijns, Kirschner, & Jochems, 2003) indicates a strong relationship between the social context of the TML environment and learning effectiveness (Hiltz, 1994). Thus we hypothesize that:

H5: Greater perceptions of social presence will be associated with greater learning effectiveness outcomes (learner satisfaction, perceived learning performance, and actual learning performance).
H6: Greater perceptions of sense of community will be associated with greater learning effectiveness outcomes (learner satisfaction, perceived learning performance, and actual learning performance).

Research Setting and Procedure

Participants in this study are from an introductory IS course taught at a university in the southeastern United States. The course is required of all business majors and is taught entirely online, with no face-to-face sections taught during the semester in which the data was collected (Spring 2004). The course was taught using the WebCT platform. Approximately 1100 students enroll in this course each semester. To effectively manage such a large number of students, groups of approximately 35 are created and the students in these groups interact only within the group. The course is taught by one instructor with multiple teaching assistants. The course is set up as six independent modules in which the students have two weeks to complete the material. Each module focuses on different topical areas such as the strategic use of information and technology, e-commerce, and decision support systems. Within each module students are required to make a minimum number of postings utilizing the asynchronous capabilities of WebCT. At the end of each module an examination is given and students are assessed based on the total of the five highest module grades. Students are not allowed to proceed to the next module until the established opening date and time for the module. In other words student have relatively little control over some aspects of the learning process.

The course was designed around the communication tools available in WebCT, which included threaded discussions, course e-mail, and online chat. The discussion capabilities of WebCT were
Culture’s Impact on Technology Mediated Learning

the backbone for the course. For each of the six course modules, learners were required to post their answers to assigned questions from an end of chapter case and to respond to at least one other student’s answers. Although chat and e-mail capabilities were available, their use was not required. Chat capabilities were rarely used.

A survey to capture the elements of the model was delivered via WebCT as part of the first and fourth Module. Demographic data and cultural items related to HI, VI, HC, and VC were collected during the first module of the course. During the fourth module, questions regarding perceptions of social presence, sense of community, satisfaction and perceived learning were gathered. Actual learning was assessed from the grade received as a result of the end of module examination.

The study variables were measured as follows: Perceived Satisfaction was measured with a 7-item instrument developed by Biner (1993). Perceived performance was measured using the 12-item instrument utilized by Alavi (1994), and actual performance was measured using the results from the first three examinations. Social presence is measured with a 5-item instrument developed by Short, Williams and Christie, (1976). HI, VI, HC, and VC was measured with a 32-item instrument developed by Singelis et al. (1995). Sense of community was measured using a 10-item instrument developed by Rovai (2002a). To measure the use of the Web-based technology, we focused on asynchronous discussions as this was the primary means of communication within the course. Logs were provided in which we were able to tally the number of posts read, the number of posts made and the number of follow-up posts (a response to other students’ posts). The actual numbers of posts were used in our analysis. We combined these three values to form an overall measure of communication use.

Students were given extra-credit towards their final course grade for participating in this research. 524 usable results were obtained. Respondents included 229 men and 295 women.

Analysis: Measurement Model

Analysis was conducted using Partial Least Squares (PLSGraph 3.0) with scales measured as reflective, with the exception of communication use and actual performance. Several tests were performed on the measurement model to test for validity and reliability. Table 3 includes loadings of the reflective measures on their respective constructs along with composite reliability scores, standard errors, and t-statistics. It also includes the weights of the formative items. All reflective items are significant at the .99 level and all have high loadings. Most are above the 0.70 threshold, though the few loadings below this threshold are above the 0.50 suggested by Fornell and Larcker (1987), demonstrating convergent validity. The composite reliability scores of the latent constructs are all above the recommended 0.80 (Nunnally, 1978), demonstrating internal consistency.

Table 4 presents the correlations among the constructs and provides discriminant validity statistics. The square roots of the AVE scores (diagonal elements of Table 4) are greater than the correlations among the constructs, demonstrating discriminant validity. Furthermore, all items loaded higher on their respective constructs than on others, providing additional support for discriminant validity.

Structural Model

The results of the tests of the structural model and associated path coefficients are found in Table 5. Consistent with previous research and recommendations (Chin, 1998), bootstrapping (100 subsamples) was performed to determine the statistical significance of each path coefficient using t-tests. Results indicated that social presence, sense of community, communication utilization, and the cultural dimensions of HI, VI, HC, and VC were related to the TML outcomes. Each of the individualism-collectivism dimensions were related to at least one of the TML process constructs of

* $p \leq .10$ ** $p \leq .05$ *** $p \leq .025$ **** $p \leq .01$ ***** $p \leq .005$ (one tailed)

SP, sense of community or communication use. HC (.132, $p \leq .01$) was related to perceived social presence and explained 2% of its variance. HI (.217, $p \leq .005$) and VC (.107, $p \leq .01$) were related to sense of community and explained 7% of its variance. HI (-.081, $p \leq .10$) and VI (-.071, $p \leq .10$) were negatively related to communication use, whereas HC (.109, $p \leq .025$) was positively
related to use of communication tools; together they explained 2.4% of its variance. Social presence (.282, p ≤ .005), sense of community (.098, p ≤ .025), communication use (.125, p ≤ .005), HI (.116, p ≤ .005), and HC (.194, p ≤ .005) were positively related to perceived learning, explaining 24% of its variance. Social presence (.161, p ≤ .005), and use of communication tools (.234, p ≤ .005) were positively related to declarative knowledge, whereas sense of community (-.124, p ≤ .05) and HI (-.09, p ≤ .05) were negatively related to declarative knowledge; together they explained 10% of its variance. Social presence (.399, p ≤ .005), sense of community (.066, p ≤ .10), communication use (.193, p ≤ .005), and HC (.113, p ≤ .005) were positively related to satisfaction, whereas VI (-.085, p ≤ .05) was negatively related to satisfaction; together they explained 29% of its variance.

These results provide support for the research hypothesis that the cultural patterns of HI, VI, HC, and VC are related to various aspects of TML. In particular these cultural patterns have a large impact on TML outcomes (satisfaction, perceived learning, and declarative knowledge) explaining upwards of 30% of the variance compared with the emergent processes of TML (perceived SP, sense of community, and communication use) where upwards of 7% of the variance is explained. The next section will provide some insights and implications regarding the unbalanced impact that HI, VI, HC, and VC have on TML processes and outcomes.

**Discussion**

The results of this study provide overall support for the proposed research model. As predicted, the cultural patterns (HI, VI, HC, or VC) affected the learning outcomes in a TML environment, although not uniformly. Interestingly the attribute HI was the only cultural value to be associated with actual learning (although it appears to have had a negative impact). This suggests that HI individuals’ strong tendency to favor self-directed learning was not suitable for a TML environment in which collaboration plays a significant part of the learning process. With respect to perceived learning, the horizontal aspect turns out to be an important factor. Consequently, we can conclude that values associated with the horizontal aspect impact how persons perceive their performance in an online TML environment. Regarding satisfaction with the learning environment, our findings show that the attributes associated with HC, well being of their in-groups (presumably students from the class became their in-group), cooperation, and concordance with group members, contributed to a positive outlook of TML; whereas VI attributes, such as power and achievement, led to a negative view of TML, as the collaborative nature of the environment was not structured to support an individual but rather the interactions among individuals.

The two social context variables, SP and sense of community, were influenced by the collectivist dimension, with HC impacting perceived social presence while HC and VC both had an impact on sense of community. The importance of this finding underscores the effect that SP and sense of community has on TML outcomes. In TML environments in which interaction and collaboration are integral to learning outcomes, persons’ collectivist tendencies need to be nurtured for the positive effects they have on the processes associated with better TML outcomes. In contrast, the finding that the individualist dimension had no effect on either of these social context variables is an indication that an important structure in the learning process (i.e. the social context) may be inhibited as a result of a focus on individuality and self-direction, creating a situation where the connections necessary for a social learning environment are absent.

The attributes associated with HC, harmony of the group and cooperation, led to a strong association with communication use. Interestingly, both HI and VI with their tendency to value the
self over the collective led to lower levels of communication use. Pedagogically, by encouraging the characteristics associated with HC, we expect to indirectly increase the effectiveness of TML by increasing use of TML communication capabilities and perceptions of social presence and sense of community. Similarly, we would expect to directly increase the effectiveness of TML by simultaneously encouraging the characteristics associated with HC and HI and discouraging those associated with VI. Priming procedures have been effectively used to induce individualistic or collectivistic responses in previous research (Mandel, 2003; Trafimow, Triandis & Goto, 1991) and thus might prove an effective method for stimulating the positive attributes of HC within a TML environment.

Our results indicate that if HC characteristics can be positively encouraged, we can increase the intermediate TML processes of communication use (i.e., interaction) and the formation of a social context for learning in a TML environment to take place (SP and sense of community). We would also expect that in TML environments where interaction and collaboration are central to learning effectiveness that the ability to enhance HC characteristics will also lead to increases in satisfaction with the learning environment, perceived learning, and the extent to which declarative content is learned.

While the four patterns related to individualism and collectivism have been found to be associated to varying degrees with the effectiveness of TML, more research is needed. Other aspects of the TML environment might be affected by these culture patterns. Other dimensions of culture may also play a role. For example, Hall’s (1976) High and Low Context dimension might be very useful in understanding how individuals utilize TML communication capabilities, which in turn should both directly and indirectly impact learning outcomes.

Limitations

While the results of this study provide insights into designing effective TML initiatives, a number of limitations must be considered when interpreting the results. First, this study should be subjected to further testing with different participants, contexts, and technological architectures. Second, the research participants were undergraduate students who were completing the course as part of a degree requirement, so the results may not generalize to other settings and contexts. The cultural dimension of individualism-collectivism is but one individual cultural aspect that can affect TML process and outcomes, thus the conclusions drawn from this study should be done so cautiously as other influences may be as or more important to TML effectiveness.

Conclusion

This study has found support for the dimensions of horizontal and vertical individualism-collectivism as proposed by Triandis (1995). It extends the work of cross-cultural TML studies to investigate the impact that individual cultural beliefs have on the processes and outcomes of TML. We found that HC is positively associated with the process of social context formation — perceptions of social presence and sense of community, use of the communication tools, and with the outcomes of TML. Strengthening various characteristics of a person’s personality can lead to more effective TML initiatives.

**ENDNOTE**

1 The data for this study was gathered as part of the second author’s undergraduate honors thesis which dictated when the final data collection could take place. As a result, we were unable to gather learning outcomes at the conclusion of the course.
APPENDIX A. RESEARCH INSTRUMENT ITEMS

Horizontal Individualism
1. I often do “my own thing”
2. One should live one’s life independently of others
3. I like my privacy
4. I prefer to be direct and forthright when discussing with people
5. I am a unique individual
6. What happens to me is my own doing
7. When I succeed, it is usually because of my abilities
8. I enjoy being unique and different from others in many ways

Vertical Individualism
1. It annoys me when other people perform better than I do
2. Competition is the law of nature
3. When another person does better than I do, I get tense and aroused
4. Without competition, it is not possible to have a good society
5. Winning is everything
6. It is important that I do my job better than others
7. I enjoy working in situations involving competition with others
8. Some people emphasize winning; I’m not one of them

Horizontal Collectivism
1. The well-being of my co-workers is important to me
2. If a co-worker gets a prize, I would feel proud
3. If a relative were in financial difficulty, I would help within my means
4. It is important to maintain harmony within my group
5. I like sharing little things with my neighbors

Vertical Collectivism
1. I would sacrifice an activity that I enjoy very much if my family did not approve of it
2. I would do what would please my family, even if I detested that activity
3. Before taking a major trip, I consult with most members of my family and many friends
4. I usually sacrifice my self-interest for the benefit of group
5. Children should be taught to place duty before pleasure
6. I hate to disagree with others in my group
7. We should keep our aging parents with us at home
8. Children should feel honored if their parents receive a distinguished award

Sense of Community
1. I feel that students in this course care about each other
2. I feel connected to others in this course
3. I do not feel a spirit of community
4. I feel that this course is like a family
5. I feel isolated in this course
6. I trust others in this course
7. I feel that I can rely on others in this course
8. I feel that members of this course depend on me
9. I feel uncertain about others in this course
10. I feel confident that others will support me

Social Presence
Higher numbers represent more presence and lower numbers represent less presence.
1. Impersonal...Personal
Culture’s Impact on Technology Mediated Learning

2. Unsociable...Sociable
3. Insensitive...Sensitive
4. Cold...Warm
5. Passive...Active

Satisfaction
1. I am satisfied with the clarity with which the class assignments were communicated
2. I am satisfied with the timeliness with which articles, tests, and written assignments were graded and returned
3. I am satisfied with the extent to which the instructor made the students feel that they were part of the class and “belonged”
4. I am satisfied with the instructor’s communication skills
5. I am satisfied with the in-person/e-mail/telephone accessibility of the instructor outside of class
6. I am satisfied with the present means of material exchange between myself and the course instructor
7. I am satisfied with the accessibility of the lab instructor

Communication
1. To what extent did you utilize chat for student-to-student communication?
2. To what extent did you utilize chat for student-to-instructor communication?
3. To what extent did you use chat for general course questions?
4. To what extent did you utilize chat for help on assignments?
5. To what extent did you use chat for assistance with technical issues (e.g., server down, WebCT problems)?
6. These next set of questions focus on your use of WebCT discussions.
7. To what extent did you utilize discussions for student-to-student communication?
8. To what extent did you utilize discussions for student-to-instructor communication?
9. To what extent did you use discussions for general course questions?
10. To what extent did you utilize discussions for help on assignments?
11. To what extent did you use discussions for assistance with technical issues (e.g., server down, WebCT problems)?

Perceived Learning
1. I did additional reading beyond the required assignments.
2. I did some thinking for myself.
3. I discussed topics outside the class.
4. I feel more confident in expressing ideas related to Information Technology.
5. I gained a good understanding of the basic concepts of the material.
6. I improved my ability to critically think about Information Technology.
7. I improved my ability to integrate facts and develop generalizations from the course material.
8. I increased my ability to critically analyze issues.
9. I learned a great deal of factual material in the course.
10. I learned to identify the central issues of the course.
11. I learned to interrelate the important issues in the course material.
12. I learned to value other points of view.

Chapter 5.16
Using Social Networking Analysis to Facilitate Knowledge Sharing in the British Council

Bonnie Wai-yi Cheuk
Improvement Service for the Scottish Local Government, Scotland*

ABSTRACT

Prior to the establishment of the Knowledge Management (KM) strategy, the British Council defined knowledge as objects. Knowledge sharing was about sharing documents and information on the intranet or via global databases. Since December 2002, Dervin’s Sense-Making Methodology has been applied to manage knowledge. Knowledge is seen not as a product that can be transferred from one colleague to another but as a communication practice. This means that shared knowledge has to be interpreted and made sense of by its recipients through genuine dialogue. During this phase of KM implementation, the focus shifted to linking up colleagues and providing space for dialogue through building global communities of practice and virtual teams. This article presents an example of how we have used the theory of Social Networking Analysis as a diagnostic tool to promote knowledge sharing among our newly formed 30-people global leadership team. The three steps we have taken to carry out the exercise and its limitations also are discussed.

BACKGROUND

The purpose of the British Council is to build mutually beneficial relationships among people in the UK and other countries and to increase appreciation of the UK’s creative ideas and achievements. Much focus has been on sharing knowledge and experience with customers. In order to take the organization to another level, the British Council promotes knowledge sharing among its 7,000 employees, who are located in 109 countries. The ultimate aim is to empower staff to get the knowledge they need to serve their customers to the highest standard possible.

The Knowledge Management (KM) program was launched officially in December 2002 with the appointment of the new Director of Knowledge Management. Following a comprehensive six-
month knowledge audit exercise, the global KM strategy was approved by the Senior Management Team in December 2003. The KM vision was to enable the British Council to develop and deliver world-class products and services to its customers by effectively sharing and utilizing collective knowledge. This will be achieved by finding the best ways to connect its employees with each other and by providing them with easy access to relevant documents and resources.

Over the last two years, we have launched a number of projects to increase awareness of KM and to get the buy-in of senior management for the program in order to invest in the tools and approaches needed to improve global knowledge sharing. Specific KM projects that are beginning to embedded into the organization include:

1. Knowledge audit conducted using Dervin’s Sense-Making Methodology (Dervin, 1992; Cheuk & Dervin, 1999)
2. Development of Knowledge Management strategies for business units
3. Building communities of practices using seven-phase methodology (Cheuk, 2004a, 2004b)
4. Enhancement of the intranet, collaboration tools, and global databases
5. Applying Social Networking Analysis to support collaborative working (Anklam, 2003; Cross & Parker, 2004)
6. Applying narrative techniques to conduct project debriefs

In 2005, KM was recognized widely as an enabler to deliver the British Council’s overall business strategy. More than 100 knowledge champions worldwide have attended training on KM, and more than 70 global communities of practice have been developed.

**BUSINESS CONTEXT**

During 2004-2005, the overseas operations of the British Council were significantly restructured. Thirteen regions have been introduced to replace the existing 109 country operations that each were managed as individual entities. Each new region is made up of a number of existing country operations.

Thirteen regional directors were appointed. They have to work closely with the 17 senior management team members based in the UK in order to set strategic direction for the organization. This 30-person team is referred to as Global Leadership Team (GLT).

The restructuring provides an excellent opportunity to promote knowledge sharing beyond country operations as well as to promote knowledge sharing between overseas operations and the UK headquarters. However, it also presents a challenge. Any organizational restructure leads to the creation of new teams, which can be to the detriment of any existing knowledge-sharing culture. This presents a challenge to the KM team.

**WHAT IS THE NATURE OF KNOWLEDGE?**

A review of the KM literature largely defines knowledge using Nonaka and Takeuchi’s (1995) definition of tacit knowledge (i.e., knowledge in a person’s head, which has a personal quality and is hard to formalize and communicate) and explicit knowledge (i.e., knowledge that is transmittable in formal, systematic language). Sutton (2001) defines the latter as codified knowledge (i.e., knowledge that can be written down) and uses it interchangeably with information. Taken this view, KM systems were created to capture the knowledge of experts. The capture approach continued with an emphasis on capturing knowl-
Using Social Networking Analysis to Facilitate Knowledge Sharing in the British Council

data. Hildreth & Kimble, 2002).

Wilson (2002) argues that one should not use the terms  
information and knowledge inter-
changeably. He proposes that everything outside 
the mind that can be manipulated in any way is 
defined as data or information. They take the 
form of papers in a journal, e-mail messages, 
manuscript letters in an archive, and so forth. 
However, knowledge (i.e., what we know) never 
can be managed, except by the individual knower 
and, even then, only imperfectly. Wilson (2002) 
defines knowledge as what we know. He elaborates 
that knowledge involves the mental processes of 
comprehension, understanding and learning that 
go on in the mind and only in the mind, however 
much they involve interaction with the world 
outside the mind, and interaction with others. 
Whenever we wish to express what we know, we 
only can do so by uttering messages of one kind 
or another—oral, written, graphic, gestural, or 
even through body language. Such messages do 
not carry knowledge; they constitute information, 
which a knowing mind may assimilate, under-
stand, comprehend, and incorporate into its own 
knowledge structures. These structures are not 
identical for the person uttering the message and 
the receiver, because each person’s knowledge 
structures are, as Schutz (1967) puts it, biographi-
cally determined. Therefore, the knowledge built 
from the messages never can be exactly the same 
as the knowledge base from which the messages 
were uttered. He argues that knowledge cannot 
be managed and that Knowledge Management is 
a nonsense concept.

Dervin (1992) takes on an alternative view that 
it is not important to distinguish information and 
knowledge from a communication perspective, 
because knowledge is not an object but rather 
a communication process or flow. Knowledge 
(regardless of what label you give it) is anything 
that makes sense to the users through a dialogic 
communication process. Knowledge can be de-

defined only from the users’ perspectives (Dervin, 
Foreman-Wernet, & Lauterbach, 2003).

Prior to the establishment of the KM strategy 
in December 2003, the British Council took the 
traditional view and defined knowledge as in-
formation and documents that can be managed 
as objects. KM was seen as sharing documents 
and information on the intranet or via global 
databases.

The launch of the KM strategy in December 
2003 employed Dervin’s (1992) Sense-Mak-
ing theory to provide the organization with an 
alternative perspective in knowledge sharing. 
Knowledge is no longer seen as a product that 
can be transferred from one colleague to another 
but as a two-way communication practice. In ad-
dition to connecting employees to information 
using KM systems, we begin to focus on link-
ing employees with employees, in particular to 
facilitate genuine dialogue between employees. 
Instead of asking the question “what information 
should we manage?” we begin to ask the question 
“who should be linked up?” in order to maximize 
business outcomes.

During this phase of KM implementation, 
the focus was on providing space for dialogue 
through building global communities of practice 
and virtual teams to deliver strategic programs. At 
the British Council, we put in facilitators to man-
ge these communities and supported them with 
Web-based collaboration tools. Social Networking 
Analysis also was introduced as a diagnostic tool 
to support team building as well as to evaluate 
the performance of the communities.

**THEORY BEHIND SOCIAL NETWORKING ANALYSIS**

Social Network Analysis has emerged as a set 
of methods for the analysis of social structures, 
methods that are geared specifically to an investi-
Using Social Networking Analysis to Facilitate Knowledge Sharing in the British Council

gation of the relational aspects of these structures. The use of these methods, therefore, depends on the availability of relational rather than attribute data (Scott, 1992).

Social Networking Analysis can be used to address various organizational issues such as supporting partnerships and alliances; assessing strategy execution; improving strategic decision making in top leadership networks; integrating networks across core processes; promoting innovation; ensuring integration post-merger or large-scale change; and developing communities of practice, personal networks, and leadership development (Cross, 2004).

The importance of social networks is highlighted by Cross, Parker, Prusak, and Borgatti (2001), who found that despite easy access to a world-class KM system, 85% of managers got information (that had an impact on the success of a project) from their personal networks.

Snowden (2002) emphasizes that knowledge is stored not just in documents. He argues that “we always know more than we can say, and we can always say more than we can write down” (p. 104). He suggests that we must pay attention to managing social networks—this is how knowledge in people’s heads is transferred naturally and rapidly across an organization.

Informed by these theories and associated research findings, the British Council has introduced Social Networking Analysis as a diagnostic tool to improve strategic decision making in the newly-formed Global Leadership Team.

WHAT HAVE WE DONE TO PROMOTE KNOWLEDGE SHARING?

We started with 13 newly appointed regional directors in charge of setting strategic direction for the British Council and the delivery of products and services overseas. They are geographically dispersed, they have to work closely with the 17 senior management team members in the UK headquarters, and this Global Leadership Team will meet only twice a year in the UK.

The KM team wanted to help them to understand what knowledge sharing across countries and regions was really like. They needed to understand what knowledge had to be shared, how to help them and their staff get their work done, and what needed to be in place in order to make knowledge transfer effective. The KM team wanted to give them practical experience before they went on to introduce new knowledge-sharing approaches to the teams within their region.

A series of activities were designed to promote knowledge sharing among the 13 global leaders as well as between them and the 17 senior management team members in the UK. They included:

1. An initial community-building meeting to help them get to know one another.
2. An audit exercise to find out what knowledge, resources, expertise, and help they need to get work done.
3. The establishment of a Web-based collaboration site.
4. The appointment of a community facilitator.
5. The establishment of an events calendar.
6. Carrying out a Social Networking Analysis exercise to identify opportunities and gaps.

HOW DID WE CONDUCT THE SOCIAL NETWORKING EXERCISE?

The KM team conducted a Social Network Analysis exercise for the 30 global leaders as part of a global leadership development event. The aim was to help the team to visualize its existing relationships and to allow the group to reflect on how the group members network with one another.

There are three steps to complete this exercise:
Using Social Networking Analysis to Facilitate Knowledge Sharing in the British Council

• **Step 1.** A data collection template was developed and circulated to the 13 regional directors (as well as the 17 senior management team members in the UK). They were asked to complete the form prior to the event (Appendix 1).

• **Step 2.** The findings were analyzed and presented to the group during the 60-minute Knowledge Management session.

• **Step 3.** The participants were given the opportunity to discuss the findings and to come up with interventions to focus on during the next three months (Appendix 2).

The KM team emphasized that Social Networking Analysis is best employed as a diagnostic tool to generate discussion relating to team building and communications. It is not meant to evaluate the performance of the group or individual members. A step-by-step guide to the process is presented next.

**Step 1. Data Collection**

The template shown in Figure 1 was circulated to the 13 leaders (and to the 17 senior management team members in the UK) before and during the

Reflect on your interaction with the following global leaders since September 2004 and answer the following questions

1. **Q1:** To whom and from whom do you send and receive information, documents, plans, and other resources?
2. **Q2:** With whom do you have informal discussions about your work and/or new ideas?
event. Altogether, 30 colleagues were given the form. The template was designed to be simple and self-explanatory. Only two questions were asked in this case:

**Q1.** To whom and from whom do you send and receive information, documents, plans, and other resources?

**Q2.** With whom do you have informal discussions about your work and/or new ideas?

**Step 2. Data Analysis and Visualization**

Only 23 colleagues out of 30 global leaders completed the data collection template. The Knowledge Management team used UCINET software to visualize the data using Social Networking Analysis (SNA) Maps. During the event, the global leaders first were given an introduction to Social Network Analysis (SNA) and then presented with the findings in terms of three anonymous daily, weekly, and monthly SNA maps. Each map demonstrated the frequency of colleagues’ contacts with one another for formal information exchange. The nodes representing colleagues based in the UK and overseas are light grey and dark grey respectively. Figure 2 shows one of the SNA maps.

**Step 3. Discussion**

The leaders were invited to discuss the following questions:

*Figure 2.*
Using Social Networking Analysis to Facilitate Knowledge Sharing in the British Council

1. What patterns do you see?
2. Where do you think you sit in the SNA map?
3. What do you see as the key strength of this network?
4. What do you see as the potential weakness of this network?

We respected the privacy of the data, as it disclosed the relationship between colleagues. At first, we showed a diagram that did not provide names of individual nodes. To our surprise, all the participants asked for the results to be disclosed during the event and immediately gave consent for their names to appear on the SNA map.

As a result, we presented the map shown in Figure 2. They were given time to reflect on the above questions again and then to discuss these questions:

1. As a group, what needs to be changed in three months in order to achieve the Global Leadership Team’s objectives?
2. As an individual, what would you like to change in three months?

WHAT DID THE GROUP LEARN?

The newly appointed global leaders agreed that the SNA map represents a reasonably accurate reflection of the situation at that time, given that the majority of global leaders were newly in post. In addition, they highlighted the following issues regarding knowledge flow:

- There were strong relationships between UK-based staff.
- There was relatively little overseas/UK interface.
- Only a few overseas leaders were talking to one another.
- There was little difference in terms of formal and informal networking patterns.

They also reflected on the strength and weaknesses of their network. The strength was that the monthly SNA map showed the volume of communication that already was taking place. The weaknesses were:

- The preponderance of nodes in the headquarters. This might hinder widespread communication of messages.
- More networking was needed between the global leaders.
- There was a need to set clear, defined tasks to ensure that communication takes place.

As a result of the discussion, they identified some actions to improve networking:

- Several leaders agreed to form a mini group to work together on issues.
- A monthly Web meeting was arranged to allow the group to discuss issues.
- The need to nurture existing subgroups (e.g., several regional leaders were already discussing issues informally with one another). They wanted to make an effort to keep that going.

WHAT IMPACT HAS RESULTED?

As a result of the interventions that the global leaders identified to improve networking among themselves, on top of their busy schedule they made a conscious effort to touch base with one another through online knowledge-sharing sessions. Over time, they have built a better understanding of one another and have shared the challenges they face and how they overcame them in their region. Improved networking among the Global Leadership Team members also has led to unexpected outcomes, whereby knowledge exchange is not limited to topics on the set agenda but takes place on a more informal basis covering a range of other topics.
In summary, through improved social networking, the global leaders have led by example and have contributed to improve knowledge sharing in a number of ways:

1. It has increased the number of documents shared on the collaborative Web site (as a result of the need to exchange documents to prepare for or as a follow-up to a networking event).
2. The global leaders share important projects they are implementing in their regions and which employees are leading them. This information, in turn, is shared by the regional director with their regional team, which has resulted in increasing networking between managers in different regions.
3. It has opened up the eyes of global leaders to the power of social networking through good facilitation. Many regional directors have expressed an interest in conducting a similar social networking exercise with their own regional management team.

LIMITATIONS

A number of participants pointed out the following limitations of the social networking map:

- A successful SNA map requires a 100% response rate. All participants must fill in the data collection sheets. This is difficult to achieve. At the British Council, we achieved this through distributing the form at a compulsory event. However, only 23 out of 30 Global Leadership Team members completed the data collection template.
- There were many nodes on the network (especially in the UK). This can lead to the false conclusion that the more nodes there are, the stronger the network is.
- A number of leaders mentioned that the SNA map only reported the situation at that time. The maps should be used with care, as they only can provide a snapshot at any one point in time. The group thought it would be useful to go through the same exercise again at a later date in order to see the shifts in type and strength of relationships.

The other limitation is that in this social networking exercise, only 23 people participated. When applied to a larger number of staff (e.g., more than 1,000), the resulting SNA map could be more complex, and the discussion as to what a person can do as an individual to change and improve networking could be more difficult. Additional applied research has to be done to understand the value of SNA to business.

CONCLUSION

This article presents an example of how the British Council has used the theory of Social Networking Analysis as a practical tool to support our Knowledge Management program. It proves that SNA exercises are simple to carry out and that the results can provide a focal point for discussion in improving knowledge flow.

The global leaders who attended the session agreed that it was worth completing the exercise and that the SNA maps provided them with alternative perspectives on their own knowledge flow and networking habits. They began to recognize the need to balance the sharing of knowledge through documents against people-to-people networking. It helped them to improve their understanding that Knowledge Management as a subject encompasses more than document exchange. They recommended that SNA exercises be adopted for supporting team building at a regional level.

Chapter 5.17
Collaboration Challenges in Community Telecommunication Networks

Sylvie Albert
Laurentian University, Canada

Rolland LeBrasseur
Laurentian University, Canada

ABSTRACT
This article reviews the literature on networks and, more specifically, on the development of community telecommunication networks. It strives to understand the collaboration needed for innovative projects such as intelligent networks. Guided by a change management framework, collaboration within a community network is explored in terms of the formation and performance phases of its development. The context, content, and process of each phase is analyzed, as well as the interaction of the two phases. User involvement and technology appropriation are discussed. Collaboration challenges are identified and linked to the sustainability of the community network. Policy makers are presented with a model that gives some insight into planning and managing a community network over time.

INTRODUCTION
Collaboration in networks and managing performance across organizations has gained the attention of researchers (Huxham & Vangen, 2000). Our comprehension of collaborative networks has progressed substantially over a couple of decades (Oliver & Ebers, 1998), but it lacks integration (Ebers, 2002).

Collaborative networks cover a range of purposes such as innovation requiring heavy investment in R&D, international ventures, and the delivery of public services like health and education. This article is focused on telecommunication networks that operate within a physical and shared community space. The more ambitious community networks aim to become “intelligent” communities with broad participation and significant impact on the local social and
economic development. To understand them as a
dynamic phenomenon, a framework is needed that
can accommodate and organize the conceptual
pillars of organizational environment, structure,
culture, leadership, and management. Pettigrew
(1992, 1987) offers such a framework, and Ebers
(2002) and LeBrasseur et al. (2002) demonstrate
its effective application.

Organizations in all sectors have become more
interested in inter-organizational collaboration
to encourage synergy, innovation, and economic
development. Although there are many pockets
of successful collaborative efforts, there is a
continuing need to identify the challenges and
opportunities inherent to community networks.
With this focus, this article is divided into four
main sections. First, collaborative networks are
defined and described, and community telecom-
munication networks and their potential for sup-
porting intelligent communities are analyzed.
Second, key collaboration challenges that impact
on the development of a community network are
introduced. Third, the literature is reviewed and
organized according to the context, content, and
process involved in these community networks
during their two phases of development—formation
and performance. The collaboration challenges
present in each phase of development are explored,
including challenges that the users experience.
Fourth, the article concludes with policy implica-
tions for network planners.

TELECOMMUNICATION NETWORKS
AS AN EXAMPLE OF COLLABORATION

Collaboration is the pooling of resources (e.g.,
information, money, labour), by two or more
stakeholders or partners, to solve a set of prob-
lems, which neither can solve individually (Gray,
1985). It involves an interactive process whereby
organizations, using shared rules, norms, and
structures, act or decide on issues related to a
problem domain (Wood & Wood, 1991). The
intentional goal-oriented collaborative arrange-
ment that emerges is that of a network (Poyhonen
& Smedlund, 2004).

Networking represents a particular form of
organizing or governing exchange relationships
among organizations and is an alternative to
Network partners maintain their autonomy and
retain residual property rights over their resources
that have been pooled to achieve mutually agreed
outcomes (Bailey & McNally-Koney, 1996; Brown
et al., 1998; Gray & Hay, 1986; Huxham & Van-
gen, 2000; Oliver & Ebers, 1998). The principal
coordination mechanisms for allocating resources
are negotiation and concurrence. Informal social
systems, rather than bureaucratic ones, coordinate
complex products or services and reduce uncer-
tainty (Jarillo, 1988; Jones et al., 1997).

Networks have gained in importance over the
last two decades. For the private sector, global-
ization and the speed of change have encouraged
collaborative efforts. For government, down-
loading since the 1990s has forced new ways to
view management of programs and services for
resource maximization (Bradford, 2003; Bailey
et al., 1996). Municipalities and regions have also
demonstrated an increased interest in collabora-
tion efforts and network development to attract
new opportunities and maintain their competitive
advantage. Collaborative networks typically in-
crease the scale and visibility of program efforts,
increase support for projects, and leverage capital
to enhance feasibility, speed, and effectiveness
(O’Toole, 1997). Synergy is achieved through
improved resource management and intensive
exchanges on specific projects.

To achieve synergistic gains and programming
enhancements from sharing resources, risks, and
rewards, stakeholders need to shift their focus
toward collaborative rather than competitive
advantage (Lowndes & Skelcher, 1998). Too
often in the past, public sector organizations
built independent silos and their private sector
counterparts viewed potential partners as competitors rather than collaborators. Public policies dealing with ambitious or complex issues, like community sustainability, are likely to require networked structures that allow for the pooling and mobilization of resources from both private and public sectors within a government policy initiative (O’Toole, 1997).

Community telecommunication networks reflect the trend in western society away from bureaucratic government to network governance (Sorensen, 2002): the latter delivers more services efficiently with less risk and uncertainty (Considine & Lewis, 2003; Jones et al., 1997). Stakeholders and collaborators include municipalities, health, education, social services organizations, and private sector organizations. These networks are part of a wider agenda to increase the country’s capability for the knowledge-based economy.

There are several kinds of community networks (Gurstein, 2000; Pigg 2001), ranging from those serving a restricted membership (usually called private networks) to those serving a broader segment of the community or region. A private network may, for example, link several schools and/or municipal sites, and members would include the students, administration, and staff of these organizations. In contrast, a community network is built on a platform that gives broad access to community citizens, businesses, and agencies; it encourages many stakeholders to become a user and service provider. These stakeholders may come together simply to upgrade an aging infrastructure, especially when market forces cannot be relied upon to meet community needs or to co-build economic foundations. Leading communities strive to build partnerships and synergy to overcome barriers to access, job creation, and innovation (Agres et al.,1998; Eger, 2001; Tan, 1999; Industry Canada, 2002a, 2002b). Community networks facilitate information dissemination, discussion, and joint activity by connecting neighbours, creating new opportunities, and empowering residents, institutions, and regions (Carroll & Rosson, 2001; Igbaria et al., 1999; Canadian National Broadband Task Force, 2001).

A community network has four basic components: a telecommunication infrastructure with broadband capability, applications or content, devices (such as computers, cellular telephones, i-pods, and blackberries), and users. The development of a community telecommunication network typically occurs through a governing board representing the needs of users, which is supported by a small management structure (e.g., executive committee and network manager). The network relies on information and communication technologies (ICTs) and allows the community to import and export knowledge, encourage innovation, and overcome distance. The opportunities for economic and social development are contingent on attracting many users and creating a culture of “digital” use. The network must fulfill user needs and be attentive to their requirements, which may include a fair price, access to computers and the Internet, and training and education.

Infrastructure investment in the telecommunication network aims for the widest possible coverage of the community and region, with the constraint of reasonable cost. Investment also tries to ensure that users have access devices; some users have modest means, and schools and other organizations may have budget constraints. On the human resources front, technical training of local staff may be required to install the infrastructure and devices, and provide support to users. Organizations may need to re-design processes in order to meet the changing needs of their supplier and distribution partners, and to offer services online to end-users. The transformation effort may also require promotion campaigns to attract both individual and organizational users. These many resource challenges imposed on the community require a collaborative effort to pool resources and find innovative solutions.

A community network has users at the individual, organizational, and community levels of
human activity and endeavours. Individuals or end-users use the network to communicate with friends, play games, access information, obtain training, and occasionally innovate. Organizations are often stakeholders and use the network for a wide variety of purposes (Waits, 2000), including providing information and services, and selling online. They are intermediate users (Williams et al., 2005) and are the drivers of the development of the network. These organizations are the channels through which collective innovation is exercised and community change takes place (de la Mothe, 2004; Rycroft, 2003). At the community level, these individuals and organizations create aggregate demand and use of the network, and determine the sustainability of the network. The challenge is to create a culture of “digital” use that is integrated into the broader culture that is shared by community members.

During the development of the network, user involvement can be traced through participation in articulating a “digital” vision for the community, in the purchase of access devices and services that will connect users to the network (e.g., telephone, cable, wireless, computers, and Internet), and in the utilization of applications being made available through these access devices. Users may also be involved in creating employment by innovating on the network configuration, and in helping to create a culture of use by providing additional attractive applications.

Good governance requires legitimacy with an appropriate range of stakeholders, and involves building cohesion and commitment. Relationships are voluntary, and network survival depends upon the collective will and commitment of the stakeholders. The intentionally-planned network takes on a collaborative structure composed of local residents, non-governmental organizations, private sector businesses, and government. The stakeholders create a product that reflects the concerns, priorities, and aspirations of the local population. If the infrastructure, devices, and applications meet the needs of the users, a culture of “digital” use emerges as an organic extension of existing community ways and practices. Without broad participation, the network is likely to reflect narrow interests and weaken the community’s social sub-system, which in turn will limit the economic success of the network.

A sustainable community telecommunication network makes consistent and positive contributions to the economic and social development of the community (ITU, 2003), thereby enhancing the community’s capital base. In large measure, these positive outcomes depend upon the collaboration of partners. They also reinforce the efforts invested in collaboration. Networking allows individuals, professionals, and entrepreneurs to access information and knowledge, learn about a wide range of issues, recognize opportunities, and achieve innovative products and services (Suire, 2004; Martin & Matlay, 2003; Corbett, 2002; Ardichvili & Cardozo, 2000; Kickul & Gundry, 2000). Whether a community network realizes its potential depends upon how well it is developed.

The above discussion portrays the formal structure of a community network as a fluid organization composed of volunteers with the purpose of facilitating the community’s transition and participation in the information society. However tempting, this viewpoint is non-critical in nature; it ignores the community context and processes by which the network emerges (Pigg, 2001; Day 2002).

**COLLABORATION CHALLENGES FOR COMMUNITY NETWORKS**

Communities around the world have demonstrated that transformation is possible using network technology. For example, Sunderland (UK) reduced unemployment from 30% to 4% by moving from a shipbuilding and coal industrial base to a knowledge and technology economy. Similarly, Spokane Washington (USA), once a railroad town reliant on natural resources, dra-
matically improved the fortunes of its downtown by installing the highest density of broadband in the country. In Tianjin (China), a major push on broadband connectivity was accompanied by rapid user growth, from 20,000 to 2,700,000 in two years. Their stories make ample reference to the intensive collaboration of many actors, but the patterns of influence are not well articulated. Bell (2001) compared six urban communities noted for their telecommunication achievements and identified two effective patterns of collaboration: (1) a comprehensive and formal plan, and (2) a coherent pattern of individual initiatives. Similarly, Williams et al. (2005) reviewed numerous ICT initiatives, both small and large, and emphasized the overlapping nature of the planning, implementation, and use stages of development. These patterns are explored under the phases of network development section of this article.

Individuals and organizations involved in the creation of a community network face four collaboration challenges:

1. Defining and agreeing on the transformation effort (includes vision, transformation, and planning)
2. Assembling and mobilizing resources (includes interdependence, tasks, and structure)
3. Assembling and mobilizing trust (includes prior experience, communication, and distribution of power among collaborators)
4. Balancing leadership and collaborative management (includes the broadening requirements of the network, user appropriation, and power).

These challenges are tied to the coherence and adaptability of the network, and specifically to the dynamic relationship between the formation and performance phases of its development. Collaboration is inter-woven in each of these challenges. Network sustainability is achieved by collaboration efforts that evolve during the network’s development.

**PHASES OF DEVELOPMENT OF A COMMUNITY NETWORK**

We propose that network development takes place in two phases that are iterative in nature. Phase 1, the formation of the community network, is marked by the emergence of a leader and/or a board of directors, to respond to environmental pressures. These pressures may occur as a result of globalization and the need to remain competitive in the face of other communities or regions. It may occur as a result of downsizing or social development pressures (e.g., lack of medical practitioners, youth out-migration). The broad goals of the network are developed, including a representation of the future user. Phase 2, network performance, involves the concrete objectives and steps that the board takes to achieve the community goals that were agreed upon and the measures taken to attract and retain users. User involvement can and should take place in both phases of development.

Smaller communities need collaborators to solve a wide variety of challenges including infrastructure availability. Larger communities tend to have more resources and thus need collaboration to resolve economic and social pressures rather than infrastructure issues. In this second phase, the network can develop a culture and structure that gives meaning and coherence to a variety of projects. Some communities are more liberal and hands-off, allowing the private sector and citizens to develop content and opportunity. Others intentionally plan a vision of community transformation based on an improved telecommunications infrastructure. Phase 1 depends highly on leadership dynamics whereas Phase 2 is closer to managerial dynamics but with a distinctive collaborative flavor. These two phases are interdependent over time in that formation sets the stage for performance, and performance impacts on the board and leadership dynamics. Positive outcomes at the performance phase consolidate the dynamics of the formation phase; negative
outcomes challenge the board and leadership and initiate a re-formation phase. This iterative process was demonstrated in the feedback loop identified by Arino and de la Torre (1998) and Thomas (1993).

Because networks are fluid in nature (pooling from existing resources, changing membership, and varied timelines) and focused on both results and relationships, two interactive phases are considered sufficient. The two phases are supported by case studies of strategic alliances (Doz, 1996) that found that successful partners actively exchanged information, re-evaluated the project (in terms of efficiency, equity and adaptability), and consequently readjusted the initial conditions of their cooperation. They are also consistent with the ICT social learning findings of Williams et al. (2005).

**Formation Phase**

The push and pull factors in the environment impact on the community members and prompt them to consider uniting their forces to address the issue or opportunity that has been identified. Under the leadership of a visionary, and through ample interpersonal communication, a group is assembled that represents the initial membership of a potential network. If a consensus on vision and goals is attained, the group becomes the founding board of a network and plans for the performance phase. The principal outcome is a collaborative base on which to build the network. Table 1 provides an overview of the critical factors present in the formation phase.

**Context of Formation**

The outer context or environment includes factors such as economic, political, culture, demographics, funding opportunities, pressures from government agencies, and technology innovation trends (Agres et al., 1998; Bailey & McNally-Koney, 1996; Igbaria et al., 1999; Keenan & Trotter, 1999; and Tan, 1999). Global competitiveness and turbulence are the underlying catalysts for creating networks for organizations, communities, and governments (Poyhonen & Smedlund, 2004; Scheel, 2002).

Interdependencies exist because organizations possess or control vital resources (material, human, political, structural, or symbolic) and thus are the source of environmental pressures for one another (Wood & Wood, 1991). Organizations seek to reduce these pressures and manage

Collaboration Challenges in Community Telecommunication Networks

the interdependencies by gaining control over crucial resource supplies. The network form, as opposed to markets and hierarchies (e.g., vertical integration), provides a neutral space within which organizations can meet to explore solutions and synergies.

International bodies such as the World Bank (1999), the United Nations (1998), and OECD (1997) have adopted the paradigm of the information society as a guide to many of their development policies. According to Castells (1996, 1997, 1998), ICTs have produced a network society in which mobilizing knowledge and information have become more important than mobilizing physical resources. He argued that both organizations and individuals can benefit from electronic networks; they support the development and dissemination of knowledge and information, and facilitate innovation. Castells warns that these changes are accompanied by growing wealth disparities, social fragmentation, and dislocation. Governments are addressing these concerns, in part, by financially supporting the creation of community networks with broad accessibility. Locally, these new opportunities are often communicated through the chamber of commerce and other economic development agencies to mobilize or inspire stakeholders into action.

Communities come in all sizes and density, and all are influenced by the urbanization trend. Rural settings are witnessing the exodus of their youth and an erosion of their economic base as cities attract both talent and investment, including initiatives in telecommunications (OECD, 2004). Recent studies of Canadian rural communities concluded that ICTs can act as enablers of community building and development processes (New Economy Development Group Inc., 2001; Canadian Advisory Committee on Rural Issues, 2004). Given that the Internet is content-rich, offers online education, facilitates social networking, and offers a platform for the creation of new enterprises and the expansion of existing ones, the viability of the digital community network becomes crucial for the future of small communities.

When governments create generous programs to create community networks (e.g., Brown et al., 1998), communities are pressured to apply for capital funds even when they may not have the organizational and resource capacity to sustain the network. Smaller communities have relatively fewer and less diverse resources and a push-style policy may be the only way to spur action. Another example of a push factor is when a major telecom firm seeks a community partner for a demonstration project, or when the private sector chooses to make an investment to upgrade its infrastructure. The telecom supplies the ICTs, but the community stakeholders still need to demonstrate and plan on how the technology can be applied to personal and organizational purposes. Often, infrastructure is built and languishes until there are other pressures in the environment of the community, such as closure of a major employer or the arrival of a strong champion. At other times, communities struggle with the lack of open access that inhibits economic development and competition. Pushing for open access can discourage the involvement of incumbent carriers, at least at the onset. The key here is to evaluate how context issues can stimulate communities into action toward their transformation.

Content of Formation

Stakeholders need to find the community vision attractive and see a benefit for themselves and for their organization. When the problem is broad in scope and complex, such as economic development, it requires a larger variety of stakeholders with legitimate interest to devise solutions and bring sufficient resources to bear. Stakeholders must have the right and the capacity to participate, and include organizations with legitimate power as well as those who will be affected by the network.
Collaborative action necessarily involves interdependence between individuals and organizations (Ouchi, 1980) and can yield both intangible (e.g., image of citizenship) and tangible benefits (e.g., cost reductions and additional revenues). Interdependence is strongly linked to the vision of the network and the factors motivating stakeholders. It allows for an exchange among stakeholders that is built on trust, and an understanding of mutual benefit or advantage. According to Okl and Young (1997), the more ties an organization has to others in a network, the less likely is it to act opportunistically. Blois (1990) argued that collaborators should engage in bargaining on who will accept responsibility for certain elements of the transaction costs. They must come to the table understanding their role and develop a level of interdependence and mutual benefit in order to sustain the network effort.

The economic and social exchanges that take place are mediated by mutual trust. Ring (2002) distinguishes between “fragile” and “resilient” trust. The former is typical of opportunistic settings such as markets and involves the formal processes of negotiation, transaction, and administration. In contrast, the latter is the foundation of successful networks and is based on the informal processes of sense-making, understanding, and commitment. However, prescribing resilient trust does not ensure that it takes place. Ring proposed that it will emerge when the participants have a shared history of experience and when reputations for reliability are well established. On the other hand, Doz (1996) has documented the role of trusted intermediaries in helping other participants to shift gradually from fragile to resilient trust. We conclude that if a community has rich social relations, it can establish resilient trust early, but that parachuting in partners and stakeholders makes fragile trust more likely. However, if trusted intermediaries become involved, they can build the level of trust within the network.

There is a need for legitimate authority, credibility, and multiple memberships (Bailey & McNally-Koney, 1996; Gray & Hay, 1986) if a sustained transformation is to occur. Jones et al. (1997) have argued that networks need to restrict membership access and choose its members according to their reputation and status. Important stakeholders may choose to join a network or a project because of the presence of other members. A smaller number of leaders may allow the network to realize quick wins, reduce coordination costs, and improve interaction frequency. One could argue that success will breed success—trust will increase, motivation will increase, and faster output can be generated. This view is less applicable to community networks where innovation, legitimacy, and broad reach is critical and leads to a large membership and numerous exchanges. Therefore, a smaller, more restricted network may be mobilized quickly and act efficiently, but be less effective in producing varied output. The larger network may slow the pace of change, but may be important enough to attract accomplished leaders. Structure issues become important in managing a larger group of stakeholders and are discussed in the performance phase of the network.

Another content issue is sustainability. Stakeholders want to know, “How much will it cost,” but few ask “How will the network become sustainable in the long-run?” Sustainability is a function of revenues (stemming from the use of the infrastructure and its applications), and the costs of the network (human resources, equipment, and materials). There are opportunities for synergistic gains when partners chose to purchase as a group, or share the operating costs. At the formation phase, the concept of sustainability is hazy, but becomes clearer as projects develop during the performance phase. Nevertheless, the board must carefully address the sustainability issue early to ensure that it becomes incorporated into their common frame of reference.

In the formation stage, the planning includes an explicit model of future users, their communication needs, and their likely use of the telecommunication network. Williams et al. (2005, p. 112,
Figure 5.2) identify ways for direct involvement of users, such as user panels, market research, and trials. They also identify sources of indirect evidence about users through information on demand and markets for similar products, and competitive offerings. With the additional input of board members who understand their community, a representation of the users is developed. This user-centered approach is helpful in guiding the design of the system and identifying training and promotion requirements. However, Williams et al., emphasize its limitations and the design fallacy that it breeds: “the presumption that the primary solution to meeting user needs is to build ever more extensive knowledge about the specific context and purposes of an increasing number and variety of users in the technology design” (p.102). The idea of perfect user representation ignores the reality that users are active agents and appropriate the technology later, primarily in the performance phase of network development.

Communities would be wise to involve users in all facets of their formation stage, but users are often thought of as passive participants that can be surveyed for the eventual purchase of devices or services at the performance stage. Yet, users have concerns over ownership, access and distribution of information, privacy, security, and copyrights (Agres et al., 1998), and most of these issues need consideration early on. However, the design fallacy mentioned above emphasizes the limitations of comprehensive user involvement in the formation phase.

**Process of Formation**

Leaders and champions can enhance or constrain the development of a community network (Industry Canada, 2002; Jones et al., 1997; Huxham & Vangen, 2000). Leaders tap into the collective awareness of the community stakeholders and mobilize the initial change efforts by supplying a vision and practical steps to realize it (Bailey & McNally-Koney, 1996; Roberts & Bradley, 1991). Sustaining collaboration depends on the emergence of a common view of the community and shared organizational values. Leaders and champions play a role in consolidating and expanding the collaborative initiatives, but a wider involvement is needed to foster innovation. It is important to have a community cross-section of members as well as individuals with sufficient power to rally other stakeholders. The parties must freely participate, knowing and agreeing on who is involved and in what capacity (Glatter, 2004; Roberts & Bradley, 1991); prior experience and trust facilitate the membership drive.

Network goals are created, implemented, and modified through purposeful social construction among network stakeholders and partners (Van de Ven & Poole, 1995; Ring & Van de Ven, 1994). Network effectiveness may be defined as the harmonization, pursuit, and attainment of the goals sought by the various stakeholders and partners. With diverse stakeholders, it becomes difficult to satisfy all parties equally; therefore, managing expectations and potential conflicts help to maintain the social cohesion of the network. Members will likely persist so long as they can positively identify with the intermediate and long term outcomes, whether they are social or economic in nature.

According to Hardy and Phillips (1998), when individuals come to share a vision of the issues and the solutions, they become stakeholders and begin to create a collective identity with mutually agreed upon directions and boundaries that, in time, may become a permanent network. The catalyst is a transformational leader who encourages collaboration as a means to create synergy for innovation, growth, or to protect against future turbulence. Engaging the stakeholders in a planning exercise can address their many concerns; tasks and roles can be organized and assigned within the network to fit their expectations. Because work is complex and elaborate in networks, planning and coordinating task-specialized activities is required (Roberts & Bradley,
Collaboration Challenges in Community Telecommunication Networks

1924. However, planning follows the visioning that the leader has enacted.

**Challenges in the Formation Phase**

**Defining and Agreeing on the Transformation Effort**

It is argued that a multi-sectoral and multi-organizational network is needed for a transformation to an intelligent community. The wide variety of stakeholders impact the style of leadership and structure needed for joint initiatives. The leader (or leaders in the case of shared roles) shares a vision of a desirable future and initiates a flexible structure that can accommodate differences in orientation (profit versus not for profit), time horizons (short versus long term), and civic engagement (self versus community focus). Given the diversity of stakeholders, the visioning must be consistent and persuasive, but large enough in scope so that stakeholders can personalize the vision to suit their personal and organizational interests. Key activities include:

- Utilizing context issues to create a sense of urgency and sell the concept of the community network
- Identifying solutions to problems and synergistic opportunities
- Preparing a plan for producing meaningful and motivating outcomes

Agreeing on the vision depends on the availability and abilities of the local leader. Individuals with strong communication skills, an established reputation of trustworthiness, an ability to deliver on promises made, and conceptual skills to craft a vision are in short supply. While large communities have a greater pool of candidates, small communities may have to draw more on external talent and work hard on establishing trustworthiness.

**Assembling and Mobilizing Resources**

The community network depends upon its board to acquire the physical, financial, and organizational resources that make a broadband network functional. Collaboration among stakeholders and partners facilitates the pooling of their resources. Choosing board members should flow from resource requirements and the likelihood that the stakeholders recruited or volunteering are favorably disposed to sharing with other organizations. Community citizenship of board members channels the resources to create and enhance the network. Key activities include:

- Assembling the representatives of a variety of public and private sector organizations to form the board, including both small and large stakeholders;
- Mobilizing the resources controlled by board members and reaching out to obtain vital resources from the environment.

Too many resources may harm the development of the network if the board lacks the capability to make good use of them. Waste would damage the network’s reputation and make future resource acquisitions more difficult. Likewise, too few resources can harm the network because the scope of activities would be narrow and appeal to only a small segment of the community’s population. A narrow focus would appear self-serving and lack broad legitimacy.

**Assembling and Mobilizing Trust**

For the board to be effective in creating and enhancing the network’s resource base, its members must trust each other so that extensive sharing becomes possible. When stakeholders engage in joint efforts and initiatives, they are putting the community first and themselves second, making them vulnerable to exploitation by less citizen-
minded organizations. When trust exists on the board, stakeholders can tolerate some exposure. Therefore building and maintaining trust in a realistic manner is essential to the network’s resource base and projects. Key activities include:

• Assembling the board membership on the basis of reputation, prior experience, and diversity of stakeholders;
• Creating a shared vision that reflects the underlying values of community spirit;
• Distinguishing between fragile and resilient trust, and building the latter.

Building and maintaining resilient trust is at the core of the inter-dependent culture that emerges in the network. When a transformational vision is complemented with solid resources and trust, the community network has met the challenges of the formation phase of its development and is ready to shift into the performance phase.

Performance Phase of Development

The performance phase of network development is centred on concrete projects that require the pooling of resources by its members. The resources may be tangible (finances, staff secondment, office space, and equipment) and intangible (time, information, influence, and reputation) in nature. Pooling is facilitated by both the culture and structure of the network in which horizontal interactions, exchanges among equals, are based on trust. These resources are organized and controlled to attain the project objectives, and the management style is collaborative and accountable to the membership of the network. Pursuing these objectives gives collaborators opportunities to learn how they can make the network function effectively. In the short term, the level of attainment of the project’s objectives dominates; small wins and their public recognition are important to confirm the value of the network (Bouwen & Taillieu, 2004). Effective project management is needed. In the long term, the board focuses on the level of attainment of the broad goals of the network. To ensure that the projects and the general management of the network are aligned with the original vision and goals, effective leadership is required. Table 2 provides an overview of the critical factors in the performance phase.

**CONTEXT OF PERFORMANCE**

The interdependence of members within a community network is reflected in both its structure (O’Toole, 1997) and culture. Structure requires

Collaboration Challenges in Community Telecommunication Networks

careful attention because a poor structure—one that gives too much power to one partner or that does not embody the values of stakeholders—will affect the performance and longevity of the collaboration.

Poyhonen and Smedlund (2004) and Nootueboom (1999) identified three network structures: vertical, horizontal, and diagonal. The latter consists of firms and organizations from several different lines of business. A diagonal structure is appropriate for community networks because it includes as many collaborators as possible to create synergy and innovation within and between sectors; transformational, as opposed to incremental change, is facilitated. The success of collaborative networks is contingent on managing the ambiguity, complexity, and dynamics of the structure. It becomes more important in the performance phase because it must sustain an action plan and organize resources to carry it out. However, a telecommunication network is developed to resolve dynamic context issues and can only do so within a process of continuous improvement. A rigid structure that minimizes innovation diminishes the network’s sustainability. Though difficult to assess, the effectiveness of the structure can be judged by its internal coherence and fit with the culture of the network. This puzzle, identified by Bailey & McNally-Koney (1996), needs a solution that retains the fluidity of communications and decision-making, while providing for a framework for productivity and sustainability.

Collaboration is associated with incremental innovation when partners share on several levels: a larger purpose, explicit and voluntary membership, an interactive process, and temporal property (Roberts & Bradley, 1991). Hardy and Phillips (1998) pointed out that more powerful stakeholders may force collaboration on weaker players to control them. Consequently, there is a lessening of the level of interdependence and common vision. Weaker stakeholders are bound to minimize their participation and find excuses to exit the network when they are being coerced. Though asymmetrical power is a likely reality, leaders that seek innovation must put less emphasis on control and more on incentives and opportunities.

Creating a culture of collaboration gives coherence to the stream of actions that builds the community network. Collaboration is described as a relational system of individuals within groups in which individuals share mutual aspirations and a common conceptual framework (Bailey & McNally-Koney, 1996). Individuals are guided by their sense of fairness and their motives toward others (caring and concern, and commitment to work together over time). Through communication and shared experiences, they create a system of shared assumptions and values, and accepted approaches and solutions to problems, including collective sanctions, to safeguard exchanges and reinforce acceptable behaviors (Jones et al., 1997). Sanctions may include exclusion from certain benefits (present or future) and opportunities (participation in projects), and as a last measure forced exit (temporary or permanent) from the network.

Collaborators often choose to stay in a poorly performing network based on the strength of their social ties. However, if they conclude that they can meet all of their needs outside of the network, they may view the network as superfluous (Brown et al., 1998). Linkages or interdependence must be solid and intentional (Bailey & McNally-Koney, 1996) and may be a strong indicator of sustainability (Olk & Young, 1997). Conversely, Brown et al. (1998) identified that greater resource interdependence makes successful partnerships more difficult to achieve. In order to find common ground and encourage persistence, the reasons for enhancing an interdependence need to be emphasized, and stakeholders must want to belong and believe in the vision.
Content of Performance (Specific Projects)

The content of performance includes a wide variety of projects that meet the goals of the network, including the needs of stakeholders and users. Among them are projects to launch or upgrade an infrastructure, acquire devices to deliver applications, develop content for the network, and promote the network to potential users. The outcomes include cost savings to deliver services, revenues from users, and additional capability for the social and economic development of the community.

Waits (2000) described collaborative networks in terms of their pursuits:

- **Co-inform:** actions to identify members and impacts, promote a heightened awareness of the issues, and improve communication among the members;
- **Co-learn:** educational and training programs sponsored by the network;
- **Co-market:** collective activities that promote member products or services abroad or domestically;
- **Co-purchase:** activities to strengthen buyer-supplier linkages or to jointly buy expensive equipment;
- **Co-produce:** alliances to make a product together or conduct R&D together;
- **Co-build economic foundations:** activities to build stronger educational, financial, and governmental institutions that enable them to compete better.

Some of these pursuits appear easier to realize and only require fragile trust (co-inform and co-learn). They are more likely to give quick “small wins.” Others may be challenging and require resilient trust (co-market, co-purchase, and co-produce); their success will take more time but are more highly valued. Co-building economic foundations appeals less to self-interest and more to a communal interest, and depends on a broad vision that will lead to a series of concrete actions and sustained effort. Waits’ objectives are compatible with each other, but have different time horizons and commitments. The strength of the formation phase influences the commitment of stakeholders in the development phase. In particular, a strong collaborative climate encourages them to be patient and willing to invest additional time and resources to achieve long term goals.

PROCESS OF PERFORMANCE

Leaders require managerial sophistication to recognize appropriate circumstances and tools for collaboration (Glatter, 2004). In networks, collaboration depends upon an ongoing communicative process (Lawrence et al., 1999). Roles and responsibilities are negotiated in a context where no legitimate authority is necessarily recognized (Glatter, 2004; Lawrence et al., 1999; Lowndes & Skelcher, 1998). Like in partnerships, there is concern for trust, politics, emotions, and results. Furthermore, leaders require an understanding of user appropriation of the digital network to effectively channel the collaborative efforts.

Du Gay et al. (1997) describe the appropriation of technology as an active process in which users make choices around the selection and local deployment of the technological components, and create meaning and sense of the technology. Appropriation has both a technical and cultural side. In this spirit, Williams et al. (2005) have argued that user appropriation has two distinct but inter-related processes: innovation (users adjust and innovate to improve the usefulness of the technology) and domestication (users adapt the use of the technology to integrate it meaningfully in their activities). When both processes are fully engaged, the community may be said to have a “digital” culture that sustains the network.
The pace of change within the network must be properly managed. Effective use of communication will allow collaborators to react and contribute. Because of large boards and membership and turnover in representation, some collaborators may not know everyone or their status. Indeed, some may be confused over the degree of autonomy they have in making decisions for their organization (Huxham & Vangen, 2000). Changes in government mandates and organizational priorities create uncertainty as collaborators plan and structure the network. Communication and recognition of accomplishments become important to keep everyone focused.

The board’s effectiveness in tackling problems within their community as well as within their respective organizations will directly influence the achievement of the intelligent community objectives. Leaders need to guide the board and create bridges with important outside players. They must align the requirements of their own organization with the vision of the intelligent community initiative for success; they must create a high performance team environment (Albert, 2005; Wheelan, 1999; Smith, 1994). This standard is not easily achievable, especially for a volunteer board with diverse membership and affiliation.

Challenges in the Performance Phase

Continuing Challenges from the Formation Phase

The consensus on the community vision that was created in the formation phase needs to be reinforced. The leader can remind stakeholders of the urgency to capture opportunities, but must incorporate measures for sustaining collective efforts. Key transformation activities include:

- Expanding planning and monitoring projects and measures of performance;
- Marketing the network concept to mobilize and gain the support of the wider community and further engage the stakeholders.

In terms of resources, the community network continues to depend upon its board to acquire resources to develop, acquire, and develop applications to attract numerous users. Key activities include:

- Modifying board membership to improve the resource base of the network as projects change over time;
- Engaging both small and large partners for innovation to create new resources;
- Creating a small management structure for the performance phase of the network.

As for trust, the performance phase requires continuing sharing of resources in the face of uncertain outcomes. Key activities include:

- Applying different trust standards as the situation warrants;
- Encouraging the broad sharing of resources instead of specialized contributions.

Resilient trust can block new stakeholders and partners from joining the network; they may have key resources but be deemed untrustworthy. In such a case, the network requires the flexibility to resort to fragile trust with its emphasis on formal agreements and contracts. The reverse situation can also damage the network, when fragile trust dominates relationships. While formal contracts increase accountability of the parties, they are narrow in scope and participation is contingent on self-interests being satisfied. Community considerations remain secondary. In time and through active leadership, these new members may buy into community citizenship through association and success.
Balancing Leadership and Collaborative Management

Both the formation and performance phases of development have their champion. The leader dominates the formation (and re-formation) phase through visioning, planning, and attracting and retaining stakeholders with key resources and disposed to collaborate. The manager guides and maintains the performance phase, and ensures that both tangible and intangible benefits are created for the stakeholders and the community.

The “collaborative” manager is needed to reinforce the user appropriation by supporting the innofusion and domestication in which users engage. By encouraging the involvement of intermediaries (e.g., Chamber of Commerce, owner of a cybercafé, entrepreneur who wants to keep control), the network manager allows the network to evolve along lines that reflect the different groups and segments in the community’s population (Williams et al., 2005).

Formal planning becomes less important, as a pattern of coherent projects becomes established. At the same time, these intermediaries (or small groups of individuals in large networks) interact to keep the board informed and reinforce their individual efforts. By working together, they ensure that the vision of the network creates a coherent set of initiatives and projects, and opportunities and issues relevant to the board meetings are identified. Key activities include:

- Encouraging innovation and proper planning to achieve the transformation effort;
- Reaching out to intermediaries to broaden user involvement;
- Ensuring that the vision that binds the board members remains true to the community values as the network develops and expands;
- Confronting head-on the need to modify the board composition to respond to internal or external factors;
- Managing projects with a blend of fragile and resilient trust, the former with binding contracts and the latter with negotiation and concurrence;
- Choosing projects that are likely to succeed and that are valued by the stakeholders;
- Building and maintaining redundant communication systems, both formal and informal, to reflect the culture of inter-dependence that binds the stakeholders of the network.

The network can be damaged by a dominant leader or manager who insists on being involved at all times and on controlling the process, whether at the board or project level. This situation emerges when there is a failure to share multiple roles and to act as a team. The lack of experienced persons may push one individual to assume both the leadership and managerial role; this solution ensures positive momentum, but may block future sharing of roles as the incumbent becomes entrenched. Similarly, the abundance of strong and experienced personalities facilitates the sharing of roles, but may slow down momentum as too many persons insist on prominence. Developing a team spirit among members of the board and management should be encouraged as early as possible in the network’s development (Albert, 2005).

Collaboration Challenges for Users

At the formation stage, the infrastructure and applications are planned and guided by a vision. Stakeholder requirements are addressed in the planning of the network through the methods of user representation. At the performance stage, when the network is functional, the users actualize the network in both expected and emerging ways. A community network is validated by the applications it makes available to its users, and the extent to which the users actually use them. Furthermore, the design features of the telecommunication network influence the collaboration.
opportunities that the network creates. When the network design enhances collaboration, it has succeeded in creating effective socio-technical patterns (Huysman & Wulf, 2005; Evans & Brooks, 2005).

**Challenges for Individual Users**

IT and a community network challenge the individual because they put into question existing ideas and routines, and add knowledge and skill requirements. Being open to change means making efforts to understand and use the network. The younger generation makes more use of the internet than the established older generation for social contact and is likely to push for internet connection in the home (Bernier & Laflamme, 2005; Crowley, 2002). The older adults are more likely to be introduced to ICT changes in the workplace. Age aside, the Internet facilitates the local-global link through which knowledge and expertise from around the world can be channelled to community members (Stevenson, 2002). Creative individuals can interact to exchange expertise and create innovations (e.g., open source development), and are motivated by reputation and recognition built into the Web site (Fischer et al., 2004). To generate ideas, group support systems that ensure anonymity appear more effective (Pissarra & Jesuino, 2005). In general, the individual must learn to assess the trustworthiness of the Internet information sources (Franklin, 1999; May, 2002) and assume risks when making transactions online. Similarly, participating in virtual communities and discussion forums challenges the individual to change roles from spectator to contributor (Ginsberg, 2001) and activist.

**Challenges for Organizational Users**

Organizations that are stakeholders in the community network need to share their “network” vision with their board members, managers, employees, and organizational partners within their supply chains and customer/client networks. Key individuals likely were involved in the network formation stage to ensure that the design of the systems would support expected transactions and activities. At the performance stage, each organization is challenged to mobilize its ICTs, skill base and network use, and do so in dialogue and coordination with their organizational networks. Internally, this means empowering employees and lower levels of management through information systems and decision-making authority. Externally, this refers to the network of relations and the integration of the organizational and community networks. Failure to have extensive collaboration diminishes the benefits that the community network can deliver to stakeholders. Knowledge sharing (Van den Hooff et al., 2004) and knowledge management (Ackerman & Haverton, 2004) are useful frameworks for channelling this collaboration. In addition, involvement can include intra-preneurship (Von Oetinger, 2005) and joint ventures supported by collaborative groupware (McKnight & Bontis, 2002). The organization can also reach out to innovators and entrepreneurs in the community, who view the network as their business platform, and initiate partnerships. The above array of activities pushes leaders and senior managers to adopt an organizational model that incorporates trust.

**Challenges for the Community**

As the community network is fully implemented, the stewardship vision (Block, 1993) incipient in the formation phase must be reinforced by extending inclusiveness to all segments of the local population, imagining a broad culture of use, and providing for economic development with a digital component. Community leaders should have concrete programs to diminish access barriers such as network connectivity at a reasonable cost (or at no cost for public terminals) and to training...
and education. Adoption of the network will vary across socio-economic dimensions, and programs are needed that are adapted to specific groups such as youth, seniors, and the non-profit and small business sectors. Developing and implementing these programs can take place with community stakeholders in collaborative projects. An innovation culture (Martins & Terblanche, 2003), linked to the network, can be encouraged.

A culture of “digital” use is emerging in many communities; the Internet and its many activities are being integrated into everyday routines of social communication, work, and play (Bernier & Laflamme, 2005; Crowley, 2002; Wellman et al., 2001). In contrast, civic participation has had less success. The evidence indicates that internet use reinforces civic participation and makes it more sophisticated, but does not increase the levels of activity (Shah, 2002; Uslaner, 2004; Warkentin & Mingst, 2000; Wellman et al., 2001). Pigg (2001) has argued that networks can be designed to enhance civic participation, but so far, these designs have failed to incorporate the nature of participation. The designs typically focus on customer services and support instead of sharing of information, ideas, and knowledge to influence civic decisions. With a customer focus, the civic authorities may increase the satisfaction of its citizenry, whereas a participation focus obliges the authorities to share decision-making powers and accept more uncertainty in the process and outcomes.

CONCLUSION

A community network faces four inter-related collaboration challenges during its development that are tied to transformation, resources, trust, and management. When these challenges are met, the network will have a solid culture and structure of interdependence, and the flexibility to change over time. The network will maintain a positive momentum that is constructive and manageable, and lead to medium and long-term sustainability. When these challenges are not met adequately, the pace of change will be either too slow or too fast, or blocked at some point in time. Sustainability of the network will be compromised unless the underlying issues are addressed.

These four challenges are anchored in the proposed network development model where formation and performance phases, and adaptation through reformation are critical for the sustainability of the community network. Policy makers and change agents among the stakeholders of community networks are well advised to shape their interventions with the aim of establishing and maintaining positive momentum, while paying continued attention to issues of visioning, resources, trust, leadership, and management. They would do well to expand their views of technology development to include user appropriation and the challenges that users face. They must accept the uncertainty that is inevitable with user involvement to support the goal of network sustainability.

ENDNOTES

1 The authors acknowledge the helpful comments of the reviewers. By addressing their concerns and suggestions, this article found a better balance between organizational and involvement issues.

2 Multi-organizational collaboration, partnerships, and networks are considered interchangeable terms and refer to a variety of organizations collaborating for a common purpose. “Collaborative network” is proposed as an inclusive alternative.

3 A stakeholder is defined as an organization that contributes programs and services to the network. A partner is one that makes a financial contribution to the overall project.

4 The term downloading has become a popular expression in Canada as a result of higher levels of government shifting responsibility for programs to lower levels of government. Municipalities have inherited a number of costs and responsibilities previously held by the province and the province has inherited responsibilities previously held by the federal government.

5 These communities have been highlighted at the annual conference of ICF (Intelligent Communities Forum).

Chapter 5.18
Planning and Managing the Human Factors for the Adoption and Diffusion of Object-Oriented Software Development Processes

Magdy K. Serour
University of Technology, Sydney, Australia

ABSTRACT

Although there are a large number of contemporary software development processes/methodologies available to assist and guide software professionals in developing software systems, there is no specific process that can assist organizations in planning and managing their transition to this new work environment. As a result, there are still a large number of information technology (IT) organizations that have not yet implemented any object-oriented (OO) process. For them, the transition to a new work environment and the adoption and utilization of a software process implies a number of problems, commonly including necessary human and organizational resistance to the ensuing cultural change. This chapter provides IT organizations and professionals with insights into the most important key success factors that may promote the entire process of organizational change. We investigate the effect of various human factors on the adoption and diffusion of an object-oriented software development process. Some of the human factors include motivation, leadership, resistance to culture change, and willingness and readiness to change. In addition, this chapter explores the significant role of these factors in controlling the entire process of implementing an OO process in practice, emphasizing the significance of planning and managing these “soft” factors to achieve clear advantages and gain enviable results.
INTRODUCTION

This chapter investigates and examines the effect of various human behavioral patterns during the organizational transition to an object-oriented (OO) work environment, and the adoption and diffusion of an OO software development process. Technology is only a tool; what makes the difference is the individual who makes use of the technology, and the culture that motivates people to realize and understand the advantages of adopting such technology (Zakaria & Yusof, 2001).

During any paradigm shift, human tendencies play a critical role that may invariably result in either success or failure. Examples of such human aspects may include cultural change coupled with people’s resistance, motivation, education and training, communications, and leadership. Collectively, these factors can form either opposing or supporting forces that may influence and impact on the entire transition process. Therefore, human aspects must be seriously considered, well addressed, planned, and managed for a rewarding result.

Past studies (e.g., Gibson, 1999; Ioannidis & Gopalakrishnan, 1999; Nambisan & Wang, 1999; Auer & Dobler, 2000; Jurison, 2000; Burshy, 2001) of the process of organizational transition have related the transition process to how organizations adopted innovation, ideas, new technologies (e.g., Web services and e-business), or new “ways of doing things” (e.g., the adoption and deployment of an OO process).

What these processes missed in the past was the first (and the most critical) step towards the adoption of a new technology. They all missed the study of moving organizations from their current state or environment to their desired one where they can feel comfortable, familiar, and confident to adopt and diffuse an innovation or new technologies such as OO processes. Getting organizations ready to adopt and diffuse a new technology involves a number of serious managerial decisions that must be made to provide full management support, dedication, and commitment. Organizations must feel comfortable and familiar with the new way of “doing things” before any attempt is made to implement these new ways in practice to avoid or lessen people’s natural resistance to change, and also increase their acceptance and readiness.

Hence, the main objective of investigating the impact of human issues is to gain a full understanding of individual behavior during the transition and also to examine different human factors that influence the response of individuals within organizations toward the adoption of an OO software development process.

ORGANIZATIONAL CHANGE AND HUMAN FACTORS

“The greatest difficulty in the world is not for people to accept new ideas, but to make them forget about old ideas.” John Maynard Keynes

People Behavior During Organizational Change

During an organizational transition, different people play different roles, such as motivators, adopters, resistors, opposers, and neutral or observers (Bridges, 1995). How they respond to change during transition can, and in most cases does, dominate and determine the success or failure of the entire project. The inextricable reality is that people are different, and so act and react to changes differently; from time-to-time even the same person can behave in a different manner.

Bridges (1995) claims that changes are always accompanied by natural resistance, as changes often drive people out of their comfort zone. Consequently, people can develop a resistance to change and become the main obstacle to the whole organizational change.
Once an organization comes to realize what it needs to achieve and decides how it will accomplish its goals, the main challenge becomes the issue of effective and efficient management of human factors. It is quite surprising to know that 80% of project failures are traced back to mismanagement of human factors (Jacobson, Ericsson, & Jacobson, 1995).

Unfortunately, there are many organizations still struggling to deal with difficulties related to the effective management of human or sociological factors during technology adoption and diffusion. This type of problem is usually caused by management’s lack of commitment to the human factors of IT. Szewczak and Khosrow-Pour (1996) relate this problem of mismanagement of human aspects to the fact that, in general, organizations traditionally invest a significant proportion of their resources to obtain the necessary hardware and software technologies, but with insignificant investment in the human aspect of technology. An experienced software development team that has been around for more than a decade, for example, is likely to have superior expertise in (and consequently be comfortable with) traditional software modeling techniques such as Flow Charts, Data Flow, and Entity Relationship Diagrams. Professionals of this type would not be openly receptive to changing their existing work culture and switching to modern OO techniques such as Object Model, Use Case, and interactions Diagrams. This kind of human culture change can form a major challenge during the transition that may increase people’s resistance to change.

The Challenges of Human Factors

In general, human aspects are the most difficult challenge to be addressed during any organizational change (Zakaria & Yusof, 2001). The transition process to OO and the adoption of an OO process usually involves a large number of technical as well as non-technical issues. Various authors have referred to these non-technical issues as soft factors (Constantine, 1995) and sociological factors (DeMarco & Lister, 1987). We call these ‘human’ Key Success Factors in this discussion, since they deal with the ‘human aspect’ of change. These human factors necessarily require complete understanding and managing alongside the technological factors. Since OO contains elements relevant to all stages of the development lifecycle (not only coding), and includes models for requirements engineering, project management, team building, and so on, adopting OO process requires a combination of learning about technical issues as well as larger scale sociological issues.

People, procedures, and tools are the three critical aspects that must be well planned and managed during any organizational change (Serour, Henderson-Sellers, Hughes, Winder, & Chow, 2002). Certainly out of these three aspects, people are the most demanding aspect to be changed and managed. Eason (1983) argues that the human factors of technology are far more important than technical factors. The most challenging aspects of the transitioning to object-orientation remain in establishing a new software development environment and in introducing a new work culture to managers, software developers, and customers (Ushakov, 2000).

As a result, it is imprudent for management to expect every team member to agree with all the proposed changes. It may even be unwise to anticipate full commitment and belief in the new organization mission, especially at the early stage of transitioning. Organizations must face reality by realizing that change is often difficult in the best of circumstances and seldom goes exactly to plan. Management must be mindful that only a minority of individuals will wholeheartedly welcome any proposed changes to the way they have done things for so long.

The challenge to software professionals is to change and adapt to a new environment. A pos-
possible scenario may ensue where developers need to adopt new ways of ‘thinking’ about software, followed by OO modeling/designing, developing, quality assuring, and testing the software. Adopting a new approach of developing software may include technical factors (e.g., CASE tools, Programming languages, and databases) that require a reasonable degree of human culture change in order to utilize them to their maximum potential. Individuals, especially those working on software projects, work under the influence of various personal, motivational, and social factors. These factors, more often than not, remain in the background. Due to their elusive and intangible nature, these human factors are often difficult to discern, analyze, and improve on when change is about to be implemented.

As a result, moving working professionals to new ways of perceiving and undertaking various tasks is very difficult (Fingar, 1996). However, many studies such as Szewczak and Khosrow-Pour (1996) suggest many organizations are still struggling to deal with problems related to the human aspects of technology. Furthermore, they correlated this problem to management’s lack of commitment to the human side of IT.

It is vital, then, that organizations pay careful attention in addressing all human or soft factors, and be open and ready to confront and solve any conflicts that may influence the entire transition. Organizations need to appreciate individual behavior when examining the transition and the adoption of new OO process; they need to investigate and explore the different factors that influence the response of individuals within the organization towards the new technology. To accomplish a successful transition, an organization needs to advance people’s motivation and enthusiasm, maintain management commitment, and provide efficient and persuasive mentors whose leadership may be seen as the source of expert guidance (Jacobson et al., 1995).

The art of managing cultural interfaces has become an everyday business challenge at every organizational level (O’Hara-Devereaux & Johansen, 1994). The main question here, and management’s major challenge, is how an organization makes the transition a driving force for all people involved in being adopters and supporters of the change, instead of opposers or neutral players. Constantine (1996), during the OOPSLA’96 panel discussion pertaining to human factors, contended that it is quite easy to communicate with machines and solve problems, but with people it is difficult. The main reason is because people are very difficult to “generalize.”

**Human Factors and Risk Issues**

Organizations must be aware of the consequences and the possible risks involved in mismanaging the human factors during the introduction of a new work culture such as OO process. The improper planning and managing of human factors can easily lead to undesirable consequences, such as building resistance to change, and adding more confusion, uncertainty, and fear that can considerably diminish the chance of success. Schein (1999) interestingly states that there was no such failure for technology adoption; instead it was a failure to understand the organizational and the individuals’ culture.

As a result, organizations that are aiming to adopt an OO process need to address not only the technological factors of the adoption, but also the human factors. As an example, organizations must provide adequate education and training to their people in order to understand and grasp the fundamentals and underpinning concepts of object-orientation and development processes, as it is a critical factor to avoid those risky consequences. Bridges (1995) argues that the most prevailing cause for the unsuccessful implantation of organizational changes can be attributed
to a lack of planning in managing the impact of change on individuals. He also emphasizes that many organizations that are not properly geared to handle this facet of change can run the major risk of jeopardizing their own existence.

Therefore, management may be very well advised to create a plan to manage and mitigate these potential risk factors by answering the following questions:

- How are people likely to respond to the change?
- What is required to convince people that the change is worth the effort?
- What actions are necessary to earn people’s support and commitment to the change?

In addition, management needs to identify the ultimate and most effective means in achieving the following objectives:

- Selling the change to all people involved, including customers.
- Motivating people to make the transition.
- Reducing people’s resistance to change.
- Eliminating people’s fear and uncertainty.
- Minimizing the change’s disruption to people.
- Mitigating the increasing tensions between people during the change.
- Encouraging people to be enthusiastic for the change, as opposed to being apathetic and an obstacle.

By answering the above questions and achieving the related objectives, organizations will be able to use persuasive approaches to human change, ensuring that everyone is comfortable and willing to accept, and make use of, the new OO process with all its associated changes.

**THE HUMAN FACTORS**

**Human Culture and Necessary Culture Change**

“In a time of rapid change, standing still is the most dangerous course of action.” Brian Tracy

The Oxford English Dictionary (9th edition) broadly defines human culture as the arts and other manifestations of human intellectual achievement regarded collectively as the improvement by mental or physical training. In particular, Palvia, Palvia, and Roche (1996) define the culture of IT professionals as the set of values and practices shared by these members of an organization involved in information technology activities, including managers, developers, and customers/end users.

Personal culture is usually characterized and distinguished by the individual’s values, such as behavior, attitude, experience, and beliefs. There are people who work well under pressure, whereas others work well only when properly supervised and directed, and then there are the ‘cowboys’ (Constantine, 1993) who prefer to work on their own. Cooper (1994) asserts that an IT person’s culture may resist the introduction of a new process which realigns status, power, and working habits, especially when they violate some of the group’s shared values. Current personal culture can be incompatible with certain new processes to the degree that risky consequences may be incurred, including resistance to change, a negative attitude and behavior, implementation failure, or the achievement of totally unsatisfactory results. Human culture change—that is, the physiological change that people undergo to alter the way they carry out their work on a daily basis—is one of the hardest and most longstanding parts of the adoption of an OO software development process (Fayad & Laitinen, 1998).
Natural Resistance to Change

Coupled with the introduction of a new work culture, people tend to naturally build resistance to any challenge of changing their culture and/or learning new things. The unfamiliarity with the new changes can lead to a discomfort that naturally increases people’s resistance. In general, change is often seen as a personal threat by those involved in transition (Huse, 1975).

Resistance to change can also come from management, project leaders, and customers/end users for similar reasons, including fear of change and uncertainty of their capability of carrying out these changes (Fayad & Laitinen, 1998). Furthermore, adopting an OO process also requires people to advance their skills and knowledge, and/or gain new ones, as well as learning new tools and techniques. All these changes can lead to a threat that, if people are not capable of changing their culture, they will be out of the workforce, and be replaced by others who possess the required OO knowledge and skills and are capable of utilizing the new process. Resistance may also happen during the course of adoption when people are faced with serious impediments. For example, people may reach a stage when they feel that they cannot use their old ways (ad hoc) and at the same time they are not comfortable with the new ways (OO process). They then try to escape or oppose the changes. This leads to an increased level of resistance.

During organizational change, managing people’s resistance becomes a critical issue that must be seriously considered so as to accomplish satisfactory results. For that reason, organizations must be able to effectively manage people’s resistance to leading and directing the change process. To do so, management must first understand what resistance really means. What do people really resist? Do they resist the new environment, new technology, or the changes they have to undertake? And finally, why do people really resist? Do they resist for psychological reasons, technological issues, personal concerns, or a combination of all?

What Resistance Really Means?

Naturally, people want to improve and find better ways of doing things. A part of making improvements is causing changes, and changes are always faced with different types of resistance. People’s resistance can be a result of different human reactions that sometimes form obstacles, impediments, hindrances, and difficulties to change. One of the risky issues regarding people’s resistance is that, sometimes, managers see resistance as a sign of laziness, stupidity, or just unwillingness and opposition to change (Fayad & Laitinen, 1998).

In actual fact, resistance can be a sign of people’s disinterest or they could be busy with more pressing issues. Resistance could also be a signal of conflict of interest or contradictory point of views. Moreover, resistance could be a silent request for assistance, more information, or an assertion of different priorities. Resistance can be viewed as an opportunity to gather information and learn better about current and desired state (Bamberger, 2002).

What People Really Resist?

Naturally, people do not like to lose. They do not like their own things to be taken away from them, and that is exactly what people resist. People associate change with the loss of their existing comforts. People do not resist the change itself, so much as they resist the uncertainties, fear, and discomforts associated with it. People, especially those who are confident and comfortable with their existing culture, resist the idea of changing their ways of doing things, and facing the risk of becoming unfamiliar and uncomfortable with the new ways. In addition, every change involves a degree of risk, and people are naturally reluctant to take risks and face the unknown.
Why People Really Resist?

To manage the resistance to change, it is important first to understand the various reasons behind it. Resistance could happen at an early stage of the introduction of the new change and/or at a later stage, during the change process. People resist change when they are unaware of the need to change and, accordingly, are uncertain of the final result. On the other hand, Bamberger (2002) notes that change often meets with resistance because it is seen as a personal threat that leads to fear of failure and rejection. Fayad and Laitinen (1998) relate resistance to the lack of a clear view of the current state and objective goals. They further note that resistance to change often exists as a result of structural conflicts within the organization. Lack of management’s commitment and inconsistent actions with the new change can also elicit resistance.

Bridges (1995) declares that when changes take place, people get angry, sad, frightened, depressed, and confused. These emotional states can be mistaken for bad morale, but they rarely are. Rather they are more likely to be a sign of grieving, the natural sequence of emotions people go through when they lose something that matters to them. People resist the loss of competence that they once had and which was associated with their old familiar tasks. Transition is tiring; during the change, people build resistance when they feel unfamiliar and uncomfortable with the new ways. Resistance happens when people feel that they cannot use their existing old ways, and at the same time they are not comfortable and familiar with the new ways. From a different perspective, people build resistance when they feel that the new ways they have to follow can negatively affect their productivity. For example, an inappropriate new process or technique can discourage people to change, as it can lead to a drop in people’s productivity.

Accordingly, with the introduction of a new OO process, people’s resistance to transition and culture change could be a result of one or more of the following human behavior factors:

- They see the transition with its necessary changes as a threat to their jobs.
- They do not have inadequate knowledge and experience related to the new OO process.
- They are afraid of learning new ways of carrying out their jobs.
- They doubt the benefits of adopting a new OO process.
- They are afraid of failure or that they will not be able to understand the new process.
- It is exhausting to learn new things, and some think they are too old to learn a new process.
- Some prefer to do what they know best, even when they acknowledge there may possibly be a better way (The devil you know!).
- They are overloaded with their current projects with no time to learn new things.
- They are not in favor of the new process with its associated modeling language and/or CASE tools.

Even during the transition process, and when changes take place, people can develop more resistance and be less motivated for different reasons including:

- Anxiety rises and motivation falls.
- They are afraid of failing.
- They are unsure of the new way.
- They are afraid that they may be blamed if something goes wrong.
- They try to avoid learning new things.
- They become self-protective.
- They respond slowly and want to go back to the “old way.”
- They doubt the benefits of the new way.
- They feel panic and confused.

Unsurprisingly, even customers may develop some resistance and be reluctant to accept the
changes as a result of the risk factors involved in introducing a new process that would affect their products. Therefore, customers must be involved in the change process owing to their effective role in supporting the organization’s adoption of a new OO process. The customer role needs to be changed from being just a customer requesting and running a software application to that of being an effective and supportive partner in the whole process of producing their products.

Defeating People’s Resistance to Change

As discussed above, many managers see resistance as a sign of laziness, stupidity, or just plain perversity on the part of employees (Fayad & Laitinen, 1998). Lawrence (1969) suggests that resistance to change should not be treated as a problem, but rather as an expected symptom and an opportunity, or a request, for learning and better knowing the unknown. Also, Senge (1990) stated that resistance to change generally has a real basis that must be understood in order for it to be dealt with. In order to manage people’s resistance to change, organizations need to understand better the very human reactions they face when they are asked to do something differently or change their work habits. Management must plan and practice some strategies to manage and deal with people’s resistance.

To do so, management must begin to understand what “resistance” really is? What are the major reasons for people to build resistance to change? Then they must establish a suitable work environment for people to undergo the required changes. Management cannot change people, they have to change themselves and they only change when they have the appropriate and supportive environment (Boyett & Boyett, 2000). Bridges (1995) reported that most managers and leaders put only 10% of their energy into selling the problem, but 90% into selling the solution to the problem. Management must put more energy into “selling” the problem that is the reason for the change, because people are not interested in looking for a solution to a problem they do not know they have. Management must realize that culture change is very tiring. People will feel tired, overwhelmed, down, and depressed. Management must look at those symptoms as a natural human reaction, and work hard to rebuild its people self-confidence and give them the feeling of competence in mastering the new way. Management must realize their people’s capabilities and give them what they can do best without any fear of failure. Anxiety is natural, and the best way to defeat it is to educate and train people on their new environment. Adequate education and training regarding the newly adopted process can easily eliminate the fear of the unknown, the uncertainties about the final result, and thus lead to elimination of people’s resistance.

Defeating Resistance with Participation

One of the most effective ingredients to defeat people’s resistance to change is by encouraging them at an early stage to participate in planning for the change; Huse (1975) confirms this fact by assuring that people—during transition—see change as a threat unless they have participated in its planning. Lawrence (1969) has demonstrated through one of his case studies, where an identical change was introduced to several factory groups, that the first group, who was not offered any explanation, resisted all management’s efforts, whereas the second group, who was involved in the change planning, carried out its transition with minimal resistance, and an initial small productivity drop was rapidly recovered.

Involvement of people in planning their change allows them to understand why they need to go through it and what they should expect. Humphrey (1995) affirms that people’s resistance can be gradually changed to acceptance, once people are convinced of the necessity of the changes, and also they can see the value of undergoing
the change. So, management must show and convince people that the change they need to go through is not a threat, but rather an opportunity for improvement.

Defeating Resistance with Small Wins

Humphrey (1995) asserts that people’s resistance to change is proportional to its magnitude. Therefore, resistance can be reduced by planning a number of small changes instead of a hefty change. Transitioning an IT organization to OO environment and adopting an OO process involves outsized changes. Psychological, organizational, and technological changes that can be planned in an incremental manner are “small wins.” By introducing the new changes in small increments, each increment will be easy to sell and implement. People will feel confident and positive every time they successfully achieve one increment, and become even more enthusiastic and motivated to implement the next increment. This technique can lead to a smooth transition by enhancing people’s willingness to participate and reducing their total resistance. For example, the process of adopting a new OO method could well be started by addressing the Requirements Engineering (RE) activity as a major focus to engender everyone’s involvement. An initial RE approach, using a well-defined technique such as the use case technique, can be introduced and utilized without the burden of all other activities and techniques. Once people feel confident in carrying out the RE activity, another major activity such as user interface design can be introduced in the same manner and so on for all other activities.

Education and Training (Knowledge and Skills)

Younessi and Marut (2002) define education as an opportunity to learn and ideally master a number of theories—principles that enable the recipient to assess, analyze, and act appropriately to a broad range of relevant situations. The impact of education is usually more abstract and wide in scope. They also defined training as the provision of an opportunity to learn and ideally practice some skills in a controlled environment to carry out a particular task(s). The impact of training is usually more focused, direct, and narrow in scope. In other words, education provides people with the answer to “know what,” whereas training provides them with the answer to “know how.” People can gain knowledge and skills either through education and training courses provided by their organization and/or through real-life work experience.

In general, people need education and training in their discipline to enable and empower them to assess and perform their duties in a professional and satisfactory manner. In the context of the adoption of a new OO process, technical people need to learn about the new process and associated technology to feel comfortable when using it (Zakaria & Yusof, 2001). The individual’s knowledge and experience related to the new process play an effective role in making the decision for the adoption. People with adequate and appropriate knowledge and experience of their new OO process can be more self-motivated and enthusiastic to make a transition than others. On the other hand, during an organizational change, lack of knowledge and/or experience could elicit people’s resistance to change and increase their feeling of incompetency and frustration.

Necessity of Education and Training for Transition

Younessi and Marut (2002) have emphasized the vital role of education and training during the adoption of a new OO process by suggesting that education and training is an obligatory component for the successful introduction of software processes into an organization. Furthermore, they considered education and training as a Critical Success Factor for adopting these processes. Perkins and Rao (1990) stated that
the more knowledge and experience people have, the more they are able to contribute to decisions regarding the adoption of OO processes. They also emphasized the impact of training related to the new technology that increases their ability to adopt, diffuse, and master processes, techniques, and tools. Conner (1992) demonstrates the imperative role of education and training in adoption by saying that people change only when they have the capacity to do so.

People’s experience towards OO processes should have a positive impact on the adoption (process) of such technology. In the context of adopting a new OO process, Sultan and Chan (2000) stated that the greater the knowledge and skills of individuals, the more likely they are to adopt it.

Management must recognize the critical nature of proper education and training, since experience has shown that between 25 and 40% of the total cost of an extensive project will be spent on education and training (Mize, 1987). More experience enables people to contribute more towards the transition and the adoption of new OO processes. People’s appropriate knowledge, experience, and education may have a positive impact on their transition. The greater the work experience of individuals with the organization, the more likely they are to transition and adopt the new process. Highly skilled staff can manage themselves more easily, particularly during a paradigm shift. Therefore, an individual’s satisfactory level of knowledge and education towards the new technology and processes forms another imperative management challenge.

Motivation has a remarkable power and is a major influence on people’s behavior towards any achievement (Humphrey, 1997). In order to investigate the importance of motivation during the organizational adoption of OO processes, we need to understand what motivation is, its role during the adoption, and what motivates people.

What is Motivation?

Bolton (2002) defines motivation as a sociological concept used to describe individual factors that produce and maintain certain sorts of human behavior towards a goal. Hence, motivation, as a goal-directed behavior, is a driving force that stimulates people to achieve a set of planned goals.

Motivation is often driven from a desire or an inspiration to accomplish a defined objective, combined with the ability to work towards that objective. In other words, Motivation is the ability of taking good ideas or serious changes, and coupling them with appropriate knowledge and skills to achieve desired objectives.

Consequently, people who are aiming to achieve a specific goal must be both motivated and have the power and ability to work towards that goal. People who are motivated towards an accomplishment must be also capable and empowered to do so (carry out the work).

In the context of this chapter, motivating people during the adoption of a new OO software process could mean those factors which cause individuals within the organization to do more than they otherwise would. For example, to transit a development team to a totally new OO environment and/or adopting a new process, people need to work more than usual to change their existing work culture and adopt a new way. Then, motivation becomes a measure of an individual’s level of readiness and willingness to participate effectively towards a successful transition.

"Motivation is the release of power within a person to accomplish some desired results. It is a major key for achievement and success.” Dr. Len Restall
Role of Motivation During Adoption

Pfeffer (1982) states that when people understand and accept a goal, and believe they can meet it, they will generally work very hard to do so. Additionally and from a different perspective, Maslow (1970), when he described his “Hierarchy of Needs,” stated that people are capable of achieving their goals if they believe that they can achieve them.

Motivation provides people with the understanding of the reasons for the change that increases their acceptability, which in turn improves their ability to accomplish a successful mission. Moreover, motivated people more often than not are capable of defining and achieving their own goals.

During an organizational change, people need to have compelling and persuasive reason(s) why they have to go through changes. Once they are convinced and believe in their mission, they will feel more competent to carry out their necessary changes successfully. This becomes a positive motivation that makes people desire to accomplish their goals that result in their very best performance (Humphrey, 1997).

On the other hand, lack of motivation during adoption can lead to negative consequences that may contribute to undesirable results. Those consequences may include fear, confusion, frustration, and uncertainty. Humphrey (1997) confirms the vital role of motivation by saying, “Without motivated and capable employees, no technical organization can prosper.”

As a result, management must improve and maintain people’s motivation to help them to be more effective and efficient in moving to their desired work environment with the adoption and utilization of a formal OO process. Motivation addresses the degree to which people want to, and are willing to, complete the work necessary to change their existing work culture. Furthermore, during transitioning to a new work environment, management must maintain people’s motivation if they try to give up easily, or too soon, so as to encourage them to keep trying as long as they believe in their goals.

What Motivates People?

Bolton (2002) suggests that a good first step towards understanding what motivates people is to know what people want from their jobs. The answer could be gaining financial advantages, acquiring more skills and knowledge, or working with the latest technologies. In reality, it is very difficult to predict and judge on people’s desire because it depends on the individual’s values and beliefs.

What motivates people to change their work culture and adopt a new process differs, all depending on their needs and perception of the new process. Hence, not all people can be motivated by the same things and to the same degree. Therefore, management—especially during transition—needs to understand why their people do their work, and consequently elicit what motivates them and how to maintain that motivation through the entire process. Understanding people’s aspiration can help management not only motivate people, but also support their motivation by maintaining and increasing the reasons for motivation.

Motivation is often seen as the driving force that moves people to perform some actions. Then, in the context of the adoption and diffusion of an OO process, people need a comfortable, familiar, valuable, and convincing driving force or “motivation factor” to move them to perform more effectively than they usually do.

People feel comfortable when they confidently know how to do their jobs. Enhancing people’s skills and knowledge to the required level for transition makes them feel comfortable with the new process. Formal and professional education and training pertaining to OO processes are considered to be effective and efficient techniques.
Human Factors for the Adoption and Diffusion of OOS Development Processes

In order to motivate people, training must include clarification of language and jargon or commands used to avoid further frustration and anxiety, as new technologies usually have a mystifying and alienating potential. The more comfortable people feel with the new technology (here OO process), the more willing they are to experiment with it (Zakaria & Yusof, 2001).

Motivation factors must also add extra values for people such as financial reward, or learning a new language, process, or tool. For example, someone likely to retire in a year is unlikely to learn a new way of doing things. On the other hand, an enthusiastic newcomer to the project is likely to put in the extra effort needed to pick up new methods of thinking and modeling.

People who are in the move (e.g., changing profession, changing company, or reaching retirement) will not be interested in changing their culture, and they become difficult to motivate to change their current culture because they will not gain any benefits. To motivate people to change their culture, they need assurance of benefiting from the change.

The driving force must also be convincing, it must be relevant to what people usually do, and it must be in a way that people can believe and make use of. Most people must be convinced of the need to change before they will willingly comply (Humphrey, 1995).

Leadership

“Leadership is the ability to provide those functions required for successful group action.”
Weldon Moffitt

Leadership is well thought-out by many researchers and authors as a fundamental activity of project management, and they simply describe it as motivation plus organization (Stogdill, 1974; Thite, 2001; Phillips, 2002; Castle, Luong, & Harris, 2002).

In general, leadership plays a significant role in how people effectively perform their jobs. Rogers (1995) defines leadership as the degree to which an individual is able to guide, direct, and influence other individuals’ attitudes informally in a desired way. Stogdill (1974) describes leadership as a process of influencing group activities toward goal setting and goal achievement.

Leadership is a practice that needs special skills and talent to motivate people to get things done in a favorable and constructive way. Bridges (1995) affirms that leading a team of professionals efficiently is an invaluable resource to any leader who is eager and willing to understand how to inspire team members. Also, it is a vital ability to augment teams’ cooperation and individuals’ commitment and productive participation. Above all, an effective leadership is a Critical Success Factor on how team members become adaptable to changing circumstances (Thite, 2000).

Leadership is basically situational. Fiedler (1967) suggests that there is no one style of leadership that suits every project situation. Rather, it should be contingent upon the nature of the organization, the team, and the project situation. Leadership style should be flexible and agile enough to be adapted to suit the project at hand in the most appropriate manner. Phillips (2002) claims that the “appropriate” leadership style is the style with the highest probability of success. Additionally, a good leader should effectively mix and cooperate with team members.

Leadership Style for Adoption

“A leader is best when people barely know that he/she exists.” Whitter Bynner

During an organizational change situation, leadership style must be adapted to promote and support the organizational change. Social factors such as the style of leadership can influence the individual’s ability to transit to a new work climate. Thite (2000) emphasizes the importance of
the appropriate leadership style during a change situation by considering it as a Critical Success Factor.

Changing people’s work culture and introducing them to a new way of doing their job is usually accompanied by increasing anxiety, ambiguity, and insecurity. During such time, a supportive leadership style can effectively contend with and overcome these problems.

Due to the fact that an effective leadership style should depend on the follower and the project situation, leaders must use the most appropriate style of leadership that best suits the project situation that yields the best chance of success (Phillips, 2002). Furthermore, Phillips states that managers must be able not only to determine the most appropriate leadership style, but also to apply that style correctly.

Stodgill (1974) supports that argument by saying, “The most effective leaders exhibit a degree of versatility and flexibility that enables them to adapt their behavior to the changing and contradictory demands made on them.” Moreover, Hersey, Blanchard, and Johnson (1996) proclaim that successful and effective leaders are able to adapt their leadership style to best fit the requirements of the situation. Therefore, leaders within an organization about to introduce a major change to their work environment—such as the adoption of a new OO process—must have adequate resources (mainly time), a strong interest in the mission, and a greater exposure to the new process they are about to adopt. Sultan and Chan (2000) firmly assert that the greater the opinion leadership among group members, the greater the chance of a successful transition and adoption.

Leadership always means responsibility. Consequently, an effective leadership style for a transitioning organization must be driven from top management with full support and commitment, and it must be also coupled with a rational degree of authority. Co, Patuwo, and Hu (1998) support that by saying: “Ideally, the team leadership should come from top management: one who is a ‘doer’, and who commands respect throughout the entire company.”

During the organizational transition to a new work environment, leadership should foster strong alignment with the organization’s vision. Team members that depend primarily on strong alignment with their organization’s vision are at their best with well-understood practices applied to well-understood problems. Furthermore, successful leaders must be able to create a new work environment in which team members feel comfortable and familiar, and also enjoy what they are doing.

Lockwood (1991) and Constantine (1994) affirm that the working culture shapes the style in which software development is carried out. Different styles of organization during different situations require somewhat different forms of leadership style and management, and each will tend to have somewhat different software practices.

Leaders who are leading their teams through a serious change—such as adopting a new OO process—must be able to:

- Define a clear vision and mission.
- Provide convincing and compelling reasons for the change.
- Focus on and be concerned with the why to aspect of the transition, rather than the how to.
- Manage and motivate team members.
- Maintain an authority level to make appropriate decisions in the face of uncertainty.
- Provide full support and commitment to their followers.
- Provide adequate and appropriate resources including time, education, and training.
- Establish clear communication channels with team members.
- Monitor and review tasks allocated to team members.
- Recognize and appreciate achievements, and reward people for doing good work.
Perception of OO Processes

While IT organizations perceive new OO processes as an essential means to advance their existing software development culture and effectively compete in the marketplace, individuals could have a different perception. Since people are different, their needs and expectations are also different. The more positively people perceive their new process with regard to its characteristics—advantages, observability, compatibility, complexity, and trialability—the more likely it is that the process will be adopted and utilized.

Management of Expectations

From past projects, it has been proven that people with life experience are able to deal with conflicts of interest that may arise due to their ability to make any decision regarding the transition (Hill, Smith, & Mann, 1987). To emphasize the vital role of education on conflict resolution, Barclay (1991) stated that any organization’s members who have adequate education and significant real-life experience are well prepared to deal with interdepartmental conflict. It has to be made very clear from the beginning, to both managers and developers, that following a new OO process is not a magic wand or a silver bullet to make the entire organization’s dreams come true, but rather is simply today’s best approach option for software development. Nonetheless, it is also important that managers appreciate not only the benefits of adopting a new process, but also become aware of all the pitfalls and consequences of changing people’s existing work culture.

Different stakeholders such as managers, developers, and customers may look at, assess, and evaluate OO processes, as a new technology to be adopted and utilized, from a different perspective. Senior managers are always looking for the dollar value return for their spending and investments. They evaluate the technology based on how much it will reduce the cost of software production with improved quality. Project managers and team leaders may assess the new OO processes from a different perspective. They emphasize project management aspects, gaining more control and meeting customer’s expectations with on-time delivery based on building the software system from the pre-tested and proven software components. Software developers may value the proposed process for adoption as the new fad and trend to developing software. They view the transition process as a good opportunity to acquire new skills, and learn new tools and techniques. Unquestionably, this will insert desirable additions in their resume, add value to their worth in the market, and make them in more demand.

From the above discussion, unrealistic expectation from adopting a new OO process and also any conflict of people’s interest can have a negative impact on the entire transition process. People will be reluctant to work effectively together as a team if they do not share the same interest and/or have different expectations.

In order to overcome the barrier of the conflict of interest, management and champion teams must include a specific plan to resolve that conflict between people, and reach mutual perceptions, consensus, and understanding.

Proper education, mentoring, and open discussions are examples of good techniques that can be used to achieve good understanding and realistic expectations of the new process. Stakeholders must come to some sort of consensus as to what they can expect from adopting a new process and also should be fully aware of the new technology pitfalls as much as its benefits. Stakeholders’ consensus and shared understanding, as well as realistic expectations of the new process, can lead to a good working environment that can positively impact on the process of transition and thus the quality of the software produced.
Sharing the Vision with the Organization

People perform better if they feel that they share the value of the change with their firm. Managers need to provide the right organizational climate to ensure that their employees can see that, by working towards the organizational goals, they are also achieving some of their own goals. These goals could be financial rewards, or personal rewards such as the respect of their colleagues, or job satisfaction, or a combination of any number of things that the employee considers to be important.

During organizational change, such as the adoption and diffusion of an OO process, to gain people’s acceptance, management should get people involved during the initial stage, listen to what they have to say, respect their view, and involve them in discussions and debates regarding the change. Follow up with them on any further progress. Give them the feeling that they are the owners and supporters of the change. Give them the impression that we are only interested in the change if it will help them and make their job more efficient and more enjoyable. Never blame the people for any faults or mistakes, but rather blame the product, the techniques, and/or the tools being used. Organizations need to try everything they can during the adoption of a new process to gain their people’s willingness and support such as:

- Choose a flexible software development process/methodology to be tailored to best suit the organization’s environment.
- Obtain senior and middle management support and commitments.
- Set an appropriate change management plan.
- Establish a transition support team to sell the changes to everyone and to deal with all transition issues.
- Plan for adequate resources.
- Plan for rewarding people behind the transition.
- Carry out the changes gradually and avoid overloading people.
- Plan for the appropriate type of education and training to enhance people’s skills that minimize their fear and confusion.
- Introduce new ways in formal and informal ways as required.
- Never blame people for any failure; instead blame the process (no criticism).
- Listen to people and encourage their individual contribution.
- Reinforce the new way of following the new adopted process.
- Start with small jobs with high chance of success so they to gain self-confidence.
- Celebrate success with people.

Organizations should set a well-defined set of guiding beliefs that the mission of the transition and adopting a new OO process is worthy and must be shared with people. Individuals must be in harmony and agreement with an organization’s value and goals. When individuals share the same values and beliefs as the organization, they form a psychological union as a group. They become more congruent to the organization. Thus, the efforts of adopting a new process are determined and rigorous. The sharing of ideas and commitments through cooperation and harmony within an organization often leads to an effective change and positive participation. Needless to say, whenever individual goals are in alignment, or close to alignment, with the organizational goals, then any initiative undertaken by the organization to adopt and diffuse a new technology—in our case, OO process—will be easily accepted and utilized by individuals. When people share the vision and beliefs with their organization, they feel that they share the ownerships of their new process and the accountability of the whole transition procedure.
This feeling can motivate the individuals and assist management to defeat resistance to change should it arise. A strong organizational culture is usually measured by the way in which the key values are intensely held and widely shared. It has a greater influence upon employees than weak culture.

**Communication Channels**

When Zakaria and Yusof (2001) analyzed the implementation of technological change from a user-centered approach, they asserted that communication is a critical element in ensuring the success of a new technological change such as the adoption of OO processes.

Communications are defined as a process by which individuals exchange information through a common system of behavior. The process of communication between individuals has an influence on organizational transition, because it has a strong impact in conjunction with the leadership. A strong and effective communication network has a strong positive impact on adoption of a new technology. Proper and open communication channels can, from one side, help management to express their commitment and support to their people. From the other side, these channels can give people opportunities to discuss and exchange their concerns regarding their transition in order to adopt the new process. This can strongly increase people’s cooperation, which enhances their ability to carry out the required changes effectively. From a project management point of view, open communications keep management in continuous contact with their people, and they can closely observe the transition progress to quickly resolve any problems that may occur. Communication can take different forms such as meetings. During an organizational transition to a new work environment and adopting a new process, meetings—driven by management—are seen as ways of undoubting management’s commitment and support to change.

**CONCLUSION**

It can be clearly noticed that by considering and managing the human factors in great detail, the chances of successful adoption and diffusion of a software development process are enhanced significantly. Based on our research projects and several empirical studies, we conclude the following:

- Human factors play a vital role during the organizational transition to adopt and diffuse an OO process, as they can form either a promoting or resisting force.
- Understanding of the new desired OO process work environment can assist management in putting together a plan to manage the necessary cultural change.
- During an organizational change, managing people’s resistance becomes a critical issue that must be seriously considered so as to accomplish satisfactory results.
- Organizations must be able to effectively manage people’s resistance to leading and directing the change process.
- Involving individuals in planning and making decisions can positively eliminate their resistance to change and enhance their ability to carry out a successful transition.
- The individual’s knowledge and experience related to the new process play an effective role in making the decision for the transition.
- More knowledge and experience enable people to contribute more towards the transition and the adoption of new technologies, including OO processes.
- The greater the work experience of individuals with the organization, the more likely they are to transition and adopt the new process.
- Gaining adequate knowledge and proper training on OO processes and associated
tools can significantly contribute to enhancing people’s ability to positively involve themselves in the transition process.

- The more knowledge and experience the organization’s individuals have regarding OO processes, the more likely they are to change and adopt the new work culture and thus enhance the chances of a successful transition to a totally new OO software development environment.
- When people understand and accept a goal and believe they can meet it, they will generally work very hard to do so.
- Motivation provides people with the understanding of the reasons for the change that increases their acceptability, which in turn improves their ability to accomplish a successful transition.
- Maintaining and enhancing people’s motivation during transition can be a driving force for people to wholeheartedly and positively participate.
- Successful and effective leaders are able to adapt their leadership style to best fit the requirements of the situation.
- The greater the opinion leadership among group members, the greater the chance of a successful transition and adoption.
- The more positively people perceive the new process with regard to its characteristics—advantages, observability, compatibility, complexity, and trialability—the more likely that the process will be adopted and effectively used.
- Management of expectations of the new process and conflict resolution can lead to a good working environment that can positively impact the change process.
- When individuals share the same values and beliefs with the organization, they are more likely to effectively participate towards the change.
- When people share the vision and beliefs with their organization, they feel that they share the ownerships and the accountability of the whole change practice and thus their new OO process.
- The sharing of ideas and commitments through cooperation and harmony within an organization often leads to an effective change and positive participation.
- The more individuals find values in the organizational change, the more likely they are to contribute to the transition success.
- The more congruent and rewarding the individuals perceive the organization’s values, the more positive is the influence on the transition and the adoption.

Product Customization on the Web:
An Empirical Study of Factors Impacting Choiceboard User Satisfaction

Pratyush Bharati
University of Massachusetts, Boston, USA

Abhijit Chaudhury
Bryant University, USA

ABSTRACT
Choiceboards are Web-based systems that allow consumers to customize their orders. The study investigated factors that affect consumers’ intention to use choiceboards. The research is based on Masons’ theory and DeLone and McLean’s model of information system use. It was found that intention to use is affected by overall satisfaction. In turn, these two factors are positively impacted by factors such as system quality and information quality. In spite of support from theory, the evidence for the factor, information presentation was weak.

INTRODUCTION
E-commerce is coming of age (Markillie, 2004). Sales in the year 2003 exceeded $55 billion, and revenues in 2004 are expected to be at least 20% higher (Syre, 2004). The total impact of e-commerce, however, cannot be expressed in simple sales figures; rather, it lies in changing consumer behavior. Increasingly, consumers visit the Web site of a company to familiarize themselves with the firm’s offerings and prices before deciding to buy. A Web site is becoming the gateway to a firm’s brand, even in the case of off-line firms. Companies that realize the importance of their Web sites use technologies such as e-mail, FAQ, online customer support, bulletin boards, and search
Product Customization on the Web

engines to assist customers in the buying decision process and, obviously, to persuade a purchase of their product.

The choiceboard is a recent addition to this repertoire of technologies, aiding consumers in the decision-making process (Andal-Ancion, Cartwright, & Yip, 2003; Bharati & Chaudhury, 2004a; Collins & Butler, 2003; Liecht, Ramaswamy, & Cohen, 2001; Slywotzky, 2000). A choiceboard is a system that allows customers to design their own products by choosing from a menu of attributes, components, prices, and delivery options (Slywotzky, 2000). For example, in the automobile industry (buyatoyota.com), users can “build” or customize a Toyota and then follow up with a local dealer. In the construction industry (kitchens.com), users can get help to design a kitchen and actually place an order. In the apparel industry (acustomtshirt4u.com), users can select color, fabric, and a suitable logo and lettering. In the entertainment industry (www.apple.com/itunes), customers at the itunes music store can build customized CDs by selecting individual tracks from existing CDs. Finally, in information technology, the Web sites of most computer firms (e.g., www.ibm.com) present individuals with a basic configuration defined by a processor and then flesh out the full configuration with choiceboards, offering hard-drive size, memory, and add-ons such as CD/DVD drive, monitors, and printers.

Although choiceboard technology is being used widely to enhance the customer’s experience, very little is known about the actual impact of this technology on overall user satisfaction or on the intention to use the choiceboard. Similar concerns have been expressed for Web-based decision support systems (Bharati & Chaudhury, 2004b). In particular, it remains unclear how the provision of more information, facilitation of decision making through what-if analysis, and choice comparisons through the use of choiceboard technology affects user satisfaction and the intention to use. In this research, the relationships are developed and operationalized between system-level factors (i.e., quality of the system and information in choiceboards and presentation of information) and user’s decision making and interface satisfaction. Furthermore, the analysis investigates the relationship between information and decision-making satisfaction, with overall satisfaction and intention to use. The statistical analysis consists of path analysis, assessing a pattern of predictive relationships among the measured variables. This research employs the Structural Equation Modeling (SEM) technique to analyze the data and then to assess the pattern of predictive relationships.

The research views information systems’ success in the new domain of e-commerce and, in particular, in the context of choiceboard systems. It attempts to understand how choiceboards facilitate user decision making in the Web-based environment. It then develops a conceptual model that relates system-level factors, user satisfaction factors, and use factors. Specifically, it investigates interrelationships between components of user satisfaction (i.e., interface satisfaction, decision satisfaction, and overall satisfaction) and their combined impact on intention to use.

LITERATURE REVIEW

The research is related to multiple theories such as the consumer decision-making model (Mowen, 1995), consumer information processing model (Bettman, 1979), cognitive decision-making model (Simon, 1955), and information systems (IS) success model (Delone & McLean 1992, 2002). According to Mowen (1995), a consumer transits through several phases, such as problem recognition, a search for alternatives, and an evaluation of alternatives, before making a choice; that is, there is an information-processing phase and then a decision-making phase. In this process, a consumer tries to minimize the cognitive effort required to make a decision and yet maximize
the quality of the decision reached (Bettman, 1990). Furthermore, Bettman (1990) suggests that because of bounded rationality constraint (Simon, 1955), consumers actually will trade off decision quality for a reduction in information processing effort.

Consumers employ decision aids such as calculators, spreadsheets, consumer guides, and Web-based comparison pricing in order to lessen the impact of bounded rationality constraints on decision quality. E-commerce retailers are incorporating choiceboards on their Web sites in order to assist customers in several phases of the decision-making process (Bharati & Chaudhury, 2004a, 2004b). The information search phase, for example, is facilitated by easy revelation of product alternatives, and the decision-making phase of alternatives evaluation is made easier by price and feature comparison. The IS success model (Delone & McLean 1992), with its focus on issues relating to information processing and decision making and its previous research on Web-based DSS (Bharati & Chaudhury, 2004b), is useful in investigating the role of choiceboards in assisting users. In the recent literature, this model has served as the basis for investigating similar research areas such as IS and service quality (Bharati & Berg, 2003). The research on quality of information systems services (Jiang et al., 2000, 2002; Kettinger & Lee, 1997, 1999; Pitt et al., 1995, 1997; Van Dyke et al., 1997, 1999; Watson et al., 1998) and WebQual (Loiacono et al., 2002) also has attempted to investigate this topic in a slightly different way.

Communications theory (Shannon & Weaver, 1949) was illustrated and modified in Mason’s (1978) work to show that classes of information output are at the technical level, semantic level, and influence level. The IS success model (Delone & McLean, 1992, 2002) expanded the concept of levels of output in order to illustrate stages within those levels. Information is communicated to a recipient who either is influenced or not; he or she then impacts organizational performance.

In other words, the information flows from its production to influence the individual and then the organization.

System quality and information quality both singularly and jointly impact use and user satisfaction. This research model is based on the IS success model and employs some of the constructs of that model, specifically at the technical level of system quality and information quality, in the context of choiceboards, and in their impact on different components of user satisfaction (interface satisfaction, decision-making satisfaction, and resultant overall satisfaction). User satisfaction then influences the intention to use. The next section explains the research model and hypotheses.

**RESEARCH MODEL AND HYPOTHESES**

The research model (Figure 1) shows that system and information quality and information presentation impact the different components of user satisfaction and then intention to use. The various constructs and the resulting hypotheses of the model are explained in this section.

**System Quality**

System quality is the individual perception of a system’s overall performance, which is itself a manifestation of system hardware and software. Ease of use (Belardo, Karwan, & Wallace, 1982), convenience of access (Bailey & Pearson, 1983), and system reliability and flexibility (Srinivasan, 1985) are measures employed for the service quality construct.

**Information Quality**

The user estimates the value of an information system after evaluating the quality of information it provides (Gallagher, 1974). Information accuracy (Bailey & Pearson, 1983; Mahmood,
Figure 1. Model with results

1987; Miller & Doyle, 1987; Srinivasan, 1985), completeness (Bailey & Pearson, 1983; Miller & Doyle, 1987), relevance (Bailey & Pearson, 1983; King & Epstein, 1983; Miller & Doyle, 1987; Srinivasan, 1985), content needs (Doll & Torkzadeh, 1988), and timeliness (Bailey & Pearson, 1983; King & Epstein, 1983; Mahmood, 1987; Miller & Doyle, 1987; Srinivasan, 1985) are the measures employed in the information quality construct.

**Information Presentation**

In information presentation, the display of information based on formats, colors, and graphs vs. tables is examined (Vessey, 1994). The interface evaluation has included presentation, format, and processing efficiency characteristics of the interface (Swanson, 1985-1986). The measures used for information presentation construct are graphics, color, presentation style, and navigational efficiency (Swanson, 1985-1986).
Interface Satisfaction

The quality of the information system interface is measured in interface satisfaction. The indicators used to measure interface satisfaction construct are easy to work (Doll & Torkzadeh, 1988; Goodhue, 1990), useful format (Doll & Torkzadeh, 1988; Goodhue, 1990), user friendly (Doll & Torkzadeh, 1988; Goodhue, 1990), does what I want it to do (Davis, 1989; Goodhue, 1990), and clear and understandable (Davis, 1989; Goodhue, 1990).

Hypothesis 1: System quality will contribute positively to interface satisfaction.

Hypothesis 3: Information quality will contribute positively to interface satisfaction.

Hypothesis 5: Good information presentation will contribute positively to interface satisfaction.

Decision-Making Satisfaction

Decision-making satisfaction is the system’s ability to support the user’s decision-making and problem-solving activities. The system’s support to the individual in recognizing problems, structuring problems, and making decisions related to the goal of controlling a business process are part of the construct (Garrity & Sanders, 1998). The construct measures the decision-making satisfaction using decision effectiveness (Chervany, Dickson, & Kozar, 1972) and decision confidence (Goslar, Green, & Hughes, 1986; Guental, Surprenant, & Bubeck, 1984; Zmud, Blocher, & Moffie, 1983).

Hypothesis 2: System quality will contribute positively to decision-making satisfaction.

Hypothesis 4: Information quality will contribute positively to decision-making satisfaction.

Hypothesis 6: Good information presentation will contribute positively to decision-making satisfaction.

Overall Satisfaction

Satisfaction is an important and widely used construct in the IS literature. Numerous researchers have modified the Bailey and Pearson (1983) user satisfaction instrument. The construct of overall satisfaction, a result of interface and decision-making satisfaction, was measured using extremely useful system (Sanders, 1984) and satisfactory in meeting user needs (Alavi & Henderson, 1981; Sanders & Courtney, 1985).

Hypothesis 7: Interface satisfaction will contribute positively to overall satisfaction.

Hypothesis 8: Decision-making satisfaction will contribute positively to overall satisfaction.

Intention to Use

Intention to use a system often has been employed as an important measure of IS success (Chang & Cheung, 2001; DeLone & McLean, 1992; Lucas, 1978; Van der Heijden, 2004; Welke & Konsynski, 1980). Possible to use and intend to use (DeSanctis, 1982) have been employed to measure the intention of the user to use the system construct.

Hypothesis 9: Overall satisfaction will contribute positively to intention to use.

RESEARCH METHODOLOGY

The instrument was constructed based on prior research, and most indicator items were adapted or borrowed from previously validated instruments. The survey was first pretested with a smaller sample and then subsequently refined.
Product Customization on the Web

The survey was administered to subjects who were undergraduate and graduate students at two universities. They were selected as subjects, because they were users of or familiar with choiceboard systems. The experiment was conducted in a laboratory setting with PCs running on the Windows operating system. In conducting the experiment, the researchers adopted the following procedure.

First, the experimental procedure was explained to the subjects. Then, each subject was randomly assigned a Web site that employed a choiceboard that allowed the user to configure a product. The choiceboard sites were of a very similar nature, despite being owned by different firms. After configuring a product on the Web site, each subject completed a survey questionnaire. The total sample for the experiment was 192 subjects.

Structural equation modeling (SEM) was used to analyze the data. SEM subscribes to a causal indicator model with the operational indicators reflective of the unobserved theoretical construct. It allows the specification of measurement errors within a broader context of assessing measurement properties. Confirmatory factor analysis, content validity, unidimensionality analysis, reliability analysis, convergent validity, and criterion-related validity tests were conducted to evaluate the model and constructs (Anderson & Gerbing, 1988; Bollen, 1989; Chin, 1998).

DATA ANALYSIS

Confirmatory Factor Analysis

The measurement properties of the survey instrument were assessed with confirmatory factor analysis. A measurement model comprised of a weighted linear combination of the items in the scale was analyzed. In confirmatory factor analysis, each theoretical construct is specified and analyzed to assess the fit of the data with the measurement model (Ahire, Golhar, & Waller, 1996; Ravichandran & Rai, 1999; Venkatraman, 1989). For constructs with four or more indicators, these guidelines were followed. As some constructs have fewer than three indicators, these constructs were pooled with constructs having four or more indicators. This was done to ensure adequate degrees of freedom for estimation of the model.

Content Validity

Content validity is ensured when the constructs are defined using the literature. The construct should adequately represent and measure the domain of meaning that it is supposed to represent (Bohrnstedt, 1983). If all the items grouped together for each construct reflect the underlying meaning, then content validity exists (Dunn, Seaker, & Waller, 1994). Since there is no rigorous way to assess content validity, in order to ensure thoroughness, multiple items were used to measure the construct (Bohrnstedt, 1983; Churchill, 1979). The instrument employed in the research used several indicators for each construct that were derived from an in-depth literature review, and thus, content validity was ensured (Bohrnstedt, 1983).

Unidimensionality Analysis

A multidimensional construct helps with content validity and is acceptable as long as the scales are unidimensional. A scale has to be unidimensional in order to have both reliability and construct validity (Gerbing & Anderson, 1988). The condition for a unidimensional scale is that the items of a scale estimate one factor. The goodness of fit index (GFI) measures a good fit of the measurement model, as it indicates that all items load significantly on one underlying latent variable. There is no evidence of lack of unidimensionality when GFI is 0.90 or higher for the model. The GFI indices for all the scales are
summarized in Table 1, and the results suggest that all the scales are unidimensional.

**Reliability**

Reliability of a scale is ensured, if the scale is dependable, consistent, or stable (Gatewood & Field, 1990). Cronbach’s alpha coefficient was used to measure reliability, as the items of a scale explain the majority of the variation in the construct vis-à-vis measurement error (Cronbach, 1951). The results indicate that the scale is reliable, because the alpha coefficient is greater than 0.70 (Table 1).

**Convergent Validity**

Considering each item in the scale as a different approach to measure the construct usually assesses convergent validity. This was measured using the Bentler-Bonett coefficient ($\Delta$)(Bentler & Bonett, 1980). The Bentler-Bonett coefficient ($\Delta$) value of 0.9 or above means high convergent validity. All the scales had a Bentler-Bonett coefficient ($\Delta$) of greater than 0.9 (Table 1).

**Criterion-Related Validity**

Criterion-related validity tests the degree to which the outcome is predicted by the constructs.
Product Customization on the Web

Using SEM, the constructs are correlated with outcome constructs. As the correlation of the various constructs are positive and statistically significant (Table 2), criterion-related validity exists for these constructs.

SEM produces parameter estimates of links between the latent variables and so is also called latent variable analysis, or causal modeling. AMOS 4.0 and SPSS 10.1 (Arbuckle & Wothke, 1999) were employed for the SEM analysis.

### RESULTS AND DISCUSSION

In summary, this research examined the impact of systems’ quality, information quality, and information presentation on user satisfaction and intention to use in the context of choiceboard systems. The IS success model was used as the basis of the research model. The model was based on Shannon and Weaver’s (1949) communication theory, Mason’s (1978) theory, and the Delone and McLean (1992) model. The research model employed the constructs at the technical level (i.e., systems’ quality and information quality) in the context of choiceboards and finally its impact on different components of user satisfaction such as interface satisfaction, decision-making satisfaction, and resultant overall satisfaction. The path coefficients calculated for the estimated model support the hypothesized relationships in both direction and magnitude with few exceptions. Overall, the statistical conclusions support the research model (Figure 1).

System quality is directly and positively correlated to interface satisfaction (H-1); so, an increase in the quality of the system leads to an increase in satisfaction in using the interface. Information quality is directly and positively correlated to interface satisfaction (H-3); so, an increase in the quality of the information leads to an increase in satisfaction in using the interface. Information presentation is not directly and positively correlated to interface satisfaction; (H-5); therefore, this hypothesis is not validated.

The path coefficients calculated for the estimated model also support the hypothesized relationships in both direction and magnitude in the case of decision-making satisfaction. Most

of the hypotheses in the area of decision-making satisfaction have been validated using the data. System quality is directly and positively correlated to decision-making satisfaction (H-2); so, an increase in the quality of the system leads to an increase in decision-making satisfaction. Information quality is directly and positively correlated to decision-making satisfaction (H-3); so, an increase in the quality of the information leads to an increase in decision making. Presentation is not directly and positively correlated to decision-making satisfaction (H-6), as this hypothesis is not validated.

System quality includes system ease of use, convenience of access, and system reliability. Thus, a net positive effect from these factors will result in a positive effect on interface satisfaction and decision-making satisfaction. In choiceboards, as in other systems, the ease of use of the system, convenience of access, and system reliability are important considerations for the user. Information relevance, accuracy, completeness, and timeliness constitute the construct information quality. Thus, a net positive effect from these factors will result in a positive effect on decision-making quality. Choiceboard systems should provide relevant, accurate, complete, and timely information for better decision-making satisfaction.

Graphics, color, presentation style, and navigational efficiency measures information presentation. Therefore, information presentation measures how information is displayed. It was hypothesized that a net positive effect from graphics, color, presentation style, and navigational efficiency would result in a positive effect on interface satisfaction and decision-making satisfaction. The data did not support this hypothesis.

The statistical conclusions support the hypotheses on user satisfaction. Interface satisfaction is directly and positively correlated to overall satisfaction (H-7); so, an increase in interface satisfaction leads to an increase in overall satisfaction. Similarly, decision-making satisfaction is directly and positively correlated to overall satisfaction (H-8); so, an increase in decision-making satisfaction leads to an increase in overall satisfaction. Overall satisfaction also is found to be directly and positively correlated to intention to use (H-9); so, an increase in overall satisfaction leads to an increase in intention to use. The results from the research model also demonstrate the relative weight of system quality compared to information quality. Interestingly, decision-making satisfaction of end users, the quality of the system, is more important than the quality of the information.

As with all regression and structural equation modeling techniques, correlation does not prove the causality of the relation. However, since these causal relationships are based on an established literature, and since the theoretical grounding of the causality is adequate, it is reasonable to concur with the causality, where it has been validated (Gefen, Straub, & Boudreau, 2000).

MANAGERIAL IMPLICATIONS AND FUTURE RESEARCH

The research results empirically demonstrate the relationships between interface satisfaction, decision-making satisfaction, system quality, information quality, and information presentation. It also demonstrates the relationships among variables such as interface satisfaction, decision-making satisfaction, overall satisfaction, and the intention to use. These relationships are useful in influencing the intention to use among users of choiceboard systems. IS professionals need to understand these relationships to help their firms design choiceboard systems that are effective. This research provides an understanding of those interrelationships.

In the context of choiceboards, the quality of information influences decision-making satisfaction. For example, for a choiceboard system that allows users to develop their own holiday itinerary, the research suggests that users would value
Product Customization on the Web

complete, accurate, and relevant information about holiday sites, weather, local costs, flights, rentals, and hotels. Similarly, users will have better decision-making satisfaction with timely, accurate, and complete information as they develop alternative scenarios for their holidays.

The research suggests that ease of use, convenience of access, and system reliability also influence the decision-making satisfaction of users. A choiceboard, other than just being available and accessible, also should be easy to use. A user should not feel overwhelmed by available choices. The research also suggests that ease of use, convenience of access, and system reliability and flexibility influence interface satisfaction. The quality of the choiceboard system makes an impact if it is user-friendly, clear, and understandable. Interface and decision-making satisfaction influences if the choiceboard has been satisfactory in meeting user needs, which affects intention to use. For choiceboard users, it is not only important that the quality of the choiceboard system and the information it provides be adequate, but also that it provides them with interface and decision-making satisfaction. Thus, they will intend to use the choiceboard if they find it useful and if it meets their needs. This research shows that choiceboard users are deriving satisfaction with the system in a more complex fashion. If the choiceboard provides interface as well as decision-making satisfaction such that there is overall satisfaction, only then will they be a repeat user.

The empirical data suggest that the presentation of information is not important to the user in decision making. Users are not particularly impressed by color, graphics, and presentation style; they are more interested in the pertinent information being provided to them via the system. This is an interesting result, because in the recent past, there has been an increase in color and graphics on Web sites; but this presentation is of limited use if these Web sites are not able to provide the desired quality of information.

This research has examined the perceptions of users relative to their intention to use and how that perception is affected by overall satisfaction, which, in turn, depends on decision-making satisfaction and interface satisfaction. Much of the model has been validated by the data. Even the hypotheses that were not validated provide interesting insights. Studies should be conducted using other Web-based systems to test if the results of the present study can be extended to other situations. Qualitative studies also can be conducted to study choiceboard systems. These studies have the possibility of providing insight about choiceboard system users. These studies will help to build a wider body of research, which is needed for designing effective choiceboard systems.

ABSTRACT

This research examines the impact of computer-mediated communication, distributed communication, and knowledge of prior baseline behavior on an individual’s propensity to make veracity judgments. This study found that more detection confidence can come from knowledge of a person’s prior baseline behavior, being proximally located, the type of communication media used, and perceived relational closeness. These factors indirectly lead to less deception detection through more detection confidence and reliance on the truth bias, a fundamental belief in the truthfulness of others, even in a computer-mediated environment.

INTRODUCTION

Today’s firms are relying more on non-traditional communication media such as e-mail, voicemail, and virtual meetings (Burke and Chidambaram, 1999; Guicking, Tandler and Grasse, 2008; Hoffman and Novak, 1996). In a globalized work environment, these types of communication media are important to quality decision-making (Fjermestad, 2005). However, a question arises...
as to whether the use of these communication media, together with distributed information sources, may mitigate an individual’s ability to detect deception. Deception is a regular part of daily communicative interaction (DePaulo and Kashy, 1998), accounting for 26-33% of daily social interactions (DePaulo, Kashy, Kirkendol, Wyer and Epstein, 1996; Hancock, Thom-Santelli and Ritchie, 2004). As computer-mediated communication use continues to spread, the ability to detect deception using lean communication media will be increasingly important in the workplace.

Research in the area of deception detection over distributed media has not been widespread. While individual research streams such as media richness, computer-mediated communication, and deception detection have extensive bodies of literature, the intersection of these streams has scarcely been examined (George and Marett, 2005). For example, deception detection research has focused on techniques such as training to recognize deceptive cues (Feeley and Young, 1998; Ekman and O’Sullivan, 1991), and suspicion arousal (Stiff and Miller, 1986) to increase face-to-face deception detection rates. Face-to-face deceptive cues such as greater pupil dilation, more blinking, decreased response length, more speech errors and hesitations, greater voice pitch, more negative statements, and more irrelevant information (Feeley and Young, 1998) are of limited applicability to deception detection in computer-mediated or distributed environments.

Similarly, the ability to detect deception between communication partners is widely believed to be related to the type of personal relationship that exists between them (Feeley and Young, 1998). Past research in the area of deception detection has mainly focused on individuals who are either strangers or intimate partners (Anderson, Ansfield, and DePaulo, 1997). However, working relationships typified by high levels of familiarity but low levels of intimacy, have been largely ignored. The relationship between partners impacts deception detection rates because of a fundamental assumption that their partner is being truthful. This fundamental assumption of truthfulness is often referred to as the truth bias (McCornack and Parks, 1986).

The purpose of this study is to investigate the effects of differing contextual factors on deception detection confidence and the relationship between confidence and truth bias. More specifically, this study will contribute to existing IS literature by examining the effects of working relationships, computer-mediated communication, and distributed environments within the context of deception detection. The next section of the paper presents the theoretical background for the study, including a research model and hypotheses. This is followed by a discussion of the research method, findings, and implications for research and practice.

THEORETICAL BACKGROUND

Research surrounding deception detection has focused on detection skills of observers (Brandt, Miller, and Hocking, 1982), conversational task demands (Burgoon and Newton, 1991), honesty judgments (Fiedler and Walka, 1993), the influence of relational closeness (Anderson et al., 1997), environmental influence (Storms, 1973), observer ability to detect deception (Buller, Strzyzewski, and Hunsaker, 1991), and the impact of suspicion on detection accuracy (Buller, Strzyzewski, and Comstock, 1991). Findings have shown that individuals have significant difficulty discerning truth from deception. Deception detection rates have been shown to range from 55% to 60% (Feeley and Young, 1998). However, other studies have found that deception detection rates may be as low as 35-40%, while truth detection rates have ranged from 70-80% (Levine, McCornack, and Park, 1998). It is important to note that deception detection and truth detection, correctly identifying lies as lies and truths as truths respectively, vary in overall task difficulty.
Deception Models

In order to identify the factors influencing differences in deception detection, several theoretical models were developed and later empirically tested. McCornack and Parks (1986) developed an important theoretical model looking at the antecedents of the truth bias. Specifically, they looked at the impact of relational closeness on deception detection. They found that as relationships develop and people become closer, they tend to be more confident of their ability to detect truths/lies. This increased confidence causes participants to subsequently rely more on their basic assumption of truthfulness (i.e., the truth bias).

The model, shown in Figure 1, has received additional support in a recent meta-analysis indicating a strong linkage between relational closeness and detection confidence (DePaulo, Charlton, Cooper, Lindsay, and Muhlenbruck, 1997). As detection confidence increases, individuals will reduce the amount of effort they put forth in detecting deceptive behavior by relying increasingly on truth bias and reducing detection accuracy. Some scholars have operationalized truth bias as the percentage of truthful judgments during lie detection; others as the number of truthful judgments (McCornack and Parks, 1986); and yet others have operationalized it using self-report measures (Stiff, Kim, and Ramesh, 1992).

Stiff, et al. (1992) similarly showed that there is a significant relationship between relational development and truth bias. They note that there is substantial support for the claim that more developed relationships, typified by intimacy, reduced uncertainty, satisfaction, and commitment, and tend to be much more subject to truth bias. They also note that participants in those relationships are only marginally less able to detect deception. In turn, participants who rely more on the truth bias in making veracity judgments also tend to view their partner’s statements as truthful. Stiff, et al. (1992) found that aroused suspicion had significant negative correlations with both truth bias and judgments of truthfulness. However, the study procedures used to induce heightened suspicion may produce findings that are only generalizable to situations where individuals already anticipate deception (Miller and Stiff, 1993). In sum, both theoretical models suggest that an increase in relational closeness will increase the level of truth bias and reduce deception detection.

**RESEARCH MODEL**

The research model shown in Figure 2 depicts the new constructs and relationships tested in this study. The model hypothesizes associations from baseline knowledge, detection confidence, and truth bias to deception detection. The model extends the work of McCornack and Parks (1986).
with constructs for baseline knowledge, media richness, and proximity. Unlike prior studies, the research model presented distinguishes baseline knowledge from relational closeness in order to separately test the influences of relational intimacy and knowledge of prior baseline behavior on detection confidence. Prior research has also focused on deception detection within nominal groups. This study adds to existing theory by examining the impact of computer-mediation and distributed communication on deception detection. These new constructs will allow us to investigate the impact of new methods of communication on deception detection.

In deception detection research, it is important to note the distinction between deception detection and detection accuracy. Deception detection refers to the correct identification of a deceptive statement, while detection accuracy refers to the correct identification of a truthful statement, a deceptive statement, or both. In order to distinguish deception detection from a broader definition of detection accuracy, this study measures deception detection, truth detection, successful deception, and false accusations separately. Figure 2 shows the decomposition of the construct detection accuracy into four separate dependent variables. Decomposing detection accuracy into four separate variables provides a more rigorous methodology and greater clarity when interpreting outcomes.

**Relational Closeness and Baseline Behavior**

As previously mentioned, baseline behavior is a key factor in predicting deception detection. In order for an individual to recognize deviations from nominal or truthful behavior he or she must first acquire a “baseline” of truthful behavior. This baseline knowledge is important because an individual may naturally exhibit cues typically associated with deceptive behavior (Brandt, et al., 1982). Feeley and Young (1998) note that the majority of deception detection studies are based on the premise that there is a set of identifiable cues that are specifically related to deceptive behavior. However, other researchers argue that identifying changes in individual-specific behaviors during deception greatly reduces the possibility of misinterpretation (Anderson, et al., 1997; Walters, 2000). Brandt, Miller, and Hocking (1980) found that observers with truthful baseline knowledge were three times as accurate in detecting deceptive behavior as individuals without truthful baseline knowledge. Similar studies have shown that observers with a small amount of baseline knowledge had better detection rates (72%) than observers without baseline knowledge (56%) (Feeley, deTurck, and Young, 1995). The fact that many previous studies have used zero-history dyads may well explain the low detection rates. Constructs such as suspicion (Stiff and Miller, 1986), anonymity (Kahai and Avolio, 2006), and trust (McKnight, Cummings, and Chervany, 1998) have also been shown to influence group interactions. However, the addition of these constructs to the research model is beyond the scope of this paper.

While baseline knowledge is vital in making veracity judgments, more relational closeness, which often comes in obtaining baseline knowledge, can severely mitigate any advantage. Miller and Stiff (1993) demonstrated that individuals in intimate relationships may not want to view their partners as deceptive due to emotional attachments. In fact, studies have shown that relational intimacy is unrelated to detection accuracy (Comadena, 1982). McCornack and Parks (1986) examined the relationship between relational closeness, truth bias, and detection confidence and found that increased relational closeness decreases the ability to detect deceptive behaviors. This leads to the conclusion that, while knowing truthful baseline behaviors and cues are essential to deception detection, relational closeness is detrimental to veracity judgments and significantly increases an individual’s level of truth bias.
Knowledge of the other person’s baseline behavior is predicted to have a positive influence on detection confidence and detection accuracy. In other words, as individuals become more able to “read” their communication partner, their ability to detect deceptive behavior will increase. Detection accuracy can be broken down into deception detection accuracy and truth detection accuracy. Knowledge of baseline behavior is predicted to have a positive influence on truth detection and deception detection. Individuals will be able to detect truthful cues, deceptive cues, and deviations from nominal behavior. With regards to social interaction, the model predicts that optimal deception detection is obtained by minimizing relational closeness, not being proximally located, and maximizing the amount of baseline behavior knowledge. By minimizing intimacy and maintaining familiarity in a relationship, an individual should theoretically be able to detect deception. Thus, the following hypotheses are put forth:

**Hypothesis 1:** Knowledge of baseline behaviors will be positively associated with deception detection.

**Hypothesis 2:** Knowledge of baseline behaviors will be positively associated with detection confidence.

**Hypothesis 3:** Relational closeness will be positively associated with detection confidence.

**Communication Media**

As previously noted, media richness theory (MRT) suggests that as media become richer, the amount of information cues conveyed increases (Daft and Lengel, 1986). Within the context of truth bias and deception detection, the ability to detect information cues is critical in evaluating the truthfulness of a message (Zuckerman and Driver, 1985). Information cues can consist of verbal, visual, paralingual, and textual cues (Williams, 1977; Zuckerman, DePaulo, and Rosenthal, 1981). Cues provide receivers with the evidence necessary to make veracity judgments. It has been shown that individuals assume a person is telling the truth until additional cues indicate otherwise (McCornack and Parks, 1986). For this study, deception will be defined as a message knowingly transmitted by a sender to foster a false belief or conclusion by the receiver (Knapp and Comadena, 1979).

Zuckerman and Driver’s (1985) meta-analysis of 24 possible deceptive behaviors yielded 14 specific behaviors that were related to deception. An analysis by Feeley and Young (1998) shows that eight cues are significantly correlated with deception: greater pupil dilation, more blinking, decreased response length, more speech errors and hesitations, greater voice pitch, more negative statements, and more irrelevant information. Recent studies have explored the ability to detect deception using linguistic based cues (Zhou, Burgoon, Nunamaker, and Twitchell, 2004).

The ability for decision makers to make correct veracity judgments may be dependent on the quantity, quality, and variety of information cues (McCornack, 1997). The quantity, quality, and variety of information cues is dependent upon the type of media used. Media selection may be, as suggested by Media Richness Theory, dictated by the need to make veracity judgments. Media Richness Theory (MRT) (Daft and Lengel, 1986) has been used to explain the effects and choice of communication media in a variety of tasks such as planning, creativity, intellectual tasks, decision making, and brainstorming (Hollingshead, McGrath, and O’Connor, 1993). Prior research has also shown that partners with a history of working together communicate differently across varying types of media (Yoo and Alavi, 2001; Carlson and Zmud, 1999). Media richness can be defined as the ability of information to change understanding within a given time interval (Daft and Lengel, 1986; Dennis and Kinney, 1998). Depending on the degree of equivocality and task uncertainty,
an individual will choose a richer medium in order to provide better feedback, draw upon a wider variety of cues, use a variety of language, and convey a more personally focused message (Daft, Lengel, and Trevino, 1987). With respect to the current study, the focus is not on what type of media is best for deception detection, but rather, how different levels of media richness affect an individual’s ability to make veracity judgments and mitigate the truth bias.

Communication media, or the richness of the communication media, is predicted to have a positive influence on detection confidence, and detection accuracy. Increased media richness increases the number of information cues individuals can use to make veracity judgments. More cues should lead to higher levels of confidence in deception detection because of reduced equivocality. Thus, the following hypotheses will be tested in this study:

**Hypothesis 4:** The richness of the communication medium will be positively associated with deception detection.

**Hypothesis 5:** The richness of the communication medium will be positively associated with detection confidence.

**Proximity**

Social facilitation, as conceptualized by Zajone (1965), focuses on changes in behavior due to the physical presence of others. In a review of 287 studies examining the effects of social facilitation, Guerin (1986) notes that the presence of another person may cause behavioral changes in four ways. First, the physical presence of another individual may cause more apprehension due to the expectation that he or she will be evaluated. Second, the physical presence of someone else may cause “cognitive or physical conflict” between task focus and having to attend to the other person. Third, the presence of another person may enhance task performance in order to make a good impression on the other person. Fourth, another’s physical presence may cause an increase in “conforming to public and private norms” because of greater self-focus and comparison of behavioral standards (Guerin, 1986).

Distributed communication has been shown to have a significant impact on the final outcome of a process, communication act itself (Rice, 1984), and the effort an individual puts into maintaining social networks (Miranda and Carter, 2005). Research has also shown that distributed teams can experience escalation in conflict (Armstrong and Cole, 1995) and the formation of hostile coalitions (Cramton, 2001). Whitty (2002) showed that there was a propensity for anti-social behaviors in chat rooms where individuals were relatively new. However, more intimate relationships did develop over time. Despite the significant effects of presence on behavior, the influence of proximity and computer mediation has typically been difficult to separate due to methodological inconsistencies (Hedlund, Ilgen, and Hollenbeck, 1998).

In sum, distributed communication decreases the level of social influence, thereby changing individual behavior and expectations. The presence of another person encourages an individual to conform to social norms and to restrain from engaging in anti-social behaviors (Berger, Hampton, Carli, Grandmaison, Sadow, and Donath, 1981). Proximally located subjects may be more confident of their ability to detect deception due to their belief that their communication partner is more likely to conform to social norms (i.e., be truthful).

The proximal influence of another person has not only been shown to cause a change in behavior, but also a change in the level of cognitive effort put forth (Geen and Gange, 1977; Zajonc, 1965). Individuals will put forth more effort toward task performance in the presence of others. Subjects may put forth more effort in detecting deception when proximally located to their communication partner. As a result, subjects may be more
confident in their ability to detect a deceptive decision. In this study it is predicted that physical proximity will influence individuals to be more confident in detecting deception. Therefore, the following hypothesis is put forth:

**Hypothesis 6:** Proximally located subjects will have higher detection confidence than subjects that are distributed.

**Truth Bias and Deception Detection**

Truth bias is the inherent belief that people are telling the truth (Stiff, Kim, and Ramesh, 1992). While this fundamental assumption of truthfulness simplifies decision making by reducing the quantity and quality of veracity judgments, it may also inhibit deception detection. Research on truth bias has been aimed at trying to reduce an individual’s reliance on this fundamental assumption of truthfulness. Studies have explored reduction techniques such as training (Ekman and O’Sullivan, 1991) and suspicion arousal (Stiff and Miller, 1986). In these studies, subjects were trained to recognize cues (e.g., eye twitching, specific words) thought to be specifically associated with deception, or were told that their communication partner may be lying. Efforts have also been made to reduce truth bias by lowering the level of cognitive demand through passively observing dialogue (Buller, et al., 1991). This was accomplished by allowing subjects to watch video recordings or read the dialogue between two other subjects. In general, research has focused on enabling individuals to better detect deception.

As hypothesized and reported by McCornack and Parks (1986), the level of confidence an individual has in his or her assessment of truthfulness should positively affect his or her reliance on the truth bias as a simplifying heuristic. In turn, greater dependence on the truth bias should negatively affect his or her ability to detect deception and lead to fewer false accusations due to the general belief that his or her communication partner is telling the truth. Conversely, the truth bias should have a positive affect on an individual’s ability to detect truthful statements and the individual’s susceptibility to being successfully deceived. The authors argue that as individuals become more certain of their evaluation, they devote fewer cognitive resources toward determining truthfulness. Subsequently, they will rely more on cognitive heuristics to make veracity judgments and, therefore, will be less able to distinguish between truthful and deceptive statements. Thus:

**Hypothesis 7:** Detection confidence will be positively associated with truth bias.

**Hypothesis 8:** Truth bias will be negatively associated with deception detection.

**Hypothesis 9:** Truth bias will be positively associated with truth detection.

**Hypothesis 10:** Truth bias will be positively associated with successful deception.

**Hypothesis 11:** Truth bias will be negatively associated with false accusation.

**METHOD**

This study utilized a controlled laboratory experiment employing a 2x2x2 factorial design (computer-mediated/non-computer-mediated, proximal/distributed, familiar/unfamiliar with communication partner). A total of 97 dyads were randomly assigned to one of eight possible treatment conditions (N=194). Dyads comprised of subjects familiar with each other were recruited from groups in the preceding semester taught by the first author. Proximal dyads completed the task in the same room, while distributed dyads completed the task in separate rooms (even though the rooms were adjacent to each other, subjects
could not see each other or communicate directly). Computer-mediated dyads exchanged messages using the Microsoft NetMeeting® chat software. Non-computer-mediated groups communicated using either face-to-face or cellular telephone.

**Task**

The prisoner’s dilemma task, developed by Albert Tucker (c.f., Axelrod, 1984), was chosen because of its characteristics in studying deception detection. The classic version of the prisoner’s dilemma task does not allow for communication between subjects. However, this study used a derivative of the prisoner’s dilemma task that allowed for real-time interpersonal interactions where subjects were motivated to deceive and detect deception. Anticipation of deception was not heightened by the researchers, nor was deception sanctioned in the experiment. Scoring allowed for measurement of deception, deception detection, and truth bias. Matching of participants with prior experience allowed individuals to use their prior knowledge to detect deception. Lastly, playing the prisoner’s dilemma game does not raise any serious ethical or human subjects concerns.

In the classical prisoner’s dilemma game, there are two players. Players can choose to either “defect” or “collude.” Each player makes his or her decision without the knowledge of what the other person will do. Defection always yields a higher payoff than collusion. The dilemma is that if both players defect, they will loose more than if they had both colluded. In other words, the greatest positive and negative payoffs are achieved when one player defects and his or her partner colludes, respectively. Since both players are trying to obtain this optimal solution, it is in their best interests to convince each other that they are going to collude and then defect.

Within the context of the game subjects were given the options to either “confess” (defect) or “stay quiet” (collude). Possible decision outcomes have the following reward structure \( T > C > 0 > D > S \) (Dawes and Orbell, 1995). The “temptation” payoff \( T \) of +$5 was rewarded for unilateral defection of one player, while the other remains silent. The “cooperative” payoff \( C \) of +$1 was rewarded for joint cooperation between individuals (i.e., both remain silent). The “defect” payoff \( D \) of -$1 was rewarded for joint defection of both individuals (i.e., both confess). The (more negative) “sucker” payoff \( S \) of -$3 was rewarded for unilateral cooperation. Negative dollar payoffs were given for mutual defection, and even greater negative dollar payoffs for unilateral cooperation.

*Figure 3. Detection matrix*
Distributed Deception

Figure 3 shows how each combination of decisions form the final dependent variables in the purposed research model.

Consistent with prior research, participants were able to lose all of their money, or more than double the amount they possessed before the game began. Subjects were told that they were to be given $3 for participating in the experiment and would gain or lose money according to their decisions. Researchers paid each subject in cash a week after the conclusion of the experiment. Subjects were paid at a later time to avoid any possible reprisal from another subject due to defection during the experiment.

Measures

The constructs in the research model were operationalized as described below. Relational closeness was operationalized using a 14-item short form of the relational closeness inventory (RCI) 27-item measure from Berscheid, Snyder, and Omoto (1989) (Polimeni, Hardie, and Buzwell, 2002). These items assess the strength of the relationship and frequency of contact between conversational partners. Items are measured using seven-point Likert scales with higher scores indicating a higher level of relational closeness. The RCI scale has been shown to be highly consistent, with a coefficient alpha of .90 (short form Cronbach alpha = .87) (Polimeni, et al., 2002).

Baseline knowledge was operationalized by pre-assigning subjects to the baseline knowledge condition if they had worked together on a large group project for three months during the semester prior to the experiment. Subjects who had never met before were assigned to the no baseline knowledge condition. Subjects were coded 2 = baseline knowledge and 1 = no baseline knowledge depending on their respective experiment condition. To ensure that subjects were correctly identified as having sufficient baseline knowledge a manipulation check consisting of three previously validated measures (Cronbach alpha = .90) was implemented. These measures indicated a subject’s general knowledge about their communication partner, nature of their relationship, and length of time they have known each other (Berscheid, et al., 1989).

Proximity, an individual’s awareness that another person is proximally located, was indicated as a factor of the treatment condition. Proximal subjects were seated such that they faced each other at a distance of no greater than three feet, while subjects in the distributed condition were seated in separate rooms, and could not see or communicate visually or verbally with each other. Responses were coded 2 = proximal and 1 = distributed, depending on their respective condition.

Richness of the communication media was operationalized using eight seven-point items (Cronbach alpha = .85) (Daft and Lengel, 1986; Dennis and Kinney, 1998). In the CMC group, subjects communicated with their partner through a chat program. In the non-CMC group subjects communicated face-to-face or by cellular telephone.

Detection confidence was operationalized using a single item that asked subjects their level of confidence in predicting their communication partner’s choice (confess, stay quiet). This self-report measure ranged from 0 (not sure) to 100 (very sure) with a mean of 86.13 (S.E. = 18.512).

Truth bias was operationalized using four seven-point Likert measures of perceived truth bias (Stiff, Kim, and Ramesh, 1992). Truth bias was computed as an average with scores ranging from 1 to 7 and a mean of 5.6 (S.E. = 1.18).

The four constructs: truth detection, deception detection, successful deception, and false accusation, were calculated based on subjects’ decisions to either “stay quiet” or to “confess”. Deception detection was operationalized as a correct estimation of a communication partner’s choice to confess. Truth detection was operationalized as a correct estimation of a communication partner’s choice to stay quiet. Successful deception and false accusation were operationalized as incorrect
estimations of a communication partner’s choice to confess or stay quiet.

SAMPLE

Subjects (N=194) were juniors and seniors majoring in management information systems (MIS) at a large southeastern university in the U.S. Subjects’ mean age was 23.4 years (S.E.=4.3) with 58.8% of the subjects being male. To ensure that subjects were correctly identified as having prior baseline knowledge of their partner’s behavior, subjects were asked how long they had known their partner. Subjects in the baseline group indicated that they had known their partner for an average of 9.18 months (S.E.=8.5) and had a mean relational closeness measure of 1.72 (S.E.=0.094). Individuals in the no-baseline condition indicated that they had known their partner for an average of 0.85 months and had a mean relational closeness measure of 1.29 months (S.E.=0.074). The mean difference in the time subjects had known their partner in the baseline and no-baseline groups was statistically significant (F=13.172; p<0.001).

A manipulation check asking subjects if they could see their partner indicated that the proximal/distributed manipulation was successful and statistically significant (F=45.335; p<0.001). To address a possible concern of information leakage in proximal groups, subjects were asked if they were able to gain information from overhearing other conversations during the experiment. Responses across all conditions indicated that subjects were not able to gain information from other groups (Mean = 1.28; S.E. = 0.737).

ANALYSIS AND RESULTS

Scatter-plots and histograms indicated that some measures experienced minor departures from normality. The distribution of detection confidence scores was somewhat peaked (Kurtosis=2.06). The distribution for relational closeness was also peaked (Kurtosis=4.02) and somewhat skewed (Skewness=2.09). Despite minor departures from normality, the F statistics reported in this study were robust. Kirk (1995) notes that the F statistic remains robust when “populations are symmetrical, but not normal, and the sample sizes are equal or greater than 12.” (Kirk, 1995; Clinch and Keselman, 1982). Analysis of histograms across experiment conditions indicated that populations were homogeneous in form (positively skewed), and sample sizes were approximately equal. Therefore, minor departures from normality were not a threat to the validity of the statistical procedures used in this study.

Factor Analysis

Three of the seven constructs (relational closeness, truth bias, and communication media) were measured using multiple items to identify specific underlying latent constructs in the measurement model. The remaining independent, intermediate, and dependent variables were operationalized using single measures. Factor analysis was used to condense information gathered from multiple variables into a minimal number of factors representing the theoretically proposed latent constructs. The dimensionality of relational closeness (RC), truth bias (TB), and communication media (CM) were determined using principal components analysis (PCA) (Kaiser-Meyer-Olkin=0.796).

A series of initial unconstrained principal component analyses were done to determine the amount of variance explained by the latent factors. Initial analyses indicated that several items did not explain a significant amount of variance. Factors with loadings below .50 or cross-loadings above .30 were dropped (Hair, Anderson, Tatham, and Black, 1998). Factors having loadings of .50 or greater are considered practically significant and a factor will account for 50% of the variance if the factor loading exceeds .70 (Hair, et al., 1998). Based on these criteria, seven of the items
in the relational closeness factor and two items from the media richness factor were eliminated. All other constructs yielded acceptable statistics and, therefore, no other items were dropped. The follow-up factor analysis revealed that all factors had loadings of .70 or greater except for RC2 (.681) when using a constrained three-factor solution. There were no cross loadings greater than .25.

Table 2 shows the variance explained by each item and respective factor loadings. Varimax rotation was used throughout the factor analysis to give a better interpretation of the underlying factors by reducing the ambiguities that often accompany initial unrotated factor solutions (Hair, et al., 1998).

All factors exhibited reliabilities consistent with prior research scoring above .70. Constructs exhibited convergent and discriminant validity by having Cronbach’s alpha values greater than 0.70 (Nunnally, 1978) and by each indicator loading more highly on its associated construct than any other construct. Means, Standard Errors, Cronbach’s alphas and intercorrelations for all constructs can be seen in Table 3.
Distributed Deception

Research Model and Hypothesis

Results

Partial Least Squares (PLS) was used to test the research model because it accommodates limited sample sizes, a large number of constructs, and restrictions on measurement scales (Chin, Marcolin, and Newsted, 2003). PLS has also been shown to be robust when dealing with discrete single-indicator variables (Pavlou and Fygenson, 2006). While PLS is typically used in exploratory research, it can also be used in confirmatory research if sample size is an issue (Gefen, Straub, and Boudreau, 2000). Given the relatively small sample size used in this study, PLS is considered an appropriate modeling technique. Path coefficients and $R^2$ values for the purposed research model are shown in Figure 4.

Hypothesis 1 (H1) stated that knowledge of baseline behaviors will be positively associated with deception detection. Surprisingly, individuals with baseline knowledge about their partner had a significantly lower deception detection accuracy rate ($b=.063$, $t=2.06$, $p=0.020$) than those without. Overall, deception detection rates were 31.6% for baseline groups and 68.4% for groups with no baseline knowledge. A “hit” included successful detection of deceptive decisions. Thus,

| Relational Closeness (RC) | 1.50 | 0.860 | 0.86 |

Table 3. Intercorrelations and reliabilities
we reject H1. However, we did find a significant relationship in the opposite direction.

Hypothesis 2 (H2) stated that knowledge of baseline behaviors will be positively associated with detection confidence. Detection confidence was scored on a scale from 1 (very unconfident) to 100 (very confident). Subjects in the baseline condition (N=92) had a mean detection confidence level of 91.54 (S.E.=15.9), while subjects in the no baseline condition (N=102) had a mean detection confidence level of 81.31 (S.E.=19.2). Individuals with baseline knowledge were significantly more confident (b=.226, t=3.32, p<0.001) than those without baseline knowledge. Thus, there is evidence to support H2.

Hypothesis 3 (H3) stated that more relational closeness will be positively associated with detection confidence. Consistent with prior research, results confirmed that relational closeness had a positive relationship on detection confidence (b=.120, t=2.56, p=0.006). Therefore, there is sufficient evidence to support H3.

Hypothesis 4 (H4) stated that the richness of the communication medium will be positively associated with deception detection. Table 4 shows deception detection rates, attempts at deception, successful deception rates, and deception detection confidence rates. Subjects in the non-CMC condition did not have significantly higher detection accuracy rate than subjects in the CMC condition (b=0.00, t=0.685, p<0.247). Overall, deception detection rates were low for both manual (42.9%) and computer (47.6%) groups where subjects were deceived. Thus, we find that there is insufficient support for H4.

Hypothesis 5 (H5) stated that the richness of the communication medium will be positively associated with detection confidence. Subjects in the non-CMC condition communicated with their partner either face-to-face or by cellular telephone, while subjects in the CMC condition communicated with their partner using NetMeeting®. Subjects in the manual condition (N=94) had a mean detection confidence level of 89.61 (S.E.=16.8), while subjects in the computer condition (N=100) had a mean detection confidence level of 82.92 (S.E.=19.4). Results indicate that the means were significantly different (b=.151, t=3.17, p<0.001). Thus, H5 was supported.

Hypothesis 6 (H6) stated that proximally located subjects will have higher detection confidence than subjects that are distributed. Subjects
in the proximal condition (N=102) had a mean detection confidence level of 88.45 (S.E.=16.8), while subjects in the distributed condition (N=92) had a mean detection confidence level of 83.62 (S.E.=19.8). Results showed that proximally located subjects did have significantly higher detection confidence than subjects that were distributed (b=.128, t=2.19, p=.015). Overall, baseline knowledge, communication media, proximity, and relational closeness accounted for 12.9% of the variance in detection confidence (R^2=.129). Thus, there is sufficient evidence to support H6.

Hypothesis 7 (H7) stated that detection confidence will be positively associated with truth bias. Results showed that detection confidence had a positive effect on truth bias (b=.519, t=8.75, p<0.001). Detection confidence accounted for 26.9% of the variance in truth bias (R^2=.269). Therefore, there is sufficient evidence to support H7.

Hypotheses 8 (H8) and 11 (H11) stated that truth bias will be negatively associated with detection and false accusation respectively. Truth bias had a negative effect on detection (b=-.137, t=1.97, p=.025) and a negative effect on false accusations (b=-.485, t=6.38, p<0.001). Truth bias and baseline knowledge accounted for 2.8% of the variance in detection detection (R^2=.028), and truth bias alone accounted for 23.5% of the variation in false accusations (R^2=.235). Therefore, H8 and H11 were supported.

Hypotheses 9 (H9) and 10 (H10) stated that truth bias will be positively associated with truth detection and successful deception, respectively. Truth bias had a positive effect on truth detection (b=.360, t=4.46, p<0.001) and a positive effect on successful deceptions (b=.016, t=1.37, p<0.086). Truth bias accounted for 13.0% of the variance in truth detection (R^2=.130), and truth bias accounted for less than 0.1% of the variation in false accusations (R^2=.001). Therefore, H9 and H10 were supported.

**DISCUSSION**

This study investigated the direct and indirect effects of differing contextual factors on deception.
Distributed Deception

detection and the relationship between detection confidence and truth bias. The contextual factors studied were the closeness of the relationship between the communicating partners, their baseline knowledge of each other, whether the partners were co-located or dispersed, and the particular media used for communication. All four hypotheses dealing with detection confidence were supported. Subjects who were familiar with their communication partners, who had baseline information about them, were co-located, and who used richer communication media had higher levels of confidence in their abilities to detect deception in their partners compared to subjects in the opposite conditions. The positive effects of baseline knowledge, richer communication media, and proximity on deception confidence are significant contributions of this study to existing research. High levels of detection confidence also were found to be associated with high levels of truth bias, supporting another hypothesis, and confirming that existing deception theories are robust within computer-mediated environments.

Of the two factors thought to directly affect deception detection (baseline knowledge, communication media), only the link from baseline knowledge to deception detection was supported. Further, this relationship was negative. This finding indicates that in some work situations, there will be little or no relationship between communication media and deception detection. Results confirm the existence and potency of the truth bias within computer-mediated environments by

negatively influencing deception detection and false accusations. Conversely, the truth bias was shown to positively influence truth detection and successful deception. Each of these findings is explored in more depth below.

Knowledge of Baseline Behavior

As noted earlier, a surprising finding of this study is that subjects with prior knowledge of their partner’s baseline behavior were less accurate in detecting deceptive decisions made by their communication partners. Past research has indicated that individuals who have known their partner for a short period of time should be more accurate in detecting deceptive behavior (Brandt, Miller, and Hocking, 1980). Past studies looking at deceptive behavior examined the ability of individuals to detect deception in intimate relationships, between friends, and among strangers (Anderson, et al., 1997). The proposed model theorized that familiarity with an individual’s baseline behaviors would aid in detecting deception cues. Results, however, indicate that even a small amount of familiarity reduces an individual’s ability to detect deception. This may be due to increased levels of trust and/or individuals’ inability to correctly recognize deceptive behaviors. Thus, by separating baseline knowledge from relational closeness, this study adds to existing theory by showing that both familiarity and intimacy (Feeley and Young, 1998; Comadena, 1982) are separate factors contributing to decreased deception detection.

Results indicate that more knowledge of baseline behaviors was significantly associated with more detection confidence. This suggests that individuals draw upon past experience when making veracity judgments and feel more confident about those judgments. Overall, the effect of having knowledge of a partner’s prior behavior caused individuals to be more confident in their veracity judgments, yet were significantly less accurate in those judgments.

Communication Media

This study extends existing deception detection theory by showing that individuals who communicate with their communication partner via face-to-face interaction or telephone are significantly more confident of their ability to detect deceptive behaviors, yet are not any better at actually detecting deception. In fact, they were indirectly less able to detect deception due to more detection confidence and subsequently more truth bias. Changes in behavior and decision making due to richer communication is supported by prior research (Barkhi, Jacob, and Pirkul, 1999).

In the context of deception detection, a richer communication media provides more information cues that might be used to detect deception. More truthful/deceptive cues in a richer communication medium can lead to more confidence in veracity judgments by providing more evidence and reducing equivocality. While cues may cause individuals to be more confident, it is the inherent uncertainty in discerning between truthful and deceptive statements that makes deception detection so difficult. In fact, most successful deceptions consist of many truthful statements and contain only a small, albeit critical, number of deceitful statements. By providing more informational cues that might indicate deceptive/truthful behavior, an individual may have greater justification for making a veracity judgment. Of course the results presented here are not meant to imply that information cues are not important. Rather, a minimal amount of information cues may be necessary to make a simple veracity judgment within the context of this study.

Proximity

In this study the physical presence of another individual led to more detection confidence due to the fact that individuals most likely felt compelled to conform to public and private norms.
In this study the public norm would be to tell the truth. Individuals in the proximal condition may have assumed that their communication partner would tell the truth to make a good impression and to avoid possible confrontation (Guerin, 1986) thus leading to more confidence in their decision. The converse would also be true in the distributed condition. As noted earlier, distributed communication decreases the level of social influence, thereby changing individual behavior and expectations. This study adds to existing theory by showing how proximity affects deception confidence, and ultimately deception detection, in computer-mediated environments. It should be noted that more detection confidence does not necessarily imply more deception detection.

**Relational Closeness**

As noted earlier, prior research co-mingled the constructs familiarity and relational closeness (Anderson, et al., 1997). This study has expanded existing research by showing that relational closeness itself is a contributing factor to detection confidence separate from baseline knowledge. This finding was significant (p=0.045) and consistent with prior research (DePaulo, et al., 1997).

Relational closeness is believed to have a direct, positive influence on detection confidence because, as feelings of closeness to another person grow, an individual will feel more confident of his or her ability to detect deception/truthfulness. Prior research indicates that this confidence may stem from the fact that individuals in intimate relationships may want to view their partners as truthful because of emotional attachments (Miller and Stiff, 1993). The results from this study imply that even minor levels of relational closeness developed over the course of a few months in work-related relationships might lead to significantly more detection confidence.

**Detection Confidence**

As predicted, the relationship between detection confidence and truth bias was positive and significant (p=0.001). Consistent with prior research, the level of confidence subjects had in their assessments of truthfulness positively affected their reliance on the truth bias as a simplifying heuristic (McCornack and Parks, 1986). Subjects who were more certain of what they believed their partners were going to do devoted less cognitive resources toward making veracity judgments. In this study, more detection confidence was shown to come from levels of perceived relational closeness (H3), knowledge of a person’s prior baseline behavior (H2), being proximally located (H6), and the type of communication media used (H5). Consistent with cognitive bias research, subjects inherently proscribed to the “cognitive miser” paradigm and attempted to reduce mental effort by using simplifying heuristics when possible. Subjects felt comfortable relying on the truth bias as a way of making veracity judgments about their communication partners because of their confidence in their decision.

**Truth Bias**

Consistent with prior research, truth bias had a negative relationship with deception detection and false accusations. Using the assumption of truthfulness, individuals systematically mislabeled deceptive statements as truthful statements. Conversely, truth bias also had a positive relationship with truth detection and successful deception. Individuals who relied more on the truth bias to make veracity judgments were more likely to identify deceptive statements as truthful. This study adds to existing deception by showing that the truth bias is robust in computer-mediated environments, across varying types of studies, and differing operationalizations of the construct.
In fact, this study matched all nine of Miller and Stiff’s (1993) criteria for an ideal deception detection study. This study also showed that prisoner dilemma scenarios are an acceptable method of studying deception detection and the truth bias without the negative side effects mentioned by Miller and Stiff. It is also interesting to note that there were almost twice as many truth bias errors (N=21) as there were lie bias errors (N=13).

**LIMITATIONS AND IMPLICATIONS**

This study is limited in that subjects were offered monetary rewards from $0 to $8. Subjects indicated that they viewed these rewards as nominal and, consequently, may not have been motivated enough to exert significant amounts of motivational effort to affect changes in cognitive bias. However, even with small financial incentives, subjects did attempt to deceive their assigned partner and detect deception from that partner. Increased monetary rewards should lead to more motivational effort and more deceptive behavior. In fact, in transcribed recordings and chat logs subjects indicated that they would willingly deceive even close friends for $25.

This study may also have limited generalizability due to differences between student subjects and workers. However, given the general nature of the deception detection process it is unlikely that there will be significant variation between students and workers.

**Implications for Researchers**

This study has three main implications for researchers. First, this study furthers our understanding of new communication media because it shows that richer media may provide more confidence in predicting behavior. However, richer media do not necessarily improve predictive accuracy. In the context of deception, researchers must account for the fact that computer-mediated communication may lead to comparable deception detection rates, compared to face-to-face communication, without additional detection confidence.

Second, researchers gain an understanding of how distributed communication can lead to low levels of detection confidence. The widespread use of new communication media has allowed real-time communication across vast distances, yet the impact of proximity on deception detection has not been investigated. Researchers must recognize that the presence of another individual is a vital factor in studying deception.

Third, researchers must recognize that familiarity and intimacy are separate constructs that both contribute to detection confidence. Researchers also need to be aware that individuals who have known each other for even a relatively short period of time are less accurate at detecting deception than complete strangers. Future studies using subjects that know each other must account for the familiarity and intimacy between subjects.

**Implications for Practitioners**

This study has three main implications for practitioners. First, practitioners need to understand that richer communication, such as face-to-face meetings, can actually lead to less deception detection compared to traditional face-to-face interactions. While richer communications may not directly affect an individual’s ability to detect deception, the findings indicate that they may reduce the individual’s ability indirectly by mistakenly relying on the truth bias. Conversely, using less rich media may comparatively increase deception detection compared to face-to-face communication. This means that corporations...
Distributed Deception

could use non-traditional communication media such as e-mail, voice mail, and virtual meetings to boost performance and, actually, be less susceptible to deception. Improved deception detection within corporations would be valuable for both employers and stakeholders.

Second, individuals can expect higher detection confidence and worse veracity judgments when proximally located to the person with whom they are communicating, regardless of the communication medium. Managers can be confident that increasing utilization of distributed teams for productivity enhancements will not increase susceptibility to deception. In fact, it will lead to relatively higher deception detection rates compared to proximally located teams. However, it may also lead to more false accusations.

Third, practitioners need to understand the impact of working relationships and relational closeness on deception detection. While it may not be possible to eliminate familiarity (baseline knowledge) from the workplace, it would be beneficial if businesses limited the amount of relational closeness among co-workers. By limiting relational closeness and, to the extent possible, familiarity, practitioners will indirectly increase their ability to detect deception.

Future Research

Results from this study have generated several new research questions and directions for future research. First, further research exploring the impact of suspicion, trust, and deception detection in computer-mediated environments, is clearly warranted. The inclusion of these closely-related constructs in a larger model is likely to lead to a clearer picture of how they affect deception detection rates. Examinations of workplace deception within a small group context would also yield valuable clues relative to the impact of deception detection beyond dyadic communication.

Second, future research would benefit from iterated prisoner dilemma sessions with different partners at both the group and individual level. Iterated prisoner dilemma games played in both computer and manual conditions would yield valuable insights into the effect of media richness on negotiation, deception, and strategic decision making. Future research could also include a comparison of different monetary rewards on deception attempts and an individual’s ability to detect deception.

Third, future research should focus on measuring the influence of both situational veracity judgments and past experience. Past research has been driven by the assumption that there is a set of identifiable cues that are specifically related to deceptive behavior (Feeley and Young, 1998). However, the relationship between deceptive cues and pre-established valuations of personal truthfulness has not been investigated. Current knowledge would benefit from additional research aimed at determining the relative predictive powers and interaction of these two factors.

CONCLUSION

This study has yielded several valuable insights into the effects of computer mediation, distributed communication, and knowledge of baseline behavior on deception detection and the truth bias. This study showed that more detection confidence can come from knowledge of a person’s baseline behavior, being proximally located, the type of communication media used, and perceived relational closeness. These factors lead to less deception detection through more detection confidence and reliance on the truth bias. Knowledge of an individual’s baseline behavior also had a direct negative relationship with deception detection. This study found that subjects with a high level of confidence in their ability to detect truthful/deceptive behavior were more reliant on the truth bias to make veracity judgments even in a computer-mediated environment.

Chapter 5.21
Extrinsic Plus Intrinsic
Human Factors Influencing the
Web Usage

Manuel Jesús Sánchez-Franco
University of Seville, Spain

ABSTRACT
Researchers are confronted with a choice among models to explain Web acceptance and usage. Therefore, as Venkatesh et al. (2003) suggest, there is a need for a review and synthesis in order to progress toward a unified view of Web acceptance and usage. In this situation of development, a theoretical model based on technology acceptance (TAM) and flow, is proposed to describe the extrinsic and intrinsic motivations, respectively, for Web users. The aim of the research is thus (1) to investigate how well flow-model theory can be aligned with TAM and (2) to provide a relationship with the Web acceptance and its proper usage. Furthermore, better measures for predicting and explaining Web use will have greater practical value. Singular Web sites would like to assess user demand for new design ideas to facilitate electronic service quality and flow. Users would like to find a Web site leading to an enduring and cost-effective relationship.

INTRODUCTION
The Web can be conceived as a media for contents to build and maintain individualised relationships with profitable customers through its proper usage. In this e-CRM (electronic Customer Relationship Management) context, the viewpoint must change from (1) a traditional perspective with a short-term focus to (2) a long-term perspective with a (2.1) user-retention and (2.2) enduring-involvement focus based on optimal experiences and greater expected Web use to avoid switching suppliers at virtually comparably low direct and indirect costs. Marketers must be interested in users’ profitable sessions at their Web sites being longer and more frequent to increase the degree to which a customer (i.e., Web site user) voluntarily interacts with them. Therefore, it becomes important to examine the human factors that (1) reduce time pressure as a cost for users and (2) influence the acceptance and, in turn, length and
Extrinsic Plus Intrinsic Human Factors Influencing the Web Usage

frequency of Web site sessions (Sánchez-Franco and Rodríguez-Bobada, 2004).

With the growing reliance on computerised systems and increasing speed of the introduction of new Information Technologies (ITs) (e.g., Web), understanding the factors that promote acceptance and effective utilization of Web technology continues to be a vital issue for researchers and practitioners. Specifically, research in HCI (Human-Computer Interaction) tradition has long asserted that the research of human factors (1) is a key to the successful design and implementation of technological devices, and (2) should analyze extrinsic and intrinsic motives. Thus, there is a need for a review and synthesis in order to progress toward a unified view of Web acceptance and usage (Venkatesh et al., 2003).

Accordingly, it is important to consider the human beliefs and affects based on a Technology Acceptance Model (TAM) (i.e., ease of use and usefulness) and a flow model, respectively, to understand: (1) attitude towards using the Web; (2) behavioural intention to use; and (3) Web actual usage. On the one hand, the two beliefs based on TAM, perceived usefulness and ease of use, are the most important human factors determining usage of computers or IS (Information System). On the other hand, flow, defined as an optimal, intense and intrinsically enjoyable experience, has been proposed as a useful framework (1) for studying the experience of individuals as they learn and use the Web, (2) for identifying the factors that influence this experience, and (3) as a way of defining the nature of compelling online experiences (Novak et al., 2000). In fact, creating compelling experiences in this distinctive consumption environment depends on facilitating a state of flow (Csikszentmihalyi, 1975, 1990; Hoffman and Novak, 1996b; Novak et al., 2000).

However, very little is theoretically and empirically known about users’ interactions with Web-based technologies. Few studies actually focus directly on (1) Web acceptance and usage and its antecedents and consequences adopting a user-centered perspective, and (2) the extrinsic and intrinsic motives that affect Web usage. In this sense, Novak et al. (2000) suggest that among marketing academics and Internet practitioners alike, there is a lack of genuine knowledge about the factors that (1) make for effective interactions with online users and (2) make using the Web a compelling user experience. More recently, Parasuraman and Zinkhan (2002) point out that there is a considerable knowledge gap between the practice of online marketing and the availability of sound, research-based insights and principles for guiding that practice.

In this situation of development, a theoretical model based on technology acceptance (TAM) and a flow model (concerning an Information System), is proposed in this chapter to describe the extrinsic and intrinsic motives for online users. Chan and Swatman (2000) stated that there is very little literature which discusses the process of Internet-based marketing, so that researchers must (1) start with the literature concerning more general IS implementation and (2) hope to develop a body of theory, which is more explicitly focused on the area of Internet marketing (Eid and Trueman, 2002). Our objective in this chapter is thus to evaluate the mediating role of main intrinsic and extrinsic motives explaining users’ Web acceptance and affecting the Web usage (1) to explain and (2) to improve the users’ experience of being and reacting in the Web, and, in turn, (3) to run a profitable business.

THEORETICAL FOUNDATIONS

Over the last two decades, a significant body of research has focused on identifying various factors that influence user-acceptance behaviour, putting forward several theoretical models. In particular, the Technology Acceptance Model (TAM), introduced by Davis and his colleagues (Davis, 1989; Davis et al., 1989), has received considerable attention (see Lucas and Spitler, 1999, for a
review). Several researches have demonstrated the validity of this model across a wide variety of IS (see Moon and Kim, 2001). Specifically, the model was shown to have good predictive validity for the use of several ITs including e-mail and the Web (Fenech, 1998; Gefen and Straub, 1997).

It has thus become established as a parsimonious yet powerful model for (1) explaining attitude towards using IS, and (2) predicting usage intentions and its adoption. In other words, to understand (1) the causal link between external variable and user acceptance of PC-based applications (Fenech, 1998); and, more recently, (2) human Web acceptance (Johnson and Hignite, 2000; Lin and Lu, 2000).

**Technology Acceptance Model**

Davis adapted the Theory of Reasoned Action (TRA) to TAM by developing two key beliefs (i.e., usefulness and ease of use) that specifically account for IS usage as a basic dependent variable of IS. TAM adopts the well-established causal chain of beliefs → attitudes → intention → behaviour (TRA) that has been put forward by social psychologists, Fishbein and Ajzen (Ajzen, 1991; Fishbein and Ajzen, 1975). Consistent with TRA, both users’ beliefs determine the attitudes toward using the system. Behavioural intentions to use, in turn, are determined by these attitudes toward using the system. Finally, behavioural intentions to use lead to actual system use (see Figure 1).

The first of these main beliefs is perceived usefulness. It is defined as “the degree to which a person believes that using a particular system would enhance his or her performance” (Davis, 1989). Perceived Usefulness was originally seen as a fairly simple concept including components of effectiveness and efficiency (that are mainly related to extrinsic motivation in work contexts). As shown by Davis (1989), perceived usefulness affects usage of computers. Specifically, Teo et al. (1999) found that perceived usefulness has a strong significant relationship with the Web usage. For example, e-shoppers will use the Web

**Figure 1. TAM**

(*) Attitude was originally included as a mediator between the personal belief-based constructs and the behavioural intention (Davis et al., 1989), but later was dropped from the model because it was finally found to be a weak mediator (Davis et al., 1992).

(**) Some researchers (see, for example, Thompson et al., 1991; Adams et al., 1992; Al-Gahtani and King, 1999) also dropped the behavioural intention to use because they were interested in actual behaviour (system usage) and not intentions.
sites more if they find them useful for shopping offering quality information helpful for shopping as well as useful functionality (such as online order status tracking capability, Baty and Lee, 1995; Bellman et al., 1999). In short, individuals will use IS if they perceive that such usage would help them to achieve and enhance the desired task performance, even if it is at first difficult to use (Eid and Trueman, 2002).

The second belief is perceived ease of use, defined as “the degree to which a person believes that using a particular system would be free of effort” (Davis, 1989), being determined by the users’ skills and the usability of the system (Venkatesh and Davis, 1996). Perceived ease of use has been (1) used as a measure of system quality in studies of IS success (Seddon, 1997); (2) considered a component of a Web site’s system quality (Liu and Arnett, 2000); and (3) found to influence computer usage and the Internet usage indirectly via (3.1) perceived usefulness (Davis, 1989; Teo et al., 1999) and (3.2) perceived enjoyment (Igbaria et al., 1995; Teo et al., 1999). Thus, ease of use is an important component when measuring user satisfaction with a Web site (Wang et al., 2001) and its usage (Elliot and Fowell, 2000).

In this context, as perceived ease of use has an inverse relationship with the perceived complexity of use of the technology, it can affect perceived usefulness. A system that is difficult to use is less likely to be perceived as useful. Assuming other things being equal, users consider a system more useful when it is more effort-free. These relationships have been examined and supported by many prior studies (Davis, 1989; Davis et al., 1989; Venkatesh and Davis, 1996; Venkatesh and Davis, 2000). Moreover, if the challenges of an activity are beyond the individual’s skill level, demanding more than the individual can handle, a state of anxiety ensues and users (1) interpret challenges as simply functional complexity or obscurity (and not as opportunities for action), (2) do not perceive the system as useful, and thus (3) tend to use the system sporadically. Likewise, a system perceived as difficult to use is less likely to be perceived as enjoyable, leading to decreased usage (Lim, 2002). Thus, from a causal perspective, ease of use may be an antecedent to usefulness rather than a parallel determinant of usage.

In short, as Hubona and Geitz (1997) reported, perceived usefulness and perceived ease of use have sound theoretical foundations. They are therefore widely accepted as valid and predictive measures of future Web usage levels. TAM yields highly consistent results in the acceptance behaviour of the users towards new systems.

However, most of the TAM research has only been conducted from an extrinsic motivation perspective (Igbaria et al., 1996). Researchers have become increasingly aware of the relevance of the non-cognitive aspects of use motives such as emotions, symbolism and hedonistic desires in understanding facets of behaviour. For example, user behaviour-based findings in the intrinsic motivation and self-efficacy research indicate that emotional responses play important roles in determining (1) a person’s attitude towards using the Web, (2) a behavioural intention, and (3) an actual behaviour.

Following Human-Computer Interaction (HCI) Research, several researchers propose the need for incorporating intrinsic human factors or integrating other theories in a specific study to improve its particular and explanatory value (Hu et al., 1999; LeGris et al., 2003; Venkatesh and Davis, 2000). For example, psychologists have proposed a variety of theories explaining how behavioural reactions are influenced both by cognition and affect (Berkowitz, 1993; Epstein, 1994; Leventhal, 1984; Zajonc, 1980). Specifically, one of the intrinsic human motives related to prior factors is “flow.” Next we analyse the proposed flow models.

Flow Theory

Flow has been particularly studied in the context of ITs and hypermedia computer-mediated

Ghani et al. (1991) argued that two key characteristics of flow are (1) total concentration in an activity and (2) the enjoyment one derives from an activity. Control and flow predicted exploratory use, which in turn predicted extent of use.

Trevino and Webster (1992) described four dimensions of the flow experience in the context of ITs: (a) the user perceives a sense of control over the computer interaction, (b) the user perceives that his or her attention is focused on the interaction, (c) the user’s curiosity is aroused during the interaction, and (d) the user finds the interaction intrinsically interesting, implying that the user’s interaction with the technology extends beyond mere instrumentality, becoming a pleasure and enjoyable as an end in itself.

Webster et al. (1993) refined the model to just three dimensions: (1) control; (2) focus attention; and (3) curiosity and intrinsic interest coalescing to become cognitive enjoyment (a construct comprised of curiosity and intrinsic interest that were highly interdependent). Flow would be associated with specific characteristics of the software (specifically, perceptions of flexibility and modifiability) and with certain technology use behaviours (experimentation and future voluntary computer interactions) (Agarwal and Karahanna 2000).

In a later study exploring flow occurring among individuals using computers in the workplace, Ghani and Deshpande (1994) analyzed skill as well as challenge. Skill leads to control which leads to flow. Skill also directly affects flow, as does perceived challenge, with an optimum level of challenge relative to a certain skill level existing. A second factor affecting the experience of flow is a sense of control over one’s environment.

*Adapted from Agarwal and Karahanna (2000) and Sánchez-Franco (2003)*
A significantly more complex version of flow was described by Hoffman and Novak (1996b). Examining the role of marketing in CME, Hoffman and Novak argued that the dimensions of control, curiosity, intrinsic interest, and attention focus were antecedents to flow. Their model included several other antecedents of flow such as the perceived congruence of skills and challenges and the telepresence of the medium, defined as the mediated perception of an environment (Steuer, 1992). Hoffman and Novak indicated that the primary antecedents to flow are challenges, skills, and focused attention.

From the literature on communication media, they added secondary antecedents: (1) interactivity, and (2) telepresence. Furthermore, Hoffman and Novak added the construct of involvement, which encompasses intrinsic motivation and self-reliance and is influenced by whether the activity is goal-directed or experiential (Finneran and Zhang 2002). They further theorised that flow would result in several outcomes such as a positive subjective experience, increased learning, and perceived behavioural control.

More recently, Novak et al. (2000) took the definition of flow to the operational level (in a CME), stating that flow is “determined by: a) high levels of skill and control; b) high levels of challenge and arousal; c) focused attention; and (…) d) enhanced by interactivity and telepresence.” Thus, flow occurs when an activity challenges and interests individuals enough to encourage (1) playful and exploratory behaviour without the activity being beyond the individuals’ reach, and (2) greater expected Web use.

*Adapted from Agarwal and Karahanna (2000) and Sánchez-Franco (2003)*

Flow, defined as “the holistic sensation that people feel when they act with total involvement” (Csikszentmihalyi, 1975), has been recommended as a possible metric of the online consumer experience (Agarwal and Karahanna, 2000; Ghani et al., 1991; Ghani and Deshpande, 1994; Hoffman and Novak, 1996b; Novak et al., 2000; Trevino and Webster, 1992; Webster et al., 1993). Therefore, we suggest that flow-based theory could contribute partly to explain attitudes towards using the Web-based technologies and behaviours.

Although a body of research suggests that flow on the Web is fleeting, rarely experienced, associated with the increases in depression and loneliness (see Kraut et al., 1998), and mostly by novice Web users, the growing research concerning theory of optimal flow has been proposed (1) as a useful framework for identifying the factors that influence this experience and, in turn, (2) as environments (CMEs, defined by Hoffman and Novak, 1996b, as a distributed computer network used to access and provide hypermedia content).
Extrinsic Plus Intrinsic Human Factors Influencing the Web Usage

a way of defining the nature of compelling online experiences (Table 1).

Next we analyse the main factors that influence this optimal experience. We distinguish two submodels for better understanding of the relationships between TAM-based beliefs and flow state.

Submodel 1

Researchers have maintained that involvement is a major socio-psychological variable that explains individual differences (Petty et al., 1981) that impact on attitude and individual behaviour. Following a review of the construct of involvement in psychology, organisational behaviour, and marketing, Barki and Hartwick (1989) conclude that these disciplines have converged in a definition of involvement “as a subjective psychological state, reflecting the importance and personal relevance of an object or event.” In this cognitive-processing context, involvement has also been argued to have a significant effect on consumer subjective perception of how much they think they know about products (Zinkhan and Muderrisoglu, 1985). In turn, Houston and Rothschild (1978) and others have found that involvement increases with familiarity with the stimulus or individual’s prior knowledge (i.e., ability) (Figure 2.)

On the other hand, involvement contributes to the attention focused on the stimulus (Zaichkowsky, 1986) and it is considered as a prerequisite for flow (Hoffman and Novak, 1996b). Ghani and Deshpande (1994) emphasise that the total concentration in an activity is the key characteristic of flow (Figure 2). According to Csikszentmihalyi and Csikszentmihalyi (1988), when one is in flow “one simply does not have enough attention left to think about anything else.” The computer screen functions as a limited stimulus field. Moreover, involved users report being mesmerised during their computer interactions. Accordingly, Park and Young (1986) note that users — for whom extrinsic motives are salient — focus their attention on utilitarian cues and evoke cognitive responses. In turn, users — for whom intrinsic motives are salient — focus their attention on symbolic or experiential cues and evoke emotional responses.

Involvement can be thus understood by distinguishing the types of involvement according to the motives underlying involvement (Park and Young, 1986). Particularly, the distinction between extrinsic and intrinsic motives of behaviour suggests two types of involvement:

- Situational involvement arises from several transitory factors that affect the relationship between the individual and the stimulus (Celsi and Olson, 1988). It is externally motivated and it is thus more likely to result in a goal-directed behaviour (Hoffman and Novak, 1996b). Extrinsic motives-based involvement (i.e., SI) is related to the performance of an activity. In this sense, the activity is perceived to be instrumental in achieving valued outcomes that are distinct from the activity itself.

- Enduring involvement is an intrinsically-motivated individual difference variable that is relatively long-lasting. In this context, intrinsic motivation refers to the performance of an activity for no apparent reinforcement other than the process of performing the activity per se. According to no apparent reinforcement, the concept of perceived enjoyment is defined as “the extent to which the activity of using the computer is perceived to be enjoyable in its own right, apart from any performance consequences that may be anticipated” (Davis et al., 1992). In short, intrinsic motives to use the Web could be associated with frequent Web use for intrinsically enjoyable purposes.

Therefore, situational involvement reflects temporary feelings of involvement that accompany a particular situation, whereas enduring involvement is an individual difference variable
representing the general, long-run concern with a stimulus that a consumer brings to a situation (Richins et al., 1992).

According to intrinsic motives related to enduring involvement, enjoyment has been identified as an important motivational factor in computer use, (1) contributing towards creativity and exploratory use behaviour (Ghani, 1991), as well as (2) being a major dimension of optimal experience or flow, which has been above described as an intrinsically enjoyable experience (Csikszentmihalyi, 1975). Specifically, research on the use of the Web has found empirical support for enjoyment as a driver of Web usage (e.g., Atkinson and Kydd, 1997; Moon and Kim, 2001; Teo et al., 1999). If individuals like and enjoy their Web browsing experience, it is likely that they are going to (1) involve in browsing and, in turn, (2) enhance their online service perceptions (e.g., perceived usefulness and ease of use). Use of the Web may therefore evoke emotional values that are not only captured by ease of use or usefulness (Hoffman and Novak, 1996ab; Singh and Nikunj, 1999). Use of the Web goes beyond utilitarian aspects to include intrinsic enjoyable experience (Berthon et al., 1996; Pine and Gilmore, 1998). For example, Davis et al. (1992) argued that “while usefulness will once again emerge as a major determinant of intentions to use a computer in the workplace, enjoyment will explain significant variance in usage intentions beyond that accounted for by usefulness alone.”

Moreover, HCI-based research using the TAM model has found that perceived enjoyment of using a system (e.g., Web) has a relationship with a perceived ease of use (Venkatesh, 1999; Venkatesh, 2000; Moon and Kim, 2001) and perceived usefulness of the system (Agarwal and Karahanna, 2000) (Figure 2).

On the one hand, Agarwal and Karahanna (2000) found a multi-dimensional construct called cognitive absorption (similar to flow state) which had a significant influence on usefulness over and above ease of use. Venkatesh (2000) showed that enjoyment influenced usefulness via ease of use without assessing its direct effect on usefulness over and above ease of use (Yi, 2003). Likewise, several researchers note that when the usage experience is more enjoyable the impact of perceived usefulness on Web usage could be relatively lower. This prior phenomenon is based on a cognitive consistency argument in which the underlying rule is that when usage is emotional, instrumental issues -such as perceived usefulness- ought not to come into one’s main decision making criteria for future usage (Chin et al., 1996). However, the

---

Figure 2. Extending model (I)

*Flow has been defined as intrinsically enjoyable experience.*
Extrinsic Plus Intrinsic Human Factors Influencing the Web Usage

effect of enjoyment on perceived usefulness is still relatively unknown.

On the other hand, Csikszentmihalyi (1975) argued that flow could be enhanced when an individual perceived an activity to be executed easily. Empirical research has also found support for this relationship in traditional settings (Igbaria et al., 1996). It is conceivable that a Web site that is easier to use provides better feedback to a visitor's stimuli, and consequently, leads to increased enjoyment and flow. Moreover, Venkatesh (1999) compared two training methods (traditional training vs. game-based training) and found that the training method with a component aimed at enhancing intrinsic motivation induced higher ease of use perceptions. Later, as we commented above, Venkatesh (2000) conceptualised enjoyment as an antecedent of ease of use, whose effect increases over time as users gain more experience and perceived control with the system (adapted from Hwang and Yi, 2002).

Finally, studies applying the perspective of flow have shown that to provide intrinsic motivation, some services must represent a certain challenge to the user as antecedent of emotional arousal. It is probably that excessive ease of use that reduces the sense of accomplishment, (1) negatively influences on perceived enjoyment and (2) leads to boredom states. In other words, ease of use is not the only key criterion for Web site design, as Web site usage would decrease with time. On the contrary, a main determinant must be its stimulating use, so that it evokes compelling experiences and therefore increases profitable Web site use (Sánchez-Franco and Rodríguez-Bobada, 2004). According to Csikszentmihalyi (1996), a Web site must be challenging, competitive, and provide feedback to its users in order to encourage the occurrence of flow. As Ginzberg (1978) recommended, system success must be evaluated in terms of the way it is used rather than just the extent of use. Therefore, an important prerequisite for this rewarding experience is that an individual is able to accomplish the task (i.e., ability). But it is equally important for it to be experienced as a challenge and the individual gets (1) stimulation (i.e., arousal) and (2) unambiguous feedback (i.e., perceived control) inherent in the performance of the activity. To complete the global model, we thus introduce a second submodel based on users’ ability, challenge, arousal and perceived control.

Submodel 2

Looking at earlier definitions of flow (Table 1), in order to experience flow while engaged in an activity, users must perceive a balance between their abilities (defined as the skill or proficiency) and the challenges of the activity (defined as their opportunities for action on the Internet) (Novak et al., 2000). Particularly, challenges are related to a sense of accomplishment rather than simply functional complexity or obscurity. Both their abilities and challenges must be above a critical threshold (Massimini and Carli, 1988). The balance facilitates the experience of arousal, perceived control and flow.

- If the challenges of an activity (i.e., those opportunities which provoke users to further explore Web sites) demand more than the individual can transitorily handle, a state of stimulation ensues (i.e., arousal: high challenge/ moderated skill). Users become aroused until they are familiarised with the system through more frequent system usage –e.g., practice or training (Gardner et al., 1989) (Figure 3). However, too much stimulation will lead users to making errors and feel out of control (i.e., anxiety as a negative affective reaction toward Web use).
- On the contrary, when the challenges are lower than the individual’s skill level, perceived control (moderated challenge/high skill) may be the result (Figure 3). However, if the challenges are too low, users lose in-
Interest and tend to use the Web sporadically (i.e., boredom or apathy).

According to arousal as an emotional response, it reflects a user's concern about having the ability to succeed with a new perceived challenge. Arousal can be thus considered as an involvement-based response. However, the user's concern must be perceived as moderate, important and relevant (1) to acquire Web-based skills and (2) to match the skill level and perceived challenge. On the contrary, too much concern will lead users to feel out of control.

Moreover, if users return to the same Web site over time, it is reasonable to expect (1) learning to occur, (2) perceived challenges to decrease, and (3) session lengths to decline (see, for example, Johnson et al., 2003, on “the power law of practice”). A main recommendation must be thus to promote its stimulating use, so that it permanently evokes (1) arousal and compelling experiences, and (2) more frequent and longer visits. For example, CMC (Computer-Mediated Communication) technologies can stimulate cognitive curiosity and the desire to attain competence with the technology by providing options such as menus that encourage exploration (Malone and Lepper, 1987) and competence attainment. In this sense, arousal, as a consequence of perceived task challenge, is a key factor in the experience of flow.

According to perceived control, it has been studied in the context of electronic commerce and found to have a positive effect on customer attitudes and behaviour (Ghani et al., 1991; Novak et al., 2000; Koufaris et al., 2001-2002). Specifically, it refers to users' perception of their capabilities to interact in CME. Perceived control comes from: (1) the users’ perception of their ability to adjust the CME; (2) their perception of how the CME responds to their input; plus (3) an environment where challenges are relatively moderate. These users thus believe their actions and abilities determine their successes or failures (Sánchez-Franco and Rodríguez-Bobada, 2004).

Therefore, users with a high level of ability and, consequently, perceived control (Ghani and Despandhe, 1994; Novak et al., 2000): (1) are likely to feel more able to perform the activity,
Extrinsic Plus Intrinsic Human Factors Influencing the Web Usage

and (2) show a high comfort level. They would be more inclined to feelings of enjoyment while become involved in the activity and, in turn, to use the Web more frequently. Likewise, users become more playful (Lieberman, 1977) and experiential, positively affecting Web exposure length. As Bandura (1982) suggested, “people do not perform maximally, though they possess the constituent skills.” He suggests that “the reason people enjoy challenging tasks is that by testing the upper limits of their competencies, they find out what they are able to do, thereby increasing their feelings of self-efficacy.” On the contrary, those with low self-efficacy expectations in a particular situation will experience unpleasant feelings, such as anxiety, and will behave in unproductive ways, such as avoiding work, and may lack persistence (Bandura, 1977).

Perceived control is thus similar to Bandura’s self-efficacy (1982) defined as “judgements of how well one can execute courses of action required to deal with prospective situations.” It is (1) specific to an action and it can be different across situations or actions; (2) facilitated by the medium adapting to feedback from the individual, and by providing explicit choices among alternatives (Webster et al., 1993), and (3) considered -by several researchers- as an antecedent of perceived behavioural control (i.e., “perceptions of internal and external constraints on behaviour,” Taylor and Todd, 1995).

Finally, perceived control (or self-efficacy) can be related to perceived ease of use. Users regard the system easier to use when their conviction in their own efficacy regarding the particular system is higher (Agarwal et al., 2000; Venkatesh and Davis, 1996; Venkatesh, 2000).

Implications for Web Usage

Based on the above theoretical development (Figure 3), two main Web user-types can be theoretically evidenced on a continuum from “pure browsing” to “pure seeking.” The distinction is a continuum rather than a dichotomy. Individual differences drive a person’s information and entertainment consumption processes. Individuals shift from one mode to the other.

When users show ritualised orientations exploring the Web (experiential behaviour), they are moved by an intrinsic motive: “to feel pleasure and enjoyment from the activity itself” (Bloch et al., 1986). Users find the interaction intrinsically interesting. They are involved in the activity for the emotional responses it provides rather than for utilitarian purposes. Thus, a main objective is that a Web site is designed to be stimulating to use and thus to evoke compelling user experiences related to playfulness, exploratory behaviour and positive affects.

According to playfulness and positive affects, Atkinson and Kydd (1997) examined the influence of playfulness on the use of the Web, defined as the degree of cognitive spontaneity in microcomputer interactions (Webster and Martocchio, 1992). They found that both playfulness and usefulness affect its use in different ways, depending on its use for entertaining or for work. Likewise, they found that playfulness is significantly associated with total Web use. Those who are more playful with computers tend to indulge in using a new system just for the sake of using it. Therefore, they in general underestimate the difficulty associated with using a new system (Venkatesh, 2000). Previous computer adoption studies have verified that if users are more playful with computer systems, they are more willing to use the systems (Igbaria et al., 1994; Webster and Martocchio, 1992). In turn, Webster et al. (1993) note that research has suggested that “higher playfulness results in immediate subjective experiences such as positive mood and satisfaction” (Levy, 1983; McGrath and Kelly, 1986; Sandelands et al., 1983). Furthermore, previous research on human-computer interactions (Sandelands and Buckner, 1989; Starbuck and Webster, 1991; Webster and Martocchio, 1992) has shown that higher degrees of pleasure and involvement during computer interactions lead
to concurrent subjective perceptions of positive affect and mood (Hoffman and Novak, 1996b).

Also, Amabile (1988) noted that “only the intrinsically motivated person (…) who is motivated by the interest, challenge, and the enjoyment of being in the maze (…) will explore, and take the risk of running into a dead-end here and there.” In this sense, Ghani and Deshpande (1994) examined flow in the context of individuals who used computers in their daily work and found that it had a significant impact on exploratory use of the computer which, in turn, had a significant effect on the extent of computer use.

When users show an instrumental orientation to the Web (goal-directed behaviour), they search for contents adapted to their needs and goals and leave the Web after an active and efficient search. Pure seekers use the Web less for experiential activities and more for goal-directed activities based on perceived usefulness. Thus, an objective is that a Web site is designed to be easy to use and useful to increase profitable Web site usage. Likewise, goal-directed users are generally involved in activities that already have a high extrinsic motivating potential. Such individuals are less likely to seek challenges and evoke arousal in Web use (Ghani and Deshpande, 1994). As users become more skilful, their information search shifts from an extensive manner to a simplified one. Web users can evidence opportunity costs of time and confront a variety of time constraints. An idea put forward in some early empirical research on the Web holds that Web users will continue to browse as long as the expected benefit or value of an additional page view exceeds the cost (Sánchez-Franco and Rodríguez-Bobada, 2004).

In short, as Novak et al. (2000) suggest, because the Web mixes experiential and goal-directed behaviours, the model can be used as a first step in evaluating Web sites in terms of the extent they deliver these two types of experience while users browse.

**FUTURE TRENDS**

The objective of this chapter was to create an opportunity for researchers desiring to advance Web-adapted theory. However, due to the limitations of this chapter, there are still some related problems that should be investigated in the future. The specific variables in each category of our framework are not exhaustive, but reflect factors that the literature suggests are most likely to be relevant to Web acceptance research and implementation. Research questions can be raised according to the major framework components.

We argue that the relationships between affective and cognitive dimensions forming both electronic service quality and satisfaction may provide useful insights for how firms should allocate resources in different psychographic segments depending on browsing behaviour. In future research, we must analyse if the relative importance of the electronic service quality and satisfaction dimensions varies from one segment to another. Therefore, service firms may benefit from allocating their resources differently in each segment.

Likewise, we restricted our investigation to intrinsic and extrinsic motives. However, user behaviour is explained via a model of triadic reciprocity in which behaviour, cognitive and personal factors and environmental events all operate interactively as determinants of each other (Hwang and Yi, 2002). Thus, it is necessary to fulfil the model with the role of consumer demographic variables and navigation context (work/home, high/low download, etc.) that are unexplored in this research. Likewise, to the extent that using a CME depends on non-motivational factors like “requisite opportunities and resources” (for example, Internet access), the traditional formulation will not accurately predict intentions and subsequent Web usage (Hoffman and Novak, 1996b).
Finally, the present research may be effectively extended beyond (1) a general analysis of Web acceptance and usage to the modelling in specific Web sites and (2) products/services suited to a relationship-oriented market approach. The research cannot provide insights into the role of personal factors on individual sites. These factors can play distinct roles depending on the nature of the Web site, or nature of the visit.

CONCLUSION

This chapter examines two theories that have been widely used over the past decade to assist in understanding of the IS/IT adoption and implementation processes, and links them to the marketing value chain. The theoretical development suggests that there is scope for further extension of TAM to adapt to the Web-based usage and its profitable consequences. Therefore, placed in this context, the theory may help to further the empirical research and to clarify and examine a Web acceptance and usage model. In other words, the aim of the research has been to investigate how well flow-model theory can be aligned with TAM and to provide a relationship with the Web acceptance and its proper usage.

In this e-CRM context, the design of a Web site based on technology acceptance and flow theories is a crucial determinant of whether visitors are likely to accept and return to the site. An effective site design has a significant influence on site traffic and the number of transactions users conduct on a Web site. A main conclusion is that a Web site must not be simply designed as easy to use thus decreasing Web site usage (aspects related to SI). It is designed (1) to be stimulating to use and thus (2) to evoke compelling user experiences to increase profitable Web site usage. The online environment must promote a long-term perspective with a user-retention focus and involvement based on extrinsic and intrinsic motives, leading to valuable behaviours and, in turn, greater expected Web use. Therefore, flow would occur during both goal-directed as well as experiential types of activities.

Likewise, rather than just evaluating the theoretical aspects, the basic model can be used to assess motivational design aspects during the browsing process. Exploring flow-antecedents and consequences for predicting and explaining Web-technology acceptance and usage would have greater practical value. (1) Web sites would be likely to assess user demand for new design ideas to facilitate flow. (2) Users would be likely to find a Web site leading to an enduring relationship and lessen users’ boredom and anxiety.

Extrinsic Plus Intrinsic Human Factors Influencing the Web Usage

This section presents contemporary coverage of the managerial implications of human-computer interaction. Particular contributions address virtual networking, knowledge blogs in company environments, and ambient business. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of the relationship between business, technology, and individuals.
Chapter 6.1
Social Impact of Virtual Networking

Hakikur Rahman
SDNP Bangladesh, Bangladesh

INTRODUCTION

Information has been defined as a set of data, facts, and figures that have been processed in such a way that they become meaningful. They make intelligence. When information is applied to doing something and is globally pertinent, it is said to have become knowledge.

Information flow can be treated as an alternate wealth for a developing society and knowledge networking through virtual communication processes can break the lags and leads of information barriers. It can create an appropriate tool for achieving and facilitating exchange of information and knowledge among development partners, academia, policymakers, and the civil society at local, national, and global level to design and implement plans for development (Rahman, 2000).

Virtual communities are the collection of online links to a particular node, examples of which are Yahoo!, eBay, Amazon, or smaller chat rooms or instant message buddy lists. These networks of links are freely chosen, democratic, unrestricted, and may even be anonymous or pseudonymous (Roberts, Smith, & Pollock, 2002).

The concept of the virtual enterprise has emerged in management literature as the result of the fusion of technological advances and a claimed major socioeconomic paradigm shift. The virtual enterprise can be seen as a temporary alliance of contracted individuals or companies linked together by ICTs, which assembles for the purpose of a specific business task. Advocates of the virtual enterprise believe that it will replace the conventional model of organization in the 21st century (Introna, More, & Cushman, 1999).

The virtual network is being increasingly promoted as a model for a new form of ICT-mediated communication endeavor. Initially, the concept of the virtual network and the supportive role of ICTs as conceived by its proponents need to be clarified. Based on the initial understanding, the establishment of community information centres as the existing instance of virtual enterprise needs to be done.
BACKGROUND

A virtual organization is a collection of geographically distributed, functionally, and/or culturally diverse entities that are linked by electronic forms of communication and rely on lateral, dynamic relationships for coordination. Despite its diffused nature, a common identity holds the organization together in the minds of members, customers, or other constituents (DeSanctis & Monge, 1998). Virtual is defined as “being in essence or effect but not in fact or name,” and network as “an interconnected or interrelated chain, group, or system” (Lau & Hayward, 2000, p. 362).

To accelerate the development processes at the marginal communities, network hierarchies must reach remote places with easy access and availability, forming a robust intercommunication network. Figure 1 shows possible networking hierarchy within a country.

Rheingold (1994) defines virtual communities as “social aggregations that emerge from the Net when enough people carry on public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace” (p. 5). Integrating this concept along with economic, politics, and social aspects, networking among the virtual communities can be bonded to form a self-sustained en masse at the outset (Fisher, Sonn, & Bishop, 2002).

Communication is fundamental to any corner of the information coordinates but is preeminent in virtual organizations. In O’Hara-Devereaux and Johansen’s (1994) view, without communication, the boundary-spanning among virtual entities would not be possible. Electronic communication enables parties to link across distance, time, culture, departments, and organizations, thereby creating “anyone/anytime/anyplace” alternatives to the traditional same-time, same-place, functionally centered, in-house forms of organizational experience.

Usually virtual networks are characterized by their (a) highly dynamic nature, (b) vibrant relationships among entities, (c) unrestricted boundaries, and (d) easily configurable structures. Relative to more traditional settings, communication processes that occur in virtual contexts are faster, customized, momentary, greater in volume, more informal, and more relationship based.

Barabasi (2002) presents a set of concepts which, taken together, comprise his science of networks. His theory addresses varied entities, from the microscopic cell to the macroscopic World Wide Web, as networks. It seems possible that his work offers to our discipline a new model, one that may address historic dichotomies of person/community, locale/relationship, gemeinschaft/gesellschaft, and one/many. It may provide a path for virtual communities to become part of our ongoing research and conversation.

Enabling the remotely located dispersed communities with contents of their own need, at the times of their own demand, at the easy reach of their own are a few preconditions to enlighten themselves with knowledge and raise their capacity to contribute for the development
of the society. Therefore, these forms of virtual networks, at the village/community level, create enormous opportunities to enhance the human capacity development processes and at the same time raise the economic platform of the community through diversified activities related to their livelihood.

**METHODOLOGY**

Networking minimizes the task of unoptimized searching and sequencing in distributed environment. Individual stations connected to cluster of networks and eventually interconnected together using similar infrastructures and optimized protocols are becoming popular throughout the virtual communities (Rahman, 2001).

Methods and approaches in organizing networked systems need intensive research, especially when the challenge is to implement information technology methodologies effectively to support organizational systems. Qureshi, Vreede, dG-J., and Vogel (2000) indicate that an understanding of organizational systems may be achieved through the use of research methods that (1) use theories to describe organizational systems, (2) provide sets of tools to enable real-world problems to be addressed, and (3) enable the researcher to interact with the organizational systems that they study.

For advanced information services, the powerful clusters/groups in society are provided with direct access to information. The information is then expected to trickle down to the majority at large. Quite often, research centres, for example,

do not establish direct contact with all small farmers. They talk only to a small group of farmers to whom they offer information. They expect other community members to learn from this chosen group. Similar top-down information channel has been evolved in the information dissemination processes for social improvement of the community. Figure 2 shows a form of information channel.

In this top-down hierarchy, information on development issues does not flow directly to everyone in the community. The information flow is a multistep process. It flows first from the media, research team, and extension workers to opinion leaders or members of the information groups. From these small groups it flows to all the peasants and community members.

Numerous forms of ICT techniques exist that can support the communication of geographically dispersed communities. The article emphasized the dual nature of ICT, “which focuses attention on how information technology shapes human action through its provision of structural opportunities and constraints, while also recognizing that information technology is itself the product of human action and prior institutional properties” (Orlikowski & Robey, 1991, p. 148).

Activity of a typical information centre can be measured by the log in behavior of its clients. Usually, participants from city centres have better access to information than from village community centres. Similarly, city centre users have been found to login to the network (Internet) more frequently. Therefore, login frequencies of these two groups are different. Their behavior of login is shown in Table 1.

The degree of a social network gives an indication of how many entities a user interacts with. The average degree is calculated by:

\[
\frac{1}{n} \sum_{i=1}^{n} d(n) \]

where \(d(n)\) = number of edges incident on node \(i\), \(i = \) node as depicted in Figure 1.

Research studies indicate that degree of around unity in a typically medium network is acceptable, while degree of around 1.5 can be taken as medium interaction, and greater than 1.5 can be referred as heavy interactions.

Similarly, density of a virtual network can also need to be defined, to give the network the completeness.

\[
\text{Density} = \frac{e}{n(n-1)}
\]

where, \(e\) = number of edges in a network, and \(n\) = number of nodes.

The actual density values will decrease geometrically as the network increases.

Another indicator about the relationship among the member of a network can be derived, if the edges of the network (Figure 3) can be set in a symmetrical matrix such as:

\[
\begin{array}{ccccc}
  & a & b & c & d & e \\
 a & - & 1 & 1 & 1 & 1 \\
 b & 1 & - & 0 & 0 & 0 \\
 c & 1 & 0 & - & 0 & 0 \\
 d & 1 & 0 & 0 & - & 0 \\
 e & 1 & 0 & 0 & 0 & - \\
\end{array}
\]
while in Figure 3, a knows b, c, d, and e. But the relationship between b, c, d, and e may not be known.

Terms such as *global information highway*, *information revolution*, and *information economy* are used routinely to illustrate the profound role of information in modern societies. Yet it is easy to make unverified assumptions about the nature of benefits being generated in an “information society” (McConnell, 1996). However, measuring the social impact of a virtual network is not so easy and directly derived by conventional definitions. The impact may be defined as dependent on several attributes (± is used, as there may sometimes be a negative value);

\[
i_s = \text{social impact of a network} \\
\approx \text{inverse of the density value} \\
\pm \sum \text{variance (relationship value of adjacency matrix)} \\
\pm \sum \text{variance (degree of social network)} \\
\pm \sum \text{factors related to socioeconomy of a society.}
\]

**RETROSPECTIVES**

This section describes a few critical issues related to the importance of content, capacity building of the stakeholders, and a few characteristics of virtual networks.

**Importance of Local Content**

Knowledge is a complete product of human thought, action, and wisdom. Each culture contains a knowledge base from which its members receive understanding and an interpretation of the outside world. In building information content, it is important to start with the information and knowledge that exist within the community itself. Indigenous knowledge forms an important part of the community’s information and knowledge resources.

**External Information and Content**

Similarly, external information and knowledge sources are also vital because some human development problems are similar globally. By gaining access to information and knowledge sources that bring this experience to the community, members save valuable time, effort, and resources. They are able to learn and adapt ideas from the best practices of other grassroots communities in other countries.

**Raising the Capacity of Semiliterate and New Literate Members**

Feeding adequate information to this group is essential because they sometimes constitute about 30% or more of all the adult population of a community. They, therefore, have a big contribution to make in the development process.
Publication of a Community Newsletter

A newsletter to inform the community about what is going on, what is planned, and what could be the future model by information sharing and interchange activities. The newsletter could be issued every month, bimonthly, or quarterly. Copies of the newsletter can be put on notice boards of the community centres and other public places, with an electronic form saved in the Web server for Internet-connected participants and global viewers.

A successful virtual network should be:

- Consistent and visible to the link partners;
- Compelled to develop trust among participants;
- Clearly identifiable with common purposes in which the objectives of the linkage fit well with the mandates of the participating institutions;
- Accommodative to the willingness of participants to give up autonomy of action within the joint activity;
- Able to establish common understanding;
- Carefully managed so that the contributions of all participants are recognized;
- Capable of obtaining feedback between the strategic management team and the researchers;
- Containing linkages based on specific scientific initiatives rather than generic common interests to ensure direct benefits;
- Generating high-quality work with respect to the community; and
- Capable of providing good communication platform among participants and the outside world.

These networks should avoid:

- Expectations that signing a memorandum of understanding (MoU) will lead to all like-groups in establishing close working relationships and joint project activity;
- Impressions that the linkage may exclude collaboration with similar parties;
- Unclear agreement on the goals of the joint activity;
- Restrictive agreements that risk impeding natural extension and flexibility in the partnership;
- Processes that may lead to failed delivery of local benefits to the stakeholders; and
- Restricting decisions and activities in the partnership to reach all stakeholders/partners.

FUTURE ISSUES

Measuring actual social impact of a virtual network is a critical issue and needs further scientific and sociological studies and research. Performance behavior of communication mechanism can be improved by creating symmetry among the adjacency matrices through proper data calculation and analysis.

Centrality of the network (especially local centrality, in case of dispersed village information centres) is another important aspect of a virtual network, putting greater impact on social behavior of the participants. By calculating degree of interactions in every node, a graph can be generated, and the node with the highest degree may be taken as the center of the network. This concept may lead to a “star topology” concept, but this pattern may not seem to fit in real-life conditions during implementation period.

The exact nature of communication processes in virtual forms, their antecedents, and consequences are, of course, unknown as of yet. However, it is possible to glean some insight the rich body of literature on synchronous and asynchronous electronic organizational communication. Communication in the virtual organization certainly will become more electronically medi-
ated than in the past, and the vast set of empirical findings regarding mediated communication can foreshadow how communication will change (DeSanctis & Monge, 1998).

CONCLUSION

Economic growth is a poor indicator of development in this globalize world, because it does not reflect the actual distribution of wealth. It fails to show the impact of this development on other social segments, such as health, education, and gender equity.

An alternate development approach has come into being. This approach recognizes the importance of the well-being of all people. The name for this approach is people-centered development.

Among other social aspects of human development, the people-centered development approach should include the following issues in accumulating contents:

- Life expectancy and the health situation of the community
- Access to basic education and literacy of the community
- Gender equity
- Greater participation of community people in government decision processes

People-centered development effort also requires large amounts of information from the various development sectors to reach the grassroots level. For the community to take responsibility in the development process, it needs information on the following:

- Agriculture and livestock
- Environment
- General consumer commodities
- Primary healthcare facilities
- Education and literacy programs
- Leisure and entertainment
- Indigenous technologies and local knowledge
- Income generation
- Basics of demography (population, child mortality rate, social organizations in the locality, land disputes, and issues on human rights)

The role of information services in the human development approach (developing country concept) is very much different from the role of information in the advanced approach (developed country concept). In this aspect,

- Access to information should be for all groups in the community;
- Information should be treated as a tool for building self-reliance, social empowerment, civil society participations, and gender equity;
- Indigenous knowledge and locally generated content should be given priority; and
- Traditional channels of communication should be given preference.

In discussing information and knowledge, it is useful to start by observing that both are human creations (or social constructs). They are designed to explain and meet some of the challenges that individuals or groups face at a particular time and place. No one can fully understand the meaning of knowledge and information without recognizing that they can be a double-edged sword. They can be used to empower the individual and the group. They can also be used to continue relations of power and control. When a ruling group uses information and knowledge to control (dominate) people, those people are led to despair, powerlessness, and unsustainable lifestyles (Mchombu, 2002).

From a cumulative perspective, this research suggests that collaborative communication cannot be completely enforced via ICTs. ICTs may be essential but they are not adequate for the soci-
etal transformation promised by the proponents of virtual networking essence. The adjustment to an open information-sharing environment instigated by virtual networking can be seen as challenging to the community participants who are accustomed to a relatively reluctant working environment. Despite the many positive reports on virtual entrepreneurship, it is crucial to consider that intraorganizational communication is burdened with unrecognized intricacies, and added complexities of interorganizational relationships.

Because purely virtual entities are still atypical, the processes for developing virtual organizations and the eventual impacts of virtuality are still unknown to the researchers. Proponents of virtual networking exalt the benefits in terms of easy accessibility, greater adaptability, faster response time, and task specialization, while critics argue on potential downsides, such as broader divergence, decreased uniqueness, and higher probability of disastrous effects, including physical network disruptions.

KEY TERMS

Development Processes: These are processes for the improvement of society and community, through diversified means, creating demands and solutions at the appropriate dimension of necessity.

Information Dissemination: Content of any book, paper, map, machine-readable material, audiovisual, or other documentary material, regardless of physical form or characteristics, making them available to the public is a form of information dissemination. Means of dissemination may be through information resource databases, information portals, the Internet, or other available media.

Information Exchange: Putting ideas and concepts in the correct formats and get them circulated to other persons can be termed as information exchange. However, experiences and prior knowledge about the content are essential for making it become knowledge.

Social Network: It is a group of peers, subordinates, and interconnected people who provide general information about what is going on within the organization, ask specific advice on how to accomplish assignments, and obtain feedback about the consequences of different strategies.

Virtual Network: A form of network that provides virtual circuits and that is established by using the facilities of a real network. The term virtual network is used to refer to the appearance of a single, seamless network system.

Virtual Networking: It is a process of using the virtual network to gain access to specific resources, and exchange of information for mutual benefit reflecting an initial level of trust and commitment among participating organizations.
Chapter 6.2
Gender and Telework in Information Technology

INTRODUCTION AND BACKGROUND

Information technology (IT) work is often distributed geographically through practices such as teleworking. Telework lends itself well to IT workers because they work easily with information technology, which is required for telework, and because many IT jobs consist of knowledge work—the creation and analysis of symbols and ideas—which may be done anywhere and anytime.

Advances in information technology make distributed work possible. Globalization and the need for organization flexibility make distributed work necessary (Davis, 1995). Organizations distribute work to take advantage of scarce and inexpensive talent, enhance innovation and product design, and to reduce real estate costs, development time, and labor costs. Workers choose distributed work to balance work and life demands, reduce commuting time, accommodate disabilities, and take advantage of distant opportunities. Telework, a form of distributed work first described by Nilles (1975), has established itself throughout the United States. We discuss telework trends and provide some data describing teleworkers in IT professions in the United States.

Four forms of telework are commonly used (see Key Terms; Bailey & Kurland, 2002; Kurland &
Most teleworkers use a combination of these forms, although home-based telework is most prevalent (Davis & Polonko, 2001). Each form of telework is practiced for different reasons and produces different work experiences and outcomes (Bailey & Kurland, 2002; Davis & Polonko, 2003; Helling, 2000).

A national survey of telework practices in the United States was conducted in 2001 under sponsorship of the International Telework Association and Council (ITAC) and AT&T (Davis & Polonko, 2001). The sample was stratified to represent all U.S. households and was diverse with respect to gender, ethnicity, occupation, organization size, and industry. Results showed that there are approximately twenty-eight million teleworkers in the U.S. Compared to nonteleworkers, teleworkers are significantly more likely to be from the Northeast and West, male (54% of teleworkers), have higher education and income, work in professional/managerial occupations, work in industries such as construction, professional/scientific/technical services, health care/social assistance, and work in very small and very large organizations. There were no significant differences in telework practice for marital status, race/ethnicity, and age.

Davis and Polonko (2001) report several findings concerning telework and its impact on ability to balance work and family demands that are relevant to IT professionals. Teleworkers, especially those who work at home, are more likely than nonteleworkers to report working longer hours and that the demands of their personal life take time away from their work. They also report more difficulty relaxing at home when doing non-work related activities. However, teleworkers are also more likely to state that their family members and friends report less unhappiness with the amount of time they spend working at home, report that their home life is less likely to prevent them from working the amount of time they want to work at home, and that working at home interferes less with other activities in their personal life.

These differences suggest that teleworkers may be better able to manage the time they spend working at home compared to nonteleworkers. While teleworkers may experience some personal costs, such as difficulty relaxing, they experience significant benefits compared to nonteleworkers in terms of less interference between work and family roles. Women may particularly benefit from telework because they are often responsible for childcare.

Research examining women teleworkers shows mixed benefits. Women teleworkers may experience less stress because they have more control over their time, do less commuting, experience fewer distractions, and are available to their families during the day (Kraut, 1988; Olson & Primp, 1984). On the other hand, women teleworkers may also experience greater stress due to reduced separation between work and family obligations resulting from bringing the workplace into the home (Olson & Primp, 1984). All teleworkers report working more hours (Davis & Polonko, 2001; Mirchandani, 1998).

Men and women adapt differently to work at home. For example, the time saved by reduced commuting gets used differently; women tend to use this time to do household chores, whereas men use this time to do more job-related work (Steward, 2000). Both men and women maintain a separation between work and family, but they do so for different reasons. Mirchandani (1999) reports that most women state that they separate work and family to reduce the stress of simultaneously attending to work and family obligations, whereas no men report such reasoning. She adds, “For women, the home is not a place of nonwork, but rather another workplace” (p. 92). Women teleworkers, especially those with children, may experience more difficulty in balancing work and family life than men (and women without children). Yet women claim to choose to telework as a means for balancing work and family obligations (Beasley, Lomo-David, & Seubert, 2001).
TELEWORK IN IT ORGANIZATIONS

Telework may be easier for IT workers due to the knowledge content of their work and their facility with using technology, although research results are mixed. A study of IBM teleworkers and non-teleworkers showed no difference in work family balance (Hill, Hawkins, & Miller, 1996; Hill, Miller, Weiner, & Colihan, 1999). In participant interviews, many claimed that teleworking helped them fulfill family obligations and strengthen family relationships, whereas others felt that teleworking blurred the boundary between work and family life and therefore made it more difficult to balance work and family demands.

Telework affects different aspects of work-family conflict. Selgrade and Davis (2005) studied a sample of teleworkers that included IT workers as well as workers from other professions from eleven organizations throughout the United States. They found that the effects of work interfering with family (WIF) were different than the effects of family interfering with work (FIW). Results showed that WIF, but not FIW, was negatively related to telework satisfaction and organization commitment and positively related to turnover intentions. Moreover, WIF increased with telework duration, whereas FIW increased with the number of children (Selgrade, 2004).

We report the following findings from a study of IT workers in eleven organizations. Major, Davis, Sanchez-Hucles, Germano, and Mann (2006) describe the research in more detail. We report here differences between IT teleworkers and nonteleworkers. All differences are statistically significant except where noted.

Forms of Telework

We found that 39.8% of IT workers report teleworking (less than one day per week to five days per week), mostly from home. Of those teleworkers who reported working at home, the majority of them do so less than one day per week (78.3%), whereas 21.7% report working from home one day per week or more. Of those teleworkers who reported working at telework centers or satellite offices, the majority of them do this less than one day per week (59.1%), whereas the remainder (40.9%) report teleworking one day per week or more. Finally, of those teleworkers who reported working on the road, 47.2% report doing this one day per week or more.

Demographic Profile of Teleworkers

Gender

Females comprise 39% of the total sample; only about 1/3 (36.3%) of them telework (see Table 1). Males make up 61% of the total sample, nearly 1/2 (48.3%) of them telework. Consistent with national data (Davis & Polonko, 2001), male IT workers are more likely to telework than women.

Race

Whites were slightly more likely to telework, but there were no significant racial differences between teleworkers and nonteleworkers. The finding of racial balance in teleworking is consistent with national patterns (Davis & Polonko, 2001).

Relationship Status

We examined whether IT teleworkers tend to be single or in a committed relationship. We define “single” as those individuals who reported being single, divorced, or widowed and “committed” as those individuals who reported being married or living with their partner. Teleworkers and nonteleworkers were similar in their relationship status. These results mirror national data (Davis & Polonko, 2001).
Number of Children

Teleworkers and nonteleworkers were similar in the number of children they had. When examining only teleworkers, we found that the gender breakdown mirrored that of the overall sample; male teleworkers tended to have slightly more children ($M = 1.29$) than did female teleworkers ($M = 1.02$).

Highest Degree and Salary

Consistent with national patterns (Davis & Polonko, 2001), teleworkers had a higher educational level and a higher salary than nonteleworkers. IT workers in our sample were highly educated; most (71.7%) had at least a bachelor’s degree. More than three-quarters of teleworkers (76.2%) had at least a bachelor’s degree, while this was true for just over 2/3 of non-teleworkers (68.5%). This difference was not statistically significant. While males and females did not differ in terms of their highest earned degree, they did differ in terms of their salary; not surprisingly, males earned significantly more than females. When examining teleworkers only, men still earned higher salaries than women.

IT Position

Participants were asked to indicate their current IT position by selecting one of the following categories: conceptualizer, developer, modifier/extend, supporter/tender (see Key Terms). The breakdown was very different in terms of teleworkers vs. nonteleworkers. Proportionally more teleworkers were conceptualizers; proportionally more nonteleworkers worked in supporter/tender positions. These findings are not surprising because supporter/tender positions require IT workers to be in close proximity to the equipment and people they are responsible for supporting, whereas conceptualizer jobs do not. Supporter/tender positions may not allow the geographic and scheduling flexibility required of telework.

Elder Care

We were interested in whether or not teleworkers more than nonteleworkers chose telework because they were responsible for the care of an elder adult and needed the freedom to work from home. There were no significant differences in elder care between teleworkers and nonteleworkers.

Individual vs. Team Work

We asked participants whether they worked alone or as part of a team. We thought that the benefit of telework might be restricted to those who do not work with others. We found that teleworkers and nonteleworkers were similar in emphasis on individual vs. teamwork; the gender breakdown within this variable was similar as well. This finding lends support to the notion that even individuals who work in teams can telework.

Total Hours Worked

We examined the total number of hours worked per week by IT workers. Previous research suggests that one of the disadvantages of telework is that teleworkers tend to work more than nonteleworkers (Davis & Polonko, 2001; Mirchandani, 1998). The findings from the current sample support previous research; teleworkers in our sample worked significantly more hours per week ($M = 48.55$) than did nonteleworkers ($M = 45.25$). In addition, for the entire sample, males worked significantly more hours per week ($M = 47.52$) than did females ($M = 45.42$). However, when we examined the teleworker and nonteleworker samples independently, the gender results were different. In the teleworker sample, males worked significantly more hours per week ($M = 49.37$) than did females ($M = 46.92$). In the non-teleworker sample, there was no significant difference between males ($M = 45.80$) and females ($M = 44.51$) in the number of hours worked per week. These results are consistent with previous
research that suggests that men and women use the extra time they save through teleworking in different ways. Males tend to use this time to do more job-related work, hence their longer working hours; whereas females may use this time to do more family-related work such as household chores (Steward, 2000).

CONCLUSION AND FUTURE TRENDS

Telework is a growing response to the need of organizations to reduce costs, enhance flexibility, and attract and retain workers with valuable skills. It is one way to create virtual teams and virtual organizations. Inexpensive information and telecommunications technologies and increasing global competition will accelerate this trend for IT organizations (Davis, 1995). IT workers, because they engage in knowledge work and are skillful at using information technology, are particularly well suited for telework.

Researchers are just discovering the consequences of telework and how to manage it effectively. Much telework research has been limited by reliance upon small convenience samples, poor measurement, inadequate statistical analysis of results, and inadequate grounding in organization theory (Bailey & Kurland, 2002). Management practice has lagged as well, with little understanding of how to alter organization structures and processes to make telework practice successful (International Telework Association and Council, 2000). There is a great need for well-designed research studies of telework in IT.

Women in many professions throughout the United States participate in telework. Women in our sample of IT workers participate extensively in telework as well, but when compared to men, they participate at a lower rate in comparison to national practice (IT teleworkers in our sample: 67% male, 33% female; national sample in U.S.: 54% male, 46% female; Davis & Polonko, 2001). This difference may be unique to the organizations in our sample. This difference also may be due to institutional barriers such as resistance to remote work among IT managers and work design barriers such as the need to tend to centrally located equipment around the clock. Future research should continue to explore gender differences in telework among IT workers and identify possible barriers and enablers. These results may then be used to help IT organizations and IT workers increase flexibility by distributing IT work away from the traditional office. This flexibility will enhance efforts to balance work and family needs as well as organizational competitiveness.

REFERENCES

KEY TERMS

Conceptualizer: Someone who conceives of and sketches out the basic nature of a computer system. Job titles include: product designer, research engineer, systems analyst, computer science researcher, requirements analyst, and system architect.

Developer: Someone who works on specifying, designing, constructing and testing information technology. Job titles include: system designer, programmer, software engineer, tester, computer engineer, microprocessor designer, and chip designer.

Distributed Work: Work that is distributed across geography and time. Distributed work may take several forms, (e.g., telework, telemedicine, virtual teams, and virtual organizations).

Knowledge Work: Work that consists of the creation and manipulation of ideas and symbols. Knowledge work is common in IT and is ideally suited for distributed work because it is easily digitized and may be done anywhere and anytime.
Modifier/Extender: Someone who modifies or adds on to already created information technology. Job titles include: maintenance programmer, programmer, software engineer, computer engineer, and database administrator.

Supporter/Tender: Someone who delivers, installs, operates, maintains or repairs information technology. Job titles include: system consultant, customer support specialist, help desk specialist, network installer, and network administrator.

Telework: A type of distributed work in which employees work at locations other than the traditional workplace. Major types of telework include: (1) home-based telework—working from home; (2) satellite offices—employees from the same company work at the same location closer to their home, often in suburbs or exurbs; (3) telework centers—similar to a satellite office except that the telework center hosts employees from different organizations; (4) mobile work—working at multiple locations away from the office (e.g., at client work sites, while traveling).

Virtual Organization: A form of organization design in which organization structures and functions are distributed across time and geography.

Virtual Team: A form of work design in which members of the same work group are distributed across time and geography; usually compared to traditional collocated teams, where all team members are located at the same site.

Chapter 6.3
Managerial Careers, Gender, and Information Technology Field

Iiris Aaltio
Lappeenranta University of Technology, Finland

INTRODUCTION

Careers are organizational and institutional, and they have know-how-based contexts. Managerial careers from a gender perspective, gendered “blind spots” in organizations and the invisibility of women in management have been an object of study since the 1970s. Gender is a part of socially constructed individual identity. Gendered identities in organizations are defined and redefined in relationships as people become socially constructed through work groups, teams and interactions. Because of this social construction, femininity and masculinity grow into human behavior and outlook. Understanding gender as an activity and a term in the making (Calás & Smircich, 1996), it is a constitution of an activity, even when institutions appear to see woman and man as a stable distinction (Korvajärvi, 1998). Beyond work-life and organizations, there are multiple institutional and gendered structures. The information technology (IT) industry and companies are also an institutional construction with gendered dimensions, and they also participate on the creation of femininity and masculinity.

Career can be seen as a conceptual artefact that reflects a culture and rhetorical context in its use. It is a kind of window to a network of values, institutions and functions, where actual careers are made. Usually, the formal organization is based on neutrality and equality, but a closer look reveals the deeper social structures that make it different to women and men. There is a concept of an abstract and neutral worker, and this worker is supposed to be highly competent, work-oriented and available, committed to work-life without any knit to private life. These characteristics support a good career climb in an organizational hierarchy, and many of these characteristics better suit men than women (Metcalfe & Altman, 2001). For instance, home responsibilities make often working hours less flexible for women than men. The notion of an essential person with no gender characteristics does not recognize these issues, whereas taking gender as a research topic shows that work-life as a context differs between women and men.
BACKGROUND

Managerial Positions within the IT Industry

Organizational structures, including managerial positions, are gendered by nature. Overall, there is a high degree of vertical segregation, which means that there are few women in managerial positions compared to men (Acker, 1992). According to the United Nations’ *World’s Women 2000* report, women’s share of the administrative and managerial labor force is less than 30% in all regions of the world. This is true also in Nordic countries, where the participation of women in work life is almost 70% and has a long tradition. Women also hold only 1% to 5% of all the top executive positions (Wirth, 2001), and the numbers seem to change very slowly. In the European Union countries, women’s share has barely changed since the early 1990s, and has remained at a less than 5% level (Davidson & Burke, 2000). This division of managerial top positions is called glass-ceiling phenomena, and it exists world wide (Powell, 1999): “The higher the managerial position the fewer the women.” As a result of this, women and the highest economic power become separated.

Taking a closer look at the numbers, the least amount of women in top positions are found in male dominated areas, such as heavy industry and construction business, where the amount of female leaders is less than 10%. IT is also a male-dominated field. There are few female directors in an organization that employs mostly men (Kauppinen & Aaltio-Marjosola, 2003). The number of female managers has increased slowly. In many fields, like IT, it is still low (Ahuja, 2002). Women’s and men’s work in organizations also differ from each other by nature; that means women and men end up doing different kinds of work horizontally.

Current statistics indicate that women account for about 25% of technology workers in the European workforce and about 20% of those in the United States’ (U.S.), and that there looks to be a polarization in the type of work women and men do. The majority of women are employed in routine and specialist work, like clerks, while men are engaged in analytical and managerial activities. In the studies, overall 10% of males and only 3% of females within IT had achieved senior managerial positions (Ahuja, 2002). Salary gaps for women and glass-ceiling perceptions are reported as well in this research. Despite that the IT profession has grown in recent years, there remains a gender imbalance and, in some cases, even evidence of a decline in female workforce numbers (Ahuja, 2002).

Managers and leaders have identities that become constructed within special circumstances, and IT constitutes a particular background for identities to grow in. As stated by Davis (1995), organizations and their activities are cultural constructs arising from the masculine vision of the world, and IT’s close connections to the male-dominated technology field and its high numbers in male participation makes its connection to masculinity evident. The glass ceiling in the IT field might even be stronger that in others, because there is evidence that women there tend to be stereotyped as staff, the ones who don’t take risks, rather than “line” people; whereas men are the innovators and designers (D’Agnostico, 2003; Russell, 2004). This results on men’s career outcomes including higher managerial positions.

The segregation of work is based on the classical stereotypes of women’s and men’s behavior and orientations. Men are oriented towards technical and industrial work, whereas women are engaged in occupations where one needs caring ability and social integration, such as teachers and nurses. Ideals for men’s and women’s work differ from each other and carry stereotypes (Aaltio, 2002). Women and men are easily valued differently because of their gender. In society, there are different places for women and men, and this holds both in families and in work organizations. Men
historically relate to the public and women to the private spheres of life (Acker, 1992). By extending their roles and breaking into public institutions, women challenge the prevalent male ideals and bring private issues into public and institutional spheres. Career opportunities mean different things for men and women and, therefore, challenge them differently.

It is also notable that the relationship between gender identity and participation in the IT profession is not the same for all women, nor is it based on monolithic values that are the same for all women. Each individual woman experiences societal influences differently and brings her personality and characteristics into the field (Trauth, 2002), even if women’s institutional backgrounds are similar.

**WOMEN’S CAREERS WITHIN THE IT FIELD**

Discourses of Career: Interviews from IT Managers

In the study, five managers were interviewed, two of them women and three men. They all work in a large, successful IT industry company in Finland, are young or early middle-aged, and are labeled as high achievers with a promising future in the company. In the interviews, it was asked how they see their managerial career development up until now and in the future. The data gathered was narrative by nature, because a lot of space was given to open talk around the topics raised at the interview (Aaltio-Marjosola, 2002).

As one of the managers describes: “Professional development is my area, and I am globally responsible [for] this part of the business. The culture here in the company is, however, where I start from. In my close network, we have a team of 10 people, but globally, it is a big circle, of course.” As seen in the citation, instead of manager-subordinate relationships, she emphasizes the close network and teamwork orientation. Another manager illustrates his job with no clear subordinate relationships: “I came here to coach a team with a few people and to coordinate things. This is more or less process management; I have to think first and then make things simple and concrete, communicate them to the others. I work closely with the head of the company in some projects, in addition. In fact, I do not see that there is a clear organization where I am a leader.”

Further, one of the IT managers describes her job: “I am a personnel consult, even if I also take care of the unit’s personnel management, and my work is multiple of things. For instance, I also do training and lecturing in our inner training seminars.” In spite of the high organizational position, she sees her job to be consultative, including support of teams.

It is also typical to describe career development that includes multiple paths, work in many organizations and rapid movements during the career. One of the managers described his work: “I find that my career is more or less a bumpy road, not going upward all the time. I have started two times from a beginning in my job and found that you have to take your space in every new job no matter what is your position when you start. You have to find your fit to the values of the enterprise, feel they are near to yours, to get the right start.” Still another manager describes his career development: “My job is changing. I will take care of the process development here, coordinate and harmonize things. I have to move as rapidly as the whole company does, this is the way it comes here. The number of my subordinates will be like 50 or 100 altogether, I am not quite sure how many they are, in fact.”

Career, in the descriptions of these managers, is advancement of abilities, seeing oneself as an important and integral person in a certain close network, and giving good support for subordinates. None of the interviewed managers started their description of their work from the organizational ladder or other kind of embodiment of hierarchy.
Managerial Careers, Gender, and Information Technology Field

This shows the IT industry’s development, being at the top of companies that themselves develop work practices and communication styles that break traditional ones with hierarchy and high formal authority. Much of the work is based on projects and close teamwork. Both men and women adapt into this if they seek to be successful in the company and get advancement.

Managerial Careers of Women within IT

Today’s careers are based on a variety of choices; careers are “boundaryless” due to multiple routes and individual choices. To predict career development is more difficult than it used to be. Individuals’ knowledge and skills give them good possibilities to move from one job to another, and organizations seldom serve for a life-time basis in a person’s career development. Flexibility and adaptability of careers have increased, and diverse assignments are common instead of a clear and one-path kind of career development (Arnold, 2001; Storey, 2000). Work will become rich from difference and requires abilities and motivation typical for women, who have always combined many roles, private and public, and thus learned flexibility.

For instance, Ahuja (2002) suggests that there are barriers to female managers’ careers within IT, and that their minor positioning in the IT industry is due to an “old boys” network. There is a large pool of qualified and experienced male professionals, whereas the pool of women is still few. This counts for a lack of female role models and mentors for the younger generations, and discriminatory practices remain. There is also evidence that women do not see IT as an attractive option, and even if they do, they are technically less equipped to come over. There are few managerial role models for women in IT industry companies, and women would benefit from career consulting.

Himanen (2001) argues that computer hackers will become heroes of the information society, and the heroes of IT are and will in the future be men, as seen in, for example, Silicon Valley, where there are very few women in higher-level positions. However, men also represent a variety rather than a unity. Taking the fluid notion of gender, we can see that masculinities are carried by organization cultures and are not unitary. In the changing work life, advancement also requires new skills and attitudes from men, not only for women as a unitary category.

Also, family-work contrast barriers were reported. A survey (Prencipe, 2001) outlined attitudes of IT women leaders, half of them in senior positions. The study showed a positive personal valuation of one’s work, but also that balancing personal and professional life was still complex for most of them. Reported stress was due to working late, constant change and sometimes reported discrimination in a social environment consisting of mainly young, often male colleagues (Prencipe, 2001). When managerial career advancement starts from lower professional levels, factors like role stress tend to decrease job satisfaction, resulting in lower career outcomes of women (Igbaria & Chidambaram, 1997). In addition, at the institutional level, where changes are very slow, women and technology are still a combination that arouses suspicion.

FUTURE TRENDS AND NEEDS OF RESEARCH

Challenges of IT women managers’ career development are in line with the results of earlier gender studies. In addition, the attractiveness of the company cultures for women managers is also questionable, because of the cultural codes that might be gender-biased, repulsive and more favorable for men to follow. These cultural codes need to be studied and better understood.

As a part of high technology, IT has taken the world by storm and is changing the way businesses learn, as well as the nature and characteristics of work. The implementation of IT within and across organizations is reducing the importance of hierarchy and command-and-control authority systems that structure power within them. High technology changes the traditional managerial and communicational style from vertical to horizontal (Zeleny, 1990). In high technology-oriented industries, power is connected with expertise, which may break down the traditional hierarchy in an organization (e.g., Gunz, Evans, & Jalland, 2002). Research is needed on the special nature of work in IT companies, in order to understand which kind of management they really need, in terms of good results and higher well-being of the work force.

IT enterprises are themselves examples of “new” ways of management and doing work. It has been stated that the IT industry is in transition between the old sense of identity and the new one (Colwill & Townsend, 1999). As argued, the old culture was directed towards providing the answers, not at meeting the needs of the users. Working in intense networks is increasing and good communication skills are highly needed in the future. Gender-biased cultural expectations and gender stereotypes still work as a barrier for female managers’ careers in IT. However, the changing nature of IT work and its prevalent practices make it open to diversity of expertise and values. Both women and men can benefit from these developments if the IT field itself learns gender-equality and tolerance.

The future’s industries also compete to commit good expertise, and women are a resource. Multiple skills and their good management are needed, and new solutions to old problems will be searched. This also will advance women’s managerial careers.

CONCLUSION

IT-field companies appreciate technology development. They have to learn understanding of social and cultural aspects that, however, are the true background for their development in the future. The field should attract both capable women and men. While there are a few managerial role models for women in the IT industry, women involved would benefit from career consulting and mentoring programs (Ahuja, 2002). The use of tele-work and e-leadership might also positively affect women in the industry, because they support combining family and work life (Avolio, Kahai, & Dodge, 2000; Beasley, Ewuuk, & Seubert, 2001). This kind of supportive activities may attract more women to the field and advance women’s managerial careers. Organizational cultures that grow towards multiplicity of values and a variety of femininities and masculinities may be better work environments, especially for women but also for men in the future.

REFERENCES

**KEY TERMS**

**Career:** Consists of the sequential choices made by a person. It is a developmental process of professional identity and personality.

**Culture:** A human process of constructing shared meaning that goes on all the time and is based on human unique capacity for self- and other-consciousness.

**Doing Gender:** Concerned with the constitution of gender through interaction, and makes gender a consequence of an ongoing activity.

**Gender:** An integral part of socially constructed individual identity that constitutes and restructures a multitude of cultural and social phenomena.

**Gender Bias:** To generalize essential individual behavior without gender dimensions.

**Gender Stereotypes:** Refer to the traits and behaviors believed to occur with differential frequency in the two gender groups of women and men.

**Glass Ceiling:** A metaphor that describes the tendency of women get excluded from top management in organizations in spite of their occupation of middle-management positions.

**Horizontal Gender Segregation:** Refers to the structure of the workforce that tends to become separated into women’s and men’s work.

**Organizational Culture:** A collective construction of practices, meanings and expressions that can be seen developed in interaction within organizational social spheres.

**Vertical Gender Segregation:** Refers to the structure of organizations that position women on lower managerial levels compared to their male counterparts.
Chapter 6.4
Social Networking and Knowledge Transfer in Collaborative Product Development

Katariina Ala-Rämi
University of Oulu, Finland

ABSTRACT

Software product development requires connecting of specialized information and know-how. Therefore, planning and production are widely done in networked projects. This chapter studies inter-firm collaboration to explore the role of face-to-face meetings and information and communication technology in knowledge transfer in product development by using case studies of software companies in Oulu, Finland. Clusters are important in forming trust and mutual understanding. Thus, a compact city region and effective social networks are beneficial for inter-firm collaboration. However, information and communication technology is very valuable for routine communication and documentation, but also in distance collaboration. Geographical distance affects inter-firm collaboration in terms of practical arrangements, such as working hours, yet cultural differences bring additional challenges. This chapter considers and scrutinizes social networking in collaborative product development, and the role of clusters and information and communication technology in such development, as among the key success factors.

INTRODUCTION

In an increasingly globalized economy, the competitiveness of an urban region depends on how well firms adjust to increasing competition and growing complexity. In knowledge-based sectors, social networks of actors are considered vitally important in keeping a firm’s information and know-how up to date. Besides being an individual process, learning is also a social process in a specific social context (Wenger, 1998). The functional urban region of Oulu (FUR Oulu),
with a population of 210,000, is regarded as one of the most successful information and communication technology (ICT)-based economic regions in northern Europe (Oinas & Lagendijk, 2005, p. 324). Strategic decisions at the University of Oulu and government investments were the starting point for the growth of Nokia’s mobile phone industry, which has with its subcontractors formed the foundation of the technology cluster in the Oulu region (Donnelly & Hyry, 2004, pp. 136-138; Männistö, 2000, p. 84). In spite of the success, the ‘Oulu Phenomenon’ could not be understood without Nokia’s development (Männistö, 2002, pp. 2002); additionally a small group of skillful people with strong mutual trust and a shared goal have been in a crucial role in that development (Donnelly & Hyry, 2004, pp. 135-136; Tervo, 2004, p. 86).

The high technology cluster in FUR Oulu consists of five different branches, of which information technology is covering over a half of the enterprises. Other technologies are multimedia, health and wellness, biotechnology, and environmental technology (Donnelly & Hyry, 2004, pp. 135-136). In the region, information technology covers mostly telecommunications and software. However, classification of different technology cluster is complicated, since a remarkable amount of telecommunication is assessed to belonging to a software cluster (Männistö, 2002, pp. 199). The software cluster, with strong connections to telecommunication and also wellness sectors, is expected to develop rapidly in FUR Oulu (Männistö, 2002, pp. 184). Moreover, software products are complex products that require many combinations of specialized information and know-how. Therefore, planning and production are more likely to take place in networked projects (Miettinen et al., 2006, p. 26).

Nonetheless, the region meets new challenges along with global development, as Nokia among other long-standing successful firms is increasingly moving its production abroad, mainly to the Asian countries, where production expenses are lower and human resources are abundant. Nokia still plays an important role in investment in research and development (R&D), but there is a significant increase in the investments of small companies (Lassila et al., 2006, p. 31). The software industry has grown rapidly also other parts of the Finland, and the sector is considered a future possibility for economic growth (Finnish Software Business Cluster, 2006). Software production does not require transporting of heavy materials; the crucial issues are skilled labor and good infrastructures, so in principal the sector is well suited for a peripheral high-cost region such as northern Finland. By peripheral region, I mean in this case its physical location as the northernmost inhabited region far away from the main market areas, and even though Oulu is sixth largest city (130,000 inhabitants) in Finland, it is a small place globally. Moreover, northern Finland outside FUR Oulu is very sparsely populated (the population density of the whole region is 4.6 inhabitants per square kilometer). However, per capita investment in R&D in FUR Oulu is the highest in Finland.

Technopolis Linnanmaa, next to the University of Oulu, is the oldest technology center in the Nordic countries with over 100 high-technology firms, 4,000 employees, but also providing a good infrastructure and meeting facilities (Jauhiainen, 2006, pp. 1413). The idea of the Technopolis concept is to build a supportive high-technology business environment by providing business and development services in same premises (Launonen, 2006). Besides wireless Internet connections, these services include all kinds of practical support for business activities, from cleaning and copying to tailored packages of more demanding clerical and personal assistant services (Technopolis, 2007). Nowadays Technopolis has several buildings in FUR Oulu, located in strategically important places such as next to the University of Oulu, the city center, or close to airport (see Figure 1). Furthermore, the Technopolis has
premises in four other important cities in Finland and most recently started in St. Petersburg, so the Technopolis group is the largest sector in Europe with its 950 companies (Launonen, 2006).

The idea behind the Technopolis concept is the collection of so called ‘critical mass’ in the same premises in order to develop growth clusters by providing technical infrastructure and possibility to meet and network, while being located in same building. Being located in close proximity is widely seen as an advantage for collaboration and networking (Howells, 2000; Torre & Rallet, 2005). This study explores the limitations of distant collaboration and the city’s urban scale and diversity in developing growth clusters. It uses a specific case as an example to explore knowledge transfer in product development. It studies social networking in collaborative product development, and the role of physical and temporary clusters and ICT in that development.

BACKGROUND

To create new knowledge and innovation faster than competitors, interaction with local and global actors is vitally important (Asheim & Herstad, 2003, p. 3). Technological development is diminishing limitations in communication, so that factors other than physical distances are increasingly decisive in collaboration and networking. The knowledge contained in a firm consists of the people working in the firm and their ability to achieve new information and knowledge. Communication between individuals, also with people outside the firm, plays an important role in staying up to date in local and global development and know-how. Geographical proximity makes networking and communication between individuals smoother (Howells, 2000, pp. 53-55; Nachuum & Keeble, 2003). The most important way to find needed know-how or capabilities is to
use existing social networks. Another is professional gatherings, which Maskell et al. (2006, p. 999) call ‘temporary clusters’. Cafés, bars, and other informal meeting places can act as temporary clusters for exchanging information, but they are more random than organized meetings.

Nevertheless, even though geographical proximity is an advantage for networking and knowledge transfer between enterprises, it is not an automatic guarantee of or a compulsory condition for networking (Bathelt, 2005, pp. 108-110; Boschma, 2005, p. 63). Furthermore, geographical proximity is not relevant if there are no shared interests and goals, created in a spatial cluster with complementary or similar capabilities. Because of the above-mentioned, proximity is seen here as being relative, suggesting that there are different dimensions of proximity that are required in collaboration, such as organizational, temporal, cultural, cognitive, social, and institutional proximity, not just geographical proximity (Boschma, 2005; Oinas & Lagendijk, 2005, p. 311). Depending on the situation, different types of proximity have to be taken into consideration along with geographical proximity (Aslesen & Jakobsen, 2007, p. 191; Torre & Rallet, 2005, p. 49).

ICT supports the activities of enterprises by means of easy and fast modes of communication. ICT has also made information more ‘ubiquitous’ by accelerating the spread of new ideas, information, and innovations. Consequently, ICT has a central role in knowledge-based economy, in which knowledge generation and exploitation play a predominant part (Roberts, 2000, p. 429). As the information is more easily reached by everybody, also competition between firms has increased, creating pressure to produce new innovations and products faster. However, not all knowledge is ubiquitous and easily expressed with words, as Polanyi’s famous concept of ‘tacit knowledge’ suggests. Some knowledge is even subconscious and tied to physical skills. Some capabilities are built up over time in certain regions, such as interpersonal connections and a particular pattern of inter-firm networking, and not possible to transfer in other regions (Lawson & Lorenz, 1999, p. 310).

Roberts (2000, p. 429) expresses that ICTs “favor the transfer of knowledge that can be codified and reduced to data.” However, ICTs increase information about sources of knowledge and communication between distant actors in the same field, especially when sharing a common social and cultural framework, and thus is promoting R&D collaboration (Roberts, 2000, pp. 435-436). It has been argued that especially new tacit knowledge can only be diffused via face-to-face interaction (Andersson & Karlsson, 2004, p. 284). Cross-cultural limitations can also result in unexpected difficulties, as tacit knowledge is embedded in a social and cultural context (Roberts, 2000, p. 431). To make it possible to reach an agreement on the distribution of work and the rules of communication, virtual projects should be started with face-to-face meetings (Pyörä, 2005, p. 50). Furthermore, also codified knowledge is context-dependent, that is, in terms of common language or professional background (Lawson & Lorenz, 1999, p. 309; Roberts, 2000, p. 431).

The theoretical framework of this chapter is based on two approaches. First of all, social networks are important in forming and dispersing networks. Especially informal relationships are vital in this phase. Secondly, activities like product development and knowledge transfer take place within the community of practice (CoP), which is defined as a group of people with shared interests and aims (Hislop, 2004, p. 38). The concept of social network refers to the idea that social relationships consist of nodes (individual actors within networks) and ties (relationships between actors). Strong ties are more likely to exist in informal contacts with family members and friends sharing the same interest, knowledge, and trust. These relationships have special importance for networking. Formal contacts that mostly exist with clients, suppliers, competitors, and workmates are weaker, but they bring new ideas and opportuni-
ties to the network (Ellis, 2000, pp. 445-446). For knowledge spillovers, informal linkages between firms, such as networks of small firms, are important (Dahl & Petersen, 2003, p. 5).

The idea of the CoP concentrates on social learning, which requires that people have a common interest in some subject or problem and that they collaborate over an extended period to share ideas, find solutions, and build innovations. Wenger et al. (1999, p. 4) state:

...these people don’t necessarily work together every day, but they meet because they find value in their interactions. As they spend time together, they typically share information, insights, and advice. They help each other solve problems. They discuss their situations, their aspirations, and their needs.

In different CoPs there are not only differences between knowledge and common interest, but there can also be different assumptions and interpretative frameworks, leading to a situation where there is no understanding of the knowledge of the other community (Hislop, 2004, p. 40).

This study uses a specific case to explore the networks of software companies and knowledge transfer in product development. What role does the city’s urban scale and diversity have on the development of growth clusters? What knowledge is transferred by using ICT? When are face-to-face contacts necessary? How does the distance between collaborative partners affect product development?

FINNISH INNOVATION SYSTEM AS A PROMOTER OF SOFTWARE INDUSTRY

A national innovation policy has been implemented in Finland since the beginning of the 1990s. Nowadays, the Finnish innovation policy is based on a national innovation system and local innovation systems (Lievonen & Lemola, 2004, p. 40; Suorsa, 2006, p. 30). The Finnish innovation system is considered internationally competitive (Finnsight2015, 2006, p. 8), but vulnerable because of its small size which leads to limited resources and funding of research. Finland’s physical location in the periphery of Europe creates additional challenges; the population and economic activities are mostly concentrated in a very small region in the southern and southwestern parts of the country. Because of the limited resources, there has been a focus on a few fields and regions (growth poles) with enough resources and quality. The Finnish innovation system emphasizes knowledge, learning, know-how, research, and innovation for the competitiveness of Finland, but also the whole society (Suorsa, 2006, p. 30).

The development of the ICT industry and growth in labor productivity were essential to Finland’s rapid recovery in the 1990s from one of the deepest depressions of the country. However, Finland’s economy is facing challenges in regional development. There is strong dependency on the ICT sector, an internationally small number of small and medium-sized enterprises (SMEs) and an aging population (OECD, 2005, p. 7). Investments in R&D have gradually increased in Finland, being almost 5.3 million euros in 2004, which is 3.5% of the GDP. Enterprises’ share of R&D has increased up to 70%, and higher education constitutes up to 20%. Even though the investment of the public sector has increased in terms of the number of euros, its share has declined to 10% (Statistic Finland, 2006). Nokia still has an important role, providing almost half of enterprises’ R&D investments (Suorsa, 2006, p. 33).

As mentioned before, the Finnish innovation policy aims to support successful industries in regions with good economic growth possibilities (Lievonen & Lemola 2004, p. 55). The Centers of Expertise Program is the main instrument of Finnish regional innovation policy. The idea is to support networking of enterprises with research...
Social Networking and Knowledge Transfer in Collaborative Product Development

universities and universities of applied sciences in the region, public sector entities, and business support services in specific fields, such as software product business (Centers of Expertise, 2006). Also, one important local investment on urban technologies is the panOULU (public access network OULU) project, which provides in its coverage area wireless broadband Internet access to everybody (panOULU, 2007).

The software industry has grown rapidly in Finland, and the sector is one future possibility for economic growth. There are about 1,100 software companies in Finland employing 12,400 professionals and generating gross annual revenues of about 1.2 million euros. About one-third of the revenues come from international sales (Finnish Software Business Sector, 2006). In FUR Oulu there are about 14,000 jobs in the 569 ICT companies, and the sector provides 18% of all jobs in the region (SeutuNet, 2006). A total of 113 firms are classified as software companies, and they provide 1,200 jobs. Hence, in relation to the city scale, the amount of jobs in the ICT sector is high in Oulu. As the production process in the software industry is complex, product development requires a combination of several actors, also subcontractors and clients, know-how, and economic resources. First of all, the end products are developed in small series or single projects. Secondly, they are formed as a combination of several parts. Thirdly, they require a combination of many specialized fields of knowledge and know-how, which often requires intensive collaboration between specialized companies (Miettinen et al., 2006, p. 26).

COLLABORATIVE PRODUCT DEVELOPMENT: CASE STUDY OF OULU

Concepts, Issues, and Problems

The Technopolis concept differs from ordinary business centers by offering development services and creating a critical mass by gathering enterprises into the same premises. Technopolis in Oulu acts as a partner in regional development, where the main working method is forums. The idea of the forums is to strengthen the competitiveness and expertise of everyone participating in the activities by launching practical joint projects involving 20 to 30 companies. Ideally, these forums will result in new, successful products or practices (Launonen, 2006). Moreover, the cluster in Oulu is very compact physically and the traffic jams are very rare and slight, which makes temporary clustering easy. Almost any time of the day, for example, it takes only 20 minutes from airport to technology center (see Figure 1). Most software companies are located in Technopolis premises or the city center, so several meetings with different companies can be arranged during one day.

The previous studies (Ala-Rämi, 2007; Ala-Rämi & Inkinen, 2008) have shown that high-technology enterprises in northern Finland find ICT and face-to-face contacts both important and complementary to each other; also geographical proximity plays an important role in the enterprises’ inter-firm collaboration. This study aims to go deeper on these issues by using the case study, which provides glimpses of the experiences of globally successful software companies. They all have their product development in the city of Oulu and were born as spin-offs from another firm or project. The study examples are based on thematic interviews of managers of software companies (three firms out of six) that were chosen in the Global Launch program. The program leader was also interviewed. The idea of these interviews, besides to hermeneutic understanding of the issues studied, was also to find some ‘best practices’, and therefore the most advanced companies globally were chosen to interview. However, the study uses multiple sources of evidence and also previous study findings, including other authors (Männistö, 2002; Tervo, 2004; Simonen, 2007; Roberts, 2000), to support these results.

Global Launch is a tool of the Centers of Expertise Program, whose task is “to use in-
ternationally competitive knowledge and skills as a resource for business activities, creation of new jobs and regional development’ (Centers of Expertise, 2006). The program uses experience from a previous successful program (Niinikoski et al., 2006), but also takes into account challenges by including firms in very different development phases and orientations in business. So the Global Launch program was targeted toward ‘born global’ companies. The criteria in choosing these enterprises were that they already have a promising product, a large potential market area, and a competitive edge, which was good selection principle also for this study. Although the program did not start as planned, the interviewed companies participate in the larger ‘Global Cluster’ project in which the original program was merged. The aim of the interviews was to deepen some themes raised from a larger survey of software companies in the beginning of 2006 (see Ala-Rämi & Inkinen, 2008) which are only possible to study qualitatively.

All these companies are classified as small companies, having less than 50 full-time employees, and they were collaborating in product development. They have their main office with product development in Oulu, but they all have at least one sales office abroad, which serves international customers. The interviewed managers saw that internationalization is essential, since local markets are very small — only some 0.3% of software markets are in Finland. As the interviewed companies are already successful globally and have the potential to develop further, this study focus on ‘best practices’ already in use in these companies.

We understood in the very beginning to start producing software products for firms, mostly to software companies, but also to other firms, meaning test tools that have only one market area, which is the whole world. There are no local markets and never will be, one has to be global or there is no possibility of surviving. As a matter of fact, we got a half of our revenue from the U.S. already in the third year, and in the U.S. these games are usually make or break. We do have an American as our chief executive officer at the moment. We seek there that kind of feeling for business that is not found in Finland or at least is difficult to find...as we aim to be market leaders in our own trade, which means we must grow as big as tens of millions of euros annually.

— R&D Manager (author’s translation)

Social Networks of Software Companies

Along with a long history, the local technology center has had time to develop as an intensive growth cluster, in which the local culture is experienced as a supportive environment where ‘everybody knows everybody’ (Lappalainen, 2007; Tervo, 2004). So, there is still strong social networking in FUR Oulu, where information about new collaboration partners spreads mostly through informal contacts, such as former fellow students and friends (Männistö, 2002). Government arrangements of companies also play an important role in networking.

Well, mostly there has been some kind of existing contact, so [the parent company] is quite natural...In Helsinki there is one firm which is kind of owned by former [parent company] employees. Here in Oulu we have used one firm, in which there is such a situation that one of my old friends went to work there and this way that firm ended up as our subcontractor.

— Chief Executive Officer (author’s translation)

A strong community of practice has its drawbacks: there is a danger of lock-in and reduction of diversity (Oinas & Lagegendijk, 2005, p. 318), in case there is a limited number of skillful actors. Knowing the local actors and their know-how
Social Networking and Knowledge Transfer in Collaborative Product Development

is an advantage and creates flexibility, but it has some challenges. Collaboration with well-known people is fast and easy, even communication routines already exist. However, that is not always the most profitable solution in the long run.

A shared interest brings actors together. Around a broader discussion of cultural events or sports, it is easier to discuss more confidential issues and bring up new ideas. Many innovations are not that actively invented, but are found as a result of social interaction. Thus, temporary clusters act as platforms for new ideas (Maskell et al., 2006). The need is often brought up through knowledge of what other firms do and can do, not that much by searching for special know-how. Even though this kind of interaction takes place in informal situations, such networking can be supported by creating a temporary cluster in which many enterprises come from outside to meet enterprises in the region. Physically more distant relationships are often born at various meetings (Torre & Rallet, 2005, p. 53), exhibitions, and through other formal but personal ‘brought contact’. Web-based databanks are not seen as an effective form of networking when there is question of more equal and trust-based cooperation, since they cannot create togetherness. However, these kinds of solutions work better in finding new clients.

Communication Practices Between Collaborating Partners

There are some differences in practices and experiments depending on whether the company is small and product development is done more equally with another company or if the collaboration is a client-type solution. In both cases personal meetings are socially important, whether it is a question of mutual trust or transmitting the message that the company has time for an important client. In close physical proximity, meetings were common, even when dealing with issues that could easily be communicated with e-mail.

Face-to-face meetings create trust and understanding. Also, personal meetings are the best way to discuss topics in which there are many different phases (Torre & Rallet, 2005, p. 54), and some ideas can be shown with drawings or by “pressing the buttons on a keyboard.” These issues are not easy, if not impossible, to transfer by codified communication; the power to enunciate is also better in personal meetings. Time is a significant issue in product development; so many solutions are done on the least time-consuming basis. For example, even though Skype is often used, some find it too slow to use for communication, compared with a normal mobile phone.

Different virtual environments were not used that much, at least not so far (e.g., for conferencing), even though they can overcome some challenges of distant collaboration (Torre & Rallet, 2005, p. 54). They still have problems related to reliability, voice, and picture. The interviewed company managers said a much-used method is to use a phone or Skype and e-mail at the same time. One possibility is to do ‘multi-site’ work—using software that makes it possible to split the screen and a phone. However, that is not yet very widely used.

E-mail is absolutely the most important way, and we try to stress that very strongly. It has that saving grace, it has many saving graces, that it is filed, so we file e-mails, so then it is possible to go back and do searches...Many times it is possible to attach some clarifying material and such things. The only problem is that sometimes the message is, it's too slow to discuss with e-mail. After joining phone meetings with it, it is quite a good combination. Surely we do visit for clients, the closer the easier.

— R&D Manager (author's translation)

Even though the possibilities of Internet-based solutions have not replaced face-to-face meetings (Ala-Rämi, 2007), there are some things that are
preferable to manage with e-mail, such as most agreements. The main reason for that is documentation; there is evidence of what is agreed and what is done, but also some things like Web links are also easier to write than to say. However, e-mail is quite slow, especially between different time zones, at least in cases where there is a need for ‘discussion’. Also, the interviewees had some cultural differences, such as the North Americans mostly prefer telephone conversation instead of using e-mail. However, ICTs and face-to-face meetings are mostly seen as complementary to each other; different modes of communication are used in different kinds of situations and communication (Ala-Rämi, 2007; Gillespie, Richardson, & Cornford, 2001, p. 128).

...such as there are cultural differences in how Finns speak and how Americans speak, and how the talk is understood, for example when something is ready and what to expect in which time and so on...a democratic example is that it can be challenging to organize a meeting when the leader of the U.S. office is meeting with us every Sunday at 11 p.m. ...

—Chief Executive Officer (author’s translation)

Formation of Community of Practice and Geographical Proximity

Concerning the activities of a collaborative project, the first condition is to create a shared goal, idea, or concept (Wenger, 1998). Strengthening of the goal takes place in special circumstances requiring caring, trust, and commitment, but also freedom, vagueness, and even creative disorder. Trust is crucial for the emergence and success of a collaborative project (Miettinen et al., 2006, p. 56). Trust is developed best in unofficial situations and through a shared interest, which by choice is not business related (Oinas & Lagegendijk, 2005, p. 312).

If the case is that they have not come to talk with me about something particular, then there are right away certain matters that you can start to talk about, kind of outside the business...in which case there are certain ties that build trust. If there is plain business talk, the game rests on some CVs and really tough values...they do have [their] own place, but it is so much easier to call a guy with whom we have talked [to] four hours about what kind of movie it was and why, what was actually said there...than to a guy with whom we had a one-hour ‘transparency drill’, in which case there is nothing personal in the game. When there is something personal, the bond is strengthened.

—Chief Executive Officer (author’s translation)

Geographical proximity is meaningful in product development (Ala-Rämi, 2007). It is especially important in the beginning to be able to create an operational culture with a new collaborative partner. It is largely a question of trust, if there is no mutual understanding of what has really been agreed on and how responsibilities are divided. Once the CoP has been developed, knowledge sharing becomes smoother (Hislop, 2004, p. 40). Moreover, distance creates breaks in communication, and spreading of information is slower. Furthermore, cultural issues, language, and a time difference play important roles in distant collaboration. These issues are major problems created by distance between collaborative partners, not physical distance as such, but causing cultural and temporal distance. Cultural differences also have some influence on collaboration, especially in more intense product development where it is a question of creative work. However, client contacts were regarded as benefiting greatly from geographical proximity (see Oinas & Lageendijk, 2005), which was the reason all the interviewed companies had a sales office close to the main markets of their product, in Silicon Valley or London.
I haven’t heard that a client or someone would have said that it (being a Finnish company) would be a problem, but I would say that as we have an American CEO and an office there, it gives credibility... Well, there has to be some kind of representation or some kind of credible operations also in the main market area. But, it does not matter that the roots are in Oulu and even that the product development and such things are here, it is not a problem. It makes it sort of exotic also, and Finland is nevertheless considered a high-tech country, so no one thinks they cannot be good because they are from Finland, I have not met that.

— R&D Manager (author’s translation)

CONCLUSION

Due to its long history and experience in the ICT sector, FUR Oulu provides a good operating environment for software companies. The software sector is strongly based on a good ICT infrastructure, and the city of Oulu has put a strong effort in developing these services through the Technopolis concept, which has made knowledge diffusion between different actors smooth and easy. Besides different services offered by Technopolis, also the city of Oulu has developed wireless connections open to everyone around the region. Since the beginning of Technopolis of Oulu, there has been a strong community of practice, the ‘Oulu Phenomenon’, and it is still meaningful for high-technology enterprises in the region. These companies play an important role in regional development, and thus they are enhanced by a national program for regional development, such as the Centers of Expertise program. One of the core industries of the city of Oulu is software production. This study explored the use of face-to-face meetings and ICT in product development collaboration, and examined views on networking by using three case studies of globally successful software companies in Oulu.

The physical compactness of the city is an advantage; movement around FUR Oulu does not require much time. Furthermore, most software companies are located in Technopolis’ premises or the city center, so several meetings with different companies can be arranged during one day. Software companies in Oulu gain from strong local social networking, which is important in mutual collaborative work. It is also an effective information channel for new ideas and needed know-how. However, the number of skilled actors is limited, which is a problem for the interviewed companies. So, the small urban scale of Oulu has a two-fold impact.

Geographical distance has a meaningful impact on collaborative work, even though relative proximity is most essential in networking. Temporary clusters are essential for networking of actors. Oulu is well known in ICT, which facilitates access to global markets. However, the studied companies saw it essential to have a sales office in the main market area. Working at a distance in product development was easier to overcome, although it has an impact on practical arrangements, such as matching working hours with people in other time zones. However, there are more complex issues to overcome, such as creation of trust and mutual understanding. Cultural differences and different languages have an impact on communication and understanding. But it is also a question of different personalities and their ability to adjust in different situations.

Face-to-face meetings are needed throughout product development, but they are needed the most in the beginning of a project, especially with a new collaborating partner, to create shared goals and trust. ICT plays an essential role in the product development of software companies, not only as the means for routine communication, but as an important tool for transferring contracts and supporting documentation. As the number of local actors and markets is limited, it is necessary for a growth-oriented company to operate globally. Software companies in FUR Oulu have good
Social Networking and Knowledge Transfer in Collaborative Product Development

possibilities to be globally competitive in their field, but government support is seen as vital in entering the global market. However, there are also challenges in keeping globally successful companies as Finnish companies. Spatial proximity has been a supportive tool, and it can be put to better use by taking it into account in urban development.

FUTURE RESEARCH DIRECTIONS

Development towards more globalization is also a trend in Oulu. The city of Oulu has started a program with the aim of “making Oulu famous for its growth companies, which act globally and inspire the region of Oulu to be competitive and develop an innovative environment of different industries” (Oulu Inspiroi, 2006). This ‘Oulu Inspiroi’ (Oulu Inspires) program, including the above-mentioned ‘Global Clusters’ project, also provides possibilities for interesting research directions. What kinds of tools would be most valuable in supporting companies in networking and how does proximity support the development of the city? Moreover, how should these issues be supported in further urban development?

The ‘Oulu Phenomenon’ is the result of a long-term effort to support and develop the ICT sector. There are working national and local policies that have supported networking and clustering of the knowledge-based sector in the region. ‘Global Clusters’ is one of these practical tools. Time will show if the ‘Global Clusters’ program, as part of the CoP, will be successful. However, the interviewed companies argued that they have benefited from earlier global software programs. Still, there have been good inventions that have failed to make a breakthrough. In the opinion of the interviewed managers, it is a question of a lack of support in marketing. However, there are already tools for that in national and local policies, such as the Centers of Expertise program, which have been meaningful in successful clustering of software companies. So, these programs can be developed further to even better fit the needs of the companies in Oulu.

According to the interviewed company managers, one main challenge is to find more skilled professionals, which are few even in the whole of Finland. The first phase is to attract more and more delegates from international companies to come to the city of Oulu to make contacts. Technopolis has expanded its operation also to Helsinki, the capital of Finland, and more recently abroad. Just as the newest parts in FUR Oulu, they are also strategically located next to the airport or the city center. The existing urban technologies in FUR Oulu and ongoing development of technical infrastructures are supporting the knowledge city well, as long as their factual content is relevant.

ACKNOWLEDGMENT

I wish to acknowledge the financial support from the Academy of Finland research project 200771 and Tauno Tönning Foundation. I also thank two anonymous referees for their comments and suggestions on ways to improve the chapter.

Chapter 6.5
Reframing Information System Design as Learning Across Communities of Practice

Kevin Gallagher
Northern Kentucky University, USA

Robert M. Mason
University of Washington, USA

ABSTRACT

This article frames the requirements definition phase of systems design as a problem of knowledge transfer and learning between two communities of practice: IS designers and system users. The theoretical basis for the proposed approach is Wenger’s (1998) framework for social learning, which involves three dimensions: alignment, imagination, and engagement. The article treats the requirements definition task in systems design as a set of activities involving mutual learning and knowledge transfer between two communities of practice (CoP) along these three dimensions. In taking this approach, the article maps the results of past research on the systems design process onto this CoP framework and illustrates that the proposed framework encompasses the same activities used by traditional methods of requirements definition. However, this approach focuses attention on the learning that must take place between the two CoPs and thereby helps resolve some of the inherent shortcomings of prior efforts and approaches. The framework provides both a more encompassing conceptual lens for research on improving the requirements definition task and practical guidance for managers who are charged with a systems design project.

INTRODUCTION

Requirements definition is a critical step in systems development that requires the identification
of information needs and knowledge of a system’s processes (Nelson & Cooprider, 1996; Vessey, 1994). Historically, researchers examined the requirements-definition stage of system design as a process of inquiry (Boland, 1978; Salaway, 1987). Problems with identification, articulation, and communication of information needs have long been identified with the challenges of information system design (Boland, 1987). There have been different approaches in attempting to meet these challenges, but none has completely resolved the issues.

Land (1998) notes that because systems are so different, a contingency approach—using different methods for different types of systems—is appropriate. Others have suggested more structured analyses of the design process itself, establishing metrics for requirements engineering (Costello & Liu, 1995) and developing tools for each aspect of the problem (Nature_Team, 1996). Some researchers have suggested that the process of design must remain flexible and that a management structure that encourages an evolutionary design process is associated with greater effectiveness (Ravichandran & Rai, 2000). In considering software project risk and software quality, organizational issues as well as technical issues are important (Wallace, Keil & Rai, 2004). Others also emphasize the critical nature of human-intensive dimensions of the process (Tamai, 1993). It also has been noted that evolutionary designs are necessary as complexity increases (Mens & Eden, 2005). Larman (2004) argues that an “agile” and iterative design process is key to software development success.

The approach that we want to explore in this article emphasizes these human-intensive dimensions of the design process. Although the design process involves many actors (Lamb, 2003), we want to focus on two roles: the designer (who has technical knowledge) and the user (who has knowledge of the application and context of use). The conceptual approach is one that considers requirements definition as an instance of knowledge acquisition (Byrd, Cossick & Zmud, 1992).

Recently, organizations and researchers have begun investigating the potential of knowledge transfer (Alavi & Leidner, 2001) to make organizations more effective when engaging in information intensive work. Such knowledge transfer is necessary because clients are not sure what is possible and are unclear about their needs, and IT designers thus are unable to work toward an outcome that meets clear specifications (as in designing a product for production) (Larman, 2004).

To date, however, conceptualizations of knowledge transfer in software development do not completely capture the complexity and richness of this process by which clients and designers work together. As Polyani (1966, p. 4) says, “We know more than we can tell.” Regardless of how well we articulate knowledge, it always contains a tacit dimension. Hence, simple inquiry is insufficient for the requirements definition process because it is able to access only explicit, leaky knowledge (Von Hipple, 1994). The information transferred through traditional elicitation approaches is only part of what someone knows, and it rarely includes how or why they know it (Lanza & Mathiassen, 1985).

Because of the tacit dimension of knowledge involved in most tasks and processes, it is difficult, if not impossible, for people to articulate exactly what it is that they need prior to design. Even if they can articulate what they need, the system development effort is hampered if the system developers do not understand why and how users need what they need. With an understanding of the why’s and how’s of information, developers can be more innovative in their delivery of requirements. For example, unless developers understand which information is used together and how it is connected, they will be unlikely to find ways to combine and simplify tasks.

If we keep the traditional concept of inquiry as the basis for eliciting requirements, the effort must
always be incomplete. The language or metaphor of “inquiry” or “capturing requirements” is part of the problem. The choice of metaphor can inhibit the range of approaches to information systems (Mason, 1991), and recently the metaphor of “engineering” has been questioned as the basis for approaching software development (Bryant, 2000).

What is needed is an approach that engages users in such a way that they can elucidate not only what they know, but also how and why they know it. In addition, users must learn about how systems in general, and this system in particular, will be developed. An improvement over current approaches is to engage designers so that they really understand what the users are telling them, and to ensure that they effectively share their knowledge of both the systems and the processes for which they are developing technology (Boland, 1978). To accomplish this, both users and developers must share their knowledge and learn from each other (Boland, 1978; Churchman & Schainblatt, 1966). In short, what is needed is a process of mutual learning in which designers and users engage in a process of learning from each other.

In order to work toward such a process, we turn to the concept of a community of practice (Lave & Wenger, 1991). The concept, first used to help understand situated learning, refers to a group of people defined by an interest in a specific subject or problem who collaborate to share ideas and resolve issues common to the group. In this article, we posit that information system (IS) designers and IS users belong to two distinct communities of practice (CoPs) as they work together in a systems development context. The system designers comprise one community and the users for which the system is being designed comprise the other (Churchman & Schainblatt, 1965). The term “users” may cover many roles, including managerial, and in the following we may use “managers” to provide a specific context for the discussion or simply say “users” for the generic situation. The requirements definition phase of IS design requires that these two groups engage in mutual learning both to share knowledge and to develop new mutual understandings of the possibilities as a system design emerges. The knowing of managers (or other users) is formed by a very different practice than the knowing of IT professionals (Brown & Duguid, 2001), resulting in different ways of knowing (Boland & Tenkasi, 1995). Knowing is not easily shared across these two groups because of their different histories and perspectives.

The article extends Wenger’s (1998) design for social learning within a CoP (p. 236) to learning across two communities of practice. Wenger’s model comprises three dimensions: alignment, engagement, and imagination. We apply this framework of social learning across the two CoPs (i.e., managers and designers) and show that the framework not only is consistent with prior research on the information system design (ISD) process but also suggestive of how the design process can become more effective.

The remainder of the article comprises three sections. The next section, Social Learning, reviews the concept of social learning and distinguishes it from simple knowledge transfer. This section further illustrates why the characteristics of social learning are the characteristics required for an effective requirements definition process.

The subsequent section presents an architecture for social learning. It reviews the three dimensions of Wenger’s model for social learning in a community of practice and notes that factors considered essential to the requirements definition phase of the system development process can be mapped onto these dimensions.

The final section summarizes the application of the model for information system design, outlines issues in implementing the architecture, and discusses the implications for research and practice.
SOCIAL LEARNING

Knowledge and Knowing

Viewed from a social learning perspective, knowledge is social, not individual (Brown, 2002), and is a matter of our competence with respect to some valued enterprise (Wenger, 1998). Knowledge encompasses aspects of experience, action, and the accomplishment of some activity. In this perspective, knowledge is more than stored information, even more than codified and structured information.

It is helpful to distinguish “knowing” from “knowledge.” In common usage, “knowledge” brings with it the context of an accumulation of facts and “know what.” On the other hand, use of the term “knowing” conveys more of a sense of engagement in a process of learning and becoming. Knowing is not only an accumulation of facts, but an accumulation and assimilation of experiences and learning that alter who we are as well as what we know. As we learn about, we also learn to be (Brown & Duguid, 2001). Levels of participation or nonparticipation reveal a sense of relation, familiarity, and belonging to the situation. These aspects of identity development affect one’s modes of involvement and willingness to engage in activities. The attributes of identity are developed, and reciprocally supported, through the process of learning.

We are constantly engaged in accomplishing activities and we typically become more proficient with experience. Our knowing, therefore, resides in our practice (Cook & Brown, 1999), which is how we accumulate experience and situated ways of knowing. Participation is our “knowing in action,” so a design process can benefit from participation by those who know the existing process.

Apprenticeship and Communities of Practice

Communities of practice provide a theoretical framework for understanding how the dynamics of social structures influence learning and practice. The origins of communities of practice are grounded in apprenticeship and their ability to support situated learning through social coparticipation (Hanks, 1991; Wenger, 1998). Understanding how apprenticeship promotes learning within a community can help in understanding how learning can occur across communities. Learning through practice is exemplified in apprenticeship, whereby a community regenerates itself through a process of participation and training. When the transfer of explicit knowledge is supported by sharing the practices in which it makes sense, it is possible to understand its meaning in a way that makes it most useful, actionable, and purposeful.

Participation is the key to developing and sustaining communities of practice, but observation also plays a critical role by allowing one to participate on the periphery of a community. While the master remains engaged in the craft, the apprentice learns by means of “legitimate peripheral participation” (Lave & Wenger, 1991), observing the practices and developing the tacit dimension of knowing. By engaging in practice, the master is able to communicate more than what can be said and the apprentice is able to learn more than what can be heard.

The roles of a community’s members are not rigidly defined; however, a key to apprenticeship is that members can engage in varying roles simultaneously. Legitimate peripheral participation supports learning without requiring members to acquire all of the necessary knowledge for full membership in that community. In this way, a member can span the boundary of a community and still be able to observe, understand, and learn.
Participation and observation (nonparticipation) together define our levels of engagement as we employ these modes of engagement in attaining knowledge of our own communities and other communities from which we may learn.

To participate on the periphery allows one access to a community through passive modes of observation and similar activities that do not overly dominate or eliminate participation altogether. This is exemplified by active listening. Conversely, marginality is a mode of nonparticipation that stifles participation, as exemplified by listening in on a conversation in which the terminology is foreign. In both cases, there is exposure to a community of new information. The first situation offers a mode of nonparticipation that facilitates learning. In the second, the learning becomes stifled.

Apprenticeship is offered here as the starting point of a model to use when designing a way for two communities to come together, share knowledge, and learn. In the case of requirements definition, it may be enlightening to consider the IT professionals to be apprentices to the user community (Beyer & Goltzblatt, 1995) and the users to be apprentices to the IT community. Through apprenticeship, the participants learn about practice. To make “know that” useful requires appropriate “know how” that we can only gain through practice in both senses of the word: to do and to improve (Brown & Duguid, 2001). The need to involve users in system design has been a long held belief for requirements definition; however, involving IT in the practices of the users is less established, but has the potential to be quite revealing.

**Knowing as a Challenge for IS Design**

The challenge for IS design is to enable participation by both users and designers in a process that both conveys knowledge and enables knowing. In any social process, our experience informs our knowing, but the structure of the relevant social arrangement orients and guides our experiences. We develop personal histories from experience, and, through practice, we negotiate and form the meanings we give to things. Identity is how we see our role in the process that then influences our level of engagement.

Both users and designers must be engaged in the process of knowing about the other’s needs and the opportunities afforded by alternative designs. Engagement is a social process, one not naturally emerging nor easily brought about by fiat.

Prior researchers have acknowledged the social aspects of information system design. For example, political arrangements in organizations and dynamics of relative power among design participants can influence the degree to which they feel safe participating in activities (Hayes & Walsham, 2001). Others have noted the importance of the relationship between users and designers in the design process (Beath & Orlikowski, 1994; Hirschheim & Klein, 1994; Ives & Olsen, 1984). Mutual learning can only take place when users and designers are able to engage in effective modes of participation when they are involved in requirements definition activities. Through appropriate modes of participation, requirements are informed both by what the participants know and by how and why they know it.

What we want to accomplish in the IS design process is to enable both designers and users to engage in a learning process that enables safe but effective participation in the design activities. The apprenticeship model of social learning in a community of practice, coupled with Wenger’s (1998) architecture for social learning (p. 237), provides a model for such a process.
AN ARCHITECTURE FOR SOCIAL LEARNING

Processes of social engagement differ in their ability to support learning. Figure 1 illustrates Wenger’s (1998) architecture for social learning in a community of practice, showing arrangements for alignment, imagination, and engagement. When engaged in practices across communities, the support of such social arrangements can facilitate a sense of belonging for members that helps to ensure participation and learning. Collectively, the three dimensions enable members of the community to learn with each other. The architecture provides a framework for considering the requirements of the process of IS design, particularly the requirements definition phase of this process.

The three dimensions are interdependent and, in fact, have inherent tensions among them. For example, a structure that assures close coordination for alignment can inhibit imagination and engagement. Conversely, imagination without alignment can result in activities that do not contribute to the overall learning process.

Alignment ensures coordination of the community’s activities and resources toward achieving an objective. In the case of system design, this means achieving a fit between the local needs of a business unit and the new design. Learning is important to such a practice, as working through the development of a design raises new questions from which participants can learn about the existing system (Kyng & Morten, 1995). However, there are many ways to establish a fit during design, some of which may inhibit future flexibility (Allen & Boynton, 1991) and lead to rapid obsolescence or an inability to adapt. Alignment alone is not enough to support learning. A community of practice, and perhaps more importantly, the interaction between two communities, must also support what Wenger labels imagination.

In Wenger’s terms, imagination provides the opportunity to create new possibilities. The ben-
Reframing Information System Design as Learning Across Communities of Practice

Advantages of creativity and innovation in the development of systems are well established in the field of information systems (Cougar, 1996). However, creativity without the appropriate information as to the possibilities and constraints of a design or an appropriate vision of the future may lead to poor implementation (Zmud & Apple, 1992). Therefore, a process of mutual adaptation is necessary to achieve an improved design and a successful implementation (Leonard-Barton, 1993). Mutual adaptation can be viewed as an accommodation of both alignment and imagination that can be accomplished through learning.

The third dimension of Wenger’s design, the concept of engagement, represents active involvement in the negotiation of meaning during the learning process. Engagement requires appropriate modes of participation. Appropriate modes of engagement by participants can ensure a balance between alignment and imagination. By supporting participants’ engagement in a social process, it becomes far more difficult for any one set of perspectives or goals to dominate the process. However, engagement is difficult to ensure. Psychologically, individuals must feel it is safe for them to engage in an activity, that it will be a meaningful investment, and that the personal and professional resources that are necessary for participation are available to them (Kahn, 1990).

In the apprenticeship model of learning, engagement in practice by the bearers of knowledge will assist in their grasping, articulating, and transferring knowledge to others. Furthermore, peripheral participation by those who are in apprenticeship roles facilitates their ability to appropriate the meanings conveyed in specifications by those engaging in the design process. In sum, engaging in the practice of design can help us to understand and transfer what we know.

The challenge in employing Wenger’s design for learning in the IS design process is balancing the tensions inherent in each of the three dimensions (See Figure 2 below.). Traditionally, IT departments have been concerned with alignment. They feel a need to align themselves with business strategy, with user functions, with business processes, and with organizational objectives (Chan, Huff, Barclay & Copeland, 1997; Reich & Benbassat, 1996). They have perceived standardization of

Figure 2. Wenger’s architecture for social learning adapted for requirements determination
systems and control over the design process as the key to alignment (Kirsch, 1996). However, with excessive alignment, imagination is curtailed and success becomes elusive (Baskerville & Stage, 1996). Excessive imagination and creativity, on the other hand, can lead to idiosyncratic designs and unworkable heterogeneity, reducing the ability to share, diffuse innovations, and efficiently develop new systems.

The quest for alignment makes it necessary for IT and users to work together. Yet, mutual engagement in these activities is in direct tension with the development of functional expertise within the organization. It also raises organizational tensions around leadership and decision making, between working together and understanding who has jurisdiction. As many IT scholars have claimed, partnership is key to IS success (Henderson, 1990). Partnership addresses the tension between conflicting power bases in the organization, but a successful design environment must also address the tension between imagination and alignment. Wenger’s design for learning recognizes the need to balance these tensions in the design of a learning environment that will support the appropriate modes of engagement and thereby facilitate and balance the tension between alignment and imagination.

The information system design (ISD) literature is consistent with this three-dimensional framework of learning in a community of practice. The literature on use of methods and controls is consistent with Wenger’s dimension of alignment. The need for imagination during system design is supported by the ISD research on learning by doing, performed through modeling and prototyping. Research on user participation and involvement supports the need for engagement.

The next section discusses the commonalities between Wenger’s framework and the ISD literature, explains further the facilities used to implement the model, and highlights the challenges of applying the principles and balancing the tensions in the ISD setting.

**Alignment**

In Wenger’s model (Figure 1), alignment is comprised of three facilities: convergence provides a common focus; coordination provides methods and procedure; and jurisdiction provides policies and procedures. Similar themes are found in the IS literature, which describes the need to pursue objectives, employ standard methods, and control the design process.

Objectives are defined based on user needs and the possibilities the system affords, negotiated through a social process of mutual adaptation (Leonard-Barton, 1993). Through methods, activities are organized to achieve these objectives. Yet, methods often give primacy to designers over users (Beath & Orlikowski, 1994) or to problem solving over alternative rationalities (Boland, 1979). Thus, formalizing methods serves to structure activities, thereby imposing controls that promote and suppress certain behaviors.

The IS design process requires more than obedience to method, it must also be a reflective activity (Iivari, 1987). System design requires iterative and adaptive planning as the acquired experience and learning from each sub phase informs the ongoing effort (Iivari, 1987). Thus, development efforts must recognize the need to balance iterative development with complimentary methods of control.

Control is complicated by the fact that coordination and communication necessary to complete the tasks spans organizational departments (Kirsch, 1997). A complex relationship exists between efficiency and quality. Different strategies of control lend themselves to different situations. Informal methods of control are used when understanding of the process and outcome measures are inexact (Ouchi, 1979) and depend on social strategies (Eisenhardt, 1985). Self-control relies on the motivation of individuals, and in IS it is strongest among personnel who take part in defining work procedures (Kirsch & Cummings, 1996).
Clan is another informal control characterizing a group that is dependent on one another to achieve a common objective (Ouchi, 1980). Boland (1979) distinguishes “control over” from “control with” in order to distinguish bureaucratic processes from those where shared values and beliefs serve as the basis for coordinated action. Through appropriate selection of members and use of appropriate training and socialization processes, individuals in a group can develop a stronger sense of identity and commitment (Kirsch, 1996). Appropriate activities serve as rituals to reinforce acceptable behaviors. The development of identity and commitment are equally vital components in apprenticeship, where methods of training and socialization are employed to facilitate learning directed toward achieving objectives. In the end, certain modes of control, especially in excess, can have a negative impact on both engagement and imagination.

**Imagination**

Imagination is comprised of three facilities (Wenger, 1998): orientation provides a location relative to the organization; reflection provides facilities for comparison and evaluation; and exploration provides opportunities for envisioning, creating and testing new ideas. Again, similar themes are found in the IS literature that emphasize a need to understand situational context and explore possibilities through processes that support discovery and innovation.

Systems requirements are the first step in defining possibilities for new information technologies. As previously noted, the development of system requirements is often conducted through inquiry and other elicitation methods, intended to identify user needs. Yet, this step is highly prone to unintended influence through bias and error (Salaway, 1987). In addition, interviewing can close down inquiry, if motivated to solve problems rather than explore the appropriateness of different possibilities for an organizational situation (Boland, 1979).

Another method of elicitation is the use of design tools, such as computer assisted software engineering (CASE) or use cases, which help users describe the organizational situations in which they are involved and convey what they know (Lanzara & Mathiassen, 1985). Such tools help users move from the current situation to the enactment of a new one (Lanzara & Mathiassen, 1985). For instance, redirecting the attention away from the existing system and refocusing on a new realm of possibilities (Wastell, 1999) is one such example. To reframe a situation leads to a discovery of possibilities.

Drawing on theories of action, Lanzara and Mathiassen (1985) are critical of most existing tools. They suggest that better tools are needed to bring the “background into the foreground” by offering ways to make procedure more explicit, thereby relating descriptions to the actual settings. This advances a user’s opportunity to question the appropriateness of existing solutions, challenge their adequacy, and take more responsibility for initiating a more positive action.

Similarly, prototyping enables a common reference point for users and developer, which helps to develop a mutual understanding and draw out and refine user requirements (Alavi, 1984). Reifying what is known helps to reveal what is not fully understood and offers alternative active techniques for articulating and defining existing situations that allow the designs and users to engage in a social process of simultaneous definition, design, and discovery.

To summarize, there is great support in the IS literature for imagination in the design process. There also is great concern regarding the mutual understanding of context among users and designers, which is necessary to define the present situation and to inform an effective process of discovering new possibilities. Furthermore, the tools we have available are limited in their ability...
Engagement

Engagement is facilitated by *mutuality* though: reciprocity and interdependence, which provides opportunities to form and share perspectives; *competence*, which supports the occasion for applying knowledge and exercising judgment; and *continuity*, which supports mechanisms of memory, which work as repositories for information created through social encounters. Similarly, IS research has found that the design process and subsequent adoption of a technology benefit from user involvement, which enhances confidence and acceptance of the technology (Hartwick & Barki, 1994; Ives & Olsen, 1984).

Including users in the design process involves more than their presence, however; it also requires overcoming conflicts of interest and effects of authority (Mumford, 1983, p. 31). Often users are given relatively passive roles, despite being required to sign off on requirements (Beath & Orlikowski, 1994). As a result, patterns of user participation vary according to who controls the selection of features and the coordination of activities (Kirsch & Beath, 1996). Participation, therefore, is often token or compliant, rather than shared.

The participative design (PD) movement highlights empowerment of users as important in their ability to influence the overall design process (Hirschheim & Klien, 1994). Joint application design (JAD) is designed to actively engage users and designers in activities, often away from their usual work settings and organizational roles, recognizing the importance that altering structures has on the dynamics of a design process.

One way that JAD involves users is through modeling and prototyping. Models support the development of shared understanding between users and developers, thereby building confidence in what is established as knowledge during inquiry. Prototypes serve to cultivate user participation and help build credibility and establish good working relations.

As with alignment and imagination, there is great support in the IS literature for engagement as a key component of RD success, but there is concern about our ability to successfully nurture it. The following section discusses the results from several researchers who have provided insight into approaches and tools that may help to overcome some of the most frequently encountered impediments to successful alignment, imagination, and engagement in the RD and ISD processes.

Summary: Designing an ISD Process for Social Learning

Table 1 illustrates the parallels between Wenger’s model of social learning, an apprenticeship model, and the factors judged important to successful design from the ISD literature. What remains is the construction of social learning processes that enable a project to implement and balance these factors.

Designing Structures for Social Learning

The social process of ISD, whereby users and developers collectively define requirements, is complicated in that participants may differ in their backgrounds, cognitive styles, personality, job characteristics, organizational circumstances, affiliations, or location (Robey & Markus, 1984). As one might expect, this leads to differing interpretation, confrontation, and misunderstanding.

A major concern, therefore, is that the discourse required for an effective process of inquiry is distorted in traditional organizational structures. Altering the structure of a design process through choices regarding the number of participants, the activities conducted, and the role of users and
designers can offer greater opportunity for users to raise issues, question the appropriateness of choices, make and demand commitments, and express attitudes and concerns (Hirschheim & Klien, 1994).

Nonaka and Takeuchi (1995) show that through organizational design actions enacted through structured mechanisms, knowledge creation is facilitated. Churchman and Schainblatt (1965) note that researchers and managers viewed problem-solving differently and propose a dialectic approach to manager-researcher communication. Boland (1979) found that structuring problem-solving processes in ways that are enabled by differing rationales encouraged participants to share their knowledge and arrive at different types of solutions. Different processes for understanding and applying knowledge are influenced by the controls placed over the process of user-designer interaction.

Altering the structures of user-designer interaction may provide benefits beyond improved specifications or overcoming user resistance. Bringing users into close interaction with designers promotes social sense making (Boland, 1984) and shared understanding (Nelson & Cooprider, 1996). Information analysis, extended to include the context within which data are interpreted, also provides design mechanisms that can support self-reflection (Boland, 1979).

In summary, the IS literature shows support for the notions resident in Wenger’s design for social learning. However, it does not explicitly address the tension inherent in alignment, imagination, and engagement. By exploring structures that balance these tensions, the process of system design may benefit, as we demonstrate in the next section.

### Resolving and Managing Tensions as a way of Explaining Successes and Failures

In this section, we revisit three previously published studies to illustrate the value that the social learning model adds to the literature in information system design. The studies we examine used three different methods: controlled experiments,
field research, and comparative analysis of previously collected case studies. The authors of each study include in their data and their analysis consideration to all three of the dimensions in our model: alignment, engagement, or imagination. However, in each study, one of the dimensions is used as the primary focus of investigation and therefore becomes a primary explanation for the results and the authors’ understanding of what distinguishes effective from ineffective design processes.

For each study, we offer an alternative explanation that encompasses the original differentiating characteristics but offers additional insights into how to manage the process of information systems development. With these insights, the tensions among all three dimensions are included in the management framework rather than emphasizing one dimension of the model over the others. Consequently, this research contributes to the research literature by emphasizing the need to balance the dimensions in the model, and the result is a broader perspective on the practice of managing the system development process.

Boland (1978)

In the first study we examined, Boland (1978) addressed the question of how a user is involved in system design. Employing an experimental research design, “two radically different processes of interaction between a systems designer and a manager were compared in an information system design exercise.” The author refers to the first as traditional and the later as an alternative. The first process was conducted by having the designer interview the manager. Afterward, the designer made suggestions for the design. In the second process, there was an initial sharing of information followed by a period of mutual suggestion and critique by each participant.

In the study, the structure (methodology and control) influences the interaction between the user and the manager. Based on how this protocol or interaction takes place, the problem solution is derived. The author states “the alternative interaction approach produced higher quality designs with important implementation advantages.” From these results, Boland suggests that the protocols “may help to define different problems, and thereby produce different, but equally rational, solutions.” As stated in the article, “the structure of their interaction is defined as the protocols or accepted patterns they follow in punctuating their exchange of messages.” Using the model proposed in this research, the causal direction between the dimensions inferred in this statement is quite clear. Alignment, which includes methodology and control, sets the stage for how users and designers will engage in the process. The author also states, “the structure of their interactions serves as the context for the generation, interaction, and interpretation of ideas between them. The protocols they followed are seen as a source of rationality in the design process, as they guide in bounding the problem space, drawing inferences, and defining an ‘appropriate’ information space.”

From the social learning model perspective, the protocol influences design activities, or, in other words, the causal direction inferred is (the words of our model) “alignment affects imagination.” A richer explanation, employing the proposed social learning model, is that the alternative process resolved tensions in the process and, compared with the traditional process, struck a better balance in what was emphasized as important. Protocols, as a part of a prescribed methodology, served to organize the process or inquiry, but as exhibited in the study, they may not engage users in ways that promote knowledge transfer or afford the ability to imagine the design of an innovative system. The alternative process certainly undertook a different rationality, as the author went on to discuss, but it also undertook a more balanced approach across the three dimensions of the proposed model. By having participants...
first share information, then describe solutions and discuss pros and cons, both engagement and imagination were enhanced.

Wastell (1999)

In the second study we analyzed, Wastell (1999) also viewed social structure as a vehicle for learning and as a critical element in information system design. The study involved field research and employed an action research approach. Opportunities for design to influence the structure of interactions between participants or the development environment and the way it is managed and controlled are surfaced in the study. Three case studies are described. In each case, the author suggests approaches, and then describes how these changes improved performance. Using a theoretical perspective from psychology, the author proposed that antilearning defenses create difficulties for information systems design.

Stress and anxiety, arising from the group defenses of those involved in the system development effort are at the center of this approach. For example, following traditional protocols allows participants to adhere to prescribed behavior rather than engaging the participants from other groups in a common set of tasks. The approach to improving method and involvement are to reduce stress and defense avoidance behaviors. As prescribed by the author, modeling and other activities of design provide the design process with transitional objects, which facilitate involvement by designers and managers. As a result, the use of these objects promotes a learning environment, or transitional space. This space is a structure that promotes learning, allowing designer and managers to safely engage in activities. Once created, management must try to support the existing environment, which is quite different from the idea that methods and controls are needed to ensure the effectiveness of a process.

The author sums up the problem in this case as a situation in which “a highly prescriptive methodology is imposed by fiat” compared with an alternative that works better. The alternative, described in a similar case study, is a process in which practitioners create their “own methodological ideas before consolidating these experiences into new working practices.”
Using the social learning framework model, we might explain the findings as one in which there was a shift in emphasis from a strong adherence to an ineffective method toward greater emphasis on both modeling and engagement of users and designers. The emphasis has moved toward greater engagement of users and what is described as a more “experimental” approach to development, and created a transitional space for those involved in the project. In this social learning explanation, the shift is toward a greater balance between the engagement and imagination dimensions of the model.

Kirsch and Beath (1996)

In this third study, the researchers again analyzed participation in system development projects. Kirsch and Beath (1996) analyzed data from eight case studies as a way to understand the relationships between different modes of involvement, the processes of coordination between designers and manager, and the product of the design effort. The process of user involvement is examined in terms of how involvement is actually enacted, as opposed to how methodologies may be prescribed in the literature. The authors examine this relationship from several directions in discussions at the end of the article, but their initial focus in terms of theoretical direction of causation is that participants will enact a methodology, rather than just following it blindly. The product of design is also examined by looking at who makes the selection of system features.

These authors focus on the effect of involvement, or engagement as defined in the social learning model. The study identified three different patterns of user participation: token, shared, and compliant. Each is shown to have different implications for a set of outcomes: task-system fit of the resulting system and management of conflict among these outcomes.

The authors propose that these patterns (token, shared, and compliant user involvement) vary in terms of who contributes technical and domain knowledge to the project and who controls feature selection. Involvement by users also influences the coordination mechanisms employed, the level of conflict, and how these conflicts are resolved. The data are examined in a number of ways, but the emphasis is placed on understanding how engagement influences the process by which the project is coordinated (alignment) and by which the system is designed (imagination).

To the first point, the authors state that the “enactment [of user involvement] is as much the choice of the client as it is the choice of systems developers.” This leads the authors to suggest that methods might focus less on the way that designers should try to engage users but more on developing mechanisms to elicit user knowledge. To the second point, regarding the influence of user involvement on the modeling and design process or the effect of engagement on imagination, the authors conclude that high user involvement is not always necessary for task-system fit. The findings show, however, that when the system design features were derived by a process of negotiation between users and designers, the process yielded two of the three highest quality designs in terms of task-system fit.

Using our social learning model, an alternative explanation is that the processes that engaged users and designers took into account what participants do (imagination) and how the learning process is managed (alignment). As a consequence, the engagement process struck a better balance among the three dimensions in the proposed model. Engaging in a complex and often ambiguous process can be troublesome, especially if there is a great deal of conflict. In this study of eight cases, the three cases that had the highest rating overall had the least conflict. And while selection of features plays an important role in
determining fit, as pointed out by the authors, feature selection does not have to be controlled by users. But their engagement and participation in negotiating the design process yielded the two cases with the highest ranking overall.

**Summary: Additional Insights Using the Social Learning Model**

As noted, each of these studies discussed the interaction of the three dimensions in the proposed social learning model. In each study, causal inference was not the primary object of their investigation, as each study undertook a process perspective in their research approach, which we acknowledge and appreciate. These studies collected and reported rich sets of data and offered thoughtful and insightful analysis, enabling us to revisit them from the perspective of the tensions inherent in the social learning model.

By using these particular studies as a baseline, we are able to explore alternative explanations for the results of each. That is, we can offer different, richer explanations for how the studies unfolded, and more importantly, how the results came about. The studies started with different foci: Boland with control and method, Wastell with modeling and design, and Kirsch and Beath with user involvement. As a result, the three studies examined their data using different theoretical perspectives and thereby derived very different causal explanations of what occurred.

The social learning model does not resolve the conflicting direction of causation implied by these earlier studies. Instead, the learning model provides a “both/and” rather than an “either/or” explanation. Our model shows the relationships between the dimensions in the model as interrelated, with tensions that need to be resolved, rather than the need to optimize any one of the dimensions.

Finally, we note that all three studies demonstrate the need to balance engagement and imagination. While Boland found that more engagement was related to more and better designs, and Wastell found that the activities of design helped to engage the two communities in a more effective social process, Kirsch and Beath found that varying combinations of user and designer involvement has differing effects, dependent on many other factors. As a consequence, simply trying to increase involvement of users does not necessarily lead to better designs. Alternatively, the availability of an innovative or a structured design processes will not insure users’ participation, nor can the design process insure that those users will acquire a sense of involvement.

**DISCUSSION AND CONCLUSION**

This article has posited that the necessary exchange of knowledge between the designers and the users of information systems during the design process may be viewed as exchanges between two communities of practice. The article further suggests that the apprenticeship model of learning is an appropriate model for this knowledge exchange in which there is mutual learning. In this model, the user is the apprentice to the designer (when learning of technical capabilities) and the designer is the apprentice to the user (when learning of the system requirements and use). Apprenticeship conceptualizes knowledge as constituted in action, so separating the tacit from the explicit is not possible. Our knowledge exists in our competencies to perform or engage in action, and these competencies are formed in our learning through the negotiation of meaning. It is through this mutual apprenticeship process that we can grasp and articulate the meanings of the information we need to transfer. Mutual apprenticeship is a means by which both communities can learn, enabling the sharing of both the tacit and explicit dimensions of each knowledge domain.
Apprenticeship is the most accessible example of the benefits of both participation and nonparticipation and how the evolution of shared histories and development of the roles played by the apprentice and the master bring about the transfer of knowledge. If a master is asked to merely explain certain knowledge to the apprentice, the conversation would be flawed by the misunderstanding arising from the differing interpretations of the words that were used. However, through a process of engagement in a situated practice, development of competencies, and the evolution of identities, knowledge is transferred across communities via the apprenticeship model. The architecture for learning provides focus for balancing the tensions among alignment, imagination, and engagement.

Changes in structure can allow a community to move beyond just transferring “know what” to sharing greater degrees of “know how” and “know why.” By engaging in common practices, communities can understand greater degrees of the tacit dimension that exists in all knowledge (Brown & Duguid, 2001). However, even communities who work at the same practices can have differing ways of knowing. These differences result in knowledge being sticky and difficult to transfer, and they demonstrate the social dimensions of knowledge arising from the situated ways in which practices may develop.

By altering modes of participation in line with an apprenticeship model of learning and by supporting alignment and imagination through each community’s engagement in practice, managers can reduce the difficulties of sharing knowledge across the communities of users and designers. Perhaps of greater value, the knowledge shared across these communities, through altering modes of participation and balancing dimensions of the learning process as defined in Wenger’s model, can result in greater degrees of “know how” as well as “know what.” Furthermore, communication of related practice associated with the knowledge transferred and communication of the historical reasons for the practices used and the meaning appropriated in activities express aspects of a “know why” dimension embedded in the community’s way of knowing. Each of these changes should yield more creative designs and systems that have a greater degree of alignment with the organization’s goals.

We examined several cases of success and failure from the perspective of the causal explanations put forth by the investigators and using the model proposed here. In particular, we found it enlightening to compare the balance among the three dimensions of the model in successful and unsuccessful projects, which showed how the former had exercised a better balance than the latter. Ultimately, alignment, imagination, and engagement must all be supported, but focusing too heavily on one dimension may disrupt the balance among them. Similarly, the various modes of participation in the apprenticeship model have the potential to benefit a learning process, but their implementation as changes to an overall process may have very subtle influences based on the number of participants and their role in the organization.

The model provides important insights into how apprenticeship and knowing across communities can contribute to the theory and practice of information system design. Through the development of learning environments that span communities and support engagement of practice and appropriate modes of participation, organizations can create, focus, and transfer system knowledge through an apprenticeship model of learning. For information systems researchers, the model provides new opportunities for examining and evaluating requirements definition approaches. All of the issues raised in this article require further investigation. Many opportunities exist for future research to further understand, validate, and extend this work.

For practitioners, the model provides insights into the importance of context in understanding what is known in organizations and the importance
of practice in forming the way that we know it. For project managers and executives, creating an environment in which both designers and users are encouraged to be both masters and apprentices may well prove to be a critical factor for project success.

Chapter 6.6
Grounding Business Interaction Models:
Socio–Instrumental Pragmatism
as a Theoretical Foundation

ABSTRACT

In the information systems field there exist several theories for guiding the evaluation and design of information systems. These theories need to be transparent and harmonious. In this chapter, business action theory (BAT) as a domain ontology for business interaction and business processes is clarified by elaborating on socio-instrumental pragmatism (SIP) as a base ontology. SIP is an eclectic theory synthesizing several pragmatic theories from reference disciplines outside the IS area. One purpose of SIP is to enable seamless theorizing in the IS area. In this chapter we put forward the foundations of BAT and SIP which are then followed by grounding BAT in SIP. This grounding means that there will be an ontological clarification of BAT by specifying the social action and interaction character of business interaction.

INTRODUCTION

Business action theory (BAT) is an ontology and a practical theory for business interaction and business processes. During the last 10 years we have been working actively to continually improve business action theory. This knowledge evolution process can be characterized as empirically-driven theory development. The goal has been to create an empirically, internally, and theoretically grounded theory for business interaction. Today, BAT has the epistemological status of a multi-grounded theory (Goldkuhl & Cronholm, 2003; Lind & Goldkuhl, 2006). In this chapter we will
further ground BAT as a business domain ontology in a higher level domain ontology (Guarino, 1998) for the distinction between different types of ontologies.

The basic characteristics of a practical theory have earlier been elaborated by Cronen (1995, 2001) and Craig and Tracy (1995). Cronen (1995, p. 231) describes practical theories in the following way:

_They are developed in order to make human life better. They provide ways of joining in social action so as to promote (a) socially useful description, explanation, critique, and change in situated human action; and (b) emergence of new abilities for all parties involved._

Practical theories should help us to see things, aspects, properties, and relations which otherwise would be missed (Cronen, 2001). The constituents of a practical theory have lately been elaborated by Goldkuhl (2006). Goldkuhl emphasizes conceptualizations, patterns, normative criteria, design principles, and models as (partially overlapping) such constituents of a practical theory. BAT is today regarded as a practical theory since all these constituents have been elaborated. For further elaboration, see Goldkuhl (1996), Lind and Goldkuhl (2003), and Goldkuhl and Lind (2004). The choice for us focusing on BAT is based on our good experiences in adopting BAT in practical situations and due to shortcomings in other theories for business interaction (Goldkuhl, 2006).

The notion of ontology is in this chapter was conceived as a particular system of categories accounting for a certain vision of the world (Guarino, 1998). Essential in the conception of ontology is conceptualization, which can be made on more or less formal foundations. According to Gruber (1993), an ontology is to be conceived as a specification of a representational vocabulary for a shared domain of discourse—definitions of classes, relations, functions, and other objects. Guarino (1998) claims that an ontology is a logical theory accounting for the intended meaning of a formal vocabulary, but not necessarily that the formal vocabulary is to be a part of a logical language, as, for example, it may be a protocol of communication between agents. Different conceptualizations of the world thus need to be included in the ontology. BAT as a practical theory is based on a pragmatic paradigm that sees scientific knowledge as means to improve human practices (Dewey, 1938). This also means a special interest in social actions constituting the world. See, for example, Goldkuhl (2005a), building on Mead (1938). The characteristics of a practical theory and requirements to put upon the domain-dependent ontology as BAT thus strongly overlap.

The starting point for the development of BAT was when Goldkuhl (1996), at the first language action perspective for communication modeling (LAP) conference, criticized the action workflow model of Medina-Mora, Winograd, Flores, and Flores (1992) for being asymmetric. See Goldkuhl (1996) for the complete criticism. An alternative to the action workflow model was presented which was the first version of the BAT model. This model emphasized business interaction as an exchange process with mutual commitments, fulfilments, and satisfaction. Both action workflow and BAT were founded in the language-action perspective (Winograd & Flores, 1986). This means that there were many theoretical affinities between the two models. There were, however, also substantial differences.

The BAT-model has since then been applied in many action research projects concerning co-design of business processes and IT (e.g., Axelsson, Goldkuhl, & Melin, 2000; Goldkuhl & Melin, 2001). Due to experiences from these applications of the model, it was continually redeveloped (Goldkuhl, 1998; Goldkuhl & Lind, 2004). Some essential characteristics of the BAT-model are that (see the section on BAT for a more thorough description) it emphasizes:
Grounding Business Interaction Models

- Business interaction between customer and supplier as two actor roles; supplier and customer
- A number of different exchanges, constituted by communicative and/or material acts organized as patterns of initiatives and responses
- The continual development of business relations and business capabilities
- The acknowledgement of other parties in the value transformation context
- The recurrence between several following business transactions
- The difference between interaction with the potential and the particular customer

The BAT-model originated within the language-action perspective with its basis in speech act theory (e.g., Searle, 1969; Habermas, 1984). However, from the start there was a criticism towards a narrow focus on only speech acts in business interaction (Goldkuhl, 1996). The fulfilments phase in the BAT model as a value exchange have been emphasized from its inception. There have been other kinds of deviation from a pure LAP orientation. The use of predefined communication patterns has been criticized by Goldkuhl (2003).

The BAT-model is built on several foundational concepts as roles, phases, and actions. One important attempt to clarify the BAT ontology was made in Lind and Goldkuhl (2003) where five conceptual layers were described. These layers were (from bottom to top): business act, action pair, exchange, business transaction, and transaction group. Through this work the need to ground this ontology not only in LAP was obvious. Other social action theories were used as basis.

Parallel to the development of BAT was the evolution of socio-instrumental pragmatism (SIP) as a foundational and progenitive theory for several practical theories in the IS area (Goldkuhl, 2002; Goldkuhl & Ågerfalk, 2002). By progenitive, we mean that SIP gives a theoretical grounding to other theories. SIP is in this chapter regarded as a domain ontology on a higher level than BAT; a base ontology since it describes general social domain concepts, which are independent of a particular problem or domain. For some ontology-researchers SIP would probably be regarded as a social domain ontology. Due to the need to distinguish between BAT as a business domain ontology (Guarino, 1998) from SIP as a social domain ontology, we characterize SIP as a base (domain) ontology. Goldkuhl and Röstlinger (2003) made an articulation of SIP as foundational basis for workpractice theory (Goldkuhl & Röstlinger, 2003), information systems actability theory (Goldkuhl & Ågerfalk, 2002), and sociopragmatic communication theory (Goldkuhl, 2005b) besides BAT. SIP is an eclectic theory synthesizing several pragmatic theories from reference disciplines outside the IS area (Goldkuhl, 2005a). One purpose of SIP is to enable seamless theorizing in the IS area (Goldkuhl, 2005).

Although important steps have been taking by Goldkuhl and Röstlinger (2003a) and Lind and Goldkuhl (2003) in grounding the BAT model in socio-instrumental pragmatism, much work remains. The purpose of this chapter is to clarify BAT as a business interaction ontology (business interaction as the domain) by elaborating on SIP as a base ontology for such clarification. Different concepts of business interaction will be grounded in foundational concepts of social interaction as they come through in socio-instrumental pragmatism. This will lead to three types of theoretical contributions (ontology clarifications):

- Clarification of business interaction concepts in the BAT-model
- Clarification of social interaction concepts within socio-instrumental pragmatism
- Conceptual grounding of the BAT-model in socio-instrumental pragmatism (conceptual relating)
After this introduction, a more thorough description of the BAT-model will follow. This description also includes, for the purpose of putting the BAT-model on the scene of contemporary concepts, relationships towards other similar concepts will be explicated. Following this description we will put forward the foundations of the socio-instrumental pragmatism as the base ontology used in this chapter. After these two foundational parts of this chapter, different business interaction phenomena according to BAT will be grounded in socio-instrumental pragmatism. The chapter will conclude with some highlights from this grounding.

**BUSINESS ACTION THEORY**

**Overview of the BAT Model**

The BAT-model is a phase-model describing a generic business interaction logic (Goldkuhl, 1998).

*Figure 1. Levels of business interaction (Goldkuhl & Lind, 2004)*
Grounding Business Interaction Models

BAT describes customer—supplier interaction. Business interaction should be understood as the performance of business acts (Lind & Goldkuhl, 2003). A vital aspect here is that a business act can be both a so-called speech act (a communicative act) and a material act. Thus business interaction is not restricted to communication but also comprises vital material acts as the exchange of products vs. money.

The BAT-model is a generic framework for business dyads. Being a generic framework means that it covers different types of business interaction as B2B (business-to-business) and B2C (business-to-consumer). It also covers different types of products, both goods and services and both standard and tailor-made products. The application scope of the model is to be used for evaluation, modeling, and design of business interaction. In the current version of BAT (Goldkuhl & Lind, 2004), two levels of business interaction are distinguished: the market level and the dyadic level (see Figure 1). On the market level, suppliers and customers search for knowledge and contacts concerning the correspondent party. The interaction on this level is, according to BAT, driven by a general business interest of both suppliers and customers.

When a contact is established between a particular supplier and a particular customer, the general business interest is turned into a particular business interest. The business interaction moves to the dyadic level where business transactions take place. According to the BAT-model a business transaction consists of four phases: (1) proposal phase, (2) commitments phase, (3) fulfilments, and (4) assessments phase (Figure 2). Each phase consists of exchanges of a particular character, for example, the first phase consists of exchanges of proposals.

The BAT-model is characterized as a comprehensive framework (Goldkuhl & Lind, 2004) that sees business action as a building block, emphasizes the exchange character of business interaction, adopts a symmetric view on business parties and their interaction, and acknowledges both communicative, material, and financial interaction.

Essential Concepts

The BAT-model is based upon the business action as the basic unit of analysis. Conditions for and results of business actions are action objects that could be of communicative and/or material character. The notion of business acts builds upon the notion of social action. Performing social actions—either communicative or material—introduces relations between two actors in roles (supplier and customer). The performance of a communicative action (like a business order) introduces clearly certain relations between sender and recipient (Habermas, 1984). Based upon the generic model of social action (see the next section) a business act is defined as “performance of a communicative and/or material act by someone aimed towards someone else” (Lind & Goldkuhl, 2003, p. 335). Business acts are often multifunctional. One example of multifunctionality is that the order both represents a request to the supplier to deliver something and a commitment of paying for the delivery corresponding to the order. Another example of multifunctionality is that a delivery of a product can both be a change of place of some material stuff and a fulfilment of a request and a promise.

The interactivity in the BAT-model is constituted by grouping two business acts into an action pair. The basis for grouping business acts into an action pair is that one business act functions as a trigger for another act, which will have the function of a response. Action pairs are patterns of triggers and responses. One example in business interaction is an order as the trigger and an order confirmation as the response of that trigger. By issuing an order the interventionist (i.e., the customer) expect the recipient (i.e., the supplier) to respond in a certain way: by confirming the order, by negotiating, or by turning the order away.
Action relations between the actors are created through such an interaction.

One or several action pairs, that is, patterns of action pairs, constitute exchanges between actors. An exchange means that one actor gives something in return for something given by another actor. Exchanges are, however, not only related to exchange of value (such as physical goods in return for money)—exchange is related to different kinds of communicative as well as material business acts. As indicated in the description of the BAT-model, exchanges are of different types (such as proposals, commitments, values, and assessments). Exchanges constitute the core of business interaction. Each type of exchange distinguishes a business phase.

Several exchanges together constitute a business transaction. There is a certain logic of interaction between the supplier and customer when doing business. This logic is the pattern covered by the business transaction (Axelsson et al., 2000; Goldkuhl, 1998). A business transaction has different states (in the social and material world) where the initial state is that the customer has a need and the supplier has a corresponding ability. The interaction between the two parties is determined by their dispositions, such as capabilities, business interests, and needs. By going through a number of phases consisting of exchanges the goal is to arrive at a state where both supplier and customer have satisfied (parts of) their needs. Patterns of exchanges, covering different phases, between the two roles continually evolve relations between the two business parties.

**BAT in Relation to Other Business Interaction Frameworks**

Within the language/action (L/A) community there is an interest for business interaction. The strength of the language/action perspective is that it is based on the idea that communication is not just transfer of information. When you communicate you also act (Searle, 1969). Actions are performed, including building commitments and agreements between business parties. Agreements are to be regarded as the backbone of L/A approaches. Both agreements on what to do and agreements on performed actions are accentuated. Such emphasis on agreements causes a division of the communication process into three or four phases.

Action workflow (AW) (Medina-Mora et al., 1992) and DEMO (Dietz, 1999) are two frameworks founded in the language/action tradition. Although valuable features exist in these frameworks, certain limitations also exist. The interactive character is not fully developed. See Goldkuhl and Lind (2004) for further explanation of this criticism. As a reaction towards these deficiencies, the BAT-model was introduced (Goldkuhl, 1996, 1998; Goldkuhl & Lind, 2004; Lind & Goldkuhl, 2003). The BAT-model has been applied in different studies (e.g., Axelsson et al., 2000; Goldkuhl & Melin, 2001; Lind, 2002).

As mentioned in the introduction, there is a need for comprehensive frameworks covering business interaction. The BAT-model is claimed to be one. Another promising attempt to create such comprehensive framework has been made by Weigand and van den Heuvel (1998) in which metapatterns for electronic commerce is proposed. This framework is built on the idea to integrate different L/A-oriented approaches, such as DEMO, action workflow, and BAT for business modeling.

Originally outside the language/action tradition, Schmid and Lindemann (1998) have presented a reference model for electronic markets that in later works (Lechner & Schmid, 2000) has been expanded to a more general framework—a media reference model (MRM). A comparison of BAT and MRM has been made in Petersson and Lind (2005).
SOCIO-INSTRUMENTAL PRAGMATISM

Social Action

Socio-instrumental pragmatism (SIP) is a foundational theory (base ontology) specifically aimed for studies concerning information systems (e.g., Goldkuhl, 2002, 2005a; Goldkuhl & Röstlinger, 2003). It is an eclectic synthesis based on several action-theoretic frameworks form reference disciplines, like, for example, philosophy, linguistics, sociology, psychology, and organization theory. It is based on foundational pragmatic insights leading to action as a core concept. Herbert Blumer, one of the founders of symbolic interactionism, claims that

...the essence of society lies in an ongoing process of action—not in a posited structure of relations. Without action, any structure of relations between people is meaningless. To be understood, a society must be seen and grasped in terms of the action that comprises it. (Blumer, 1969, p. 71)

The social world is created and recreated through human actions. This means that most actions are of social character. The great sociologist Max Weber has made a classical definition of social action: “That action will be called social which in its meaning as intended by the actor or actors, takes account of the behaviour of others and is thereby oriented in its course” (Weber, 1978, p. 4). Our interpretation of this definition is that a social action (performed by an actor) has social grounds (“takes account of the behaviour of others”) and social purposes (“thereby oriented in its course”).

From this follows the basic idea in SIP that (most) actions are directed towards other humans. There are addressees of most actions. When we, as human actors, create or change some material object, there may be addressees for this action object. When we say something, there are definitely addressees for these communicative actions. In SIP, there is a basic model of social action (Figure 3). This model consists of two actors. One actor is conducting an intervening action (a communicative action or a material action) directed towards

Figure 3. Socio-instrumental action: A basic model (Goldkuhl, 2005a)
the addressee. The addressee performs a receiving action, that is, the receipt of a material object or the interpretation of a message. The intervening actor is the focused actor in the model. This actor has social grounds for the action. The actor pre-assesses external and internal grounds in a deliberative phase before the intervening action. After intervention, the actor postassesesses the result and the effects. This builds on a continuity model of actions with a division into three stages: (1) pre-assessment, (2) intervention, (3) post-assessment (Goldkuhl, 2004). Originally, this builds on Mead’s (1938) four stage model of human action: impulse, perception, manipulation, and consummation. In SIP these stages have been renamed and the first two stages have been integrated into one.

In SIP, the action is seen as knowledgeable. The actor uses her knowledge in order to make a difference in the external world (Dewey, 1931). The actor is seen as purposeful with abilities to reflect and deliberate before intervention (Dewey, 1931; von Wright, 1971). The SIP model of human action also builds on an important difference between result and effect (von Wright, 1971). The result is what the actor produces, that is, the direct result of the action. The result is what lies in the range and control of the actor. Effects are what arise as consequences of the performed action.

Social action takes place in a temporal and spatial context. We can distinguish between an intratemporality and an intertemporality of an action. With intratemporality we delimit to the actor (an intra-actor characterization). This means the phasing of pre-assessment, intervention and postassessment described above. The intertemporality emphasises the actor interacting with other actors: In this case we follow the division of (1) social grounds for action, (2) the (interventive) action, and (3) the social effects of action.

The SIP model also acknowledges that human actions often are mediated through the use of some instrument (e.g., Vygotsky, 1962). Instruments are mediational means for human action with enabling and constraining functions for the actor. Many actions can be seen as transformation of objects. A base object is transformed into a result object (Goldkuhl & Röstlinger, 2003).

Social Interaction and Relations

As every model, Figure 3 is a simplification. It describes a one-way action from the focused actor to the addressee. There is no explicit interaction depicted in this model. Within the social grounds, there may be an implicit interactional component. There may be, for example, a request of some action from the addressee actor in the figure. This basic social action model is therefore complemented with a social interaction model (Figure 4). In this model the interactive nature of social life is more explicitly depicted. The interaction model describes two related actions. One action is an initiative for the subsequent action, which is seen as a response to the first. The response action can then function as an initiative for subsequent responsive actions. The concepts of initiative and response is fetched from the concept adjacency pair in conversation analysis (Sacks, 1992) and later refined in dialogue theory (e.g., Linell, 1998). Goldkuhl (2005a, 2005b) describes the integration and use of these concepts in socio-instrumental pragmatism.

Another important aspect of social interaction is also depicted in Figure 4. Social actions imply relational changes between actors. When one actor says something or does something else directed to an addressee, certain social relations between the actors are established. For example, when an actor is posing a question, expectations are arisen that an answer or some other adequate response will follow. SIP builds on communication theories where this kind of relational changes are emphasized; speech act theory/communicative action theory (Habermas, 1984; Searle, 1969) and conversation analysis (Sacks, 1992). Some scholars (e.g., Linell, 1998) conceive these theories as contradictory. In SIP, these theories are conceived as complemen-
tary. Goldkuhl (2003, 2005b) has described how aspects from speech act theory and conversation analysis are integrated into one congruent communication model founded in SIP.

What is a social relation? What does it mean? Where do social relations exist? In order to discuss this matter, we need to use the concepts of a focused actor (“ego”) and another actor (“alter”). Relations exist as ego’s apprehension of the alter and vice versa. In order to succeed in social interaction, parts of these relational apprehensions need to be intersubjective and not only intrasubjective (these concepts will be further discussed). Different emotions concerning each other may be personal and thus intrasubjective. However, in order to conduct a business conversation in a mutually understandable and coordinated way, different relations between ego and alter need to be intersubjective to a sufficient degree. If ego asks for a product price, then expectations are raised for some answer from alter. After this question has been posed, both parties are usually aware of the expectations for a proper response (Heritage, 1984). Otherwise there will be a breakdown in the communication. Every “move” in the social interplay of a conversation introduces new relations and changes old ones. A communicative action is usually both a response to previous actions and an initiative to subsequent actions. This means that a certain action may change earlier relations and introduce new ones. This is described in Table 1 and Table 2.

Table 1 describes the different types of relational development that occur from ego action. The table both pinpoints the ego action in relation to alter action as well as ego actions as response (to earlier actions) and projection (for future actions). As stated, an ego action has, as an initiative, connections to future actions. In a communicative act, there are often projections of possible future actions (Goldkuhl, 2005b). An ego action gives expectations for future alter actions. A request is a typical example; the request gives expectations for some future alter actions. An ego action may not only have connections to alter future actions, but also to ego coming actions. A promise is a typical example of introducing commitments for future actions (Searle, 1969). An ego action has, as a response, connections to earlier actions. This relational aspect of an ego action means that it is a reply to alter’s earlier action and the kind of expectations which are raised in this alter ac-
We call this relational aspect replication. One example of this is ego’s answer to an earlier posed question by alter. An ego action may not only have connections to alter previous actions, but also to ego own actions. Ego may have done some commitment in a previous action (e.g., a promise), and the present ego action may be in accordance or not to this commitment. Being in accordance, the ego action is a fulfilment and if not, it will be a deviation.

Table 1 described the relational meanings of an ego action. Table 2 describes the relational meanings of an alter action. Here we use the postassessment perspective explicitly. The situation described is when ego makes a (post-)assessment of alter’s conducted action. What relational changes may occur after alter’s action? If there are any action projections made in alter action, relational changes of commitment or expectations may occur. If alter requests something to be done by ego, then an expectation (towards ego) is introduced. If alter promises to do something, commitments for future actions are introduced.

What alter does can also be assessed in relation to ego previous actions and alter previous actions. If alter replies to a question earlier posed by ego, then different kinds of experiences may arise. If alter gives a proper answer then ego may conclude that alter seems to be knowledgeable person. If the answer does not seem to be adequate or correct, then ego’s experiences of alter as knowledgeable may diminish. Or ego may reflect upon ego’s question (earlier action), that it was not so properly formulated. This follows the principle of action reflexivity described by, for example, Giddens (1984). All actions have repercussions back on the actor himself. Table 1 and Table 2 have been introduced here as an important refinement of SIP and will be used when performing a SIP analysis of business actions.

### Realms of the World

With socio-instrumental pragmatism comes also a division into different realms of the world. Goldkuhl (2002) has made a principal division into
different ontological categories (realms). These are depicted in Figure 5. The different ontological categories are the humans, their inner worlds, their actions, and the external world consisting of signs, material artefacts, and nature. Actions are subclassed into three types: (1) Intervening actions, that is, making changes in the external world, (2) interpreting actions, that is, making sense of the external world, and (3) reflective action, that is, making internal changes through thought processes. This follows the division made by Schutz (1970) in overt actions (intervention) and covert actions (interpretation and reflection). Signs and material artefacts are created or changed through intervening actions.

Human inner world is divided into an intra-subjective part and an intersubjective part. The intersubjective part is knowledge that is shared with fellow-actors, for example norms, rules, linguistic competence and methods. This intersubjective part is known under different labels as, for example, social institutions (Berger & Luckmann, 1966; Scott, 1995), structure (Giddens, 1984), and culture (Duranti, 1997).

The SIP consists of some basic ontological building blocks as described in Figure 5. More complex phenomena are built from these elements. One very important phenomenon of complex nature in business interaction is organizations. An organization (a company), acting as a supplier or as a customer is of prime interest for business interaction models. What is an organization in a SIP view? Goldkuhl and Röstlinger (2003) has presented such an ontological clarification based on socio-instrumental pragmatism. “An organization exists as an agreement (a communicative

Figure 5. Different realms of the world (Goldkuhl, 2002)
fact) between the principals and other parts of the society. Through such constitutive actions, an organization is given a formal authority to act” (Goldkuhl & Röstlinger, 2003, p. 157). An organization is the result of constituting communicative acts between its principals and legal authorities. As such it is an intersubjective phenomenon depending on formal communicative acts. In a continual existence an organization must comprise different resources; financial and material resources and employed humans and their knowledge. In SIP, organizations are seen as actors (Goldkuhl and Röstlinger, 2003; Taylor & Van Every, 2000). They can, however, not act by themselves. Organizations act through their human agents and sometimes also through artificial agents, like IT systems. Organizational agents (like employees) act as representatives of the organization.

GROUNDING BUSINESS INTERACTION ACCORDING TO BAT IN SOCIO-INSTRUMENTAL PRAGMATISM

Socio-instrumental pragmatism has contributed to sharpen BAT in several respects. Lind and Goldkuhl (2003) and Goldkuhl and Röstlinger (2003) are two important earlier contributions. Further ontological clarifications are needed in order to specify the social action and interaction character of business interaction. This will be shown below.

BAT is a theory and model for business interaction. It is built from some basic concepts as

- Actors in roles (supplier and customer) can be a human actor or an organization
- Business actions (e.g., offering, ordering, delivering, and complaining) with corresponding action objects of communicative (e.g., offer, order, complaint) or material (e.g., goods) character
- Business phases consisting of actions concerning similar type of exchange (i.e., meaningful action aggregates)
- Business transactions consisting of actions within business phases from proposal to assessment (i.e., meaningful action aggregates)
- Relations between business parties which continually change through the business transaction (i.e., changes in the intersubjective world); a certain role plays the business agreement established in phase 2 and resolved in later phases
- Actor dispositions, which are preconditions for interactive business actions; for example, capabilities (of human and artefact character), business interests, and needs (human inner world and often expressed in signs)

Every generic business action described in the BAT-model is a social action and can be described in accordance with the generic model of social action (Figure 3). One actor (business party) conducts an action (e.g., offering) directed towards the other actor. An action object (e.g., an offer) is created/presented to the other actor. This other actor receives the action object and interprets it. Through this interpretation subsequent actions can be performed (e.g., ordering). This means that business actions are performed as a social interplay. One action functions as an initiative to another action, which is a response to the first action.

We will below perform a social action analysis of some generic business acts from the four business phases. In this analysis, we use concepts and perspectives from SIP. This will lead to contextual definitions of business actions emphasizing their social interaction character. When clarifying the business actions, the performing actor and the addressee must, of course, be described. This is done together with stating the action direction (from intervening actor to addressee). Social grounds for the action are also important for describing the
action. The actor should not be seen as a social marionette just functioning in a stimulus-response fashion. The actor has capabilities for deliberation before action. SIP is based on speech act theory (e.g., Searle, 1969) with the important differentiation into illocutionary force (here called action modus) and propositional contents. The focused action’s relations to future actions are important. They are, however, not described in this type of table. This aspect is instead described in special relational tables below, based on the principal Table 1 above.

The social action analysis of some of the generic business actions are thus a step towards defining key concepts and intentionally relating them to each other within the domain ontology (BAT). Relations between different concepts are to some extent elaborated on by using tables. An

important task in ontology declaration is to make intentional relations (cf. Guarino, 1998) explicit. This task has been initiated in our former work (e.g., Lind & Goldkuhl, 2003). The more explicit definitions put forward in this chapter should be seen as a further extension of this work.

In Table 3, we have described four types of actions from the proposal phase. Offer is the typical action of a supplier in this phase. We have described three types of customer actions: inquiry, invitation to tender, and counter bid. Table 3 is followed by Table 4, in which we have made a relational characterization of the offer action based on the relational development through the supplier’s actions.

**Contractual Phase**

The second phase in the BAT-model is the commitments phase. In this phase the business parties arrive at a business contract. The two main actions in this phase are the customer ordering and the supplier confirming. These two actions are characterized in Tables 5-7. We have also described the supplier’s invoicing as an action in this phase (Table 5). It might be seen as disputable. In the first BAT-model (Goldkuhl, 1996), it was described as part of the fulfilment phase. We have classified the invoicing to be part of the contract phase since these actions are concerned with directives for the exchange of value in the fulfilment.

phase. The order is a directive for delivery. The invoice is a corresponding directive for payment. Table 6 covers the relational characterization of the order action performed by the customer (as the ego). In Table 7, the relational characterization of the delivery confirmation action.

**Fulfilment Phase**

The main actions in the fulfilment phase are the delivery and the payment. These actions of exchange of value are mainly material and not communicative. Therefore we have left out the column “propositional contents” in Table 8.

**Assessment Phase**

The assessment phase can consist of positive and negative assessments. The two negative assessments, complaint and reminder to pay, are described in Table 9. A relational characterization of the complaint action is made in Table 10.

**CONCLUSION**

The purpose of this chapter has been to clarify BAT as business interaction ontology (a domain ontology). For this purpose socio-instrumental pragmatism (SIP) has been used as a base ontology. SIP uses social action as the core concept. A social action, which can be communicative and/or material, means that the action is conducted and directed towards another actor. Social actions have social grounds and social purposes. To act towards another actor in patterns of interaction implies relational changes between the actors. Every move in a social interplay introduces new

relations and changes old ones. It is thus important to consider several adjacent (social) actions, communicative as well as material, in patterns of interactive acts between the two (or several) parties. The BAT-model emphasizes phases and interaction patterns for establishing expectations, fulfilment of, as well as evaluation of fulfilled expectations.

In order to clarify BAT as business interaction ontology we have in this chapter made SIP-based social action analyses of the four business phases constituting the BAT-model. This has been done by stating action direction, social grounds, deliberation, action modus, and propositional content for essential business acts within each of the four business phases. For each of the main actions in each business phase, relational characterizations has also been made. In order to make such characterization, we have, in this chapter, introduced the notion of ego as the focused actor and alter as the other actor. In the social interplay the two actor roles, supplier and customer, alternate between being an ego or an alter. In each phase of the business interaction sequence possible business actions are determined ego’s response to earlier actions and projected actions towards the alter.

This analysis has led to a more explicit grounding of the BAT-model in SIP as an ontological
foundation. The BAT-model and SIP co-exist in the same sociopragmatic “family” of theories with SIP on a more foundational level. This pursued analysis has also implied a further sharpening of some social interaction concepts within socio-instrumental pragmatism. The typologies of different kinds of relations in social interaction are such a theoretical result.

The work reported in this chapter is to seen as a further step towards a practical theory. SIP is a foundational ontology building on social action. It can thus now be claimed that BAT has been further grounded in general social action concepts. This work also means that BAT, as a practical theory, now should be seen as a more congruent domain ontology—at least within the four phases of the BAT-model focused in this chapter.

BAT is intended to be used as a pragmatic instrument for understanding business interaction. It is a comprehensive framework to be used for several purposes. It can be used as a conceptual instrument when evaluating existing business interaction. The framework can also be used for modeling and designing business interactions. It reminds the designers about different dynamic features of business interaction as exchanges, recurrence, evolvement of business relations, and capabilities. It can give structure in the design process and be a basis for the important design of business actions and the allocation of actions to different agents (human agents and IT artefacts). Development of IT-support for business interaction is to be seen as a basic development of business capability.

The work reported in this chapter is to be seen as a rather informal metamodel (based on text and tables) pinpointing some key concepts in the BAT-model. An important step in the future is to make a more formalized metamodel based on the insights derived from grounding BAT in SIP, covering all key concepts in BAT.

Another step in future ontological clarification of the BAT-model is to investigate the relations between different business phases (initiatives and responses as the glue between different phases) as well as looking into different types of dyadic interactions. This is an important task since the logic of business interaction is conceived as establishing expectations (which is performed in two of the phases), fulfilling these established expectations and finally assessing the fulfilment. It is, therefore, important to highlight these relations since the actions in the latter phases are responses to earlier performed business actions. We also acknowledge a need to explicitly ground the differentiation between market-based interaction and dyadic interaction in the SIP ontology.

Chapter 6.7
Managing Socio–Technical Integration in Iterative Information System Development Projects

Bendik Bygstad
Norwegian School of Information Technology, Norway

ABSTRACT

The challenges of information systems (IS) development have changed significantly in the past 15 years. From a situation where the main problem was to build stable systems based on a requirements specification, the IS project manager now faces challenges of integration; for example: how to integrate a new information system into large existing information infrastructures and unstable business processes? Building on a socio-technical perspective, four types of integration were identified and analyzed: external and internal stakeholder integration, and internal and external technical integration. A longitudinal case study of an e-business development project in the airline industry identified and highlighted some managerial challenges of integration. Findings include: Internal technical and (to some extent) stakeholder integration is well supported by traditional project management techniques and software engineering frameworks, such as the Rational Unified Process (RUP). However, the challenges of external stakeholder and technical integration is underrated in IS development research, and not well supported in RUP.

INTRODUCTION

Fifteen years ago, most IS projects were greenfield projects; on the basis of a requirements specification, a brand-new system was designed and programmed. When (eventually) finished, it was installed and run, and the users were trained in new interfaces and routines. The main challenges for the project manager were to get the requirements specification right and complete, and to develop the system to be technically stable.
Managing Socio-Technical Integration in Iterative Information System Development Projects

Of course, this is still a demanding craft, requiring specialized skills, sound methodologies and competent project management. However, the project manager today faces two more challenges:

• Most information systems are developed to support a business process, whether the scope is a dramatic process transformation or process improvement (Davenport, 1993; Laudon & Laudon, 2004). It is essential that the new system integrates with the business process, because a project that fails to do so will be a failure, even if the software product is well designed and programmed.

• A new system must also relate to an existing information infrastructure. The information infrastructure is seen as a heterogeneous network, comprising an installed base of technology, organization, culture and work practices (Hanseth & Lytinen, 2004; Hanseth & Monteiro, 1996). Both opportunities and constraints are heavily influenced by the attributes of this base. In a successful organization, this heterogeneous network is an immensely valuable resource; it constitutes the backbone of the organization. But in a world of change, it also may be a barrier to business adaptation or innovation, because the information infrastructure is hard and expensive to change.

The successful IS project manager must address both these challenges. In a way, this redefines the role of the project manager, making him or her an integrator of both social and technical forces. The question is: How is the manager going make people and technology work together in a complex and unstable setting?

Ideally, the process models of Business Process Reengineering (BPR) and IS development should answer this question. Unfortunately, the BPR community never really developed a full methodology for this integration (Giaglis, 1999).

During the late 1990s, the software engineering community embraced iterative and incremental process frameworks (Larman & Basili, 2003), such as RUP (Jacobson, Booch & Rumbaugh, 1999), Object-oriented Process, Environment and Notation (OPEN) (Henderson-Sellers & Unhelkar, 2000), Extreme Programming (Beck, 2000) and Dynamic Systems Development Method (DSDM) (Stapleton, 2003). The growing practice communities contend that these frameworks have the potential to integrate the business process and the new information system through step-wise stakeholder and technical integration (Blomberg, 2001; Kruchten, 2000; Stapleton, 2003). The basic mechanism is the short iteration that produces a small release that can be tested, integrated into the information infrastructure and assessed by the business organization.

This deserves attention not only in the realm of software engineering, but also in the broader context of information technology (IT)-based organizational change. While skeptics have pointed to lack of practical integration support for e-business architectures (Smolander, 2003), and poor project management support (Henderson-Sellers & Unhelkar, 2000), the large RUP community points to a number of success projects (Rational, 2006b). This paper explores, analytically and empirically, two important questions in this context:

• How can the IS project manager integrate the new information system with the business process and the information infrastructure?
• What integration support is there in software engineering frameworks, like RUP?

The rest of this paper is structured as follows. In the next section, the concept of integration is defined and discussed. Then, the integration support in RUP is briefly assessed. The research approach, longitudinal process research (LPR), is presented. Next, the integration challenge is
investigated empirically through a longitudinal case study of an IS project in the airline industry. The findings in the case study are discussed, and implications for practice and research are assessed. The last section concludes and points to further research.

DEFINING INTEGRATION

According to Webster, integration is “a combination and coordination of separate and diverse elements into a more complete or harmonious whole” (Webster’s, 1986, p. 1174).

Building on the socio-technical IS development tradition (Avison & Fitzgerald, 2003; Coakes & Elliman, 1999; Kling & Scacchi, 1982; Mumford, 1985) and actor-network theory-inspired IS research (Ciborra, 2000; Garrety, Robertson & Badham, 2004; Hanseth, 2002; Hanseth & Monteiro, 1996; Walsham, 1997), the two key element types to integrate are seen to be stakeholders and technology. Stakeholders are anyone (both humans and organizations) affected by the process, while technology may be networks, systems and components.

Stakeholder integration is defined here as a management activity that aims at facilitating cooperation between people and organizations, and helping them work together to create value. The mechanisms for achieving this may be structural (assigning formal roles and responsibilities) or process oriented, focusing on informal interaction (Heugens, van den Bosch & van Riel, 2002). In both cases, trust is important to keep the relationships alive.

Technical integration is, correspondingly, defined as a management activity to assemble components and systems in a way that make the resulting system work as intended. These components are often a mix of internally produced software, existing internal legacy systems, commercial software (COTS) and large networks, like Virtual Private Networks (VPNs) or the Internet. To make them work together is usually dependent on a combination of different actions: Designing correct interfaces, establishing stable operations and giving sufficient support from technical personnel. In the end, however, the most important element is probably correct use, thus connecting technical integration closely to stakeholder integration.

A basic idea in the socio-technical tradition is that the object of interest is not an artifact, a piece of technology, but rather the structuring and reproduction of a socio-technical network, consisting of both technical and social elements (Kling & Scacchi, 1982). Thus, the goal of an IS development project is not primarily seen as the construction of a software system, but to establish a working socio-technical network.

Both stakeholder and technical integration may be seen as management activities aimed at establishing linkages to different elements that have to work together. In large projects, the number of linkages will grow into complex networks, and this complexity leads to increased risk (Hanseth, 2002). The risk is enlarged by the fact that both the business process and the information infrastructure are unstable; they may change during the project time, due to external pressures or internal shifts of power.

Internal and external integration. Many integration activities are internal to the project, such as managing project teams, programming and testing components. But many integration activities are external to the project; aligning the project with business needs, modeling with future users, using external components and other systems. Thus, the integration process is multidimensional. It includes both stakeholders and technology, and the activities are both internal and external to the project. Thus, four types of integration are suggested in Table 1.

It is documented that integration is usually easier if done step-wise, because it reduces the technical risk and allows both the development project and the business process people to learn
Managing Socio-Technical Integration in Iterative Information System Development Projects

Early user participation has long been established as an important success factor (Garrity & Sanders, 1998). On a more political level, it also enables enrollment of important allies into the project (Hanseth & Monteiro, 1996). Early technical integration secures the integrity of the system; testing is performed in each iteration, and performance issues may also be addressed early (Jacobson et al., 1999). This is recognized in the iterative software engineering frameworks: For each iteration, new stakeholders are drawn into the project. And for each iteration, a small piece of solution is implemented, either in a test or pilot environment or in real production.

It may sound easy, but it is not. As Giaglis (1999) noted, the problem is not getting acceptance for the need of an iterative and integrative approach, but to actually manage it. The RUP framework was selected for this study as an example of a well-known framework. Therefore, the first step in this research was to assess to which degree RUP supports the IS project manager in his or her integration challenge.

ASSESSING INTEGRATION SUPPORT IN RUP

RUP is a large framework for software engineering developed by Rational Corp. in the late 1990s, building on Jacobson’s work at Ericsson (Jacobson et al., 1999). As illustrated in Figure 1, RUP is structured in four phases: inception, elaboration, construction and transition. Within each phase are one or several iterations consisting of disciplines, starting with business modeling and ending with the physical deployment of software components. RUP is both a process framework and a commercial Web-based product. The Web product is RUP online (Rational, 2006a), with 3,700 Web pages describing the principles of RUP and providing a rich toolbox of guidelines, risk lists and document templates.

To assess the degree of integration support in RUP, a rather simple but systematic analysis was

Figure 1. Structure of RUP (Rational, 2006a)
performed. The basic material was the templates of detailed activity lists provided in RUP online to help the IS project manager to plan the phases of the project. These lists are certainly not sufficient to plan a RUP project, but they give a reasonable picture of the profile of activities in each phase.

The assessment was done as follows: Each activity was classified within the four integration categories presented in Table 1. The resulting distribution of activities is shown in Table 2.

As the table shows, integration support is unevenly distributed. It is quite strong regarding internal technical integration throughout the phases, while it gives surprisingly little external technical integration support. Internal stakeholder integration is weak thoughout the project, confirming, perhaps, the critique against RUP for poor project management support (Henderson-Sellers & Unhelkar, 2000).

Support for external stakeholder integration is strong in the inception phase, but gets weaker in the later phases. A more detailed analysis of these activities shows that RUP gives strong high-level support to external stakeholder integration, but little practical support at the operational level. The same pattern is found regarding external technical integration. This may indicate another limitation in RUP: It endorses step-wise external integration, but little practical support.

### THE CASE STUDY: DEVELOPING AN E-BUSINESS SYSTEM FOR AN INTERNATIONAL AIRLINE

To investigate the challenges in more depth, a longitudinal case study was designed, studying an IS development project in the airline carrier industry. The research approach was LPR, which aims to study organizational change over time through intensive research in the actual context (Ngwenyama, 1998; Pettigrew, 1985, 1990). LPR focuses on building theories strongly embedded in the context of study. Reflecting Giddens’ structuration theory (Giddens, 1987), context is seen by Pettigrew not only as an environment, but as “a nested arrangement of structures and processes where the subjective interpretations of actors perceiving, comprehending, learning and remembering help shape the process. The processes are both constrained by context and shape contexts” (Pettigrew, 1990, p. 270).

Important criteria for data collection are, according to Ngwenyama (1998):

---

• Ongoing engagement with the research site, to observe changes over time
• Participant observation, to contextualize and make sense of observations
• Multiple data sources, to record different interpretations of events and ensure validity of findings

The case, a RUP development project at Scandinavian Airline System (SAS), was researched for 16 months, using several techniques for data collection: Project managers, developers and users were interviewed at four intervals. Project meetings were observed, and a vast amount of project documentation was analyzed.

Data collection was done in four phases, as summarized in Table 3.

Ngwenyama (1998) suggests three modes for data analysis: (1) Comprehensive analysis, which helps to identify underlying structures and patterns of the organizational process; (2) temporal analysis, which helps contextualize findings by placing events and situations in a narrative structure; and (3) member verification, which ensures that the case description and interpretation researcher are considered correct and meaningful to the organizational actors.

The SAS case was analyzed in the following steps: Data was coded following the guidelines of Miles and Huberman (1994). After the videotaped interviews were summarized and registered into an Atlas database, texts were coded with in-vivo codes, using only domain (project) terms. The large volume of project documentation was coded the same way.

First, a timeline with significant events was produced. Then, each iteration of the project was analyzed in detail, while in parallel looking for repeating patterns. Looking for integration related terms, a new layer of codes were applied: “Technical integration” was mapped to component integration, testing, interface and also to legacy (and other) systems. “Stakeholder integration” was mapped to stakeholders, actors, users, customers, organizations and vendors. The integration context was also coded; whether it was internal (to project) or external (to business process and information infrastructure) integration.

Validating the Case Description

Suggested mechanisms and patterns were validated using criteria suggested by Klein and Myers (1999).

The principle of dialogical reasoning addresses the validity problem of the relationship between the assumptions behind the research design and the actual findings. In the case study, this aspect was important in the coding process described in the previous section. Moving from codes to patterns, systematic attempts were made to construct the opposite pattern and ask whether it could make sense on the same data.

The principle of multiple interpretations calls for sensitivity in interpreting conflicting accounts of the same case. In the case description, special care was taken to analyze instances where data was contradictory; for example, when developers and user representatives had different accounts of what had happened.

The principle of member verification (Ngwenyama, 1998) was implemented as follows: After the initial workshop with important stakeholders, a timeline for the project was constructed. This was sent to participants for verification. After about a year of studying the project, a preliminary case description was written and commented on by stakeholders. Last was a validation meeting, where project managers, developers and business users were invited to assess and comment on the final case description.

The SAS Content Management Interface (CMI) Project

The case is described from a socio-technical integration perspective, focusing on the stakeholder and technical integration challenges.

SAS is an international airline carrier based in Scandinavia. It is owned by the Swedish, Danish and Norwegian governments (50%) and private investors. In 2003, the SAS group had 34,000 employees, and turnover was 57 billion Swedish krona (SEK).

As a part of the marketing division, SAS established in 1999 the Electronic Direct Channel (EDC), directed at selling airline tickets and hotel reservations on the Internet. The EDC owns the SAS home page, including campaigns and online booking services. Simplified, the e-business process consists of these steps: Marketing air tickets in different national markets on the scandinavian.net Web site, and receiving electronic orders. Feedback mechanisms are Web hits on the home page and actual bookings.

The first generation of the SAS Web site was primarily available in Scandinavia, with content managed by editors using HyperText Markup Language (HTML) and FrontPage as publishing tools. In 2000, acknowledging the commercial potential of Web-based booking, SAS decided to establish a Web-based marketing channel in all important SAS markets, including Europe, Asia and the Americas. To support this new business process, a new content management and publishing solution was needed, and implementation was based on the Vignette platform. A project was initiated, with the following objectives:

- To establish a Web-based marketing channel in all important SAS markets, including Europe, Asia and the Americas.
- To enable the editors to publish materials and campaigns with an easy tool, a CMI.
- To integrate this new system with SAS’ (legacy) booking system and the European Amadeus booking system.

In spring 2001, the IS development project was set up by SAS’ daughter IT company, Scandinavian Information Group (SIG), with a project group of five: one project manager, one Web designer and three programmers. In parallel, an SAS project group, consisting mainly of marketing editors, was established to provide a strong business and user link with the development group.
Following a corporate decision from 1999, the project was planned within the RUP framework. Each iteration was set up to follow the disciplines in RUP, starting with a revision of requirements; proceeding with design, coding and testing; and ending with an increment, a temporary release, to be validated by users. Also, in accordance with RUP, a stakeholder and risk analysis was done.

### The First Two Iterations: Unsuccessful Stakeholder Integration

The initial requirements specification, written by IT personnel at SIG, contained 14 use cases for the CMI application. In two workshops, the two project groups extended the number of use cases into 20 detailed ones. Then they started working on a graphical prototype to visualize the use cases.

The workshops were not very successful, and they were interpreted differently by the actors: The SAS project manager, who was now elaborating the requirements specification, was moderately satisfied:

*The workshop in the first iteration was OK because it gave the users an impression of the system. The workshop in the second was useful, but we were not able to show the users how the system would work.*

Some of the editors felt alien to the whole concept:

*We spoke different languages, and they had no idea how we worked. We were polite, and there was no conflict, but that was how we felt. We thought we might get it straight later on in the process. The use cases were very – theoretical, and it was hard to participate. Also, I was so busy running the existing site that I had no time to spend on this, really. I felt guilty because of that, because I should have given much more input.*

Another editor said:

*Use cases focused on the new system, not on how things were solved today. Development was system oriented, not on the work process.*

The developers later said:

*Of course, the graphical prototype should have been a full architectural prototype – but this was not possible, because the presentation engine component was not ready. In addition, the editors did not really prioritize the workshops.*

Not surprisingly, the results were unsatisfying. Nobody felt that the graphical prototype was useful. The presentation engine component, which was crucial for creating a page, was developed in another project in Copenhagen, and it was seriously delayed. Thus, by the end of the elaboration phase, the two main goals were not reached: The users and developers did not have a unified view of the system, and the architecture of the system was not stable. The situation was analyzed and the risks were assessed by the customer and the project managers. Because of time pressures, they decided to proceed, and took care to prepare as much as possible to integrate the missing component later.

### Iterations Three and Four: Successful Internal Technical Integration

No code had been produced in the first two iterations. In the third iteration, the project group got a better grip on the technology, and started to work more closely with the SAS project manager, who was now sitting in the same room. This iteration produced the basic CMI functionality, enabling the CMI users to upload content to the content database.

In the fourth iteration, the first release of the presentation component arrived, and the crucial
functionality for creating pages was developed. In a few intense and informal work sessions, a design was developed as the application was prototyped. Commented one of the developers:

*When the SAS project manager really joined the team, the whole atmosphere changed. We were able to experiment with screens and solutions at a practical level. Also, it was important that he really understood the technical difficulties involved. We were sitting long hours together, solving real problems. It was very productive and also great fun!*

Test cases were also produced, and at this time the project group felt things were on the right track. While the user group was not involved, the SAS project manager communicated frequently with the editors, assuring them that the project was on track.

After the start of the fourth iteration, the September 11, 2001 terrorist attacks in the United States (U.S.) shook the whole airline industry, and as a result of this, combined with a tight project deadline, the project was scaled down. Only 10 of the initial 20 use cases would be developed. By the end of November, the user group started testing the system. Towards the end of the iteration, the SIG project manager went on maternity leave, and the SAS project manager was made in charge of the whole project.

**Iteration 5: Improvised Integration**

So far, the project had proceeded more or less as planned. But now a different phase started, which was not characterized by planned iterations but rather by problem solving and improvisations. The project manager commented:

*At a certain point in a project the focus changes: Budget and plans are no longer the main consideration, and everything is focused on getting the product finished.*

There were two reasons for this. First, the project experienced external technical integration problems. In the fourth iteration, the project waited for the completion of two important software components that were programmed by another SIG project in Copenhagen. Both were seriously delayed and not stable until spring 2002. There were also other technical problems. SIG had four different technical environments: Development, integration testing, production testing and production. In this case, the test environments did not fully support the CMI, and intermediary solutions had to be made. Complicating matters even more, a memory leak occurred, which took a long time to identify and fix. These problems made testing more difficult. Second, after beta testing had started, there were a rising number of change requests from the user group, and changes were introduced frequently during spring 2002. One of the editors said:

*From the end of February, we started testing at our workplace. At that time I had no mental picture of the whole systems, only fragments. In March, when we started to load real data, I was able to understand the workings of the system. Until then, it was like looking at the system through a pair of binoculars.*

As the editors got more experience, the number of change requests increased. Said the Oslo editors:

*The period around the start of the system we sat together with the developers and really understood the whole system. This was great, and the first time we really could give real input.*

In March, there was a 2-day course in Stockholm for all the editors, at that time numbering around 30. Most of them were introduced to the system, and in spite of technical stability problems and long response time due to slow interfaces (APIs) in the Vignette platform, the course was perceived by the EDC and CMI project as rather
successful for most of the editors. A few of them were less motivated, and lacked the basic IT user skills. After the course, the editors went home and started to load materials into a test database, which was later set into production. In this period, the CMI project worked hard with error corrections and use case change orders. The project manager said:

*Many new features were wanted from editors, both Scandinavian and the others, especially navigation features tightly connected to their work processes, page search and design. We were surprised by the volume of change orders.*

**Results**

Everything was set into production May 30, 2002, and has been in stable production since. The three goals of the project were achieved: a Web-based marketing channel in all SAS markets was established; the marketing editors in this organization had access to an easy-to-use tool to tailor the marketing and selling of SAS services to their local markets; and the Web pages were integrated with the booking systems, enabling customers to buy tickets online. However, during the first 6 months of production, there were still a large number of change requests from the marketing editors.

The case study highlights a number of managerial challenges associated with integration. These will be discussed in the next section.

**DISCUSSION**

This section first discusses the findings of the case study, in terms of managerial challenges of integration. Then some implications for practice and research are proposed. Finally, some limitations of the findings are assessed.

Managerial Challenges of Integration

The findings of the case study are discussed within the framework of the four integration types (presented in Table 1). They will also be related to the analysis of integration support in RUP presented in an earlier section.

In the described case, integration is seen as a process. It was partly or fully achieved through different managerial interventions, supported by the iterative and incremental structure of RUP. The managerial challenges associated with the four integration types are discussed below and summarized in Table 4.

Internal Technical Integration

This aspect was, after some initial problems, solved very nicely in iterations three and four. The CMI system was built incrementally and controlled, utilizing the rich mechanisms in RUP for step-wise integration and testing.

Findings: For the technically competent project manager, a software engineering framework such as RUP provides sufficient support for step-wise and controlled technical integration.

Internal Stakeholder Integration

At the start of the CMI project, the most central users in the business process, the Scandinavian editors, were drawn into the project and given a central role in the workshops. The workshops in iterations 1 and 2 were not successful, mainly because the project managers failed to convince the editors of the need for a new system. The project group responded to this with a certain degree of isolation, establishing a close team with the SAS project manager, who “changed sides”; that is, who identified more with the project than with the business process.

The progress of software development benefited very much from this cooperation. However, when the number of change requests increased in the later parts of the project, it was an indication that the iterative approach was not working optimally regarding user requirements.

Findings: Iterative IS development projects are not based on a frozen requirements specification, but rely on a step-wise interaction with business representatives through the iterations. Thus, it is critical to align project goals with business and user goals even after the initial top-down analysis. RUP does not give sufficient support for this task, as shown earlier.

External Technical Integration

The CMI project suffered from being dependent on components that were delayed. Thus, while skillfully planned, the step-wise technical integration was not working properly. Instead, the external integration problems appeared at a time when the editors tried to integrate the system into their organization, and it threatened the whole implementation.

The main technical problems arose from the fact that the development environment, and also the test environment, was configured differently from the production environment. In the test phase, this led to a series of small but important problems of instability. In the production phase, it led to the cache problem. As the project was designed, this kind of risk was hard to avoid, because a test environment mirroring a changing production environment would have been exceedingly expensive. In the end, the problem was gradually solved by a competent data center, using problem-solving techniques, and not a structured development process.

Findings: Integrating with a large, existing information infrastructure calls for careful planning, but also for improvisations. Often, the infrastructure is subject to change during the project, and it is therefore impossible to integrate in a step-wise manner. Obviously, the project man-
ager has to comply and adjust to these changes, whether or not they were planned. This aspect is underrated in RUP.

**External Stakeholder Integration**

The main target group for the CMI specification was the international editors, who needed a standardized and simple interface. Unfortunately, during the first four iterations they were not yet appointed, and could not participate. Thus, the continuous change of the business process made step-wise stakeholder integration unfeasible.

On the other hand, the international stakeholders were successfully enrolled in the project from March 2002, and during the busy, and partly improvised, period towards the production date, most of their requirements were satisfied. It should be noted, however, that during the first 6 months of production, there were still a large number of change requests, indicating that important business needs were not covered in the specification. It should also be noted that the late integration of stakeholders was done by improvisation.

*Findings:* Integrating with the business process calls for political skills and improvisations. Political skills are needed to build the alliances that make the solution work. Improvisations are necessary to integrate with an unstable process.

Of course, it is unreasonable to blame RUP for the late integration problems in the CMI project. But the “extended iteration” in the project, where the structured method gave little support and the project manager resorted to improvisation and problem solving, also indicates that this challenge is underrated.

*Summing up:* IS development in a complex and unstable technical and business environment, as illustrated in the SAS case, highlights the need for step-wise socio-technical integration.

Iterative IS development has an interesting potential to support this challenge, because the iterative structure allows for step-wise learning and incremental improvement. It also, to a certain degree, acknowledges the emergent nature of socio-technical interaction. However, in its present condition, RUP is too heavily influenced by its purely technical inheritance to give sufficient support to the full range of iteration challenges.

**Implications for Practice**

The CMI case highlights an important insight for practitioners: The integration challenge of iterative software development projects is larger and more complex than is described in the research and textbook literature. Even the very competent CMI team experienced serious problems with external integration. For practitioners, this is an important factor in risk management: To succeed, the project manager must manage something that is basically outside his or her control.

The root of this risk is the fact that both the business process and information infrastructure are unstable in most enterprises. As illustrated in the CMI case, the focus in a development project may change considerably over time, making it hard to plan in detail. And changes in the business process and information infrastructure should be treated as a normal feature, not as an unexpected incident. For the project manager of iterative projects, this aspect also presents opportunities, but in a world of tight schedules and budgets, the external technical and stakeholder integration is a significant risk.

For the IS project manager, this implies that risk management—focusing particularly on external integration—is as important as internal planning and control.

**Implications for Research**

At a general level, these risks are acknowledged in the IS development research (Avison & Fitzgerald, 2003) and in iterative software engineering frameworks (Jacobson et al., 1999; Stapleton, 2003).

However, as illustrated in the SAS case, these risks are not appendices in handling a
primarily technical task; on the contrary, they constitute a significant threat to the success of such projects. As the RUP analysis in the earlier section shows, the support in RUP is not sufficient to handle this challenge, in spite of some minor contributions (e.g., Kruchten, 2003).

Thus, on a practical level, RUP needs stronger support for external stakeholder and technical integration; in particular, in the construction and transition phases. In practice, this means emphasizing the external component/legacy system issues in the architecture description, and supplementing risk lists, iteration plans and task descriptions with activities that address business process stakeholder issues more explicitly. At the same time, it should be acknowledged in the RUP guidelines that the external integration cannot be planned in detail.

Planning and Improvising

External technical and stakeholder integration were seen to depend on both planning and improvisations to succeed. Finding that improvisations are important in change processes is congruent with the emergent view on organizations and with other related IS research (Ciborra, 1997, 2000; Ngwenyama, 1998; Orlikowski, 1996). However, it should not lead us to conclude that better planning is unnecessary or impossible. As the CMI case shows, improvisation puts a lot of pressure on a project manager, and introduces more risk into the project. The strength of an iterative software engineering framework is to reduce that risk, through step-wise integration. Thus, it is important to extend the capabilities of RUP and other frameworks, to include better external integration.

Limitations

Limitations to the findings presented in this paper derive from the research approach. LPR is aimed at developing contextualized theory (Pettigrew, 1985). This suggests that the area of validity is the context of a large organization with an iterative IS development process in a setting of unstable business processes and a complex technical infrastructure.

CONCLUSION

The objective of this study was to understand the integration challenge in modern iterative IS development projects. Two questions were asked:

1. How can the IS project manager integrate the new information system with the business process and the information infrastructure?
2. What integration support is there in the software engineering frameworks, like RUP?

Integration was defined in a socio-technical perspective, and four types were suggested: external and internal stakeholder integration, and internal and external technical integration. A longitudinal case study of an IS development project in the airline industry identified and highlighted some managerial challenges of integration. Findings include:

- Internal technical and (to some extent) internal stakeholder integration is well supported by traditional project management techniques and software engineering frameworks such as RUP. The iterative approach enables a step-wise and controlled internal socio-technical integration.
- However, the challenges of external stakeholder and technical integration is underrated in IS development research. Integrating a new system with an unstable business process and a large, existing information infrastructure calls for careful planning, but
also for improvisations, since it is outside
the direct control of the IS project manager.
This is not well supported in RUP.

These challenges are suggested to constitute a
significant risk for the success of modern iterative
IS development projects. For IS project manag-
ers, the implications are that risk management
of external integration is an important part of
iterative project management. For software en-
gineering research—in particular for RUP—the
findings indicate a strong need to provide stronger
support for external stakeholder and technical
integration; in particular, in the construction and transition phases.

Further research could study other iterative
projects and look closer into which integration patterns emerge. One might also investigate new
models for how IS project managers may contrib-
ute more actively to align the development projects and the business innovation, as recently done by
Boehm by the introduction of value-based soft-
ware engineering (Boehm, 2003). This is an area
well suited for cooperation between researchers and practitioners.

ACKNOWLEDGMENTS

I am indebted to the different stakeholders of the
SAS project, in particular Christian Mejlvang,
Jorun Akerberg and Gunilla Johansson, for ac-
cess to the project and for commenting on vari-
ous versions of the case description. Further, the
comments from the anonymous reviewers of the
International Journal of Technology and Human
Interaction were very helpful. Thanks also to the
following scholars and practitioners for comments:
Peter Axel Nielsen, Bjørn Erik Munkvold, Hen-
nning Denstad and Cecilia Haskins.

Chapter 6.8
Human Factors for Networked and Virtual Organizations

Vincent E. Lasnik
Independent Knowledge Architect, USA

“There are simple answers to all complex problems—and they are uniformly wrong.”

INTRODUCTION

One of the central problems and corresponding challenges facing the multi-disciplinary field of networked and virtual organizations has been in the construction of theory-grounded, research-based taxonomies for prescribing what particular strategies and approaches should be employed when, how, and in what combination to be most effective and efficient for specific business domains, organizational structures, and enterprise-wide performance objectives.

An Imperative Requirement for Human-Centered Design

Our workplaces—and certainly our daily lives—have become increasingly cluttered by a vast array of ubiquitous “high technology” products from CD/DVD/M3P players, personal data assistants (PDAs), laptops, and recently mini-palm-top computers, cell phones, digital cameras, graphic video games, voice mail, e-mail, and Web-accessible portable devices, electronic car keys, answering machines, microwaves, alarm clocks, printers, fax machines, pagers, programmable robotic vacuum cleaners, and multiple-component home entertainment systems—to name only a few. Learning to use many of these devices, far from being transparently easy, requires a steep learning curve punctuated by psycho-emotional intimidation, trial and error, frustration, and a personal sense of belittlement in the face of the impersonal, ubiquitous, and insurmountable dominance of machines. An impactful January 2001 cover story in U.S. News & World Report—“Overwhelmed by Tech!”—called these proliferating devices “fiendish new instruments of mental torture” and said that “consumers may not expect all their new gadgets and gizmos to be fun, but they are demanding that at least they don’t make them feel like idiots” (Lardner, LaGesse, Rae-Dupree, & Roane, 2001). This is particularly salient for members of networked and virtual organizations.
who rely so critically upon their tools, systems, and user interfaces to be creative and innovative knowledge workers.

It might be an elusive goal to seek a single standard or set of guidelines that perfectly integrates all of the different descriptive practice (i.e., case scenarios/situations) and prescriptive management techniques and strategies within an easy-to-implement solution paradigm for every creative, innovative, and knowledge-based requirement. Up to now, it has been a nearly intractable challenge to establish unequivocally-accepted technical standards across ANY industry, as current competing specifications for HD-DVD, HDTV, widescreen format aspect ratios, Web-streaming formats, SCORM compliance, technology transfer and transportability, product interoperability, and reusability continue to persist. While it can be argued that over time many competing technology systems find some pragmatic, functional accommodation to co-exist within the same universal marketplace (e.g., AC and DC, AM and FM, Apple and Microsoft), idiosyncratic conceptual paradigms like management theories and organizational models have ultimately “agreed to disagree” in addressing the same, similar, or related issues and problems from different perspectives in different enterprises and nations. And this is not only intelligent and mature but probably wise since the compelling task of creating comprehensive explanatory models of complex phenomena that are parsimonious and robust without being overly reductionist—and concise and cogent without being over-simplifications—continues to be formidable.

**HUMAN FACTOR DESIGN PRINCIPLES: AN OVERVIEW**

On November 3, 2005, the first World Usability Day was held by the Usability Professionals’ Association to promote “user-centered design and every user’s responsibility to ask for things that work better.” Many permeating technologies within networked and virtual organizations share the amberification paradox of textbooks, newspapers, Whitepage listings, and nightly television news programs: they are all out of date as soon as they are produced and become like artifacts hermetically sealed in amber and suspended in time from the day of their encasement. Their “one size fits all” designs are neither adaptive nor adaptable and promulgate a top-down technological imperialism penetrating every aspect of their use. The communication, collaboration, and interaction infrastructure of organizations thus remain sorely challenged with enduring problems of usability, learnability, accessibility, and adaptability. As the function and form of products undergoes increasingly rigorous scrutiny, one important design goal is emerging as a paramount priority: improving the usability of products, tools, and systems for all stakeholders across the enterprise. From the perspective of the new science of human factors in user experience design (UXD)—lowering the cognitive workload by simplifying the system interface will contribute to a less stressful, more confident task performance, and a more effective and efficient user experience.

**Enhancing Information and Communication Design Efficiency**

In user-centered design, the conceptual model of the user becomes the superordinate principle guiding the design process and outcomes (Kuniavsky, 2003). Usage-centered design is different: it focuses primarily on the empirical (i.e., observable and measurable) goal-based, task-driven behavior of users and the structuring activities, procedures, processes, and corresponding information architecture required to optimize the effectiveness of the user to efficiently accomplish those functional goals. By integrating the human factors engineering “systems approaches”, it may be possible to optimize the beneficial design quality of products and services from the perspective of the user’s
experience (Constantine, 2001; Constantine & Lockwood, 1999; Wickens et al., 2004).

While examining ways to improve the signage, self-directed wayfinding, and user-centered design of interactive public information environments like museums, science centers, and shopping malls, C. G. Screven (1999) synthesized a number of highly pliant and insightful principles that could be effectively repurposed for the home-based infosphere we are discussing. Screven’s core UXD metric is design efficiency—described as “the average time it takes viewers to find and process message-related information” (p. 147). Efficient designs (a) conserve the time and both mental (i.e., working memory) and physical effort needed by users to find, access/retrieve, quickly understand, and respond to messages and content, in effect focusing their attention and augmenting their real-time decision-making capacity; (b) reduce fatigue and “maturation effects” by providing affordances with low cognitive loads to quickly engage and involve the user in self-directed behavior that enhances their interactivity with the exhibit’s information (i.e., less noise, more signal); and (c) generally improve all aspects of the information designs themselves by systematically employing larger, easy-to-read fonts, less dense and less difficult textual content (e.g., using familiar, jargon-free vocabulary), good contrast and consistent layouts (i.e., with good “chunking”, white space, use of colors and clear mnemonic cues, and reduced visual clutter), and precise, unambiguous headings and labels. An optimal high design efficiency is thus characterized by (a) a high ratio of needed and salient information to unneeded, superfluous information stimuli to ease working memory load and reduce affective stressors, and (b) facilitates users’ abilities to process and absorb new information (Preece, Rogers, & Sharp, 2002; Ware, 2004).

Screven is an advocate for thoughtfully designing human-centered information spaces that reward and reinforce the fun and enjoyment of goal-directed experiences while intelligently reducing the aversive stimuli associated with the disconnects of failure, confusion, frustration, avoidance, task-time and effort, media overload, product complexity, and the depersonalizing emotions engendered by being continuously fettered by seemingly ineluctable, inefficient information design solutions. The enactive, intentional, unifying higher-order problem-solving endeavor is design itself—and numerous universal principles, exemplars, and epitomes of design have emerged (Lidwell, Holden, & Butler, 2003). “Designing is, therefore, more than ordering and arranging, more than constructing. It is composing. It is using the codes and pattern languages of a domain to create wholes with not only parts and relationships but also ordering-underlying principles” (Rowland, 2004, p. 40). Critical in this human-centered design process are systems thinking, creativity and evaluative judgment, metacognitive awareness, and the seemingly paradoxical nurturance for an eclectic, broad-minded tolerance for ambiguity (ACM, 2005).

Respecting The User Experience

In their insightful book “Designing From Both Sides of the Screen: Don’t Impose—Respect Mental Effort”, Isaacs and Walendowski (2001) analyzed screen-based user interfaces. They noted that every user choice, every click increases working memory load, and that every separate button increments functional overchoice and visual clutter. There is also an emotional, affective stress factor that burdens users caught in overly complex interfaces (i.e., “If they keep bumping their heads against the same problem over and over again, their tolerance capital declines each time”), and this is particularly apparent in networked and virtual organizations that depend upon sophisticated, interactive synchronous and asynchronous IT systems and tools. User experience designers need to be sharply focused on developing devices and systems that reduce (not increase) working memory loads, eliminate unnecessary features,
Human Factors for Networked and Virtual Organizations

and buttress the confidence and competence of basic user task behavior (Stone, Jarrett, Woodroffe, & Minocha, 2005). Designers should leave their product users "as much mental energy as possible so they can flow with their task and forget about the technology entirely." Their summary design guidelines recommend that designers: (a) reduce wayfinding memory by using visual elements like buttons, menus, icons, and legends sparingly; (b) make common tasks clearly visible and easy to find while hiding infrequent tasks (i.e., the main screens and remote control interfaces should “offer people quick access to the things most people do most often, while giving newcomers an easy way to get started”); (c) give users feedback (e.g., combine audible and visual cues simultaneously) and display signs of task progress, build-in good “error recovery” so users can “undo” an operation; and finally (d) if a command cannot be carried out quickly, allow users to interrupt the process and return to a previous stable system state. These design approaches are corroborated by others in the field (Kalbach, 2004; Shneiderman, 2004) who are attempting to put more “fun” into product functionality. It would also be reasonable to argue that such improved systems would also augment the sense of stakeholders’ competence, emotional well-being, and overall enjoyment of their work environments—further adding an affective resource to enhance their task performance. In describing the recent interest in usability hedonics, Hassenzahl, Beu, and Burmester (2001) declared that “the most basic reason for considering joy of use is the humanistic view that enjoyment is fundamental to life.”

DEVELOPING A HUMAN FACTORS TAXONOMY

The taxonomic concept derives from the Greek words taxis (for arrangement, order) and nomos (law). Every serious taxonomy is an organizational scheme that includes a system representing structure, order, and relationship. Some form of hierarchical structure is generally defined, but this may be multi-dimensional and nonlinear in form. The purpose, domain, attributes, and granularity of schema vary but all taxonomies attempt to provide a robust (i.e., logical, coherent, cohesive, internally-consistent) architecture. Prominent examples include the widely-adopted schema of Carl Linnaeus (biology) and Dmitrii Mendeleeev (The Periodic Table of Elements). Most taxonomies contain their own nomenclature for describing the taxons (singular) and taxa (plural) that correspond to formal units in the classification scheme, such as kingdom, phylum, class, order, family, genus, species (adapted from Linnaeus). Taxonomies may evolve over time. Neither the systems of Linnaeus nor Mendeleev are exactly in their original form when they were first presented, but they are fundamentally and substantially the same in all relevant aspects and overall structure, changing only as our knowledge of science changed over time to add additional granularity to the taxons and taxa of their brilliantly original and enduring descriptive taxonomies.

Our emerging organizational taxonomies (e.g., such as those referenced in Table 7.4 in Thamhain, 2005, pp. 180-185) will need to integrate the many complex factors involved in the human-product-project triad, including the dynamic human factors issues of manager/employee, the special nature of the particular product/service/industry domain, and the implicit assumptions of the successful networked and virtual project team environment. To illustrate a simplified taxonomic analogy of the basic conceptual issues (using seven common architectural concepts as points of comparison), Table 1 is presented.

Principles of Universal UXD

In 1997, The Center for Universal Design at North Carolina State University produced a comprehensive set of guidelines to improve the “design of products and environments to be usable by all
people, to the greatest extent possible, without the need for adaptation or specialized design.” Funded by public federal grants from The National Institute on Disability and Rehabilitation Research and the United States Department of Education, a working group of architects, product designers, engineers, and environmental design researchers collaborated to create seven core principles to help guide a wide range of design disciplines including environmental, industrial, and communications design. These user-centered guidelines were intended to be systematically applied to evaluate existing product designs, to re-focus the future design process of new products, and to educate both designers and consumers about the characteristics of more usable products and environments. They are particularly appropriate for application to all networked and virtual organizations.

One version of these Principles of Universal (User Experience) Design are presented next with the name of the principle and a concise definition of the key concept embodied in the principle (Center for Universal Design, 1997). While most of these core guidelines should be applicable to nearly all design problems, a reasonable caveat is that not every sub-component may be relevant to every design solution.

**Principle One: Equitable Use**
- The design is useful and marketable to people with diverse abilities. Provide the same means of use and provisions for privacy, security, and safety to all users.

**Principle Two: Flexibility in Use**
- The design accommodates a wide range of individual preferences and abilities. Provide choice in methods of use, facilitate the user’s accuracy and precision, and provide adaptability to the user’s pace.

</table>
Principle Three: Simple and Intuitive Use
• Use of the design is easy to understand, regardless of the user’s experience, knowledge, language skills, or current concentration level. Eliminate unnecessary complexity, be consistent with user expectations and intuition, accommodate a wide range of literacy and language skills, arrange information consistent with its importance, and provide effective prompting and feedback during and after task completion.

Principle Four: Perceptible Information
• The design communicates necessary information effectively to the user, regardless of ambient conditions or the user’s sensory abilities. Use different modes (pictorial, verbal, tactile) for redundant presentation of essential information; differentiate elements and maximize “legibility” of essential information; provide compatibility with devices used by people with sensory limitations or disabilities.

Principle Five: Tolerance for Error
• The design minimizes hazards and the adverse consequences of accidental or unintended actions. Arrange elements to minimize hazards and errors: most used elements, most accessible; hazardous elements eliminated, isolated, or shielded; provide fail safe features.

Principle Six: Low Physical Effort
• The design can be used efficiently and comfortably and with a minimum of fatigue. Minimize repetitive actions and physical effort.

Principle Seven: Size and Space for Approach and Use
• Appropriate size and space is provided for approach, reach, manipulation, and use regardless of user’s body size, posture, or mobility. Provide a clear line of sight to important elements for any seated or standing user and adequate space for the use of assistive devices.

While it is true that the practice of design involves more than consideration for the usability requirement per se, a judicious inclusion of these guidelines to the iterative information-interactivity-media design process of communication technologies for networked and virtual organizations would ostensibly accommodate the needs of as many users as possible and in effect meet or exceed many of the collateral concerns about the economic, engineering, cultural, and environmental impact (i.e., efficiency) of the design solution. Moreover, while these universal principles are not exhaustive in scope or detail, they provide a helpful starting point for a heuristic evaluation of any human-system product’s user experience portfolio.

Organizations Without Human Factors Environments

Prior to the advent of networked and virtual organizations, the very strengths of large “Industrial Age” functional organizations were consistent with their weaknesses (e.g., risk-averse, poor cross-division communication and cooperation, limited technology transfer, limited flexibility to respond to rapid change trends, fettered high-level decision-making capability, and generally inflexible “time-in-grade” hierarchies of power and influence). In dysfunctional enterprises, the rate of change is deliberately slowed to that of a moving glacier, and the future tends more often than not to look much like the past because without the implementation of human factors engineering their strategies repeat the past, aggrandize the past, recapitulate the past, preserve the past, reproduce the past, and ultimately ensure that the future and the past appear indistinguishable.
Today, “Information Age” and emerging “Knowledge Age” environments clearly require a new breed of employee and management. Individuals on all organizational levels must be much better educated, more highly skilled, predisposed to expect constant change, and be more committed to the underlying success of the broader enterprise. Specifically, the managers in these technology-intensive endeavors must be able to simultaneously: (a) direct immensely sophisticated, increasingly complex internal processes and resource-sharing operational structures (e.g., projectized and matrixized), and at the same time (b) motivate, engage, and flexibly integrate their intelligent, creative, and individual career-focused workers into cohesive, collaborative team wholes that can mutually accomplish high-demand goals under their ever-tightening production schedules and technical requirements. They must be superb leaders of both “men and machines”.

The Need to Innovate

Managers of networked and virtual organizations understand the need to innovate but often struggle to pragmatically support creative processes within demanding, requirements-driven business environments. Information architects, knowledge developers, media designers, and usability specialists often face similarly demanding contexts—but must resourcefully find ways to support conceptually creative projects and innovative processes reliably and successfully (Hughes, 2002). These new "pliant" processes must either be invented or repurposed (i.e., via breakthrough human factors engineering scaffolds), but in every case one or more persons are involved at the core (Henderson & Harris, 2000). In fact, a new professional role is emerging that brings knowledge construction and production to the epicenter of information designers and managers (Morrogh, 2003). Ostensibly then, managers can learn from designers about the process of innovation and as the need for this “learning organization” grows—economic activity moves into the realm of knowledge work, where materials are intangible and human innovation and idea-generation are the primary source of value-added creation. This is, after all, what the promise of virtual and networked organizations is able to achieve.

Principles of Corporate Creativity for the Knowledge Age

As described by Robinson and Stern (1997), the basic constructs of fostering organizational creativity include: alignment, self-initiated activity, unofficial activity, serendipity, diverse stimuli, and within-company communication. Like the principles for universal product design, these human factors principles can ostensibly augment creativity and productivity in networked and virtual organizations. This set of design considerations includes:

Principle One: Alignment

• An organization’s performance depends on its alignment—the degree to which the interests and actions of every member mutually support’s key goals. The organization cannot be consistently creative unless it is strongly aligned. Moreover, the most critical step in aligning an organization is recognizing the value of alignment and that it has to be done.

Principle Two: Self-Initiated Activity

• People have a natural desire to be creative so most unexpected creative acts come from self-initiated activity. The key to organization-wide self-initiated activity is an effective system for responding to member’s intrinsically-motivated ideas. Networked and virtual organizations can become highly efficient in this regard to the degree that the formal hierarchy becomes flexible, flatter,
Pliant and more open to evoke, foster, facilitate, encourage, accept, and reward fresh ideas, original initiatives, and “value added” innovations for processes and products.

**Principle Three: Unofficial Activity**
- Within virtual and networked organizations, many innovative and creative ideas and approaches begin with unofficial, informal, and independent human activity during which an idea is worked on without direct or official support. Unofficial “under the radar” status reduces disincentives to ongoing creative communication associated with stifling micro-management and inhibitory gatekeeping, rigid reporting hierarchies (i.e., that strictly follow the org chart), peer surveillance, political turfism, performance pressures, and personal jealousies. Unofficial activity can provide a safe haven for generating and incubating ideas, and leads to better decision making about which new high-tech project initiatives to support.

**Principle Four: Serendipity**
- Serendipity plays a role in every creative act: a fortunate accident that meets with sagacity (keenness of insight), enables the natural impulse to action, and encourages a playful, non-judgmental attitude toward tinkering and experimentation. An organizational acceptance of serendipity will foster “creative redundancy”—unused human potential for change—a vital reinvesting and self-generating augmentation of the precious human resources within every networked and virtual organization. This meta-systems value can be observed in the real benefits derived from extended employee cross-training and job-rotation, peer sharing of ideas and skills, and the meaningful individual fulfillment and powerful motivation associated with continuing professional development and life-long personal improvement.

**Principle Five: Diverse Stimuli**
- Concepts such as “breaking set”, “cognitive dissonance” and “thinking out of the box” indicate the ostensible value of divergent thinking and novel approaches to creative problem solving. The presence of any stimulus can potentially provide fresh insight into routine tasks as well as new initiatives. Networked and virtual organizations should actively promote exposing a variety of diverse stimuli to its participants and recognize that many creative acts are evoked as a result of novel, challenging, unconventional, or otherwise interesting experiential and environmental stimuli.

**Principle Six: Within-Organization Communication**
- Internal, intra-organizational communication often happens naturally at smaller enterprises but less easily at larger ones since formal communication channels (including routine and standing meetings) are of limited use for supporting creativity. Networked and virtual organizations are particularly well-suited to foster, augment, and facilitate systemic, cross-pollinating, creative, cooperative, and collaborative interpersonal communications. As posited by the effects of serendipity and other unofficial activity—the majority of creative acts are unplanned and unanticipated—informal information exchanges that allow projects that have not been planned to self-organize and incubate. Various channels for improving and supporting communication affordances for members of networked and virtual entities should be thoughtfully implemented.

**CONCLUSION**

In conclusion, superior human factor engineering requires a deep understanding of the theory
and practice of collaborative team leadership and participative stakeholder buy-in, as well as systems theory and the complete, concurrent, iterative IT development lifecycle approaches from needs assessment, task analysis, and conceptual design to production, quality assurance, usability design and testing, and courseware product deliverables and evaluation. Post-modern networked and virtual organizations become successful as their technology systems give their high-tech workers confidence, trust, and a true sense of stakeholder-ship, commitment and collaboration—and value each high-performing team member. Superb management of people and technology within these enterprises needs to support the special cohesive chemistry together with good communication that promotes openness within the organizational idea-generating infrastructure to everyone at every level. Human factor engineering also recognizes the distinction between management and leadership—both of which must become an essential component of team projects and practice. Management skills are essentially functional and structural in nature, and can effectively be performed through the implementation of unambiguous, clearly identified, thoughtfully-designed systems, and organizational approaches to problem requirements. Leadership is another realm altogether: it is essentially a dynamic, protean, flexible, pliant, and highly-adaptable quality associated with effective people skills, awareness of self and others, a coherent, creative vision about both the direction of the product and team as well as the motivated, goal-oriented mission that team members are united in achieving. These are the real “human factors” that underlie all effective leadership...a fundamental understanding that the most precious and irreplaceable resource in any IT business endeavor or enterprise are the human resources at the core of all user-centered, real-world design solutions. In a nutshell, the optimal vision statement for networked and virtual organizations should codify that people come first—both from the perspective within the organization functionally and operationally as well as on “the business end” of the equation as clients and end users of the products and services however defined and delivered.

The emerging applied profession of human factors engineering may make a positive, significant, and possibly decisive change in the way we will design our networked and virtual environments in the 21st century. The human factors and allied usability professions are in the process of improving user experience designs for more accessible, more truly universal design solutions. By simplifying and standardizing IU design affordances, metaphors, and mnemonics, reducing seldom-needed collateral features, incorporating more intuitive, familiar, parsimonious, and easily grasped mental models to reduce working memory loads while improving simple functionality—we can empower all users to “take control” over their technologies...and their networked and virtual, knowledge-centered, and learning organizations!

Human Factors for Networked and Virtual Organizations

KEY TERMS

Amberfication Paradox: Static information resources, media representations, and human-technology communication systems become non-dynamic as soon as they are produced. The paradox is that the more quickly these fixed entities are produced—the quicker they become conceptually and substantively sealed in amber and disconnected from modification, alteration, correction, and change (i.e., off the information grid) as utilities and resources.

Computer-Human Interface Design: Computer-human interface design consists of the effective functional synthesis and operational integration of three overlapping sub-design domains: information design, interaction design, and media design (See additional definitions of these terms in this article section). Each of these three layers must be clearly defined, represented, and manifested in the user interface design solution. These three sub-design realms/components are synthesized holistically by the conceptual usability glue of the principles of universal design. User interface affordances can be evaluated through usability heuristics and the degree to which these principles have been effectively applied and realized in the user experience—providing a coherent, logically-consistent, and robust (i.e., intuitive, accessible, easy-to-learn, and use) systems design.

Human Factors Engineering: Human factors is an emerging applied design field that entails a synthesis of cross-disciplines from classical ergonomics (i.e., the science of work, system-person interaction, and functional/operational performance needs), and newer research gleaned from the allied fields of cognitive science, human physiological psychology, perception, learning, memory and brain behavior science, interaction/interactivity design, product design, media design, communication design, and information design. Human factors engineering recognizes (1) the intensely cross-disciplinary nature of the human-technology system designer’s role and the transcending cultural, economic, societal, and geopolitical importance of information utilization and knowledge generation, and (2) the field’s creative, protean, and dynamically-hybrid “human-centered, user-centered, and usage-centered” systems approaches that strives to integrate existing multi-disciplinary domains (i.e., change management, computer and information science, informatics and systems theory to management philosophy, law and ethics, human cognition and perception, human resources, usability design, industrial design, and ergonomics).

Information Design: Understanding and clearly mapping the full scope, sequence, concepts, principles, examples, and underlying inheritance structure of the declarative and procedural facets of the content domain (i.e., the infosphere). Information design is essentially concerned with understanding the purpose, the organization, the context, and interrelationships within a knowledge domain: the “envisioning” of information to be communicated.

Interactivity Design: Understanding the affordances of the computer-human interrelationship from the user’s perceptual/cognitive experience; identifying and specifying the dynamic time/space transactions between the user, information, and media elements—creating a graphical user—environmental interface to navigate within that is intuitive, comprehensible, robust, and engaging. The core artifact of interactivity design is the user interface. Principal ingredients of the interface design are signage, cueing, mnemonics, style/layout conventions, and the ambient conceptual metaphor.

Media Design: Media design involves the physical, functional, and operational manifesta-
The media design is the tangible, concrete, tactile-audio-visual-sensori-motor experiential “front end” of the human-technology system. Understanding the multi-sensory nature of the user’s experience; applying human learning, memory, messaging, and perception/cognition to produce effective, aesthetic multiple media that provide cognitive/perceptual/physical affordances to improve human-machine system communications for specific audiences and organizational requirements.

**Usability:** The degree to which human-technological systems, artifacts, and products are appropriately and efficiently designed for the user (i.e., ease of use) is the indication of that product’s usability. Various heuristics and criteria can provide an objective, empirical basis against which to measure and evaluate the level and degree of design efficiency corresponding to the key construct of usability.

**Usage-Centered Design:** Usage-centered design focuses primarily on the functional goal-based behavior of learners and structuring activities, procedures, processes, and corresponding affordances to optimize the effectiveness of the learner to efficiently accomplish those intrinsic goals. In both user-experience and usage-centered approaches, however, the conventionally-deterministic structure of the communication content and the underlying information architecture of the knowledge domain are secondary considerations while the user’s own conceptual model and intrinsic goal-driven behaviors provide the guiding blueprint for the system-product design solution.

**User-Experience Design (UXD):** User-centered (a cognitive/perceptual term) and usage-centered (a behavioral/functional term) are post-modern design descriptors often arbitrarily or ambiguously defined and interchangeably used and mis-used. In the context of 21st century communication product design theory and practice, user-centered design focuses on constructing a user experience and environment with physical and virtual affordances that are manipulable, controllable, customizable, and adaptable from the essential perspective of the conceptual model of the user. This means both (a) the user’s own internal metamodel of their own goal-directed processes, activities and contextual (i.e., socio-psychological and physical) environment, and (b) the designer’s representational model of the user-activity-environmental experience, with the former driving and superseding the latter in the design solution. Thus the conceptual model of the learner becomes the superordinate principle guiding the design process and learning outcomes (i.e., the highest level of the prescriptive taxonomy).

Chapter 6.9
Trust in Computer-Mediated Communications: Implications for Individuals and Organizations

Susan K. Lippert
Drexel University, USA

ABSTRACT
This chapter explores the concepts of trust as they relate to computer-aided communications. The author defines trust for interpersonal and for inanimate technology, identifies common factors affecting quality of meaning in communication, and identifies ways businesses can foster and enhance trust independent of the medium of communication.

INTRODUCTION
The purpose of this chapter is to explore trust as it relates to computer-aided communications, commonly electronic-mail. There are four objectives for this chapter: (a) to comprehensively define trust as it appears in the scholarly literature, both for human interpersonal trust and for inanimate technology trust; (b) to explore the essence of communications, identifying the common factors that affect the quality of meaning in communicative interactions; (c) to compare and contrast trust in different forms of communication media; and (d) to offer some thoughts on what can be done in the business world to foster and enhance trust, independent of the communication medium chosen.

TRUST
Trust is a contextual phenomenon commonly applied to casual conversation without conscious knowledge of what the construct means or how it manifests in daily interactions. This suggests that trust is a latent variable in the communications process since many people are not conscious that what they say and how they say it can affect their
Trust in Computer-Mediated Communications

trust relationships with others. Scholars often debate how to operationalize trust and, consequently, how to measure whether an individual displays and demonstrates trust. While the definitions of trust vary, there is agreement that its meaning is situationally or contextually based (McKnight & Chervany, 1996; McKnight, Cummings & Chervany, 1998), which further suggests that how trust is operationalized is partly a function of the object upon which trust is being placed.

Rotter (1971, p. 443) suggested that “the entire fabric of our day-to-day living, of our social order, rests on trust—from buying gasoline, paying taxes, going to the dentist, flying to a convention—almost all of our decisions involve trusting someone [or something] else.” Other scholars have noted that trust is central to all social transactions (Dasgupta, 1988), reduces transaction effort (Bromiley & Cummings, 1995), and is classified as an important component of social systems (Arrow, 1974). Trust has been cited as a vital form of social capital within social systems (Coleman, 1990; Fukuyama, 1995), since “without trust … everyday social life … is simply not possible” (Good, 1988, p. 32).

Much of the trust literature, particularly in the area of organizational theory and management, has focused on interpersonal trust where the object of trust is another individual. This form of trust, interpersonal trust, is most commonly defined using the research of Mayer, Davis, and Schoorman (1995, p. 712), who suggest that interpersonal trust is:

… the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party.

Other definitions frame trust as “a psychological state comprising the intention to accept vulnerability based upon positive expectations of the intentions or behavior of another” (Rousseau, Sitkin, Burt, & Camerer, 1998, p. 395). The trust that one individual places in another may fluctuate during the course of a relationship based on a variety of external stimuli. That is, trust is not a naive faith that a party takes for granted, based on an interaction that occurred in the distant past (McEvily, Perrone, & Zaheer, 2003). Instead, individuals examine new information about those with whom they interact and decide if they should increase or decrease their trust in that individual (McEvily et al., 2003). Using Mayer et al.’s (1995) interpersonal trust definition, we can state that the evaluation of another’s trustworthiness is a function of three antecedents: ability, benevolence, and integrity. The key difference between trustworthiness and trust is that trustworthiness is a perceived characteristic of the trustee, while trust is a psychological state of the trustor (Sparito & Lippert, 2006). Trust becomes relevant when individuals develop dependencies on, and vulnerabilities to, the actions and decisions of others (McEvily et al., 2003).

Levin, Whitener, and Cross (2006) found differences in an individual’s willingness to trust another when they classified relationships into new, intermediate, and older relationships. In their research, they also found that in newer relationships, the basis for trust was gender parity, perhaps as a function of communication or personal style, that behavioral expectations that result from moderate social interaction affected intermediate relationships, and that a personal knowledge of shared perspectives (values, beliefs, perceptions, and environments) was linked to older relationships. This suggests that how individuals behave and reinforce trust, by communicating, may serve as a moderator for trusting relationships. Zahra (2003, 2005) suggested that familial and kinship ties encourage trust as a function of the depth of the relationship. In a recent study, Zahra, Yavuv, and Ucbasaran (2006) suggested that managers can build trust relationships with individuals and groups through solicitation of ideas, problems, and questions. This communication strategy has
the capacity to enhance trust relationships in an organizational setting.

In an empirical investigation of 18 software vendor companies based in India, Oza, Hall, Rainer, and Grey (2006) found that communication was a key component necessary to maintain trust in established outsourcing relationships. In fact, Oza et al. (2006, p. 352) reported that one of their interviewees stated that “there should be enough communication between [the] vendor and client to prosper trust in the relationship.” Henttonen and Blomqvist (2005) proposed that communication behavior that includes timely responses, open communication, and providing useful feedback were considered to build trust in virtual teams. Lewicki and Bunker (1996) along with Mayer et al. (1995) assert that trust-building is an experiential process that occurs over time as individuals engage in continual and repeated conversations. Social communication such as exchanging greetings, interests, and other personal information is important to the evolution of trust in both virtual and traditional teams (Järvenpaa & Leidner, 1998). Henttonen and Blomqvist contend that in the early stages of a relationship, both the content (social vs. work-related) and context (face-to-face vs. intranet, or e-mails) should be mixed rather than being treated separately because the combination of communication mechanisms appears to have a strong tie and connection to emotional commitment and trust.

Pepper and Larson (2006) discuss differences in the use of information communication technologies (ICTs) and face-to-face communication in geographically dispersed organizations that were recently acquired. They identified four concerns regarding the use of ICTs in organizational settings as shown in Table 1.

<table>
<thead>
<tr>
<th>Concern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Improper ICT use exacerbates commitment problems</td>
</tr>
<tr>
<td>2</td>
<td>Cultural differences influence technology use</td>
</tr>
<tr>
<td>3</td>
<td>Over-reliance on ICTs can lead to a lack of trust</td>
</tr>
<tr>
<td>4</td>
<td>The timing of ICT choices influences employee perceptions</td>
</tr>
</tbody>
</table>

Each concern demonstrates that the use of technology to facilitate communications may indeed result in unexpected outcomes such as a paucity of interpersonal trust. What one can learn from these concerns is that managed use of ICTs is important if trust between employees is to be maintained and nurtured. Trust may form in relationships in which interpersonal contact ranges from extensive to nonexistent (Wilson, Straus, & McEvily, 2006).

The above studies suggest that what is said, how it is said, and the media used to facilitate communication between two individuals in an organizational setting will serve as moderators to the trust relationship. Therefore, conscious and thoughtful reflection on these elements, prior to and during the communication process, should offer organizational members the opportunity to facilitate trust in their interactions.

While trust between individuals has received the most attention in the scholarly literature, other forms of trust exist that also require investigation. Research has shown that the object of trust determines the type of trust relationship under
Trust in Computer-Mediated Communications

consideration (Giffin, 1967). Trust may develop between individuals (Johnson-George & Swap, 1982) in both professional and personal settings. Additionally, trust can also develop between individuals and organizations (Zaheer, McEvily, & Perrone, 1998); between organizations (Gulati, 1995); between individuals and social institutions (Barber, 1983); between individuals and technology (Lippert, 2001, 2007, Lippert & Davis, 2006; Lippert & Forman, 2006; Lippert & Swiercz, 2005); as a general characteristic of different societies (Fukuyama, 1995); and as a personal trait (Rotter, 1971). The principle differentiator between the forms of trust is the object of trust, which Giffin (1967), asserts can be a person, place, event, or object.

Trust has been investigated in many social sciences including management, economics, information systems, psychology, sociology, political science, anthropology, organizational theory, and communication. Although not all inclusive, Table 2 offers a view of disciplines in which the trust phenomenon is studied.

Technology Trust: An Alternative Object of Trust

Technology trust is defined as:

\[
\text{the extent to which an individual is willing to be vulnerable to the information technology (IT) based on expectations of technology predictability, technology reliability and technology utility and influenced by the individual’s predilection to trust technology. (Lippert, 2001, p. 9)}
\]

Trust assessments are often based upon a single interaction with a technology and then reinforced or diminished each time an information system is used (Denning, 1993). If the technology is operational when needed, a positive assessment of system performance is recorded. Users may

consider frequent or inconvenient downtimes as negative experiences with the system. Past experiences with the technology, both positive and negative, influence an individual’s assessment of that system as a whole.

This suggests that the use of technology to facilitate communication may offer some additional insights into what causes individuals to develop or lose trust in others based on exchanges undertaken via ICTs. An investigation into trust in technology has the potential to offer further insight into whether a user’s trust of a specific technology is likely to impact use of that system. This suggests that dependence upon technology for the completion of daily tasks makes individuals vulnerable to the technology. Employees depend upon technology to process financial transactions, maintain corporate Web sites, schedule meetings with clients, and communicate with geographically dispersed coworkers. However, computers are fallible, experience downtimes, and sometimes fail to function consistently from day to day. Depending upon the task, the lack of functional technology can, at a minimum, temporarily disrupt employee performance, or, at worst, put a halt to any productivity for an indeterminate length of time. These potential problems may have an impact on employees’ willingness to use the technology to communicate information resulting in possible trust issues.

THEORETICAL BACKGROUND

Theory Overview

Proposed by Daft and Lengel (1984, 1986), media richness theory (MRT), also known as information richness theory, establishes a scale to rank communication media based on the quality, breath, and depth of information in order to explain managerial media selection behaviors. MRT research is a foundation for later media selection theories and a direct base for modern communication theory. MRT explains how organizations contend with uncertainty and equivocality, or ambiguity of interpretation within organizational communication.

Classification Criteria of Media Richness Theory

Media richness theory asserts that individuals use media selection to reduce ambiguity in communication. Richness, in this context, is the ability of the communication channel to not only transfer data but also, more importantly, to impart meaning. Richness is achieved by carrying equivocal information, which modifies the communication participants’ understanding. Understanding occurs when different conceptual frames of reference converge or ambiguous issues are resolved. If a particular medium provides new understanding or carries equivocal information effectively, the medium is deemed rich; otherwise, it is considered a lean medium.

Organizational tasks differ in terms of ambiguity (Daft & Macintosh, 1981) and communication reduces task ambiguity, thereby providing alternative solutions to a given problem (Guinan & Faraj, 1998). Likewise, communication media vary in their ability to reduce ambiguity in communication. According to MRT, ambiguity is reduced through a blending of four criteria based on the communication medium’s ability to: (a) facilitate feedback; (b) convey meaning through multiple cues; (c) use a variety of language; and (d) present personalized messages. Medium richness results from this blending of criteria used to rank media along a richness continuum. “Rich” media reduce high levels of ambiguity whereas “lean” media are sufficient for tasks of low ambiguity.

Communication Media and Information Richness

The classification criteria in Table 3 operationalize qualities used to assess media richness.
Communication media with more classification features rank higher on the richness scale than media with fewer richness features. The level of understanding between the communication participants determines the richness of the communication. Daft and Lengel (1984, 1986) used these criteria to rank five communication media on a richness continuum (Table 4). Media, in richness identity, rank from high to low: face-to-face, telephone, personal written text (letters, memos), formal written text (documents, bulletins), and formal numeric text (computer output). Although not included in early studies, electronic mail was later ranked between telephonic communications and written personal documents in the context of richness (Daft, Lengel, & Trevino, 1987).

Face-to-face communication ranked highest in information richness for two reasons. First, face-to-face communication provides for multiple cues (verbal and nonverbal) and second, offers instant feedback between communication participants. In face-to-face communication, a high degree of message personalization is supported.

Table 3. Media richness classification criteria compiled from Daft and Lengel (1984, 1986)

* Added by Daft et al. (1987)
The telephone offers fast feedback, and audio communication is available via the telephone. Visual and nonverbal communications including hand, facial, or body gestures are non-existent with this medium. However, nonverbal cues derived from voice inflection, tone, and speaking style still are active in telephonic communications. Message personalization is available, although not to the degree of face-to-face communication. Communication is dependent upon language content and audio cues for understanding rather than written word or behavioral cues.

Personal written letters or memoranda offer limited visual cues. Feedback is slow and dependent upon receiver response time. Message personalization is available although less than telephone and face-to-face communication. Meaning must arise from the written word without the benefit of the ancillary nonverbal cues available in richer media. Audio cues are absent and richness is conveyed only through words on the page and the structure of the written word.

Formal written documents such as bulletins are less rich, since feedback is very slow, audio cues and nonverbal communications are absent, and visual cues are limited. Richness is conveyed through written words from which meaning must arise. The nature of this type of communication is often viewed as impersonal.

Formal numeric documents are considered lean. Computer generated reports provide text and numbers which offer limited visual cues. Neither audio nor nonverbal cues are available to enhance understanding. Feedback is very slow and communication is seen as impersonal.

COMMUNICATIONS

A Definition of Communication and Medium

McCroskey and Richmond (1999, p. 7) offer a definition of communication as “the process by which one person stimulates meaning in the mind(s) of another person (or persons) through verbal and nonverbal messages.” Verbal messages consist of language where language is “a set of symbols or codes used to represent certain ideas or meanings” (McCroskey & Richmond, p. 7). Nonverbal messages are any messages other than verbal such as tone of voice, vocal pitch, body position, eye movements, hand gestures, and facial expressions. The authors also emphasize the importance of meaning rather than the physical exchange of messages (McCroskey & Richmond, 1999, p. 7). For purposes of this discussion, their definition is appended to include the notion of an appropriately rich communication channel. As such, the definition of communication becomes:

... the process by which one person stimulates meaning in the mind(s) of another person(s) through verbal and nonverbal messages via an appropriate communication channel.

This definition recognizes the role that the communication channel plays in human exchanges. The channel can be technologically based, such as with electronic-mail, or the channel can be face-to-face contact. This definition encompasses both the presence of technology and the human element. Noise is a mediating factor in the communication channel since it has the capacity to interrupt the message resulting in distorted meaning. For example, in electronic messaging, slow speed might impede the message and meaning that is intended to be communicated.

A Model of Communication

There are various models and diverse definitions of communication. Borden (1971) introduced eight different schemas including a behavioral communication and telecommunications schema. Later models of communication incorporated a “medium” or communication channel. George and Jones’ (1996) model of communication is
used to explain the process of communication, since it allows for the potential influence of the communication medium on the process.

The George and Jones (1996) model includes a communication medium in both the initial transmission and the feedback loop. The message represents the information the sender wants to share with another individual, group, or organization. The message consists of the sender’s thoughts, either conscious and/or unconscious, and can be any form of data or information. Through the encoding process, the sender expresses thoughts in symbols or language, through either written or oral form to the receiver.

**The Media of Communication**

The medium is the mechanism through which the communication is transmitted. The presence of a computer-mediated medium such as electronic-mail creates an artificial communication barrier between the sender and the receiver. This potential message distortion may be either a technological, behavioral, or interpretational error. If the data being exchanged between the sender and receiver is unclear for any reason in the transmission process, a technological error occurs. A behavioral error exists when the actions of the sender and/or receiver are distorted. The interpretational error occurs if the receiver misinterprets the intended message. This medium, regardless of the type, sets up the possibility of additional noise during transmission.

The degree of understanding shared between what the sender intended and what the receiver decoded measures communication effectiveness. Frequently, miscommunication results from noise distortions between the sender’s intent and the receiver’s understanding of the message. Noise may be positive or negative and may include a history of previous communications with the sender, the receiver’s history in decoding communications of this type, the receiver’s current mental state, the method of communication used to convey the message, or the receiver’s health. Both the sender and the receiver construct or deconstruct the message as influenced by noise.

A challenge occurs in ensuring that the message sent and message decoded are congruent. The congruity problems might include: (a) coding and decoding problems (Moorhead & Griffin, 1995); (b) lack of common experience—a lack of common experience occurs when there is no shared language between the sender and the receiver. A shared language experience arises from the use of mutually understood symbols; (c) semantics—semantic problems occur when people attribute different meanings to the same words or language forms; (d) jargon—jargon is specialized or technical language that is specific to a field or profession. Jargon is usually a hybrid form of the standard language where words hold special and atypical meaning to the members of the group; and (5) medium problems—medium problems arise from selecting an inappropriate communication medium for the message being communicated.

Another issue in the communication process is the assumption that the receiver accurately decodes the message (Moorhead & Griffin, 1995) and nothing interferes with the message translation. This problem set might include: (a) selective attention—the problem of selective attention occurs when the receiver focuses on only selected parts of a message; (b) value judgments—value judgments occur when a valiance is place on the message received. If the message corresponds to the receiver’s personal beliefs, the receiver may accept the message without reservation; otherwise, the receiver may disregard the message in its entirely; (c) lack of source credibility—if the sender is viewed as incompetent, unknowledgeable or lacking in credibility, the receiver may partially or completely disregard the message. Likewise, if the source is an expert in the field, the receiver may accept the message without
question. Vital information may be discounted if the receiver questions the sender’s credibility; and (d) overload – communication overload occurs when an individual receives a greater amount of information than they can reasonably process. Organizations are overwhelmed with information being disseminated, such as computer printouts, electronic mail, and voice mail messages.

The medium of communication becomes a complex variable when assessing the quality of a message. In the modern information age, the use of technological systems to transmit and decode messages places an additional burden on the individuals involved in the process. These burdens include the recording, organizing, and interpreting the message.

**The Importance of Effective Communication to Facilitate Trust**

In the communication process, trust becomes an ever increasingly more important phenomenon. Problems such as selective attention, value judgments, lack of credibility, and information overload become manageable elements in the development of trust in an online environment. Trust is enhanced when the receiver is encouraged to attenuate the entire message. Recognition of value judgments as untested evaluations contributes to communication errors and can negatively affect trust. Credibility is closely aligned with trust in interpersonal exchanges in which the receiver views the sender as lacking in source knowledge or competency. Trust becomes an analog to credibility. Information overload becomes extraneous noise that affects the communication process by having the receiver attend to too much information. The intended outcome of the communication process is the development of shared meaning which enhances the predictability and reliability of the information exchange.

**Enhancing Trust in Communications**

Trust is a concept that permits the formation of perceptions based on the degree of predictability, reliability, and utility an individual exhibits toward a communication medium and the degree of faith in the integrity, honesty and benevolence of others. Trust is an underlying precept for all social interactions within both personal and professional relationships. Perceptions of trust and assessments of trustworthiness are oftentimes unconscious and frequently misplaced when individuals use erroneous data to evaluate an exchange with another. The potential noise that can occur, as a function of using a computer-mediated communication mechanism, can generate additional distortions to an otherwise clear exchange of ideas and intentions. In the process of seeking clarity, individuals must guard against making judgmental trust errors, since adjustments in trust perceptions, as a function of these errors, may result in degradations of trust rather than a refinement of trust accuracy. Interactions that are trust dependent serve as a continuous learning device to upgrade or downgrade the trustworthiness dimensions.

One way to minimize these errors is to select a communication medium based on its richness that is matched to the content of the intended exchange. More ambiguous data should be conveyed through a richer communication medium to help support the other’s interpretations of the original intentions. Conscious selection of media to convey rather than using an ICT because it is convenient is a simple process to assist with noise reduction.

Communications is one of the foundations of social interaction. Humans have developed sophisticated systems to convey thought, feeling, and meaning. In the technology age, the evolution of technological systems permits the development and use of mechanical and electronic devices to aid in the speed, clarity, and meaning that is con-
veyed between two individuals. Communication technologies are subject to their own trust evaluation through the assessments of predictability, reliability, and utility offered by the intended user. Hence, trust in technological communication systems is both important and profound since it may offer further explanations for the presence of noise, the potentials for miscommunication, and the unintentional affects on trust. Each use of a system generates an experience that serves as the basis for an individual’s trust judgments about that technology.

The challenge in the modern information age is to be able to trust the conveyed meaning shared with another and to accurately recognize meaning from others, in order to improve the efficiency and effectiveness of message dissemination. Technology provides an added challenge to trust by introducing an alternate dimension, which links our perceptions and judgments about the predictability, reliability, and utility to a communications system. An objective to improve both interpersonal and technology trust through conscious recognition of the factors that affect the evaluation of trust are oftentimes difficult to operationalize. However, provided below are a few recommendations for managers and their employees to facilitate accurate communication that may lead to enhanced trust:

1. Include trust as a conscious consideration in all forms of communication rather than something that is considered when a problem in communication occurs;
2. Recognize that trust perceptions of people and technology are oftentimes distorted and in error;
3. Consistently work to say what we mean and then mean what we say;
4. Conduct continual assessments of the qualities of the communications and change the medium, the message, or the delivery to optimize transfer of meaning;
5. Clarify as many variables as possible when a technological system is used to convey a message;
6. Select media based on richness to reduce ambiguity in communications; and,
7. Take full advantage of modern information technology to aid in the communication process by using technology where feasible and desired.

FUTURE TRENDS

Sometimes the popular press suggests that we have reached the limits of our capability to effectively communicate, whether by direct human interaction or through new and more complex technology. The future, however, holds promise for the enhancement of communication styles, structures, patterns, and practices, through greater understanding of the many factors that affect the communication process. We can expect to see improvement in the quality of workplace communication, through the use of more advanced and sophisticated technologies to help the message get through accurately, effectively, and efficiently. At the same time, the workplace recognizes that because communication is the mechanism in which business is conducted, better understanding, improved skills, and more sophisticated technology will all contribute to increase capacity. The breath and depth of communications will increase and the technological system used to assist in the operationalization of information sharing will become more accurate, user friendly, predictable and reliable, and more useful, leading to an ever-increasing trust which aids human interaction. As we become more conscious of the affect of trust on communications, we need to continue the development of our knowledge, skills, and attitudes toward improved practices both within and outside the work environment.

Chapter 6.10
Understanding an ERP System Implementation in a Higher Education Institution: A Grounded Theory Approach

Jose Esteves
Universitat Politecnica de Catalunya, Barcelona, Spain

Joan Pastor
Universitat Internacional de Catalunya, Barcelona, Spain

ABSTRACT

This chapter addresses the problem of enterprise resource planning (ERP) implementation in Higher Education Institutions (HEI). It attempts to contribute to the understanding of ERP implementations in this kind of organizations by identifying and analyzing the major factors that affect this type of projects. Special attention has been paid to contextual influence and to organizational factors. The conclusions of this work suggest that most problems in ERP implementation projects are not technological but may be attributed to organizational factors. The chapter describes an in-depth case study carried out at a HEI that implemented an ERP system in 2001. The case was studied as part of a grounded theory based research project whose aim was to develop a model for the implementation of ERP systems.

INTRODUCTION

In recent years, a growing number of HEIs worldwide are exploring the use of ERP systems as a means of supporting their organizational processes, while linking areas like financial, real estate, and staff management, management of students, and support of teaching and learning. This adoption of ERP systems by HEIs is bringing problems in ERP implementation projects that are specific to these types of organizations. Because HEIs comparatively have modest IT/IS resources and budgets, they expect to benefit largely from
implementing off-the-shelf application products like ERP systems. They do not usually have the depth of experience or a constant availability of adequate expertise to be able to handle the in-house development of an enterprise-wide system.

This chapter reports the results of an in-depth case study carried out in the economics management area of a Spanish HEI that implemented an ERP system in 2001 by following a “big-bang” implementation approach. The big-bang approach is characterized by the “go live” of all implemented ERP modules at the same time.

The interpretive perspective adopted in our research reflects our aim for understanding the phenomenon of ERP implementation in a HEI within the full-fledged organizational context where it occurs. In order to keep the confidentiality of the research site and the people involved in this case study, we deliberately omitted the name of the institution and ERP product. The chapter is structured as follows. First we present the literature review on ERP. Then we describe the case study background. Next, we present the research methodology. Subsequently, we describe the findings. Finally, the conclusions and the implications for further research are outlined.

PRIOR RESEARCH ON ERP

Esteves and Pastor (2001) reviewed 189 articles on ERP topics that were published in conferences and top information systems journals. They noted that implementation approaches have been studied and that new ones have been proposed. However, they detected that “implementation” does not mean the same to all authors. Specifically, in what concerns the process, different authors consider different models with different phases and stages. The survey findings suggested that research on the critical factors relevant to ERP implementation success was covered with some studies that did not provide precise definitions of those factors found. Therefore, more effort should be put into defining ERP implementation critical success factors and their subsequent validation.

Aladwani (2001) stated the following:

Past ERP implementation research may be described as factor research, which involves identifying the factors or variables that are critical for implementing ERP successfully. Although factor research is valuable for advancing our understanding of ERP implementation success, it adopts a static view, which limits its adequacy in explaining the dynamics of the implementation process. (p. 267)

Aladwani (2001) and Robey, Ross, and Boudreau (2002) suggested a process research approach or a combination of factor and process approaches, in order to improve research in ERP topics. Using a process approach, ERP implementation may be conceived as sequences of discrete events that lead to outcomes of particular interest. Some studies focused on ERP impacts at organizational, technological, and business levels, business process reengineering, and organizational change management issues. However, the few studies developed so far are not enough to create a body of knowledge in the area. Case studies, not necessarily in-depth, constituted the largest category of articles. From the perspective of research methodology, Esteves and Pastor (2000) detected that in some of the referenced studies, there was a lack of explanation of the research methodology applied, lack of data to support the presented results, and lack of assumptions or hypotheses (in theoretical terms) for further studies. Furthermore, although some studies attempted to identify critical success factors for ERP implementations in general (e.g., Esteves & Pastor, 2000), and more specifically to HEI (Nielsen, 2002), there is a lack of research on the management of these critical success factors.

In sum, as Robey, Ross and Boudreau (2002) mentioned, the research on ERP has been mostly descriptive. They pointed out that “little atten-
tion has been paid to developing a compelling theoretical explanation of ERP implementation, which is needed to explain contradictory findings and to allow generalization of findings to related phenomena” (p. 21). Due to lack of theoretical foundations on the ERP domain, it seems appropriate to investigate ERP implementations by using grounded theory applied to data drawn from in-depth case studies.

CASE STUDY

The Spanish HEI of our case study defines its mission in terms of quality teaching, research, and technology transfer. It was created in the 1970s, and it is composed of several academic schools and research institutes with more than 30,000 students and more than 2,000 teachers.

The HEI economics management area is composed of two general departments: the economics department and the technology transfer unit. There are also economics management personnel in each structural unit. Until 1999, both the economics department and technology transfer unit had their own legacy systems that were totally independent. The units (schools and institutes) were responsible for sending the accounting documents to the economics department or technology transfer unit, and these departments processed them in the respective legacy systems. Table 1 describes the different actions taken to improve information technology infrastructure in this HEI.

This HEI followed a typical big-bang ERP implementation approach with a well-known European ERP package. The number of expected end users was around 220. The HEI implementation project followed the typical implementation phases: planning, design, realization, go live, and support. At the beginning of the project, it was estimated that some be-spoke development would be made to fulfill some special requirements.

This ERP project had a delay of 1 year in relation to the initial project plan. Based on a process research approach, we describe the main events and activities that may have caused this delay.

RESEARCH METHODOLOGY

As we believe that the understanding of ERP implementations cannot be achieved without considering the organizational context in which they occur, the main research method chosen was in-depth case study (Yin, 1994). Furthermore, we opted for an interpretive research approach. Interpretive research does not predefine dependent or independent variables, and it attempts to explain phenomena through the meanings that people assign to them (Orlikowski & Baroudi, 1991).

We started the case study by defining a data collection plan. The main technique chosen for data collection was semistructured interviews. The HEI president (vice president at the time of the ERP implementation) and the ERP project manager were initially contacted in order to permit the study to be carried out and to collaborate in this research project. After permission was obtained, the project manager granted access to most of the documents produced during the project. Later, we asked to visit and interview them, as well as other people who played relevant roles (external consultants, project team members, key users, end users) during the ERP implementation project.

Our first task was to analyze the documentation created during the ERP implementation project. This documentation helped us to understand the project background and to prepare the questions for the interviews. Later, data from interviews were triangulated with the documentation so far accumulated. In order to build theory from this case study, we decided to adopt the grounded theory method.

Grounded theory is a general method developed by Glaser and Strauss (1967) for building theories that are grounded in data systematically gathered and analyzed. Strauss and Corbin (1990) explained the use of grounded theory:

A theory is inductively derived from the study of the phenomenon it represents. In Grounded Theory method one does not begin with a theory, and then prove it. Rather, one begins with an area of study and what is relevant to that area is allowed to emerge. (p. 23)

In our study, the coding process of all interviews and documentation allowed for major themes and categories to emerge. Then, we used the paradigm model proposed by Strauss and Corbin (1990) to relate these categories. Briefly, the paradigm model encompasses the following elements: causal conditions, phenomenon, context, intervening conditions, strategies and actions, and consequences.

A Grounded Model from ERP Implementation

In this section, we describe the specific paradigm model (Figure 1) that we developed by using grounded theory from the data collected from our case study.

Phenomenon

Strauss and Corbin (1990) stated that phenomena are “the central ideas in data represented as concepts” (p. 101). According to their account, the purpose behind naming phenomena is to enable researchers to group similar events, happenings, and objects under a common heading or classification. The phenomenon in the paradigm model is represented by the central category (sometimes called the core category) that represents the main theme of the research. The phenomenon addressed in this study is the implementation of an ERP system in a HEI.

Causal Conditions

Based on the project documents and the interviews, we identified the following reasons to adopt the ERP system: legacy system obsolescence, complex and expensive maintenance process, Y2K problem and Euro conversion, and existence
Understanding an ERP System Implementation in a Higher Education Institution

Environmental Context

By the time ERP implementation at our HEI took place (beginning in 1999), none of the Spanish universities were implementing ERP systems. However, most Spanish universities were thinking about improving their information systems, possibly through abandoning their legacy systems and migrating to ERP systems. Again, problems related to the Y2K problem and the new Euro currency were viewed as strong justifications for carrying out deep changes in information systems. At that time, ERP vendors started approaching the HEI market, and they began to offer ERP solutions adaptable to the HEI market.

The Spanish government also started changing legal requirements and obligations in terms of financial reporting, especially with regard to budget control.

Organizational Context

The organizational culture of our studied HEI is characterized as a bureaucratic culture. According to Wallach (1983), bureaucratic cultures have
clear lines of responsibility and authority and work is highly organized, compartmentalized, and systematic. The information and authority flows are hierarchical and based on control and power. Overall, bureaucratic companies tend to be mature, stable, and relatively cautious.

Our HEI possesses a culture in which most of the times, delays in decision making and expected results are explained in terms of “due to the process,” which refers to the high procedure orientation within this HEI. In this context, it was expected from top management that the ERP implementation would change the way things worked in the organization. However, there was the general perception that organizational culture would not allow for maximum benefits from the ERP system to be achieved, mainly due to the lack of power of some of the involved units.

Intervening Conditions

Because an adequate project manager role is one of the ERP implementation critical success factors, we describe this aspect in the next section - actions and interaction strategies. The HEI started on the selection of the consulting company after the selection of the ERP system. The main arguments for selecting the consulting company were ERP vendor recommendation and experience with ERP implementation in the public sector. At the time of the implementation of the project, this consulting company lacked senior personnel in the ERP implementation area, a fact that was then unknown to the HEI.

Action/Interaction Strategies

In the action and interaction strategies, we used as a priori categories the critical success factors from the unified model first proposed by Esteves and Pastor (2000) and shown in Table 2. Although some studies such as Nielsen (2002) tried to identify critical success factors specific for HEI projects, we opted for our generic model for ERP implementation projects.

Due to space limitations, in this chapter, we focus on the strategic and organizational perspectives within Table 2. The strategic perspective is related to the core competencies accomplishing the organization’s mission and long-term goals. The organizational perspective is related to concerns like organizational structure and culture and business processes. Next, we describe the findings according to each critical success factor within these perspectives.

Sustained Management Support

According to the interviewed stakeholders, in the case of the HEI, the continuous support of the top management was exercised specifically by the then vice president of the university. It was he who participated more actively in the ERP implementation process, mainly after the initial deviation regarding the first project plan. The vice president participated in almost all the meetings of the steering committee. He motivated the project team and contributed with his knowledge about the operation of the university, both at the general level and in terms of its financial management.

The vice president role was crucial as a mediator during some tensions arising from resistance to change. A member of the steering committee manifested that “a project of this type was not high priority for the university.” Initially, top management presented the ERP project like a project bounded for the economics management area; they did not look at it as a strategic project for the whole university.

Effective Organizational Change Management

According to the implementation consulting company, the change management process was in the charge of the HEI, because the HEI decided

On the most favorable side, the economics department presented optimistic expectations of the project, not because of the ERP system but because of the obsolescence of its own legacy system. According to some interviewees, they also had the opportunity of taking advantage of the ERP implementation project to carry out an internal reorganization of the unit. On the other hand, some of those unit managers who showed a rejection to the system from the beginning did it mainly for three reasons: they knew of some bad ERP experiences in nonacademic organizations; they were already sufficiently satisfied with the economics management functionality locally offered by their respective dedicated and isolated legacy systems; and they did not see justification for changing their local economics management processes. These three reasons were argued explicitly in the case of the technology transfer unit.

On the planning and materialization of the change management associated with the ERP project, widespread agreement exists about the convenience of having approached the change management analysis and preparation tasks before the beginning of the implementation project, instead of addressing them during the implementation, mainly in what refers to the integration and standardization of economics management criteria and information among units.
Good Project Scope Management

The interviewed stakeholders said that, in general, the project scope did not vary much along the ERP project. With enough flexibility, the project manager and the steering committee were agreed in their justifications to make some incorporations and changes in the implementation priorities of some functionalities and modules. For example, in the middle of the project, they decided to incorporate the inventory management module, which was not initially planned. Regarding the flexibility in project scope management, some stakeholders complained about the lack of documentation about the decisions taken and lack of justifications in terms of functionality to be implemented, incorporations of new functionality, priority changes, etc., which left these stakeholders with the impression of certain improvisations or decisions being made “on the run.”

Adequate Project Team Composition

With the exception of the software vendor role, the project team covered the rest of areas of interest along the whole project. However, the unanimous opinion, including that of the interviewed implementation consultants, is that the excessive turnover of the implementation consultants complicated the implementation process. With regard to the internal project team, almost all their members continued doing their full working functional activities in parallel with the ERP project. This factor complicated the progress of the project and diminished the satisfaction of team members. And, this factor is given as a justification for the little and poor cooperation of these members with the external implementation consultants.

Following the same line of previous IT/IS department outsourcing decisions, top management decided not to create an internal team of experts in the implemented ERP system; they decided to outsource the future ERP system maintenance. According to some interviewees, the transfer of knowledge to the external consultants should have been made through the IT/IS department personnel specialized in economics management and initially assigned to the project. These people knew extensively the needs of the economics management, the limitations of the existent legacy systems, and some of the limitations of the ERP systems. However, the IT/IS department totally avoided any implementation tasks from the beginning of the project, limiting its intervention to offering services related to the technological infrastructure. Several interviewed stakeholders, among them some from the IT/IS department, related such avoidance to the previous outsourcing of the IT/IS department to a new IT company owned by HEI, with a business model that was at odds with the maintenance of business applications. Some opinions pointed to an additional reason for such an attitude from the IT/IS department: the incorporation of an external project manager for the ERP implementation project, in detriment to the internal leadership from the IT/IS department.

Some interviewees also complained about the insufficient representation of the units in the project team and the steering committee.

Comprehensive Business Reengineering

Before starting the ERP implementation, the steering committee commissioned a project team member to model the existent economics management processes, a task that he completed during the first phase of the implementation project. This factor complicated the progress of the project and diminished the satisfaction of team members. And, this factor is given as a justification for the little and poor cooperation of these members with the external implementation consultants.

Following the same line of previous IT/IS department outsourcing decisions, top management decided not to create an internal team of experts in the implemented ERP system; they decided to outsource the future ERP system maintenance. According to some interviewees,
According to most of the interviewees, after the as-is analysis, both the “to-be” synthesis (description of the redesigned processes) and the “gap-analysis” (description of the differences between the previous processes and the pursued ones) were made on the march for each economics management process approached and were immediately configured on the ERP system. This approach did not allow for the creation of a global transversal model of economics management that would include most of the processes analyzed before their configuration. In general, the ERP system was adapted to the existent processes rather than the other way around.

During the functional analysis phase, no method or modeling tool was used and the final model of economics management processes was not documented.

With regard to the tensions around the analysis and possible process changes, the case of the economics management processes associated with the technology transfer unit deserves special attention. In the steering committee, the people responsible for this unit often showed their strong rejection to changing their processes and their system.

Several interviewees think that in this aspect, a true abyss appeared between the philosophy of operation of the ERP standard for economics management and that of the technology transfer unit. Those practices were very well covered by its legacy system, but they were at odds with the new economics management rules. Interviewees pointed out the following reasons behind the technology transfer unit position: they were used to the autonomy of having their own legacy system; they feared possible loss of personnel, organizational autonomy, and power; and the technology transfer unit rejected the decentralization of part of their processes to the units and to the economics department.

The technology transfer unit case has been the topic of greatest conflict in the whole ERP implementation project in the HEI. After many meetings, debates, and tensions, the ERP implementation in the technology transfer unit has become a big set of bespoke developments around the ERP system, rather than an ERP configuration starting from the ERP standard. On the other hand, the current system has facilitated greater integration between the technology transfer unit and other units.

Adequate Project Sponsor Role

Officially, the figure of ERP project sponsor did not exist. However, there is overall agreement that the then HEI vice president acted as such. One of his crucial functions was to act as mediator. He helped to energize the activities of the team, to define objectives, and to reach small goals, and he contributed decisively to the resolution of the most conflicting situations. As the expert on the management model of the university, because he had lived the whole process of its creation, the vice president helped the people that represented central departments such as the economics department. The units were listened to and they worked together, working out consensus from some initially opposed ideas.

Adequate Project Manager Role

The project manager was hired after the selection of the ERP system, after the selection of the implementation consulting company, and after the creation of the initial project team. According to him, this circumstance already limited his initial performance. His external origin, on one hand, helped him to maintain neutral positions in relation to some organizational conflicts, but was, on the other hand, an initial inconvenience for understanding the organizational culture of the university. There is agreement among the interviewees about the convenience of incorporating somebody external to the organization to manage a project of this type.
A positive aspect of the project manager, commented on by various interviewees, was his open attitude to discussing and to solving conflicts, always trying to follow the legal mechanisms and the appropriate procedures for economics management. The main negative aspect indicated by most of the interviewees was his lack of previous experience in ERP implementations.

Some interviewees noted the lack of monitoring and formal control of the project transmitted by the project manager and the project team in some moments. The project manager and the consulting company did not adopt any implementation methodology, which is also behind the projected uncertainty.

User Involvement and Participation

The implication and wider participation of users refers, according to the interviewees, to the end users of economics department and technology transfer unit. According to the project documentation and the opinion of most of the interviewees, the levels of implication and participation of users from the units was low, probably because the project team and the steering committee did not involve them sufficiently. According to the then vice president, this situation was due to the limitation of budgetary resources that did not allow for the partial liberation of some users from their usual tasks, so that they could be devoted more to the project.

Although both the project team and the steering committee included representative members of the units, some opinions manifested that those people acted more personally than as representatives of the units. Some interviewees indicated that the units were asked for explicit opinions on several occasions, for example in the validation of the definition of the processes, but that the units did not respond to such demands.

Only at the end of the project, in the validation phase, were key users from the units involved and helped key users from the economics department to validate the resulting economics management model. Some economics department users commented that the conjunction of the following facts caused a lot of stress: late implication of the units, lack of time to assimilate the training of the new system, and the coincidence of the end of the year (and the related accounting procedures) with the training and testing activities.

Trust Between Partners

Initially, during the ERP selection and the beginning of the implementation, there was a high level of trust between the HEI, the implementation consulting company, and the ERP vendor branch in Spain. Soon after, a crisis developed in the mutual trust for various reasons.

Regarding the initial relationship between the HEI and the implementation consulting company, most of the interviewees say that the HEI surely trusted excessively in the consulting company. This company at the beginning was sold with the mark or they were hung the medal of being the only consulting company with experience in such a type of ERP implementation in Spain. However, at the beginning, the consulting company omitted that their previous experience consisted in extensive customization and little configuration of the international standard maintained by the ERP vendor.

On the other hand, the ERP vendor in Spain openly referred initially to the HEI as its strategic partner for the HEI sector in Spain, and it committed to facilitating the Spanish standard of all the needed modules by the beginning of the implementation. This did not happen, and, in fact, the ERP vendor several times postponed the delivery of one key module, causing considerable delay in the beginning of the project. Such uncertainty on the delivery of the ERP system caused a lot of insecurity and stress in the implementation consulting company, and in the atmosphere transmitted to the rest of the project team and the steering committee. In some way, the HEI
was aware that the consulting company was also suffering from the lack of commitment and collaboration of the ERP vendor. In fact, the ERP vendor was detaching itself gradually from the project, even ending up with one of its high-level commercial representatives manifesting that the project was no longer considered as “strategic” for his company.

**Consequences**

**Business Process Reengineering (BPR)**

Although BPR started in the design phase, its effective change occurred in the go-live phase. Parallel to the implementation of the ERP system, managers started changing the business processes while explaining them to the organization. The project team admits that this should have been done before the implementation, because some processes were obsolete or inadequate. Currently, during the postimplementation period and using the knowledge that the project team acquired, they are continuously improving processes by extending functionality through the current discovery of functionality in the ERP system. The ERP system brought in new business processes and is helping in the reengineering of the old ones. As the project manager mentioned, the HEI does not have any distinctive economics management processes. Therefore, they would not have lost competitiveness by adopting the ERP best practices. On the contrary, the adoption of practices that the ERP provides helped to reengineer the existent business processes and simplified implementation and future maintenance efforts.

**Change of Mentality**

One of the most interesting consequences of this ERP implementation was the induced change of mentality. At the beginning, most of the users disagreed with the implementation of the system, but their attitudes reversed progressively after the go-live phase. Nowadays, they recognize that the ERP system is useful and that it has helped to improve the HEI processes. They think that more business analysis is still necessary, with managers demanding more people to improve the work. Some users were moved from their old functions, while others had intensive training. Now, only a few employees are still not using the system. Some of them are managers of small units that do not have enough economics management documents to justify one person being allocated to economics management tasks. The solution has been to create a special group in the economics department that manages all the economics management documents from the small units. Now, users are not afraid of changes. They are aware that the system is about continuously improving processes.

**Lack of Internal ERP Knowledge**

Following the same line of previous IT/IS department outsourcing decisions, top management decided not to create an internal team of experts in the implemented ERP system; they decided instead to outsource the future ERP system maintenance. Given the nature of the implementation carried out, this strategy is questioned by many stakeholders who consider the current situation as one of excessive dependence with regard to the implementation consulting company. HEI managers now know that they are totally dependent on the consulting company, and they are trying to change this in the near future.

**CONCLUSIONS AND IMPLICATIONS FOR FURTHER RESEARCH**

In this chapter, we attempted to provide a view of the ERP implementation process in an HEI. To the best of our knowledge, we present the first grounded theory model for ERP implementa-
Understanding an ERP System Implementation in a Higher Education Institution

tions in HEI. We think that the main conclusion of this study is the evidence that organizational and cultural issues have a strong impact in ERP implementation projects. In the particular case addressed in this study, if those issues had been taken into account during the planning phase, it is very likely that some problems would have been avoided or at least mitigated.

In our case study, the findings suggest that organizational culture and structure may have an influence on the management of critical success factors. These could be helpful in explaining some ERP project issues and, therefore, defining a strategy for ERP implementation. Research on critical success factor identification does not explain why some factors are more relevant in some organizations than others. Cultural issues can be responsible for this. The influence of culture has mainly focused on the IS solution and how it fits with the organizational culture or the cultural changes.

We believe that our study of the ERP implementation process is a valuable contribution to the literature, yet the generalizability of our propositions is limited due to the scope of the sample, only an in-depth case study. We would like to emphasize that this was an in-depth case study combined with grounded theory method that took more than a year of documentation analysis, interviewing, and data coding and analysis.

ABSTRACT

This chapter discusses scalability problems and solutions to services-based ubiquitous computing applications in real time enterprises. The scalability problems are (1) identifying relevant services for deployment, (2) verifying a composition by a logical rule framework, and (3) enabling the mapping of required services to the “best” available device. We argue that ontologies can help to counter these challenges. Subsequently, we provide a detailed introduction to ontologies. We focus on the ontology languages emerging from the corresponding W3C Semantic Web activity. The W3C recommendations have a high impact on future tools and the interoperability of ontology-based applications. We contrast the pros and cons of ontologies at a general level and demonstrate the benefits and challenges in our concrete smart items middleware.

INTRODUCTION

Ubiquitous computing for real time enterprises calls for novel approaches to distributed applications since both the economic and technical scale of these applications will increase dramatically. Regarding the economic scale, applications grow beyond enterprise boundaries and potentially involve frequently changing, partly unknown participating entities. Therefore, much more open
Ontologies for Scalable Services-Based Ubiquitous Computing

approaches are desired. In the world of enterprise computing, service-oriented architectures and Web services are considered important steps on the road to economic scalability as discussed in the chapter “Ubiquitous Services and Business Processes.”

The concepts and technologies of service-oriented architectures can be fruitfully applied to ubiquitous computing for real time enterprises to counter the economic scale. However, the technical scale of services-based ubiquitous computing, which concerns the number of nodes and processes involved, still remains a challenge. We discuss the use of ontologies as a possible means of countering the scalability problem, and evaluate their promises and limitations for services-based ubiquitous computing applications.

Services-based ubiquitous computing applications are highly distributed applications that run in the form of cooperating services on a variety of possibly heterogeneous devices. The devices run services that can be combined, that is, “composed,” into more complex services or applications. Such a services-based approach to the development of ubiquitous computing supports the distribution of functionality across the set of available devices, enables better reusability of components in new or different applications, and the division of the overall functionality into independent services with clearly defined interfaces that can be developed and tested separately.

However, the capability to decompose business processes into individual services and to deploy them on different smart devices poses new technical challenges. In particular, the services to be executed on the devices need to be modeled and described for identification and selection, mapped to appropriate smart devices, remotely deployed, configured, and monitored. The reason for such additional tasks is the heterogeneity of the underlying hardware platforms in terms of different communication protocols and technologies.

To facilitate such tasks, a service composition model tailored to smart device interaction is required. The service composition model has to enable the explicit modeling of the heterogeneities of different device platforms and has to support the identification, deployment, and composition of services for smart devices. While the identification, deployment, and composition are fairly simple with a small number of services and devices, the challenge of coping with such tasks increases with the number of devices and services.

In the remainder of this chapter, we show how ontologies may counter the fundamental scalability challenges of: (1) identifying relevant services for deployment, (2) verifying a composition by a logical rule framework, and (3) enabling the mapping of required services to the “best” available devices.

We begin by detailing the scalability challenges in a service-oriented smart items middleware. The chapter continues by introducing the reader to ontologies. We focus on the recent W3C recommendations RDF(S) and OWL that, for the first time, provide standard languages for ontology specification. These recommendations have a high impact on future tools and the interoperability of ontology-based applications. We proceed by contrasting the pros and cons of ontologies on a general level. Finally, we sketch how ontologies are used to counter challenges (1)-(3) in a service-oriented smart items middleware.

CHALLENGES IN SERVICE-ORIENTED SMART ITEMS MIDDLEWARE

As mentioned in the introduction, the technical scale of services-based ubiquitous computing applications struggles with the heterogeneity of the underlying smart devices, and the inherent complexity of a system that requires automatic or semi-automatic monitoring and deployment of services. In this section, we refer to the service-oriented smart items middleware presented in the
chapter “Smart Items in Real Time Enterprises” and detail where such challenges occur. We argue that ontologies should be used to describe services and devices. Ontologies provide the means to identify available services, verify given service compositions, and guide the deployment of services.

**Smart Items Middleware**

The architectural overview of smart items middleware in the chapter “Smart Items in Real Time Enterprises” introduces five logical system layers. The technical scalability challenges occur in both the Device Layer and Device Level Service Layer. We would like to recap these layers in the following paragraphs.

The **Device Layer** comprises the actual smart item devices, the communication between them, and the presentation of the available hardware services to the next higher layer. Available devices usually provide different communication means and operating systems. For example, in the case of RFID, the reader always initiates the communication and the tags cannot directly communicate with each other. In case of wireless sensor networks, simple services can be pushed and executed on them and tasks can be accomplished in cooperation, since the sensor devices have integrated processing power and are able to use peer-to-peer communication.

The **Device Level Service Layer** manages the deployable services used by the device layer. It contains a service repository that stores a service description and one or more service executables for each service. Compound services rely solely on other services to fulfill their task and have a service composition description that is stored in the service repository. Atomic services, on the other hand, are associated with directly executable code. Since a service may be deployable on different platforms, an atomic service may have more than one service executable—one for each device platform.

**Running Example**

In order to illustrate the challenges in the smart items middleware, we first describe a running example (see Figure 1). We assume we are in a warehouse, where goods are tagged with RFID chips and shelves are equipped with RFID readers. The RFID readers feature both Ethernet and encrypted WLAN communication. Further, we assume that temperature sensors and gateway nodes are deployed at strategic locations within the warehouse. The gateway devices are linked to the RFID readers in the smart shelves via Ethernet cables and are equipped with antennas for wireless communication with the temperature sensors (e.g., via 433MHz) and for nonencrypted WLAN (about 2.4 GHz). Every warehouse employee is equipped with a PDA. The PDAs are integrated into a WLAN and provide an adapter for communication with the sensor devices.

Warehouse employees should be informed via their PDAs whether perishable goods are on shelves where the measured temperature exceeds a predefined threshold. The implementation and deployment of the corresponding services in the middleware can take place in the following three main steps. In the first step, a developer chooses

![Figure 1. Running example: Goods, RFID, and temperature sensors in a warehouse](image-url)
the services from the middleware service repository required for our application. In the second step, the developer implements the new application by composing services and device types. Finally, the services of the verified composition plan are mapped to the appropriate devices. Each of the three steps is afflicted with fundamental scalability challenges.

**Fundamental Scalability Challenges**

As the number of services and devices increases, identifying required services, verifying service compositions, and mapping services to devices becomes correspondingly more complex for the system developer. In the following section, we discuss three fundamental scalability challenges of the smart items middleware, which occur independently of any application. A technical scalability challenge is one that increases with the number of services and devices. Tool support is required because the developer can no longer handle the challenges manually.

**Challenge 1: Service Identification**

The descriptions of services available for deployment in the smart items middleware are stored and maintained in the middleware’s service repository. At system deployment or during service composition, relevant services must be selected from the repository. The challenge here is to enable selection based on the semantics or behavior of the available services, rather than on the available interfaces or service signatures.

In our running example, the developer should be able to conveniently search for a “temperature sensing” service rather than having to conduct the tedious task of checking and examining all the services’ interfaces.

**Challenge 2: Verification of Service Compositions**

Services available in the service repository can be composed into new, more powerful, services or applications. However, when composing services at the level of smart devices, heterogeneities of the underlying hardware platforms need to be addressed (Ziekow, Avanes, & Bornhövd, 2006). Heterogeneities concern different communication protocols and technologies as well as different programming models. An abstraction to a common, homogeneous service platform is not possible due to the limited computing capabilities of typical smart devices. The challenge here is to verify a composition plan with respect to the heterogeneities of the underlying hardware.

In our running example, the gateway devices can be used with a service that informs all PDAs about perishable goods that are too warm. As an alternative, the PDAs could also directly receive and evaluate the sensor values, and could request the required RFID data. However, in the setting described, there is no communication channel shared by RFID readers and PDAs. Composition plans for both situations can be specified, but only the first one can be implemented.

**Challenge 3: Intelligent Service-to-Device Mapping**

In addition to manual deployment using dedicated deployment tools, the system should be able to automatically map required services onto the most suitable available devices, or relocate services from one device to another based on changing system conditions. Such automatic deployment of services is essential to manage the increasing complexity of a distributed smart items solution (Ziekow et al., 2006).

In our running example, it would be worthwhile to define a deployment constraint that the
Ontologies for Scalable Services-Based Ubiquitous Computing

temperature filter service gets deployed on only 30% of the nodes, and that these nodes also have to have a certain amount of battery power left. This constraint imposes the need to remap services, if some sensor nodes are running out of power.

In the remainder of this chapter we argue that ontologies can help to counter these challenges. Therefore, the section “Ontologies and Semantic Web Specifications” continues with a general introduction to ontologies. We focus on the ontology languages emerging from the corresponding W3C Semantic Web Activity. The W3C recommendations have a high impact on future tools and the interoperability of ontology-based applications.

What is a Conceptualization?

A conceptualization is a representation of a relevant domain in a more or less formalized model expressed via cognitive modeling primitives. Modeling primitives are cognitive, when they resemble the way humans think and conceive of the world. Ontologies usually provide classes, relations between classes, and instances as cognitive modeling primitives. The backbone of every conceptualization, and thus, each ontology is a hierarchy of classes (also called a taxonomy). This means that sub- and superclass relations are very prominent in ontologies and that special modeling primitives are devoted to them.

Let us model the domain of our running example to clarify this notion. We start by identifying relevant classes in the warehouse domain and putting them into a taxonomy. In the section “Running Example” we learn about Ethernet cables, antennae, RFID chips, sensors, gateways, and so forth. As a first categorization we introduce the classes Specification, Communication Means, and Node. The three classes become direct subclasses of Entity (the most general class). In turn, we classify Antenna and Cable underneath Communication Means, and Sensor, Gateway, Reader, and PDA underneath Node. Furthermore, we introduce the relation describes between Specification and Communication Means as well as accesses between Node and Communication Means, as shown in Figure 2.

With a set of instances, we are able to capture a specific setting in our domain. Figure 3 depicts a specific situation where we can find specific Nodes, viz., Gateway#1, RFIDReader#1, and PDA#1. All of them are linked to their respective Communication Means via the accesses relation. In turn, concrete Specifications, that is, WLAN, WLANencrypted, Ethernet, describe the Communication Means. The reader might wonder, however, where to start and when to stop model-
ing. This leads us to the following requirements for a conceptualization:

Relevance

The conceptualization must represent only relevant classes, relations, and instances. Relevance depends on what we want to achieve with the conceptualization. In our case, we would like to counter the three challenges mentioned in the previous section. For this purpose, it is unnecessary to represent the warehouse as a class, for instance. With respect to these criteria, all classes and relations depicted in Figure 2 are relevant.

Completeness

The conceptualization must represent all relevant classes, relations, and instances. In the running example, Specifications, Communication Means,
and Nodes are all relevant, but will not suffice to address the three challenges. Thus, the conceptualization depicted in Figure 2 is not complete. We have skipped many details for the sake of brevity. The interested reader may refer to Oracle (2006) and Spieß, Bornhövd, Haller, Lin, and Schaper (2007) for the details.

Correctness

The conceptualization must reflect the domain in a consistent way. That means each class, relation, and instance must have counterparts in the domain. This requirement holds for the conceptualization shown in Figure 2.

This way of modeling a domain is very similar to UML class diagrams (Booch, Jacobson, & Rumbaugh, 1998) in object-orientation or entity relationship models (Chen, 1976) in database design. However, ontologies require an explicit, logic-based representation of the domain, as explained in the next section.

What is an Explicit Specification?

The definition of an ontology as given by Gruber (1995) requires an explicit specification of the conceptualization. This means that ontologies must be specified in a formal, logic-based language. Such languages typically provide a wealth of modeling primitives and can avoid ambiguities bound to graphical notations. In addition, the underlying logic is a prerequisite for automatic reasoning, that is, drawing inferences on the basis of the conceptualization. This is in stark contrast to purely graphical modeling techniques. These can be seen as conceptualizations as well, yet are only implicitly specified by graphical representations.

Until recently, there has been a plethora of logic-based ontology languages and corresponding tool suites in research and academia which do not allow any interoperability. However, the W3C’s Semantic Web Activity (W3C, 2001) has gained momentum and specified several recommendations (“standards,” in the W3C jargon). The recommendations (in particular RDF and OWL) are a significant step towards tool interoperability and will thus have a high impact in the future.

According to Tim Berners-Lee, the semantic Web augments the current WWW by giving information a well-defined meaning, better enabling computers and people to work in cooperation (Berners-Lee, Hendler, & Lassila, 2001). This is done by adding machine-understandable content to Web resources. The result of this process is metadata, usually described as data about data. Descriptions such as this acquire semantics by referring to an ontology. The semantic Web’s vision is that once all the layers shown in Figure 4 are in place, we will have an environment in which we can place trust that the data we are seeing, the deductions we are making, and the claims we are receiving have some value. The goal is to make the user’s life easier through the aggregation and creation of new, trusted information from the Web, to enhance search functionality, and, in the ideal case, to infer additional knowledge.

Figure 4 depicts the original “layer cake” proposed by Tim Berners-Lee (Berners-Lee et al., 2001)
The role of Unicode, URIs, XML, and Namespaces is limited to that of a syntax carrier for data exchange. An XML Schema defines simple data types such as string, date, or integer. The standardization process has currently reached OWL; the remaining layers are not yet fully specified. Hence, many changes to the original layer cake are possible and quite likely. In the following section, we discuss the layers one by one. In doing so, we focus on the two most stable recommendations so far, namely RDF and OWL.

**RDF(S)**

The resource description framework (RDF) (Lassila & Swick, 1999) can be used to make simple assertions about Web resources or any other entity that can be named. A simple assertion in RDF is called a statement and consists of a triple (subject, predicate, object). Subjects, predicates, and objects are URIs; objects may also take a literal value (e.g., a string). For instance, a statement (example:WLAN, rdf:label, “IEEE 802.11 WLAN Specification”) associates a name with the entity identified by the example:WLAN URI.

RDF Schema (RDFS) extends RDF with additional modeling primitives (Lassila & Swick, 1999), viz., classes and relations (called properties in RDFS) that can be specified, put into hierarchies, and interlinked to specify simple ontologies. For example, the classes, relations, and instances shown in Figures 2 and 3 can be specified by a set of RDF(S) statements. Below, we list the statements that define the Specification class, the describes relation, and the example:WLAN instance.

(example:Specification, rdf:type, rdfs:Class)  
(example:Specification, rdfs:subClassOf, example:Entity)  
(example:describes, rdf:type, rdfs:Property)  
(example:describes, rdfs:domain, example:Specification)

**OWL**

RDF(S) has one SQL-like query language, which is called SPARQL (Prud’hommeaux & Seaborne, 2006). However, the lack of a formal logical underpinning of RDF(S) prevents automatic reasoning tasks. In addition, the RDF(S) modeling primitives are limited with respect to expressiveness. Therefore, the W3C has come up with a dedicated set of logic-based languages called OWL (Web ontology language) (McGuinness & Harmelen, 2004). This set of languages allows the explicit specification of conceptualizations by logical theories, making intelligent reasoning tasks possible. For instance, using OWL, relations can be specified as transitive, and the transitive closure of the relation can be inferred automatically. OWL consists of:

**OWL Lite**

OWL Lite is the simplest variant of OWL. Its modeling primitives are a strict subset of the OWL DL modeling primitives. The modeling primitives were chosen using an 80:20 rule: OWL Lite contains the modeling primitives which are most often required. Furthermore, OWL Lite’s reduced expressiveness leads to more efficient reasoners.

**OWL DL**

OWL DL is the most prominent variant of OWL. It is based on an older variant of Description Logic.
Ontologies for Scalable Services-Based Ubiquitous Computing

(Baader, Calvanese, McGuinness, Nardi, & Patel-Schneider, 2003) which essentially has been made Web-compliant. Description Logics are a family of knowledge representation languages which can be used to represent the terminological knowledge of an application domain in a structured and formally well-understood way. Web compliance means that URIs are used for identification, XML schema datatypes are introduced, and there is an RDF serialization for representing OWL DL ontologies. Below, we list the modeling primitives that exceed the expressiveness of RDF(S)². The additional modeling primitives can be leveraged to specify our conceptualization more precisely:

- **Transitive Relations:** If a relation \( P \) is specified as transitive, then \( P(x,y) \) and \( P(y,z) \) implies \( P(x,z) \).
- **Symmetric Relations:** If a relation \( P \) is tagged as symmetric, then \( P(x,y) \) holds if \( P(y,x) \).
- **Functional Relations:** If a relation \( P \) is tagged as functional, then \( P(x,y) \) and \( P(x,z) \) implies \( y = z \).
- **Inverse Relations:** If a relation \( P_1 \) is tagged as the inverse of \( P_2 \), then \( P_1(x,y) \) holds if \( P_2(y,x) \).
- **Inverse Functional Relations:** If a relation \( P \) is tagged as inverse functional, then \( P(y,x) \) and \( P(z,x) \) implies \( y = z \).
- **allValuesFrom:** The allValuesFrom modeling primitive restricts the range of a relation to a (complex) class. In our running example, we would restrict accesses to Communication Means, for instance.
- **someValuesFrom:** The difference between this and allValuesFrom is that there must exist at least one instance in the range of the specified relation.
- **Cardinality:** The cardinality primitive permits the specification of exactly the number of elements in a relation.
- **hasValue:** The hasValue primitive allows us to specify classes based on the existence of particular relation values.
- **equivalentClass:** The equivalentClass primitive is used to indicate that two classes have precisely the same instances.
- **equivalentRelation:** In order to tie relations together in a similar fashion, we use equivalentRelation.
- **Identity between Instances:** This primitive is similar to that for classes, but declares two instances to be identical.
- **Different Instances:** This primitive provides the opposite effect from the previous.
- **Complex Class Definitions:** OWL DL provides additional primitives for forming complex classes. The basic set operations, namely union, intersection, and complement, are provided. Additionally, classes can be defined by enumeration, and it is also possible to assert the disjointness of classes.

**OWL Full**

As the name suggests, OWL Full supersedes the expressiveness of OWL DL. For example, the distinction between classes and instances is no longer strict. Instances can also be classes simultaneously, and can have instances themselves. In essence, OWL Full equals first-order logic (also called predicate logic), which is known to be undecidable. This means that sound and complete reasoners cannot be constructed for this logic, which makes it very impracticable.

The explicit specification, that is, logical representation, of a conceptualization is a prerequisite for automatic reasoning tasks. Reasoners (also known as inference engines) enable such tasks, as they are implementations of logic calculi. Examples of OWL reasoners are KAON2 (Motik, Sattler, & Studer, 2004), FaCT (Horrocks, 1998) and Racer (Haarslev & Möller, 2001). Next, we give a partial overview of typical OWL DL reasoning tasks:
Class satisfiability: A class is satisfiable with respect to an ontology if the ontology can be interpreted such that the extension of the class is nonempty, that is, the class can potentially have an instance.

Ontology consistency: An ontology is consistent if all of its classes are satisfiable.

Class subsumption: A class X subsumes a class Y with respect to an ontology if any instance of Y is also an instance of X, no matter how the ontology is interpreted. A pairwise subsumption test of all classes in the ontology obtains an automatic classification of the taxonomy.

Class equivalence: A concept X is equivalent to a class Y with respect to an ontology if X and Y subsume each other.

Class disjointness: Two classes are disjoint with respect to an ontology if they do not have a common instance.

Instance retrieval: Instance retrieval specifies which instances in the ontology are subsumed by a query.

Instance realization: Instance realization specifies to which classes an instance belongs.

Rules

The Rule Layer provides an interoperable language for describing the sets of deductions one can make from a collection of data, that is, how, given a ontology-based information base, one can derive new information from existing data. At the time of writing this chapter, SWRL, the Semantic Web Rule Language (Horrocks, Patel-Schneider, Boley, Tabet, Grosof, & Dean, 2004), F-Logic (Kifer, Lausen, & Wu, 1995), and Business Rule approaches (Morgan, 2002), are in discussions for standardization within the context of the W3C Rule Interchange Format (W3C, 2005).

In our running example, we can specify a rule which automatically infers whether there is a communication channel between two nodes. This is the case when two nodes access a communication means with identical specification. The corresponding rule is depicted next, and can be leveraged for countering challenge (2) as detailed in the section “Ontologies for Verification of Service Composition.” channel(Gateway#1,PDA#1) would be inferred because both nodes access the same Ethernet cable. A counterexample would be channel(RFIDreader#1,PDA#1) because the nodes access antennae with incompatible WLAN specifications.

\[
\text{channel}(x,y) \leftarrow \text{Node}(x) \land \text{Node}(y) \land \text{accesses}(x,a) \land \text{accesses}(y,b) \land \text{Specification}(z) \land \text{describes}(z,a) \land \text{describes}(z,b)
\]

Proof, Trust, and Digital Signatures

The Proof language will provide a way of describing the steps taken to derive a conclusion from the facts. Proofs can then be passed around and verified, providing shortcuts to new facts in the system without requiring each node to make the deductions on its own. The vision of the Trust layer on top is to create an environment in which we can place trust on the data we are seeing, the deductions we are making, and the claims we are receiving. For reasoning to be able to take trust into account, the common logical model requires extension to include the keys with which assertions have been digitally signed. The Proof and Trust layers, as well as the Digital Signatures, are not yet specified.

BENEFITS OF ONTOLOGIES

In the previous section, we introduced ontologies and focused on recent W3C recommendations emerging from the Semantic Web Activity. The latter are likely to have a high impact on future tools and the interoperability of ontology-based applications. In this section, we discuss the general benefits of ontologies. We give concrete examples
of the benefits in the section “Ontologies for Improving the Smart Items Middleware”, where we detail how ontologies can be used to counter the three challenges introduced in the section “Fundamental Scalability Challenges”.

**Benefits through Conceptual Modeling (Conceptualization)**

The first set of benefits concentrates on conceptual modeling. All the advantages are conceivable at first sight. However, they are hard—or sometimes even impossible—to measure.

**Reuse, Flexibility, and Maintainability**

With modeling techniques, such as UML, ERM, or ontologies, we make the conceptual model underlying a specific application explicit. In our running example, we analyze the domain of smart devices, identify relevant classes and their relations, and represent this knowledge explicitly. Thus, the ontology can be reused in other applications in the same domain, and can be used to facilitate communication with domain experts. The alternative would be to hard-code domain knowledge, resulting in an inflexible application with high maintenance costs (every change of the domain knowledge would require code adaptation and recompilation).

**Reuse of Best Practice for Conceptual Modeling**

Recent developments allow us to talk about the quality of ontologies as well as ontology design patterns. In addition to purely structural approaches, for example, the normalization of relational data models, the ontology design patterns consider the conceptual level (Gangemi, 2005). For example, a simple participation pattern (including objects taking part in events) emerges in domain ontologies as diverse as enterprise models, legal norms, software management, biochemical pathways, and fishery techniques. Ontology design patterns are useful to acquire, develop, and refine an ontology.

**Standardization**

We already learned in the section “Section Ontologies and Semantic Web Specifications” that the standardized ontology languages of the W3C are a significant step towards tool interoperability and will thus have a high impact in the future. So far, there have been a plethora of ontology languages in research and academia without any interoperability. In addition, the Object Modeling Group (OMG) is currently developing an Ontology Definition Metamodel (IBM, Sandpiper, 2006). Once established, ODM will allow using UML tools to specify OWL ontologies as well.

**Benefits from Explicit Specification**

The second set of benefits focuses on the explicit specification, that is, advantages that are a consequence of the logic-based representation. As with the aforementioned benefits, the following ones are also hard to substantiate in numbers.

**Unambiguous, Formal Representation of Shared Meanings of Terms**

The advantage of ontologies over other conceptual modeling techniques is the decreased ambiguity of the modeling. This is due to the increased formality of the logic-based representation. For instance, relations can be defined as symmetric, transitive, or inverse. A reasoner can leverage the formal representation to infer additional knowledge, perform consistency checks, and so forth. A user of the ontology can leverage the increased formality to avoid ambiguity. Depending on the expressiveness of the ontology language, one might add further rules or integrity constraints. While
something similar can be done with approaches such as OCL (the Object Constraint Language in UML), ontologies demand agreement at the modeling level. All this results in a formal, machine executable description of the shared meaning of terms and relations.

Reasoning Saves Development Efforts

We discussed in “Ontologies and Semantic Web Specifications” that ontology languages are based on logics, possibly with a rule mechanism on top. Reasoners let us leverage the advantages of the logics and offer powerful functionality, such as instance retrieval (all instances of a class $x$), subsumption checking (is a class $x$ subsumed by a class $y$?), automatic classification of an ontology, consistency checking, and potentially a rule mechanism. This means that such functionality does not have to be developed from scratch.

Many problems can be reduced to such functionality. For example, the matching of services can be reduced to the subsumption problem. A detailed example follows in the section “Ontologies for Improving the Smart Items Middleware,” where we apply rules to realize a verification mechanism. In essence, we can say that ontological modeling and the associated reasoning capabilities can be used to save development efforts.

Standardization

So far, there has not only been a plethora of ontology languages in research and academia, but also a multitude of existing ontology editors, stores, and reasoners. Hence, standardization also comes in handy for interoperability between such tools.

LIMITATIONS OF ONTOLOGIES

Despite all the benefits discussed in the previous section, every ontology-based application encounters limitations. In the following section, we proceed by giving a general explanation of each limitation. We give concrete examples of the limitations in the section “Ontologies for Improving the Smart Items Middleware.”

Theoretical Limitations

The first set of limitations is of a theoretical nature. Among them is the fundamental trade-off between expressiveness and efficiency, as well as the widely known frame problem.

Expressiveness vs. Efficiency

Representation languages for ontologies encounter a trade-off between expressiveness and efficiency. The search for expressiveness is an elaborate process of finding consensus on what modeling primitives might be required most urgently by potential users. Requirements for more modeling primitives, that is, expressiveness, must be traded off against efficiency or even decidability of the corresponding reasoner. In essence, we can say that the more modeling primitives the language provides, the less efficient the respective reasoners are. The decision for the right language has to be taken on a case-by-case basis: if expressiveness is important, use a language with many modeling primitives but with a less efficient reasoner. If fast run-time reasoning is important, use a less expressive language.

The most recent example of this trade-off is shown by the three increasingly powerful variants of OWL, viz., OWL Lite, OWL DL, and OWL Full. OWL Lite and OWL DL are languages from the family of description logics (DL) and, thus, strict subsets of first-order logic. If chosen carefully, as are OWL Lite and OWL DL, they are decidable, which means that sound and complete reasoners can be constructed. OWL Full equals full first-order logic which is known to be undecidable, that is, no sound and complete reasoner exists for this language.
The Frame Problem

Ontologies are ideally suited to categorize the entities in a relevant domain and to capture their interrelationships, as well as specific situations, via instances. User groups can agree on the ontology with the ultimate goal of information integration and mutual understanding. However, ontologies exhibit fundamental limitations when describing the behavior of entities. As an example, consider the preconditions, postconditions, and the functionality of a service. All these aspects are required for semantic service discovery, yet their representation via ontologies is severely limited. The reason is to be found in the logic-based representation and is called the frame problem.

Put succinctly, the frame problem in its narrow, technical form is this: Using mathematical logic, how is it possible to write formulae that describe the effects of actions without having to write a large number of accompanying formulae that describe the obvious noneffects of those actions? This means that in standard first-order logic, one would need to describe the properties that change as the result of an action as well as the properties that do not change (Baader, 1999). The challenge is to find a way to capture the noneffects of actions in formal logic. What we need is some way of declaring the general rule-of-thumb that an action can be assumed not to change a given property of a situation unless there is evidence to the contrary. The main obstacle to doing this is the monotonicity of classical logic. In classical logic, the set of conclusions that can be drawn from a set of formulae always increases with the addition of further formulae. This makes it impossible to express a rule that has an open-ended set of exceptions. The solution to the frame problem requires special logic languages which are, however, not aligned with common ontology languages, for example (Levesque, Pirri, & Reiter, 1998).

Practical Limitations

Unlike the theoretical limitations, which are rooted in the fundamentals of ontologies, the limitations discussed in this section typically occur when ontologies are applied in practice.

Development vs. Modeling Efforts

In the section “Benefits from Explicit Specification,” we learned that reasoning could be used to reduce the development efforts. Reasoners provide us with powerful functionality, such as consistency checks, automatic classification of an ontology, rules, and so forth. A specific problem might be reduced to the services offered by the reasoner. Therefore, one is able to avoid developing a solution from scratch.

The drawback here is that we have to invest modeling efforts to apply the reasoner. First of all, developers have to be skilled enough to build an ontology and rules. While building the actual ontology is a one-off effort, every relevant entity has to be modeled via the ontology as well. This is a linear effort based on the number of entities. Finally, we cannot expect the ontology to remain stable over time. Changes will be necessary, and will lead to maintenance efforts.

In our example, we have to come up with the ontology depicted in Figure 2 and extensions for specific domains. While this is a one-off effort, it is not to be underestimated. The ontology has to be built in such a way that the rules can be efficiently applied. This requires a lot of expertise from the ontology engineer. Furthermore, all entities in our example have to be classified and modeled via the ontology. As shown in the section “Ontologies and Semantic Web Specifications,” the WLAN instance has to be classified as an instance of the Specification class and has to be related to the ontology shown in Figure 3. As mentioned before, this is a linear effort based on
the number of entities we have to model. In addition, the rules must be modeled, which requires detailed domain expertise.

In conclusion, there is a trade-off between development and modeling efforts. On the one hand, we save development efforts by reducing specific problems to the functionality provided by reasoning. On the other hand, we have to invest modeling efforts in order to model the ontology and relevant entities. Modeling is a prerequisite for using the reasoner. Identifying the sweet spot between both efforts is a difficult undertaking, because it is hard to measure. Therefore, the trade-off must be made on a case-by-case basis.

Modeling Scope

Ontologies are afflicted with several other problematic aspects, which we subsume under the term “modeling scope”. First, ontologies formalize the shared understanding of a user group to enable information integration. However, different user groups will use different ontologies: we cannot expect the usage of an all-encompassing ontology. Manual reconciliation or sophisticated ontology mapping algorithms will be required. (Ehrig, 2006) discusses several different approaches to ontology mapping. Most of them are probabilistic and require manual revision. Another approach is to use a common foundational ontology to align the ontologies (Guarino, 1998). The foundational ontology can be seen as a generic modeling basis which is used for several domain-specific ontologies. It is expected that having a common basis facilitates mapping between domain-specific terms. However, this has not been proven so far.

Second, ontologies model a specific domain. There have been attempts for an all-encompassing ontology, but they have failed, typically because of the lack of agreement and because of the rapidly changing and expanding universe of discourse. One of the most prominent examples of the past has been the CYC project (Guha & Lenat, 1990). In our example, we also encounter expansions of the universe of discourse, that is, the ontology must account for future technologies.

ONTOLOGIES FOR IMPROVING THE SMART ITEMS MIDDLEWARE

In this section, we leverage the advantages of ontologies to counter the challenges (1) - (3) presented in the section “Fundamental Scalability Challenges.” Of the three challenges, we sketch solutions to (1) and (3) and discuss (2) in more detail. Furthermore, we highlight which of the benefits and limitations apply.

Ontologies for Service Identification

Descriptions of services available for deployment in the smart items middleware are stored and maintained in the service repository. At system deployment or during service composition, relevant services must be selected from the repository. This selection usually takes place based on the available interfaces or service signatures, rather than on the semantics or behavior of the offered services. Ontologies can be used as the common vocabulary for the semantic description of services in the repository. They provide the formal basis for the mapping of a service request to available services (cf. benefits unambiguous, formal representation of shared meanings of terms as well as reuse, flexibility, and maintainability). However, such semantic service descriptions do not include the specification of the operation performed, for example, provision of temperature readings or the filtering of incoming sensor readings, as well as pre and post conditions of a service (cf. limitation frame problem).

In our running example, a developer chooses the services from the service repository required for our application. A request for a “temperature sensing” service gets translated by the repository into a request based on the common vocabulary used to describe the semantic inputs and outputs
of the available services. Through a couple of refinement steps, the system enables the developer to identify the required services. In a similar way, the developer identifies the desired device types based on their profile and availability.

**Ontologies for Verification of Service Composition**

Ontologies provide the means to conceptually model the heterogeneities of different device platforms. Software, platform, and device components must be enriched by additional information about the communication technologies they apply. The biggest challenge in modeling is the heterogeneity of communication aspects of different device types that must be represented. Required attributes may range from shapes of plugs to frequencies of radio signals. For example, to model applications for a system using different types of data cables, details about plug shapes and their specifications must be represented in the ontology. Also, in order to make the ontology adaptable to details of every application domain and to enable extensions for future technologies, it must be extensible.

The problem with this flexibility is in finding verification algorithms that work in spite of changes in the structure of the ontology. This problem can be solved by using the rather generic ontology depicted in Figure 2. This ontology serves as the basis on which more specific domain ontologies can be defined.

Combining the modeled information, the required and provided technologies for cross device interaction can be automatically derived and used to verify composite applications by a reasoner. The verification is achieved by compatibility rules for composition validation defined only on the basis of classes and relations in the ontology. Consequently, these rules apply to all descriptions that are based on this ontology. We have already seen an exemplary rule in the section “What is an Explicit Specification?” Therefore, it is ensured that the descriptions can be adapted to the required level of granularity and can be extended in the future. For example, new protocol standards to access upcoming generations of RFID tags must be included in the ontology once they become available. As long as the generic ontology is respected, no changes in the verification algorithms are needed. With this solution, we leverage the benefits of reasoning saves development efforts as we do not have to realize the verification from scratch. The drawback of this approach is that we have to expend efforts for modeling the ontology and rules, which can only be done manually (cf. limitation development vs. modeling efforts).

**A Prototypical Implementation**

Ziekow et al. (2006) provides a first prototype of a verification tool that can be used to compose and verify service compositions for smart device applications. As input, it uses an ontology together with verification rules. In addition, the tool requires descriptions of compositions (composition plan). These are models of functional components, for example, services or devices, and a specification of how these components are combined into a more complex service or application.

The verification tool includes a reasoner that checks the rules against the given composition plan. In this way, the correctness of the modeled composite service or application is determined. The tool returns a report about the check results. This can include errors and warnings or may just indicate a correct composition. In case of an error, information about the cause of a failure is provided to support the correction of the encountered problems.

During the verification process, intermediate results of composition steps are created. These are models of composite components resulting from the respective composition step. These models are also part of the verifier’s output and describe already-verified combinations of components, which can be stored and reused for future compositions.
In this way, the tool supports the development and utilization of composite services or applications for collaborative smart devices. Detailed knowledge about the low-level communication issues is modeled once and automatically used by the tool. Another system component or a human can use the described tool to check for correctness of a composition, leaving the burden of considering details of the communication layer to the tool.

Revisiting our Running Example

In our running example, the developer might want to reduce energy-intensive communication. For deployment on the nodes, a service is chosen which identifies and filters temperature readings to the gateway when they exceed a specified threshold. For the gateways, a service is selected that issues read-requests to the RFID readers if more than 15% of the sensors report temperature readings above the threshold. Based on the RFID data, it can be determined if perishable products are on the shelves. Another service on the gateways informs all PDAs about perishable goods that are too warm. The specified composition of services and device types can now be validated based on the service description and device profiles.

From a software perspective, an alternative implementation without using gateway devices would have been possible. The PDAs could directly receive and evaluate the sensor values, and could request the needed RFID data. However, in the setting described, there is no communication channel shared by RFID readers and PDAs. Although both have WLAN access, the RFID readers use encrypted communication whereas the PDAs do not. Consequently, their alternative composition plan would be falsified by the verification tool and rejected in the implementation process.

Ontologies for Service-to-Device Mapping

In addition to manual deployment using dedicated deployment tools, the smart items middleware should be able to automatically map required services onto the most suitable available devices, or to relocate services from one device to another based on changing system conditions. Such automatic deployment of services is essential to manage the increasing complexity of distributed large-scale smart items solutions or scenarios, where available devices change frequently.

An automatic “intelligent” mapping of required services to the most suitable available device requires a formal description of the service requirements (e.g., CPU power, available main memory, or communication means) as well as the capability profiles of the available target devices. Ontologies can provide the formal description means for the specification of service requirements (which can be stored together with the semantic service description in the service repository) and the device profiles (cf. benefit unambiguous, formal representation of shared meanings of terms). Based on this foundation, reasoning can be used to
specify appropriate metrics to identify the “best” target device for a given service to be deployed (cf. benefit reasoning saves development efforts). Note, however, that significant modeling efforts (for the ontologies as well as for the rules) have to be expended before the benefits can be reaped (cf. limitation development vs. modeling efforts).

In our running example, services of the verified composition plan are mapped to appropriate devices. Services chosen for the gateways, RFID readers, and PDAs are to be installed on all those devices that have appropriate locations and properties (e.g., sufficient memory). Also, at this point, deployment constraints are specified (e.g., that the temperature filter service gets deployed to only 30% of the nodes, which are also required to have a certain amount of battery power left). This constraint imposes the need for a remapping of services if some sensor nodes are running out of power. The service mapper then maps the given services to the most suitable devices available by taking into consideration a formal specification of these mapping constraints and the service and device profiles. The actual service deployment is done by a service injector component which installs the respective service binaries for the respective platform.

**CONCLUSION**

The chapter introduced the reader to ontologies with the focus on the recent W3C recommendations RDF(S) and OWL that, for the first time, provide standard ontology languages. The recommendations have high impact on future tools and the interoperability of ontology-based applications. We further contrasted the pros and cons of ontologies on a general level and showed where ontologies can be used to counter fundamental challenges to enable scalable services-based ubiquitous computing applications in real-time enterprises.

**FUTURE RESEARCH DIRECTIONS**

One future research direction of this work is the collaboration between the nodes of the sensor network. By using collaborative algorithms, the nodes are able to perform business processes autonomously and independently from the back-end, only reporting exceptional situations (such as a dangerous constellation or the change of a monitored value). The expected outcome is a system that is highly autonomous, fault-tolerant, and scalable. Powerful tools will be developed, that allow business professionals to model the business logic to be executed by the nodes, simply by combining basic services.

Another area of future work is concerned with closing the information loop for the manufacturer of a product over the whole product lifecycle. At the beginning of the life of a product (including design and production), the manufacturer has detailed information available. However, once the product is delivered and used (middle of life), as well as at the end of its life (when it is recycled or refurbished), the information available to the manufacturer is scarce. By attaching product embedded information devices (PEIDs, such as rewritable RFID-Tags, embedded systems, or sensors) to the goods that can gather and store information during their lifetime, the information loop can be closed. This will allow business applications that are integrated in complex business processes to uniformly access data stored on or gathered by PEIDs in real time. This also enables the applications to configure and control PEIDs and update their memory.

Finally, there is a body of work in research and academia around what is called Semantic Web Services (McIlraith, Son, & Zeng, 2001). The principal objective of Semantic Web Services is a wide-reaching formalization that allows full automation of the Web service management tasks, such as discovery and composition. The core of the proposals lies in creating semantic standards
for the markup of Web services. Hence, another research direction is to evaluate whether the existing proposals can be used to also counter the technical challenges of our domain. The existing proposals are OWL-S (Martin, Burstein, Hobbs, Lassila, McDermott, & Mellraith, 2004), WSMO (Fensel & Bussler, 2002), and WSDL-S (Akkiraju, Farrell, Miller, Nagarajan, Schmidt, & Sheth, 2005).

ENDNOTES

1 Depending on the specific language used, classes are also called concepts or universals, relations are also called properties or roles, and instances are also called individuals or particulars.

2 Note that many of these primitives are also part of the OWL Lite language. Furthermore, Web compliance as described above holds for all three OWL variants.

ABSTRACT

As the Web is growing exponentially, online marketing has been changed by the newly provided technological capacities and digital channels of sales. Online marketing or e-marketing is the adaptation and development of marketing strategies in the Web environment and includes all factors that affect a Web site's efficiency, like the idea, the content, the structure, the interface, the implementation, the maintenance, the promotion and the advertising. Since more and more businesses are using the Web to conduct their activities, issues like interface usability, easy navigation and effective supporting services become critical and influence their success dramatically. However, one important problem that arises is that Web users are confronted with too many options. Currently, Web personalization is the most promising approach to alleviate this information overload and to provide users with tailored experiences. It improves user interaction with Web sites and offers them the ability to establish long-term and loyal relationships. The scope of this chapter is to give a comprehensive overview of research issues on personalized e-marketing applications. We focus on the importance of personalization as a remedy for the negative effects of the traditional “one-size-fits-all” approach. Next, we explore the different steps of the personalization process providing information about interesting research initiatives and representative commercial tools for producing personalized Web experiences. Finally, we demonstrate the close relation between per-
sonalization and Web mining and discuss open research issues.

INTRODUCTION

In today’s competitive business world, understanding and leveraging the power of the four Ps of marketing, namely product, price, place and promotion has become one of the major factors that determines a company’s marketing future survival or success. However, these four Ps have all been modified by technological evolutions and especially the Web and they have been converted into the four Ps of e-marketing, namely permission, privacy, profiling and personalization (Goldsmith, 1999). According to (Mobasher & Dai, 2003) “personalization is the provision to each individual of tailored information, products, or services” and the subject of this chapter is to study the significant role of personalization in intelligent e-marketing applications.

The roots of personalization are traced back to the introduction of adaptive hypermedia applications in Brusilovsky (1996, 2001). Adaptive hypermedia were introduced as an alternative to the traditional “one-size-fits-all” approach, building a model of the goals, preferences and knowledge of each individual user, and using this model throughout the interaction, in order to adapt to the user’s specific needs (Perkowitz & Etzioni, 1997, 2000a).

Personalization is a broad scientific and technological area, also covering recommender systems, customization, one-to-one marketing, and adaptive Web sites (Blom, 2000; Mulvenna et al., 2000; Schafer et al., 2001). It is the process of gathering and storing information about Web site visitors, analyzing the information in order to learn users’ patterns, habits and preferences, and based on this analysis, delivering the right information to each visitor at the right time (Eirinaki & Vazirgiannis, 2003).

Personalization can be deployed by e-businesses (any Web site whose operation is related to commercial purposes, e.g., e-shop, e-procurement, e-auction, e-mail, portal, etc.) and be used as the key technology for managing customer relationships, running targeted advertisement campaigns, promoting products or services and customizing Web site content (Perner & Fiss, 2002). Besides, according to the forth of the five mutable laws for Web marketing (Wilson, 1999) the objective of e-commerce sites should be to “pull people to the site by its attractive content, then push quality information to them regularly via e-mail.” However, personalized content apart from e-mail can be advertising, recommended items, screen layout, news, or anything else accessed via commercial Web site.

The digital channels that can be deployed by an e-business to reach its customers are numerous: Web, e-mail, ftp, chat, search, voice over IP, interactive multimedia, etc. The power of these digital channels is significant, since they can dramatically change the way the e-business listens, understands and responds to its customers and suppliers. Moreover, these channels facilitate instantaneous responses to the information gathered by various touch-points (buttons’ selection, hyperlinks, transactions, log files, etc.) without the need for human intervention (Yao et al., 2001).

Web personalization may be implemented in the form of:

- personalized content presentation and delivery (inserting or removing thematic units/sections/paragraphs, optional explanations or detailed information, personalized recommendations/offers/prices/products/services).
- personalized structure (sorting, hiding, unhiding, adding, removing or highlighting links), e.g., yahoo.com (Manber et al., 2000).
Web Personalization for E-Marketing Intelligence

- personalized Web site layout presentation and media format (from images to text, from text to audio).

The above can be based on the analysis of data from online and off-line sources using a variety of techniques: association rules mining, clustering algorithms, classification techniques, collaborative filtering, patterns discovery, prediction, log files analysis, etc. (Vassiliou et al., 2002).

The benefits for the businesses can be significant and include among others increasing site usability, converting users to buyers, retaining current customers, re-engaging customers, penetrating new markets, etc. (Nielsen, 1994). On the other hand, personalization applied to the e-commerce domain is an effective way to provide added value to customers by knowing and serving them as individuals. Customers need to feel that they have a unique personal relationship with the businesses they come in contact with. Users have now the ability to visit Web sites that allow them to find information or choose products and services to buy fast and easily. Moreover, they can receive e-mail, newsletters or other information that they attach importance to. And even though a significant percentage of online users give their permission to receive these kinds of information from marketers, they tend to unsubscribe and take back their permission when their preferences and needs are not met and they end up receiving useless or irritating information. This observation brings up the importance of quality and precision in producing and delivering personalization, as a means for assuring customer faith and loyalty.

There are two general approaches to personalization in e-commerce applications:

- **Buyer driven**: the customer subscribes to different services, fills in forms or questionnaires, rates products, participates in surveys, etc.
- **Seller driven**: the adaptation is controlled by the owner of the e-shop. Content is served up using pre-defined business rules, targeted online advertising, as well as product cross-selling and up-selling. It typically uses a rules engine which captures and encodes business rules, describes workflows and automates manual tasks.

The basic steps comprising the personalization process (depicted in Figure 1) are the following (Cooley et al., 1999a; Srivastava et al., 2000):

- Data collection.
- Data processing.
- Personalization output.

![Figure 1. Personalization process](image-url)
This chapter aims to define Web personalization for intelligent e-marketing applications, describe the tasks that typically comprise the personalization process and demonstrate the close relation between personalization and Web mining. Moreover, our goal is to illustrate the future trends in the field and, in this way, suggest directions that may trigger new scientific research.

**DATA COLLECTION**

By understanding consumers’ behavior, more efficient e-marketing strategies will become available to drive Internet use and e-commerce applications. Marketing efforts intended to enhance Web site use are expected to follow a two-fold strategy:

- Turn non-users into users.
- Expand usage of current users.

Consumers supported by a personalized system will be more likely to either turn from non-shoppers into active shoppers or increase their previous shopping volume. Web sites need to encourage users to discuss problems, and use this feedback to improve both products and services. Web sites should try to collect customer information and use that information to develop a relationship with customers. Customer satisfaction is the key for customer retention. Like traditional stores, online stores also need to build strong relationships with their customers. Technology provides many advantages over traditional ways of business with commercial Web sites using techniques such as online user groups, input from previous customers (rankings, comments, opinions, product assessments, etc.), order tracking and more.

So, the first step in the personalization process is the acquisition of data about the users (a task that is in continuous execution in most of the cases). User data must be transformed into an internal representation (modeling) that will allow for further processing and easier update. Indeed, personalization in order to produce satisfactory results needs different kinds of data. Some data can be observed by the system while other have to be provided by the user. The collection of information that describes a particular user is called a user profile, and consequently, a good such model comprises the basis for personalization activities. These profiles may be static or dynamic based on whether -and how often- they are updated. More specifically, the information incorporated in a use model may include: the user’s identification profile, the preference profile, the socio-economic profile, user’s ratings, reviews and opinions, the transaction profile, the interaction profile, the history profile, etc.

There are two general methodologies for acquiring user data depending on whether the user is required to be actively engaged in the process or not:

- **Reactive approach**: the user is asked explicitly to provide the data using questionnaire forms, fill-in preference dialogs, or even via machine readable data-carriers, such as smart cards.
- **Non-reactive approach**: the system implicitly derives such information without initiating any interaction with the user using acquisition rules, plan recognition, and stereotype reasoning.

Static profiles are usually acquired explicitly while dynamic ones are acquired implicitly by recording and analyzing user navigational behavior. In both approaches, we have to deal with different but equally serious problems. In the case of explicit profiling, users are often negative about filling in questionnaires and revealing personal information online, they comply only when required and even then the data submitted may be false. On the other hand, in implicit profiling, even though our source of information is not biased by the users’ negative attitude, the problems encountered derive once again from the
invaded privacy concern and the loss of anonymity. Personalization is striving to identify users, record their online behavior in as much detail as possible and extract needs and preferences in a way they do not notice, understand or control. The problem of loss of control is observed in situations where the user is not in control, a problem known as loss of control (Kramer et al., 2000; Mesquita et al., 2002; Nielsen, 1998).

Moreover, to maximize data gathering opportunities the Web site should collect data from every customer touch point, online and off-line. Online customer touch points include:

- **Registration:** the Web site asks some basic information about the customer (e.g., name, address, phone number, fax, interests, preferences, etc.), including the e-mail address and the password. Being a registered user makes future purchases faster, easier and friendlier.
- **Transactions:** purchase data or information requests.
- **Sign-ups:** newsletters, e-mail notifications, samples, coupons, partner offers, etc.
- **Customer profiles or user preferences.**
- **Customer surveys:** research-related and entertaining content surveys.
- **Customer service.**
- **Web log files:** pages viewed, categories searched, links clicked, etc.
- **Incoming and outgoing URLs (URL linking to the store, and links leading outside the store).**
- **Advertising banners.**
- **Sweepstakes** and other promotions requiring customer data.

Off-line customer touch points on the other hand may comprise:

- Customer service by phone, stored in the customer profile database.
- In-store transactions (meaning physical store purchases).
- Various surveys.
- Paper submissions (e.g., sweepstake or promotion entries).

Perhaps, the most important data source is the initial registration. In most cases this registration process is more important than the first transaction, in that the act of registering indicates that a customer wants to start a “conversation” or a relationship and gives the store permission to begin this process. When adequate data is collected, subsequent interactions with the store may well exceed the visitor’s expectations. Ensuring that the store allows customers to update and modify their own profile data not only will keep the customer information up-to-date, but it will also engender more trust because customers know what information is maintained about them by the e-store.

Another equally effective way to gather data about the customer is when the system does not explicitly ask for any information at all. Many successful Web sites use cookies and unique identifiers to make customer-specific data collection invisible to the customer.

Different kinds of data are used in personalization process:

- data about the user.
- data about the Web site usage.
- data about the software and hardware available on the user’s side.

**User Data**

This category denotes information about personal characteristics of the user. Several such types of data have been used in personalization applications. One source of information affecting customers’ decision-making process and attitudes is their **demographic traits**. These traits include...
name, address, zip code, phone number, other geographic information, gender, age, marital status, education, income, etc. All customers are not equal. Different customers and customer segments value different things, so for some it is important for a Web site to provide lower prices and faster delivery, while for others the priority focuses on quality, number of choices and convenience. An example found in Liebermann and Stashevsky (2002) reveals differences in attitudes based on sex and according to it males worry more than females for the vast volumes of Internet advertising.

Another source of information relates to user’s knowledge of concepts and relationships between concepts in the application-specific domain (input that has been of extensive use in natural language processing systems) or domain-specific expertise.

Moreover, valuable types of data may be user skills and capabilities in the sense that apart from “what” the user knows, in many cases it is of equal importance to know what the user knows “how” to do, or even further, distinguish between what the user is familiar with and what he/she can actually accomplish.

Finally, interests and preferences, goals and plans are used by plan recognition techniques where identified goals allow the Web site to predict interests and needs and adjust its contents’ structure and presentation for easier and faster goal achievement.

Usage Data

Usage data may be directly observed and recorded, or acquired by analyzing observable data (whose amount and detail varies depending on the technologies used during Web site implementation, i.e., Java applets, etc.), a process known as Web usage mining (Markellou et al., 2004, see also section “Personalization and Web Mining”). Usage data may either be:

- Observable data comprising selective actions like clicking on an link, data regarding the temporal viewing behavior of users, ratings (using a binary or a limited, discrete scale) and other confirmatory or disconfirmatory actions (making purchases, e-mailing/saving/printing a document, bookmarking a Web page and more), or
- Data that derive from observed data by further processing (measurements of frequency of selecting an option/link/service, production of suggestions/recommendations based on situation-action correlations, or variations of this approach, for instance recording action sequences).

Environment Data

On the client side, the range of different hardware and software used is large and keeps growing with the widespread use of mobile phones and personal digital assistants (PDAs) for accessing the Web. Thus in many cases the adaptations to be produced should also take into account such information. Environment data addresses information about the available software and hardware at the client side (browser version and platform, availability of plug-ins, firewalls preventing applets from executing, available bandwidth, processing speed, display and input devices, etc.), as well as locale (geographical information that can be used, for instance, to automatically adjust the language, or other locale specific content, such as the local time or the shipping costs).

DATA PROCESSING

The step following after the collection of data from all sources and the building of users’ profiles is data processing. Initially, some preparation activities take place in order to clean the data and facilitate their manipulation. For instance, entries that do not reveal actual usage information are
removed and missing data are completed. Then follows the application of statistical and data-mining techniques in order to detect interesting patterns in the pre-processed data. The most well-known techniques that are used for data analysis include clustering, classification, association rules mining, sequential pattern discovery and prediction. A more detailed description of each technique follows.

**Clustering**

*Clustering algorithms* are used mainly for segmentation purposes. Their aim is to detect “natural” groups in data collections (e.g., customer profiles, product databases, transaction databases, etc.). They compute a measure of *similarity* in the collection in order to group together items that have similar characteristics. The items may either be users that demonstrate similar online behavior or pages that are similarly utilized by users. The produced groups (database segmentation into clusters of similar people, e.g., customers, prospects, most valuable or profitable customers, most active customers, lapsed customers, etc.) can be based on many different customer attributes (e.g., navigation behavior, buying behavior or demographics). There are several clustering algorithms available: Hierarchical Agglomerative Clustering or HAC (Rasmussen, 1992; Willett, 1988), k-means clustering (MacQueen, 1967), Self-Organizing Maps (SOMs) or Kohonen (1997).

**Classification**

The main objective of *classification algorithms* is to assign items to a set of predefined classes. These classes usually represent different user profiles and classification is performed using selected features with high discriminative ability as refers to the set of classes describing each profile. For example the profile of an active buyer can be:

- sex = male
- 30 ≤ age ≤ 40
- marital-status = single
- number-of-children = 0
- education = higher

Web Personalization for E-Marketing Intelligence

Figure 3. Classification

Association Rules

Association rules connect one or more events. The aim is to find out associations and correlations between different types of information without obvious semantic dependence. In the Web personalization domain, this method may indicate correlations between pages not directly connected and reveal previously unknown associations between groups of users with specific interests (Agrawal et al., 1993; Agrawal & Srikant, 1994; Chen et al., 1996, 1998). Such information may prove valuable for e-commerce and e-business Web sites since it can be used to improve Customer Relationship Management (CRM). Some examples of association rules are the following:

- 20% of the users that buy the book “Windows 2000” also select “Word 2000” next,
- 50% of the users who visited the “Help” pages belong to the 25-30 age group,
- 30% of the users who accessed the Web page “Special Offers” placed an online order for product “DVD – Lord of the Rings,”
• 60% of the users who ordered the book “Harry Potter” were in the 18-25 age group and lived in Athens,
• or 80% of users who accessed the Web site started from page “Products.”

Sequential Pattern Discovery

Sequential pattern discovery is an extension to the association rule mining technique, and it is used for revealing patterns of co-occurrence, thus incorporating the notion of time sequence. A pattern in this case may be a Web page or a set of pages accessed immediately after another set of pages. Examples of sequential patterns can be:

• “45% of new customers who order a mobile phone will spend more than 50 Euros using it within 30 days.”
• “Given the transactions of a customer who has not bought any products during the last three months, find all customers with a similar behavior.”

Prediction

Predictive modeling algorithms calculate scores for each customer. A score is a number that expresses the likelihood of the customer behaving in a certain way in the future. For example it answers questions such as:

• What is the possibility of a user to click on a certain banner?
• How likely is a user to re-visit the Web site in the next month?
• How many orders will be placed by customers from abroad?

These scores are calculated based on rules that are derived from examples of past customer behavior. Predictive Modeling methods include
Decision Trees, Regression Models and Neural Networks.

The prediction can be:

- **Off-line**: the decisions are pre-calculated and picked-up at the start of a repeated visit (the click-stream of the current visit is not used).
- **Online**: the current visit’s click-stream is used for decisions.

Moreover, predictive models can be used in order to decide the content to be displayed to a user (which constitutes a crucial part of CRM).

**PERSONALIZED OUTPUT**

After data processing, the extracted knowledge has to be converted into intelligent information, interaction, or interface for each customer. Every segment or cluster is a separate e-marketing opportunity that should be fulfilled differently. This section focuses on the output of e-marketing personalization: content, structure and presentation adaptations based on the constructed user, usage and environment models, as well as the resulting secondary inferences.

**Personalized Content**

This type of adaptations is applied to the informational content of a Web site. The information is filtered and then presented to the users. This can have many forms including additional or reduced information, optional explanations, recommendations, offers, special prices, products, services, news, e-mails, help, etc. The techniques used for producing such adaptations include inserting, removing, altering, sorting, coloring, dimming text fragments, using stretch-text, etc.

**Personalized Structure**

This type of adaptations relates to changes in the link structure of a Web site. It is important for the user to see only the information of interest. Here, we refer to changes that can be applied to the link structure of Web pages, sections, categories, etc., as well as to recommendations for products, services, information, navigation, etc. The techniques used for producing such adaptations are sorting,
hiding, unhiding, adding, removing, enabling, disabling, or highlighting links.

**Personalized Presentation**

This type of adaptations refers to changes that affect not the content itself, but its format and layout (e.g., from images to text, from text to audio, from video to still images) and it is mainly used for Web access through PDAs or mobile phones, or in Web sites that cater to handicapped persons.

**Recommendations**

Although recommendations belong to the personalized content output category, they are examined separately because they feature as an important component of e-commerce Web sites. Their purpose is to provide access to specific items through promotional links, such as those that are supplied by cross-selling or up-selling options.

- **Cross-selling**: it suggests products related to the one(s) the user is currently viewing. In many cases, these are complementary products. For example, proposing a music CD with a book or batteries with toys.
- **Up-selling**: it suggests products perhaps more expensive or advanced to the one(s) the user has chosen. The customer will be informed about products available in the next (upper) price level, which he/she may not have known about. The degree of applicability of this tactic depends on the type of products, and this also applies to cross-selling and up-selling as well.
- **Opinions of other customers**: it suggests additional products that the customer may also like to purchase, based on what other customers (considered as like-minded) have bought.
- **History data**: analyzing the history of past purchases (stored in a transaction database), the e-shop is able to offer customers a targeted range of choices that are most likely to fit their profile.

It is worth mentioning that the home page of a Web site is a good place to put items in order to be promoted, as it is a place that draws by default user attention. This page should be constantly updated to keep people coming back. A good Web site design should provide an option (in the administrative page) that allows the store manager to determine whether a product is to be treated as a featured product appearing on the home page, or not.

**PERSONALIZATION AND WEB-MINING**

A big part of Web personalization as we experience it nowadays is based upon the core technologies of Web mining. In fact, in this chapter we have referenced a number of Web mining techniques (clustering, classification, association rules mining, sequential pattern discovery and prediction) when discussing the phase of data processing. Web mining is broadly defined as “the use of data mining techniques for discovering and extracting information from Web documents and services and it is distinguished as Web content, structure or usage mining depending on which part of the Web is mined” (Kosala & Blockeel, 2000). It is a converging research area using techniques and methods that derive from various research fields such as: databases (DBs), information retrieval (IR), artificial intelligence (AI), as well as psychology and statistics.

The distinctions between the three main categories of Web-mining are not clear-cut. Web content mining might utilize text and links and even the profiles that are either inferred or explicitly inputted by users. The same is true for Web structure mining—it may use information about the links in addition to the link structures. Or, the traversed links can be inferred from the pages that
were requested during user sessions and can be found recorded in server logs (which is a typical Web usage mining task). In practice, the three Web-mining categories can be used in isolation or combined in an application, especially in Web content and structure mining since links may be considered as part of the content of a Web document (Chakrabarti et al., 1999). In the majority of cases, Web applications base personalization on Web usage mining, which undertakes the task of gathering and extracting all data required for constructing and maintaining user profiles according to the “logged” behavior of each user.

Web industry and researchers from diverse scientific areas have focused on various aspects of the topic. There are many research approaches and commercial tools that deliver personalized Web experiences based on business rules, Web site content and structure, as well as the user behavior monitoring. The most well-known applications of Web personalization at a research level include: Letizia (Lieberman, 1995), WebWatcher (Armstrong et al., 1995; Joachims et al., 1997), Fab (Balabanovic & Shoham, 1997), Humos/Wifs (Ambrosini et al., 1997), SiteHelper (Ngu & Wu, 1997), Personal WebWatcher (Mladenic, 1999), Let’s Browse (Lieberman et al., 1999), SpeedTracer (Wu et al., 1998), WebPersonalizer (Mobasher et al., 2000), WebSIFT (Cooley et al., 1997, 1999b; Cooley et al., 2000), Web Utilization Miner - WUM (Spiliopoulou & Faulstich, 1998; Spiliopoulou et al., 1999a, 1999b; Spiliopoulou & Pohle, 2000), MIDAS (Buchner et al., 1999), IndexFinder (Perkowitz & Etzioni, 2000b).

Moreover, many vendors provide a variety of commercial tools that support mining for Web personalization. These tools can be integrated directly into a Web site server in order to provide users with personalized experiences.

CONCLUSIONS

The explosive evolution of the information technology and the Internet has introduced enormous changes in the way marketing strategies are being
implemented. This growth was followed by problems concerning effective and efficient methods and techniques for supporting consumers and providing them with tailored Web experiences.

Personalization has the potential to be the answer and e-marketing should further focus on it. This technique can be applied on different dimensions of a general Web site marketing strategy, including: sales, advertisement, communication, customer support, etc. In this way any e-business, i.e., information portal, e-commerce site, or e-learning system can improve its performance by addressing the individual needs and preferences of each user, increasing satisfaction, promoting loyalty, and establishing one-to-one relationships.

Many research approaches, initiatives and techniques, as well as commercial tools provide Web personalization based on business rules, Web site contents and structuring, user behavior and navigational history as recorded in Web server logs.

Customers expect to be able to interact with an e-commerce site, find information and make online purchases easily and effectively. On the other hand, e-businesses expect to sell as many products and services as possible easily and cost-effectively as well. Thus, an effective e-marketing strategy should be considered from both the perspective of the customer and the e-business owner.

Specifically, from the customer’s point of view, the Web site should ensure that:

- Efficient recommendations about new products, product discounts, special offers, coupons, sweepstakes, etc., are produced and delivered.
- All second-time visitors receive personalized content to meet their needs and that this content is embedded into recommendations about additional relevant products to be purchased.
- Browsing through the products of the online catalogue is easy.
- Useful assistance is available during all steps of the shopping process.
- Customers’ time is respected and irritation is minimized.
- Customers’ individuality is respected.
- Customers are allowed to specify and modify their own profile settings.

As regards the standpoint of the e-business, the Web site should:

- Promote the products effectively.
- Maintain customer profiles. This means that the system should capture customer behavioral information from the login procedure, completed purchases, response to questionnaires, etc. The data should be updated (if not dynamically) at predefined time intervals.
- Generate consumer demographics.
- Manage navigation data.
- Analyze sales data.
- Gather statistical data.
- “Remember” and analyze everything the store needs to “know” about the customer.
- Encourage customers to “leave something of themselves behind” by multiple and “invisible” methods.
- Increase second-time purchases (in the sense that the customers should keep coming back and thus develop a sense of loyalty towards the e-store).

An open issue in the field relates to the fact that in order to fulfill its aims, personalization needs rich data about users (e.g., demographics, behaviors, structure, etc.). If the data are poor, the produced personalized output will be unsuccessful in understanding and satisfying user needs and goals.

In most cases, users are negative about revealing personal information and resist to the idea of being stereotyped. Therefore, another issue that must be taken into consideration when planning
and implementing personalization is privacy (Earp & Baumer, 2003; Kobsa & Schreck, 2003; Markellos et al., 2004). Tracking users’ behavior means collecting (potentially sensitive) information about them. Many research and commercial tools are available ensuring to some degree that privacy is not jeopardized (Cingil et al., 2000). However, if customers resist doing so, they will not be able to join the personalized segment.

Finally, a relatively recent development that is foreseen to greatly affect Web personalization is the expansion of the semantic Web. Semantic Web mining combines the two fast-developing research areas of semantic Web and Web mining with the purpose of improving Web mining by exploiting the new semantic structures in the Web. Berendt et al. (2002) gives an overview of where the two areas meet today, and sketches ways of how a closer integration could be profitable.

Summarizing, in this chapter we presented the importance of personalization for intelligent e-marketing Web site applications. We explored the different phases of the personalization process (data collection, data processing and personalization output), we demonstrated the close relation between personalization and Web mining and concluded by discussing some open issues in the field.

INTRODUCTION

Knowledge sharing in today’s distributed organizations is a challenge. Hierarchical structures may not support the fast flow of information or the efficient co-creation of knowledge from specialized and tacit individual knowledge bases (see Grant, 1996; Miles et al., 2000; Adler, 2001). There is therefore a need to devise new patterns for leveraging dispersed knowledge within organizations and across organizational borders. In the following we explore internal company weblogs as a potential new channel for sharing knowledge and expertise.

Knowledge is deeply embedded in social interaction. Recent advances in ICT have led to the production of social software, the primary purpose of which is knowledge sharing (Teigland & Wasko, 2005). One example of this is the emergence of weblogs (or blogs), personal Web pages that incorporate regular posts in reverse chronological order about a particular topic, current events or personal thoughts and expression (Blanchard, 2004; Herring et al., 2004; Wagner & Bolloju, 2005). Our focus is on internal knowledge blogs. A small proportion of blogs could be classified as knowledge blogs, implying the online equivalent of professional journals in which authors share new knowledge in their professional domains: they report on their research progress, share references and make observations (Wagner & Bolloju, 2005). However, the application of blogs in knowledge management is a new phenomenon, and firms have been slow to do so. Current research fails to promote understanding of the applicability of blogs in networked teams and organizations, and
of their role in the social processes of knowledge sharing and creation.

Thus we contribute to the emerging literature by exploring the critical factors involved in applying internal company blogs. Most studies have addressed only the rational part of mediated communication, that is, the characteristics of communication technologies and their capacity for managing and transferring information. Our aim in this article is to include the social perspective, and to provide a categorization that combines the rational-social and individual-organizational dimensions. We then report on a mini-case study in order to illustrate the identified factors. We argue that anyone wishing to exploit the potential of knowledge sharing through internal blogs should understand their nature and characteristics in order to be able to make the best possible media choices.

BACKGROUND

Knowledge Blogs

Knowledge blogs are used in internal communication for knowledge-sharing purposes (Zerfass, 2005): to promote a shared understanding of the perspectives of CEOs and employees (Dearstyne, 2005), to coordinate projects and present ideas, and to bridge the gaps between individuals with various views in order to identify new trends in innovation communities (Wagner & Bolloju, 2005). Knowledge sharing, collaboration and best practices are endemic in blogs (Ojala, 2004).

Knowledge blogs appear at the intersection of professional communication and personal reflection. They serve as an ideal medium for experts sharing an interest in a specific topic: they enable storytelling, reflection, the capturing of information, and the sharing thoughts or ideas, thus making individuals’ “hidden” processes more visible and promoting both personal and collective learning (Röll, 2004; 2006). Thus, they can offer business representatives a means for expanding the boundaries of knowledge sharing and creation (Herring et al., 2004). Blogs as a social medium facilitate the sharing of both objectified (codified) and collective knowledge (social/organizational practices and experiences).

Approaches to Computer-Mediated Communication

Theories of computer-mediated communication (CMC) have been categorized as rational or social (see Kock, 2005; Webster & Trevino, 1995). The former rely on the hypothesis of rationality and effectiveness, involving users who select the communication medium of appropriate richness and level of social presence for each task. According to the early theories regarding the effects of CMC, the “richer” the media are (i.e., the more they allow nonverbal cues, provide immediate feedback, and convey personality traits), the better suited they are to human-to-human interaction (Short et al., 1976; Daft & Lengel, 1986).

From a social perspective, alternative approaches concentrating on the applicability of CMC have emerged, including the social-influence model devised by Fulk et al. (1990), social information processing theory as developed by Walther (1996), and Lea and Spears’ (1992) theory of social identity and de-individuation (SIDE). According to the social-influence model, the technological features are not inherently decisive in the choice of communication media, but they are influenced by social-group norms and membership (Fulk et al., 1990; Markus, 1994). Walther (1996), in turn, suggests in his theory of social information processing that the “cues-filtered-out” conditions in CMC do not prevent relational communication, although social relationships take a longer time to develop in computer-mediated groups than in face-to-face groups. The SIDE theory concerns processes of social identification and self-categorization, that is, in-group and out-group membership (Lea & Spears, 1992). Attention should be paid to
these processes given that similarity with group members is believed to strengthen the individual's identity, which in turn has a positive effect on their willingness to co-operate (Kramer et al., 1996; Järvenpää & Leidner, 1999).

THE MAIN FOCUS OF THE ARTICLE

In the following we discuss the critical factors involved in applying internal knowledge blogs. Some of the issues are naturally also related to other organizational communication media, but here we assess them in the context of blog communication, its defining characteristics and patterns of use in organizations.

The Nature of Blog Communication

We strongly believe that there should be conscious media choice in both firm-internal and firm-external knowledge sharing and creation (Robert et al., 2005). In order to exploit their concrete benefits, organizations should be aware of the strengths of blogs: they offer continuity, they concentrate on one or a few topics, and they promote efficient information management, the forming of networks around specific issues, the maintenance of shared narratives and the telling of stories (Cayzer, 2004; Röll, 2004; Wagner & Bolloju, 2005). They also facilitate the building of personal identity/status and simultaneously provide users with high connectivity, thus cultivating the development of online networks. As a medium, they are time and space flexible as they do not tie the receiver to a certain place or time. They also allow the receiver to process the message until it is wholly understood, and to search for extra information to ease understanding or to evaluate content and credibility. Blogs leave a record of the issues discussed, which is an advantage in business situations, and typically offer easy access to additional resources through hyperlinks, trackbacks (reverse hyperlinks) and other recommended blogs (Cayzer, 2004; Herring et al., 2004).

High-presence media seem to set demands on us that cannot always be fulfilled as we are not able to process so much information at once. Hence, Robert et al. (2005) came to the conclusion that rich media with a high social presence may ease the exchange of simple ideas, and hinder the exchange of more complex ideas (see Markus, 1994). This would imply that blogs could be well suited to more complex information exchange, to generating ideas, developing insights, and maintaining shared narratives (Wagner & Bolloju, 2005). On the other hand, they must attract the attention of the receiver: such low-presence media can be easily ignored (see Robert et al., 2005).

Individual Motivation and Competence

To be able to contribute through mediated communication, individuals have to possess the necessary skills and knowledge (Vartiainen et al., 2003). There is also the crucial question of motivation, as contribution requires time and effort (Kimble & Li, 2005). Articulating ideas through writing and storytelling seems to be one of the major motives for blogging (Nardi et al., 2004). It is also a means of self-regulated learning: reflecting on one's own learning and simultaneously accessing others’ reflections facilitate the development of a collective understanding of a topic (Baggetun & Wasson, 2006). In general, the main reason why people attach themselves to online social networks seems to be the motive to gain access to valuable information and knowledge for their personal benefit (Wasko & Faraj, 2000). It is probably employees’ intrinsic motivations that are decisive for active participation in blogging. However, employee motivation can also be enhanced by providing interesting content in the early stages of the implementation, and encouraging the free exchange of ideas (Nardi et al., 2004; Waterson, 2005).
The Role of Technology

In general, blogs are free, lightweight and relatively easy to apply, as blogging software offers a platform for Web publishing with no need for additional tools. They are also easy to maintain. Much of the knowledge is in text form, possibly enhanced by multimedia attachments (Herring et al., 2004; Kelleher & Miller, 2006). Syndication formats such as Really Simple Syndication (RSS) and Atom allow individual and community aggregators to collect, merge and sort blogging data from the ever-growing contents of the blogosphere (Cayzer, 2004).

Organizational Policies and Support

Kock (2005) stresses the fact that social influence may affect media choice, referring to the study conducted by Markus (1994) showing that employees used e-mail at the request of managers even if they perceived it as a “poor” communication medium. Support from managers and team leaders should be valued in the implementation of internal blogs. According to Holtz (2005), it is also important for policies on employee blogging to be clearly defined: the duality between personal reflections and professional status requires explicit norms. For instance, general guidelines covering each author’s personal responsibility should be provided—blogs convey individual thoughts and interactions, not corporate communication. Blogging policies should be made explicit before the implementation phase (Dearstyne, 2005) in order to prevent misuse of confidential or proprietary information, for example.

The Critical Mass of Users

The defining feature of communication technologies is that they require a certain proportion of users, or a critical mass, and when this has been achieved their use should spread rapidly: having a critical mass allows the users to reach the largest number of people with the least effort (Markus, 1987). Blog communication provides users with high connectivity, as it is easy to form social networks of people who share similar interests. From the rational perspective, efficient communication still requires a number of bloggers who regularly post their thoughts and comment on others’ posts. On the other hand, growth in volume becomes a critical issue, as blogging networks require a balance between enough connections and the amount of information: one individual can reasonably manage only a certain number of community ties.

Organizational Culture

In order for knowledge sharing to succeed and be useful, organizations must value open-minded and non-hierarchical idea exchange (Wagner & Bolloju, 2005), and share a common ground with membership, identity and communication procedures, as the organizational culture is the binding factor for collaboration (Huq, 2005; Kimble & Li, 2005).

Kelleher and Miller (2006) considered the potential advantages of organizational blogs over Web sites in three experimental groups; they found that blogs were perceived to have a more conversational tone, which appeared as an appropriate relational maintenance strategy for virtual contexts. They also seemed to enhance identity-building and information richness through storytelling, which transfers personal and even tacit knowledge (ibid., Röll, 2004). Both personal and collective identities may be built up through blogging networks. Shared identity is critical for coordination as it lowers the costs of communication, and establishes explicit and tacit rules of coordination and influence. According to Kogut and Zander (1996), a shared identity leads to social knowledge that supports coordination, communication and learning: it implies a moral order, rules of exclusion, and norms of procedural justice. Some behavioral studies show the
critical role of group *membership* in attributing the “insiders” and “outsiders”, and also suggest that attribution could ease potential dissonance between opportunism and loyalty (ibid., Kramer et al., 1996).

**Trust**

A lack of trust may prevent knowledge sharing (Kimble & Li, 2005). In general, trust is a multi-level concept. First, it takes self-confidence to be willing to express oneself openly and to reveal one’s identity through blogging. Trust in the information and in the competence of the author(s) is also required. Knowledge has to come from a trusted source if it is to have a desirable effect on the receiver: processes of word-of-mouth are inherent in blogging (see Torio, 2005). Sufficient trust in the enabling technology is also needed, regardless of whether it is open-source software or a standardized company offering. Finally, the employee needs to be confident enough to express her/himself through blogs despite the possible threats and sanctions, such as being punished for making local information transparent organization-wide (Dearstyne, 2005).

Figure 1 summarizes the ideas presented above in terms of the social-rational and individual-organizational dimensions in applying blogs. We propose that the rationally constructed factors provide the enabling structure for communication, while the actual outcomes are determined by both the social and rational factors.

**A Mini-Case of Applying Blogs in a MultiNational Firm**

The following is a real-life story of blogs in practice in a large ICT company. The mini-case demonstrates some success factors of knowledge blogs. We conducted a one-and-a-half-hour telephone interview with four representatives of the company in order to discuss why and how an internal blog platform had been implemented. The interview was tape-recorded and transcribed. Earlier, one of the interviewees had introduced his own wiki for research purposes. The use of wikis then expanded further, and in January 2005 an internal blog platform was taken into use. Initially, the organization did not support the development work: the evolution of wikis and blogs unfolded “bottom-up.” However, later the key developer was rewarded for his efforts.

The use of blogs was minimal at first, but it expanded due to easy implementation and use, word-of-mouth inside the company, and motivated people, who also blogged in their spare time. Thus the critical mass of users was eventually reached. “People realized the value of blogs …It serves as a means of internal marketing, i.e. ‘I know about this, so you can ask me’. This, in turn, reduces internal overlap.” Bloggers are able to trust each other’s ability, as blogs efficiently convey expertise. The existence of both intrinsic and extrinsic motivations (personal status, enjoyment, access to valuable knowledge for personal benefit, getting to know who knows what) was also implied: for the individuals concerned, blogging was a means of capturing knowledge, gaining status and forming relationships within the network. On the organizational level, blogs potentially increase efficiency.

The interviewees explicitly described the differences between various communication channels and awareness of the pros and cons of blogging. Due to their highly personal nature, blogs carry an informal and conversational tone. They offer a more “human voice” than other low-presence media. On the other hand, they represent “a shout in the dark, where the echo may or may not resound…”. In this respect, e-mail was also strongly contrasted to blogging: “E-mail is a channel of power, control and information-hiding. This conflicts with the blogging culture, which is the equivalent of open-source ideology. You want to share what you know.”

Thus the various cultures in organizations may conflict with each other and form barriers to the
use of knowledge blogs. “Very often people come and ask ‘Can I write this? Who can publish it?’ The Net is still seen as it was with us, a highly official system. People do not yet understand that blogging is about bringing the informal coffee-room discussions into another kind of social space.” Again, the coin has two sides: sometimes bloggers unwittingly broadcast confidential “coffee-room wisdom” and make it available organization-wide. It is difficult to define company blog policies, and they seem to form through trial and error.

The case could be summarized as follows. The process of internal knowledge blogs was initiated by a small core group, the members of which were aware of the opportunities and challenges of blogging, and were very familiar with technology-mediated social interaction. A critical mass of users was reached due to processes of word-of-mouth and related trust, employee motivation and the easy implementation of personal blogs. On the other hand, the blogging culture is in its early stages and there is still uncertainty about its role as a medium, and about personal authority in terms of making contributions. It is also difficult to identify highly confidential issues from “knowledge to be shared.”

DISCUSSION

Theoretically, our article contributes to the increasing understanding of how technology changes the way in which people interact socially and exchange knowledge with each other in a firm-internal context. We also categorized the critical factors involved in applying knowledge blogs for internal purposes. On a practical level, we presented a mini-case to illustrate the implementation process and the related critical factors.

The role of storytelling and expressing knowledge for its further construction and refinement could be essential in the transfer of organizational knowledge (Brown & Duguid, 1991; Lave & Wenger, 1991; Brown, 2001). Blogs seem to be a potential medium to be applied in firm-internal knowledge sharing and creation in networked and virtual organizations. They are conversational, inexpensive and easy to use, they allow empowerment and the free expression of thought, and they convey expertise and contribute to building personal and collective identities. However, identity-building may also lead to exclusive types of social networks if insufficient attention is paid to developing a trust-inclusive organizational culture, offering employee education on how to use blogs, and developing related organizational policies.

FUTURE TRENDS

In the emerging field of the knowledge-management applications of blogs, the success factors discussed above should be empirically validated and refined further. More research is also needed in order to enhance understanding of blogs as socio-technological innovations. Rice (1987) argues that, while computer-mediated communication systems process information about innovations, they are also an innovation that organizations must process, a phenomenon that has recently been illustrated in the development of blog communication. However, it is apparent from our emerging understanding of the co-evolution of innovations that organizations must also consider complementary and administrative innovations, such as organizational structures and processes that support the implementation of new communication technologies.

CONCLUSION

We identified several critical factors for applying internal knowledge blogs: understanding the nature of blog communication, individual com-
competence and motivation, the role of technology, organizational policies and support, a critical mass of users, the organizational culture, and trust.

Knowledge blogs may make organizational knowledge-sharing and related social networks more transparent through their ability to build identities, mediate both personal and collective knowledge, and serve as an institutional memory. They enhance storytelling-type of knowledge-sharing, and thus contribute to the transferring of tacit knowledge in networked and virtual organizations. They also have the potential to link the informal and the formal organization, which is a major challenge for organizational innovativeness (see Dougherty & Hardy, 1996). The formal organization may enhance the application of blogs by promoting open communication and a culture of sharing, while also providing technological and managerial support.

Knowledge Blogs in Firm Internal Use

KEY TERMS

Blog (or Weblog): A personal Web page including regular posts in reverse chronological order about a particular topic (Blanchard, 2004; Herring et al., 2004; Wagner & Bolloju, 2005).

Information Richness: Refers to the ability of the media to transfer cues and provide immediate feedback (Daft & Lengel, 1986).

Knowledge Blog: A weblog for experts sharing an interest on a specific topic and for documenting knowledge in their professional domains (Wagner & Bolloju, 2005).

Knowledge Management: Refers to a range of practices organizations use to identify, distribute and leverage knowledge to gain competitive advantage.

Media Choice: Refers to the examination and selection of communication channels, that is, in terms of media richness and the level of social presence (Robert et al., 2005).

Organizational Blog: A Weblog that is endorsed by an organization and maintained by its official or semi-official representative whose affiliations to the organization are public (Kelleher & Miller, 2006).

Social Presence: The degree and type of mediated interpersonal contact and intimacy (Short et al., 1976).
ENDNOTE

According to Markus, 1994, less rich media are often used by managers for handling complex tasks.

ABSTRACT

Ubiquitous computing enables the development of new innovative applications and services. Particularly influential on future business services will be the connection of the real with the virtual world by embedding computers or smallest processors, memory chips, and sensors into the environment and into physical objects, as well as using natural, multimodal customer interaction. Bearing in mind that ubiquitous computing entails the interaction of mobile smart objects and local smart environments hosted by different service providers, we propose an open approach to encourage the development of new and innovative smart applications and services. Considering the Open Source community, we assert that such an open approach reveals innovation potentials that cannot be achieved in proprietary information system environments. Most research projects, as well as commercial initiatives, however, focus mainly on specific, proprietary applications like smart shopping environments, and do not incorporate further prospects of using an open approach. Therefore, this chapter discusses as a first step the impact of Open Innovation in a world of ubiquitous computing from an economic perspective. Then, the design of an Open Object Information Infra-
Towards Ambient Business

structure (OOII) that enables Open Innovation in the context of ubiquitous computing is presented. Finally, an innovative smart service called the Federative Library (FedLib), which represents a first instantiation of the OOII, is introduced to demonstrate the feasibility of the design.

INTRODUCTION

The connection of the real and the virtual world encourages the development of new and innovative applications and services. Google is a prominent case which distinctly underlines the creative power of combining both worlds (Roush, 2005). In June of 2005, Google released an official API for Google Maps and Google Earth. Through this, consumers and external developers now have access to detailed aerial and satellite maps and advanced geographical visualization tools that can easily be used to display data atop the Google maps. Almost immediately, a community of “geotagging” map makers was formed that ties information on the Web to geographical coordinates in order to build geospatial applications (examples of so-called “map mash-ups” can be found in Gibson, 2006). Geotagging means amplifying physical places with information so that, for instance, users of mobile devices with location technologies can retrieve additional information related to their current locations. This includes location-based ads and listings for nearby shopping, dining, entertainment, and business outlets or even photographs, videos, stories, and other personal information uploaded to the Internet and pinned to specific latitudes and longitudes. As a result, the community participates in the innovation process and in building “a browser for the earth,” as John Hanke, general manager of Google’s Keyhole Group, describes Google Earth (Roush, 2005). This could enable a new and natural means of accessing location-based information. Wade Roush (2005) describes this vision by drawing a comparison: “Every page on the Web has a location, in the form of a URL. Now every location can have a Web page [...] it means that navigating both the Web and the real geography around us is about to become a much richer experience, rife with occasions for on-the-spot education and commerce. It means that we will be able to browse the Web-and the virtual earth encompassed within it-simply by walking around.” (p. 60)

As the Google case also illustrates, opening access to information systems and intellectual property (IP) to complementors, suppliers, users, and even to competitors encourages innovation, increases the attractiveness of platforms, and enriches service provision through the incorporation of external information sources. With the world evolving from Electronic Business to ubiquitous computing (Weiser, 1991) (and pervasive computing (Hansmann, 2003) or ambient intelligence (Aarts, 2001) respectively), even more comprehensive opportunities for implementing innovation are likely to arise. Innovative information gathering and access is enabled by the connection between the real with the virtual world by embedding computers or the smallest processors, memory chips, and sensors into the environment and into physical objects (Gershenfeld, 1999), as well as using natural, multimodal user interaction (Dam, 2001).

However, existing approaches frequently rely on rather proprietary information systems that reveal their data and services only partially or under certain conditions. Bearing in mind that ubiquitous computing entails the interaction of mobile smart objects and local smart environments hosted by different service providers, we propose using an open approach to encourage the development of new and innovative smart applications and services. Considering the Open Source community, we assert that such an open approach reveals innovation potentials that cannot be achieved in proprietary information system environments. Various developers with different perceptions can then search for relevant smart
services, as well as information gathered by smart objects or environments, combine them freely, and hence create their own innovative services.

The rest of the chapter is structured as follows. The following section presents related work. Then, we first introduce our framework for ambient business. We then discuss the impact and potential of Open Innovation in a world of ambient business from an economic perspective. Next, we present the design of an architecture called the open object information infrastructure (OOII) that enables open innovation in the context of ambient business. To demonstrate the feasibility of the design, we introduce an innovative smart service called the Federative Library (FedLib) that will be the first instantiation of the OOII. The chapter concludes with a summary and further research questions.

BACKGROUND

Several authors have considered the impact on business that comes with ubiquitous computing. Most work starts with a discussion of technological progress and the business impact arising from that progress. Roussos (2006) adopts this perspective. In his view, contingencies for ubiquitous commerce arise from emerging technologies which again have an impact on business innovation, as well as on society. Similar to that view, Mattern (2005) discusses technological progress that allows deploying smart objects in an informatized world around us. Within this world, informational counterparts of everyday objects and of people induce social and political challenges and pave the way to new applications. Fleisch and Tellkamp (2006) act on this assumption and provide a framework that helps to identify value-creating application areas and discuss challenges in implementing these applications. Whereas Fleisch and Tellkamp focus on processes within a company or between companies, Fano and Gershman (2002) consider the impact that smart services will have on relationships between customers and the service provider. These relationships will be profoundly affected by new classes of services emerging in smart environments. Based on the vision that a service provider will steadily be able to access customers, they make a set of assumptions about how services will be provided in a world of ubiquitous computing.

By discussing technology, smart environments and several business aspects, the present literature gives considerable insights into how ubiquitous computing will impact future business. However, current frameworks do not even consider the potentials for innovation. For example, the German Federal Office for Information Security provides a framework to discuss the socio-economic impact of ubiquitous computing (BSI, 2006). It considers “determining factors,” “enabling technologies,” “pervasive computing features,” and “Impacts” without addressing innovation. Therefore, we propose in the following section our framework for ambient business before discussing the impact of ambient business on innovation.

THE FRAMEWORK FOR AMBIENT BUSINESS

The framework for ambient business divides the analysis of ubiquitous computing in the context of entrepreneurial activities into four perspectives (see Figure 1).

First, the emerging technologies layer focuses on advances in technology during the last few decades that allow the development of new types of IT-infrastructures. These emerging technologies present new qualities that open up new forms of IT usage covered in the smart environments layer. Thus, new applications (smart services layer) can be implemented within smart environments. Finally, the ambient business layer deals with the impact of these innovative smart services on economy, business environment, and society.
Emerging Technologies

Advances in networking as well as embedded technology, display technology, and nanotechnology have been driving the research on ubiquitous computing during recent past decades (Hilty, 2005). Smaller and more powerful, but less power-consuming, information technology has facilitated the development not only of common IT-devices. Even objects such as coffee cups (Gellersen, 1999) and pens (Anoto, 2007) can be equipped with sensors, processors, storage capacity, and actuators. The objects can be connected with each other in order to “cooperate,” thus forming joint embedded IT environments. As a result, new opportunities for applications scenarios arise.

Current progress in the layer of emerging technologies is indeed quite remarkable. An in-depth discussion of technologies, therefore, is beyond the scope of this chapter. The remainder of this chapter assumes a portfolio of technologies which designers and developers of applications and services can use as a basis for presenting technical solutions for application demands in a world of ubiquitous computing. In this context, Semantic Web (Berners-Lee, 2001) technologies are of particularly great relevance.

Smart Environments

In the second layer, the qualities of emerging technologies are explored. The role of these qualities is twofold. First, they are the means for revealing new applications and services based on the emerging technologies. Second, when analyzing the shortcomings of current applications and services, the qualities can pave the way
Towards Ambient Business

for satisfying people’s innovation needs at the emerging technologies level.

An environment equipped with an IT-infrastructure as described above is able to gather information about people, things, and other surrounding conditions. The information can be used to recognize the context in which people and things are embedded, so that the environment becomes aware of the real world. Thus, the environment is able to estimate the needs arising from the real world and to adapt itself to (mobile) users and situations (Coutaz, 2005), or may even act autonomously. The environment becomes “smart.”

Emerging technologies not only facilitate extensive information gathering, but also provide new ways to interact with users. Information access and services presented by the smart environment can be almost seamlessly integrated into the user’s world. Interfaces become natural and interaction with them subliminal. The technology even disappears from the user’s perception (Weiser, 1991; Norman, 1998; Want, 2002).

Although different qualities reveal different potential applications, the qualities of emerging technologies are not independent from each other. In fact, like the emerging technology layer, only by analyzing the interplay of different qualities and by transferring them to the application domain, can the full breadth of application potentials be revealed. Accordingly, these qualities point to smart services that may be developed on top of smart environments.

Smart Services

Merging the real and the virtual world, every relevant object in the real world acquires an informational counterpart in the form of a data object (Mattern, 2005). Thus, a service that uses this informational counterpart may know the location and condition of a physical object. Such services are already applied to ensure efficient logistic processes (Angeles, 2005) and whenever assets have to been managed. Due to the decreasing costs of corresponding technology, services will not only be offered to companies, but a vast range of services is also conceivable for individuals. Books, clothes, and CDs may be managed in a similar manner in the future. By analyzing the current and past context of an object, which comprises additional information from outside the environment, appropriate supportive services can be developed and offered through a so called smart product (Maass, 2006). Additional services may be presented for use, for example, at a medicine cabinet when the medicine runs short (Floerkemeier, 2003). Such services can also be individualized, so that they adapt to the preferences, habits, and current situation of the user (Coutaz, 2005). When services become fully aware of their context, they could be invoked automatically, without explicit manual interaction by the user (Tennenhouse, 2000).

Ambient Business

The ability of smart services to adapt themselves to situations and provide a huge amount of information instantly not only supports current business processes and distribution channels, but it also opens new ways of doing business.

Services in the application domain of supply chain and asset management reveal opportunities for monitoring tangible assets more closely and thus creating a higher degree of control. Yet, the costs of control decline at the same time. Not only high-value products, but also lower-value ones can be managed by efficiently smart services. This results in a very tight mesh of control throughout the company (Fleisch, 2005). Through means of such control, processes can be adjusted to incidents that are internal or external to the processes. This may result in more efficient and reliable processes within an organization.

Inter-organizational processes that utilize smart services may also cut costs in the supply chain. Through crossing internal company bor-
Towards Ambient Business

ders, information flows that are highly aligned with the flow of physical goods reduce losses, and control overhead that frequently occur at such borders (Strasser, 2005). Furthermore by, opening up their data base, companies are able to offer smart services to each other, for example, control and information services (Fleisch, 2005). Functions that were previously closely linked to one’s own organization can now be outsourced. It becomes feasible for companies to offer their outstanding capabilities that were previously bound to the organization to suppliers, customers, and even to competitors.

In the future, products may be provided more as a bundle of the physical product itself and the services linked to it. It may be sold as a platform for generating additional revenues by means of services in the after-sale phase. In this case, the vendor comes closer to the customer through two means. First, he is able to address a customer not only through traditional sales channels like a store. He can also address the customer at the preferred location (Fano, 2002), which may have an enormous impact on business models and sales channels. Second, information may flow in the other direction as well. Users can provide usage information to the vendor and receive special services or a monetary reward in return. The vendor can use this information to align R&D-efforts to users’ needs. Going one step further, smart services can be used to involve users in the R&D-process, whether directly or via mediators like Innocentive (Innocentive, 2007).

It can be assumed that ambient business entrepreneurs will find themselves in markets with short innovation cycles. Like the internet, smart environments follow the end-to-end principle. This principle states that the intelligence of an information system rests, that is, in the end-user-devices, not in the network (Saltzer, 1984). Someone who can exercise control as a central authority typically owns the network. In contrast, the “ends” of the network are typically in user’s control. The user is able to replace or enhance the ends and to deploy innovative applications and content. Thus, Lessig (2002) argues, systems that put the end-to-end principle into practice encourage innovation. The short innovation cycles in the internet can largely be explained by the fact that they implement this principle. Smart environments are largely considered to be built out of smart devices and, therefore, follow the end-to-end principle as well. Users of smart environments can decide what device they want to use and what smart services they should deliver. Therefore, the innovation cycles in ambient business are likely to be at least as short as in Electronic Business. Moreover, consideration must be given to the fact that smart services can be invented around all instances of our life that allow the creation of manifold potential applications. New entrants may attend to these potential applications, enter existing markets, and shift competition (Watson, 2002). Companies have to reconsider how to cope with new competitors in a high-velocity market as well as what strategies and business models to apply.

Smart environments and services that are deployed in our everyday life may have considerable social, ethical, and legal implications which also have to be considered in the business perspective. Different studies reveal corresponding potentials and perils. Positive effects can be expected throughout all activities of daily life. In particular, elderly people and handicapped persons may benefit from supportive applications and natural interfaces (Coroama, 2003). These interfaces may also close the digital divide between those with and those without access to computing facilities (BSI, 2006). Hilty et al. (2005) raises the question whether positive effects resulting from efficiency enhancements may be partially undone by side effects, that is, by increasing people’s stress level, and whether smart products may lead to pollution and health hazards. However, most concerns relate to the amount of gathered data and resulting privacy issues. History suggests that balancing companies’ benefits and customers’ privacy is
Towards Ambient Business

crucial for the success of commercial smart environments (McGinity, 2004). Bohn (2005), Hilty (2005), Bizer (2006), and BSI (2006) provide an in-depth analysis of possible perils and give hints how to balance benefits and user’s privacy. Lahlou (2003) proposes a set of privacy guidelines to cope with this challenge.

In addition to these social, ethical, and legal implications, the aim of this chapter is primarily to discuss the impact of open innovation in a world of ambient business from an economic perspective.

OPEN INNOVATION FROM AN ECONOMIC PERSPECTIVE

The idea of encouraging innovation throughout openness with regard to IS was widely discussed in the early 1980s when mainframe vendors started to restrict the use of object program and source code of formerly unrestricted software. As a countermove and in order to gain independence of the software industry, Richard Stallman (1999) propagated the idea of free software. This paradigm shift away from the conventional IP regime resulted in software that can be used, modified, and redistributed by everyone. Related movements like Open Source (Lerner, 2002; O’Reilly, 1999), Open Standards (Perens, 2006; West, 2004), Open Systems (Gabel, 1987), and Open Content (Ciffoilli, 2003; Wiley, 1999) all follow a similar idea: By modifying and recombining existing work, innovation can be collectively achieved. Thus, self-organized ecosystems of Open Innovation emerge when independent actors contribute to a product system (the product and its complementary assets). These Open Innovation ecosystems have proven that they are able to compete with companies that are reluctant to open up their systems and their IP. Software like Apache, Mozilla, and Linux has achieved a considerable market share, and Wikipedia comes close to the quality of the Encyclopaedia Britannica (Wales, 2005).

The idea of openness may contradict the common approach of value extraction of a kind of assets, that is, intellectual assets, in most societies. It is widely assumed that these assets can and should be owned by someone and hence are the IP of the creator or perhaps of the buyer. However, such IP shares the fate of most intangible assets. Once it is revealed and brought into the public domain, there is the risk that it becomes common. The creator and his competitors can use the asset to create value. The potential for the creator to differentiate his products from those of competitors is reduced. Hence, the use of the asset by competitors reduces the creator’s return on the asset (Magee, 1977). In order to ensure compensation for the creators of innovative intellectual work, legislators enact laws to protect intellectual property rights (IPR). Creators and buyers of special rights are exclusively allowed to utilize property for a certain period of time. Through these laws, intellectual work should be rewarded and innovation stimulated (Chesbrough, 2006).

The management of intellectual assets often focuses on closing up companies’ borders from the intellectual assets point of view in order to keep others from harvesting the fruit of their labor. However, legal instruments often cannot hinder third parties from gaining large shares of the profit arising from innovations: The protection mechanisms are often not enforceable. They are easy to bypass by using slight modifications of the IP in question, and this results in various forms of uncompensated adaptation (Teece, 1986). Under certain conditions, IPR can be ignored. The music and software industries are examples of this phenomenon. Thus, IPR are often not capable of protecting the owner from the exploitation of assets by others.

Closed companies’ borders may not only frustrate the aim to protect assets; in fact, they may prevent companies from gaining profit from their assets at all. R&D departments regularly create intellectual assets that cannot be utilized within the company. Procter & Gamble, for example,
estimated in 2002 that it only commercialized 10% of its patents, whereas the remaining 90% virtually gathered dust on shelves (Sakkab, 2002). Licensing may be a viable option to exploit unutilized patents (Rivette, 2000). However, potential licensees are often reluctant to adopt external technology (Chesbrough, 2006), and the legal protection of an IP is often too weak to make licensing a viable option.

Companies such as Google and Amazon turn in part away from the closed way of managing intellectual assets and appear to profit from opening up their information systems and, therefore, revealing some of their intellectual assets. As another example, IBM donated 500 patents to the Open Source community in 2005 instead of generating revenue by licensing it. Moreover, IBM spends $100 million each year in the development of Linux. IBM opens up these assets to regain a prominent role in the operating system market—a position it had lost beforehand with AIX (Chesbrough, 2006)—and is now able to use Linux as a platform to sell products and services around Linux (West, 2003).

**Drivers for Open Innovation in Ambient Business**

To reveal the drivers for making assets publicly available in a world of ubiquitous computing and the resulting potential benefits, the open approach can be discussed from a resource perspective (Barey, 1991; Penrose 1959; Wernerfelt 1984). This perspective reveals the possibilities arising from a resource exchange at the layers of the device infrastructure, the information infrastructure, and of the smart service.

Resources can be considered as tangible and intangible assets that are tied somehow semi-permanently to the firm (Wernerfelt, 1984). They compass all input factors that are needed to create value during a product life cycle. Companies can leverage the resource base to achieve a competitive advantage if these are valuable, rare, imperfectly imitable, and nonsubstitutable (Barney, 1991). As such, innovative related resources that fulfill these requirements can contribute to achieve an advantageous position in markets in which innovative products and services are valued by customers.

As argued before, in a world of ubiquitous computing, innovation life cycles may be short. From innovations in technologies and services often spring a disruptive force that leads to changes in the market environment: New innovators entering the market and unpredictable demand shifts may change the market structure. However, competitive advantage can only be achieved when the company’s resources are in line with market conditions (Eisenhardt, 2000). Yet, in the changing markets of ubiquitous computing, frequent adaptation of the resource base is necessary. On the one hand, this is a major challenge for companies in UC markets. On the other hand, this should be seen as an outstanding opportunity to gain competitive advantage through superior capabilities in resource acquisition, namely adaptation, integration and reconfiguration of internal and external resources (Teece, 1997).

However, companies may not be able to alter their resource base on their own fast enough, and necessary resources may not be available for licensing. For example, when Microsoft released Windows NT and Windows 95, Apple had to innovate in its operating system to cope with Microsoft. However, Apple was not able to alter its resource base accordingly. It, therefore, published its source code partly as an open source and allowed external programmers to contribute to the software development process (West, 2003). Following this example, opening up a company’s border and letting resources and, thus, intellectual assets pass through may be a viable strategy for acquiring new resources.
Towards Ambient Business

**Open Innovation in Ambient Business Settings**

In ambient business, diverse resources can be incorporated to enhance the innovative potential that is associated with a company’s innovation processes and the innovation potential of its products. These resources can be obtained from all stakeholders of the company’s products, especially customers, suppliers and manufacturers of complementary products, and also from competitors as well. Accordingly, a transfer can be conducted at every level of the proposed framework.

The device infrastructure builds up a smart environment and, hence, provides the foundation for smart services by gathering data and interacting with the user. Access to a device infrastructure is an essential asset for service providers. A tightly restricted and exclusive access to the IT-infrastructure through proprietary standards allows the creation of a monopoly position. This facilitates the monopolist to set rules which rivals must obey (Adams, 1982). Furthermore, the proprietary standards of the infrastructure create a barrier for new entrants because a change to another infrastructure is linked with incompatibility costs. However, providers of complementary devices and services are likely to be discouraged from using a tightly controlled IT-infrastructure (Farrell, 1985; Garud, 2002). Therefore, it may be impossible for a company that is playing the proprietary game to build up the full range of different devices of various application domains. Hence, if a company opens up its device infrastructure and relies on open standards, access to foreign innovative components may be gained by allowing them to become integrated into the company’s own infrastructure.

Garud and Kumaraswamy (1993) showed through the Sun Microsystems case how companies could improve their strategic position by implementing an open system strategy. By relying on open standards and by liberally licensing some of its own know-how, Sun attracted capable complementors that helped to improve the overall systems performance. Sun ensured its head start in competition by conducting shorter innovation cycles than its competitors.

Another strategy to ensure returns is to retreat to a certain layers of the product architecture. Layers that do not contribute to a distinctive resource base generally do not help companies to gain a competitive advantage. By opening up these layers, an unrestricted foundation for higher layers may be laid that will be further developed by external innovators. Thus, the company may concentrate on extending its distinctive resource base on an upper layer, such as developing smart services. Apple, for example, published only source code of the operation system’s lower levels. However, the Graphical User Interface and certain APIs, with which Apple can differentiate its operation system from its rivals, remained closed source (West, 2003).

As demonstrated earlier, the information infrastructure is the basis on which services are growing. It is, therefore, an important resource. The richer the information pool in terms of quality and quantity, the more services can be provided. These services will also be more reliable. For that infrastructure, the same principles apply as to the device infrastructure, since both are infrastructure layers. The information infrastructure that is available can be enhanced by opening it up and allowing other information infrastructures to interlink with it. Furthermore, companies may benefit from receding that layer and to commercialize the smart service layer. As distinct from the device infrastructure, when considering the information infrastructure, the user may play a more important role. Sensors deployed in the environment allow gathering data from a user’s context without bothering the user, who may herefore willingly contribute this information to a company’s information infrastructure assuming he trusts it. In this case, a services provider as
Towards Ambient Business

well as a user may benefit from highly customized services. The user may play a more active role when it comes to semantically enriched data. Such enrichment can only be automatically conducted in exceptional cases.

Such tasks commonly require human judgment, for instance, to decide whether the Eiffel tower is ugly or beautiful. By opening up the base data, users can be encouraged to fulfill the tasks. Amazon’s mechanical Turk is an example for a platform that brings together tasks that need human judgment to be solved and people that are willing to solve such tasks. Persons like students, housewives/husbands, and pensioners may be attracted by being paid a small amount of money (Amazon, 2007). A voluntary participation, however, may be provoked whenever the user can benefit from an enriched information pool or consider his participation as an act of self-expression. Google Earth is a prime example of users being willing to contribute to a (partly) opened database (Roush, 2005). Other motivation mechanisms exist, such a mechanism, in which the work is disguised as a game (Ahn, 2006).

One of the major challenges of innovation—and therefore of creating smart services—is bringing together need information and solution information. These two types of information cannot usually be found at one and the same site (Hippel, 1994; Thomke, 2002). As a resource, solution information encompasses all information that provides a company with the technological competence and the potential that is necessary to supply customer needs and that resides traditionally in the company’s site (Thomke, 2002; Thomke, 2003). Need information encompasses the user’s preferences and requirements with respect to new products and services (Reichwald, 2006). It is generally in the user’s domain. The innovator’s lack of need information is a critical drawback for creating smart services. Thackara (2001) states that in the current ubiquitous computing research, developers know how to create amazing things with ubiquitous computing technology, but they lack in need information. They do not know how to use their knowledge to create solutions that benefit the user. However, obtaining this information is far from easy. Need information is somewhat “sticky,” that is, it can only be conventionally revealed from potential users through costly and time consuming methods. Users often do not fully understand their needs or are not able to explicate them (Hippel, 1994). Smart environments can help to overcome this problem by studying contextual data gained from the user. Thus, it may be able to observe how a user behaves in using a smart service, which problems he encounters and what needs may remain unfulfilled.

Another way to overcome the problem is suggested by von Hippel (Hippel, 2002, 2005). By outsourcing need-related tasks to users, the problem of how to directly acquire sticky need information can be avoided. Thus, the user handles a task, which the company formally conducted, and returns a solution he is satisfied with. This solution is commonly less sticky than the need information itself. However, to fulfill the task, the user needs relevant solution-information that sticks with the company. Here, the company partly opens up its information pool by providing a design tool, called toolkit, to the user. This toolkit implements the company’s solution information, which is provided in such a manner that the user can handle it easily. Smart Environment may broaden the facility of toolkits. Sophisticated toolkits may be able to be provided to the user at that point where his need generally occurs. Multimodal interfaces (Dam, 2001) may facilitate a richer interaction with the toolkit and, thus, allow solving complex tasks. Tangible interfaces can be used to let the user not only interact by “mediating” devices such as keyboard, mouse, and display, but to directly manipulate physical objects (Sharlin, 2004). An example of such a tangible interface is the “illuminating clay” from Piper et al. (2002). The computing system is able to gather the form of the clay the user works with and is able to augment it with additional informa-
Towards Ambient Business

The embedding of computers or smallest processors, memory chips, and sensors into physical objects, referred to as smart objects, constitutes a step toward connecting the real with the virtual world. Other examples are sensor networks—smallest sensors introduced into the environment, forming ad-hoc networks in order to recognize, for example, the whereabouts, speed, size, and form of objects and to observe them over a period of time (Culler, 2004). Sensors may perform an important role in the context of managing object information. This is particularly true for the use of sensors which permit a clear identification of smart objects by remote enquiry. With the assistance of Radio Frequency Identification (RFID), objects are identified automatically without line of sight, by transponders which are attached to them (Finkenzeller, 2003).

It has to be taken into account that the information content of sensor data is rather limited. Hence, the data must be gathered and formed into usable events by means of appropriate filter and aggregation procedures. Numerous projects for the development of suitable middleware have already commenced, but focus primarily on integration of sensor data in closed, business-related applications or communication between smart objects (for an overview of selected projects, see Henrickson, 2006 and Schoch, 2005). Most projects, however, ignore the further use of the information in other contexts or by external developers.

Ensuring the utilization of gathered data for external developers requires extending existing middleware technologies with mechanisms for the semantic markup of sensor data. Semantic Web standards such as Topic Maps (Durusau, 2006; Garshol, 2006; Pepper, 2001;), or RDF(S)/OWL...
Figure 2. The open object information infrastructure (OOII)
Towards Ambient Business

(Brickley, 2004; McGuinness, 2004) can be employed for this purpose. Several middleware technologies have already been extended with mechanisms for the semantic markup of sensor data. SOAM (Smart Object Awareness and Adaptation Model) (Vazquez, 2006) is one initial approach. SOAM is a smart environment reactivity model in which user preferences are formalized using the Standard Ontology for Ubiquitous and Pervasive Applications (SOUPA) (Chen, 2005). These preferences lead to adaptation on smart objects without explicit user intervention, because of the use of automatic, semantic reasoning with respect to the environmental conditions.

An extended version of this ontology is also used by the Context Broker Architecture (CoBrA) (Chen, 2005). This is a broker-centric agent architecture for supporting context-aware systems in smart meeting rooms. The project goal is to create a meeting room that can facilitate typical activities as setting up presentations (allowing users to control services via speech), or adjusting lighting and background music in a room in a manner that is tailored for the specific meeting.

Even if these projects incorporate semantic technologies, they do not consider the reuse of their smart environments within external smart services. Nevertheless, they could be suitable for application within the OOII, as they enable the combination of ubiquitously gathered information with additional semantically-enriched information provided, for example, by the Semantic Web.

Building Up Open Information

In developing smart environments, the large number of smart objects must be taken into account. Additionally, the prevailing energy and capacity limitations of embedded computers and sensors make it necessary to save accompanying virtual data objects and to process information on additional network nodes which have sufficient memory capacity and computer power. These prerequisites advise the implementation of peer-to-peer (P2P) networks that offer better scalability and a self-organized and decentralized coordination of unused or limited resources, compared to the alternative client/server architecture (Barkai, 2001; Milojicic, 2002; Oram, 2001; Schoder 2003). Other characteristics, including a higher fault tolerance and a more effective support of spontaneous networking of entities, may be advantageous as well, because no continuous connection can be ensured for smart objects, due to their mobility.

In order to enable Open Innovation, arbitrary access to the stored semantically enriched object information must be ensured for external developers. As the Napster case revealed, central approaches tend to limit access to the information offered or even deny it completely. However, P2P projects like Freenet (Clarke, 2000) and Free Haven (Dingledine, 2000) have demonstrated how an anonymous and censor-free information access can be made possible. Using P2P networks for storing and retrieving semantically enriched information requires an extension of possibilities to pose semantic queries. On the one hand, scientific research is pursuing scheme-based approaches, and, on the other hand, ontologies or P2P Semantic Web services are applied (for an overview of selected projects, see Staab, 2006).

Using semantic query facilities, various developers with different perceptions can search for relevant (object) information, combine the information freely, and, hence, create innovative services (as indicated in Figure 2). For example, information about the speed of vehicles (low speed for a number of cars) combined with their actual location (they are all in a certain area) and additional information (a road map) might indicate that they are stuck in a traffic jam on a highway. This information could then be provided to others as a traffic-information service. In order to facilitate even the reuse of this new smart service, the service has to be specified semantically and published in the OOII. Subsequently, other developers can reuse this service (and the con-

connected smart environments and objects), combine services with information gathered by another local sensor network (the outdoor temperature in a certain area is below zero), and set up a warning system (you are traveling to a snowy area—do not forget your snow chains).

In order to discover and integrate semantically enriched information, a number of semantic web services (Alesso, 2004; Fensel, 2002) and smart agents (Konnerth, 2006; Lee, 2005) have been developed. However, these projects mainly solve negotiation problems with respect to a common understanding of certain application contexts. The user-oriented framework of Task Computing (Masuoka, 2004) is a promising approach in the context of ubiquitous computing. It uses the Task Computing Environment Object Ontology (TCE, 2004) and is designed to operate dynamic ubiquitous environments in which a mobile computing user dynamically discovers the current set of available semantically defined services (Song, 2004). The end-user can easily and seamlessly integrate and manipulate services found on their own computer, the nearby devices and relevant remote Web services. However, Ben Mokhtar et al. (2006) claim that even this opportunity, or need to select the right composition among all the possible compositions suggested to the user, presents a major drawback of this framework. Accordingly, they developed a COnversation-based service Composition middleware (COCOA) that minimizes the necessary user interaction by enabling the automatic and transparent deployment and execution of user tasks.

Nevertheless, these approaches are limited to the discovery of smart services within smart environments in order to improve user interaction. They do not address global service discovery as needed within our OOI. METEO-S WDSI (Verma, 2005) and GloServ (Arabshian, 2005) are approaches that perform global service discovery through the use of P2P networks. METEO-S WDSI presents a scalable environment for Web service publication and discovery among multiple registries in general. It uses an ontology-based approach to organize registries into domains and enable domain based classification of all Web services. Each of these registries supports semantic publication and the discovery of Web services. GloServ is a global service discovery architecture that can be used to build a distributed context-aware service discovery system related to pervasive computing scenarios (Arabshian, 2006). Currently, we examine which one of these approaches would be applicable within the OOI.

Building Up Smart Services

Based on Open Information, innovative services can be developed. The Federative Library (FedLib) represents one first instantiation of our OOI (see Figure 3) and demonstrates the feasibility of the design. The FedLib is a library service for work groups that functions without the need for collecting books at a centralized location. In fact, the collection is held by the participants themselves. Book owners decide about making their books available for use by others. Thus, originally exclusive private collections of books that are common in organizations could be opened up to other would-be readers.

The pilot implementation of the FedLib will be realized within the Department of Information Systems and Information Management and includes our own office rooms and books, as well as books from the faculty library. We already built up the necessary smart environment and started to extend a reference information manager to the corresponding search-client in order to integrate the smart service into the daily workflow of a research assistant. Besides building up the smart environment, we focus on reviewing existing technology for further use within the FedLib and OOI.

Implementing the smart environment of the FedLib, bookshelves and doors of our office rooms are equipped with RFID readers (see Figure 4). Books labeled with RFID tags are distributed in the
