participants’ offices. In order to enable ubiquitous information gathering about the presence of books, the detection of a book’s current location must be combined with former “reads” to corresponding events. For instance, when the system detects a book at the door reader in Office 1, information must be available as to whether the book is leaving or entering the office. It is leaving if the book was previously detected on the bookshelf in Office 1. It is entering if the book was previously located at the door reader in Office 2.

By aggregating these semantically enriched events with additional information about the occupant of each office, the FedLib can track and allocate books automatically in terms of the current borrower. This minimizes administrative overhead, due to the ubiquitous integration of processes in the daily workflow of the research assistants. It therefore becomes possible to borrow books by collecting them directly from a colleague’s shelf, taking them to one’s own office, and placing them at the table there. In order to return a book, it can simply be put back on one’s own bookshelf. During that natural interaction with the Federative Library, the location and status of the book changes according to the events occurring (numbered 1 to 5 in Figure 4). In order to integrate even the management and the retrieval of books into the daily work of a research assistant, the corresponding search-client is integrated in a reference information manager. Furthermore, services like Amazon’s Web Service (Levitt, 2005) and special semantically-annotated resources produced by Semblogging (Cayzer, 2004), are suitable for integration into the manager in order to provide additional useful information.

CONCLUSION

Previous research and the movement towards openness suggest that an opening of information systems may reveal new contingencies for innovation. In order to analyze these contingencies in a world of ubiquitous computing, we applied the framework of ambient business. We showed that
Opening up smart environments as well as smart services, reveals potentials for innovative services that can be created by external developers. Thus, the innovative strength of companies that act in open systems cannot be achieved by those that rely on rather proprietary information systems. However, most contemporary projects ignore the further use of the information in other contexts or by external developers.

By designing the Open Object Information Infrastructure, we showed how to open up ubiquitous computing systems. Within this infrastructure, information pools that emerge from smart devices are connected by existing Semantic Web standards. This allows developers to search for and combine information they need, create innovative services, and reuse and combine them in an innovative manner. By introducing the first instantiation of the OOII, we demonstrated the feasibility of our design. The Federated Library combines information from decentralized objects and external services to an innovative library services that cannot be realized in closed environments.

However, the open approach is not only applicable from the technological point of view. Economic rationality can argue similarly in favor of opening information systems and thus companies’ intangible assets. In some instances, property rights cannot fulfill their aim of fostering innovation, but in fact encumber a further development that builds up on the protected assets. Therefore, in terms of economic and social welfare, the guarantee to freely use innovation as well as the incentive to commercialize innovations has to be perfectly balanced.

Additionally, a cross-border flow of intellectual resources can be beneficial. In high-velocity markets as can be expected in ambient business, the alignment of company resources to the corresponding market becomes critical. In particular, innovation-related resources have to cope with market developments. Opening up the company’s borders can be a strategy for acquiring external innovation-related resources and, therefore, a head start in competition with closed innovators.

**FUTURE RESEARCH DIRECTIONS**

Questions arise regarding the willingness of market players to adopt the idea of Open Innovation. First, open smart environments may infringe privacy. Consequently, we may ask what information a user considers private and in what situations. What information should, therefore, not be freely available to service providers? How should laws be formulated in a world in which information is freely exchanged? The first studies have already appeared which analyze the dangers associated with the emergence of ubiquitous computing (Hilty, 2005; Bizer, 2006; BSI, 2006), but they are only the first steps towards answering the core questions.

Likewise, companies must consider which resources and information should be allowed to cross their borders. Sophisticated strategies have to be implemented to ensure the appropriability and, therefore, the return on the innovations. Thus, a manager may ask what products and resources should be opened and to what extent. What are the company’s distinct resources that have to be maintained inside the company? What kind of resources can be utilized more effectively outside? Control of the resource transfer must be established.

Furthermore, organizational structures and processes have to be adapted to facilitate the adaptation of external resources, and employees have to be trained to interact with external stakeholders. Moreover, external innovators have to be attracted. When increasingly more companies try to harness users’ resources and creative power, how will the users react? Will their attention and time become a limited resource so that companies have to compete for it?

Chapter 6.15
Successes and Failures of SAP Implementation: A Learning Perspective

Tanya Bondarouk
University of Twente, The Netherlands

Maarten van Riemsdijk
University of Twente, The Netherlands

ABSTRACT

In this article, we conceptualize the implementation process associated with SAP_HR as an experiential learning one (Kolb, 1984), and analyze qualitative data collected during discourse analysis during a six-month case study. We saw that a lack of communication plus misunderstandings between the different parties involved in the project led to mistakes in working with the system. However, with encouragement from the “top” to improve learning, working with the system became easier for the whole group involved and for the individual users. Although Kolb’s theory is widely acknowledged by academics as a fundamental concept that contributes towards our understanding of human behavior, we propose another use: to consider this theory in association with an IT implementation strategy to identify the mechanism of IT adoption in an organization.

INTRODUCTION

This article is about the implementation of information technology (IT). Although this topic has been debated for several decades, the practical arena is still confronted with the so-called “go-live” problems with IT projects being less successful than predicted.

It is widely recognized that “go-live” IT use often develops in a different way than that in the plans made, and that the degree to which the use of a technology corresponds to the anticipated rules and norms can vary considerably, depending on the organizational context, the type of
IT, and the end users’ awareness of the system. (Arkich, 1992; Bardram, 1998; Bikson & Eveland, 1996; Ciborra, 1996; DeSanctis & Poole, 1994; Orlikowski, 1996).

There has been much research with consequent recommendations on how to introduce a new IT to employees in order to minimize or avoid troubles during IT projects. However, IT introductions are still known to be time consuming, indirect, and sometimes impulsive developments, leading to a mismatch between the initial ideas behind the information technology, and its real use seen through the employees’ perceptions and experiences.

So, why have we apparently learned so little from IT failures? There are two popular reasons. It is argued that traditional IT research, focused as it is on IT implementation factors, has failed to identify the true causes of failure (Sauer, 1999). Perhaps, the traditional factors and processes considered are symptoms of, rather than the reasons for, the failure and, if so, attacking the symptoms will not cure the disease. The other popular possible reason is that even if the identified failure factors are the causes of the IT failure, they are not easy to avoid (Kling, 1987). Arguably there is a third possibility: that the traditional studies do not mirror the interactive, complex reality of the IT implementation process in which users are involved.

Given this situation, this article proposes to look at IT implementation from an interactive prospective, focusing on the collaborations among users while working with the newly introduced technology. Almost all modern technologies have networked, or collaborative, fragments, and users are engaged in common tasks through these “fragments.” With the rise of wireless, mobile, and Internet technologies on the one hand, and with integrated office environments on the other, organizations are increasing their demands for cooperative working. Cooperative “fragments” can often be recognized in various work situations ranging from document sharing, cross-functional and cross-departmental projects, to incidental correspondence between employees linked by a given task. Stand-alone computers nowadays are generally used only for trials and experiments in organizations, the most common situation sees workstations hooked up to an organizational network.

Fundamentally, users communicate with one another when using IT. The communications during an IT implementation project reflect a situation in which groups of users are developing a common understanding of the technology they are forced to (or want to) use through learning processes amongst themselves.

The importance of several aspects of learning within collaborative settings has been seen in various IT studies:

- Changes in technology may lead to changes in various aspects of professional competency such as knowledge, skills, and attitudes. These, in turn, can influence the ongoing use of the system. Hence, in theory, there is an ongoing process of professional and technological development which is referred to as a learning process by Neilson (1997).
- User groups have to adapt to a novel way of working when a new technology is introduced. Adaptive structuration theory has shown that not all groups do this in the same manner, and the adoption process, referred to as “appropriation,” depends on the group processes and the way in which people interact with one another (DeSanctis & Poole, 1994; Hettinga, 2002; Ruel, 2001).
- In the “extended version” of the structural perspective, Orlikowski (2000) proposes looking at “communication, mutual coordination, and storytelling” as important determining sources for engagement with the system (p.411).

Although some “feeling” for the topic now exists, and recent research has emphasized the
importance of certain elements of learning for IT implementation, systematic insights are still lacking. In this article, we propose a new view on IT implementation; one that considers the learning processes as the key factor in “getting used” to a new system. To the end, we strive to answer the question as to the role of group learning in the IT implementation process, and to illustrate our answer with findings from a longitudinal case study.

In the following sections, we first briefly present the basics of learning, and especially of experiential learning, in IT implementation. We then discuss the research methodology, followed by the empirical results from a longitudinal case study in a Dutch university.

LEARNING AND IT IMPLEMENTATION

An examination of existing studies has revealed that there is little theoretical or empirical research with a particular focus on the role of learning in explaining and resolving the problems of implementing and using information technologies in organizations. The emerging studies that do attempt to address both organizational learning and information technology consider learning as an alternative antidote to the organizational struggles associated with IT (Robey, Boudreau & Rose, 2000).

The current view of the link between “learning” and “IT implementation” in the literature can be seen as two-fold: as formal training as a way to overcome knowledge barriers, and through the role of experience in IT implementation.

Literature on formal training in IT implementation usually focuses on the individual level and deals directly or indirectly with overcoming barriers to acquiring new knowledge in IT use.

The second, and the major, literature stream on learning and IT implementation results from research on experience-based organizational learning. There is strong evidence suggesting that an organization’s own experiences provide a knowledge base which guides future actions. Case study literature provides greater detail on the role of experience in IT implementation: some offer evidence of the benefits of experience in achieving a successful implementation (Caron, Jarvenpaa & Stoddard, 1994; Yetton, Johnston & Craig, 1994); while others illustrate the difficulties of learning from experience (Ang, Thong & Yap, 1997; Robey & Newman, 1996).

However, the reported studies do not discuss instances where organizations fail to learn from their own experiences. Another limitation is that the authors do not discuss the “competition” between recent and earlier events as sources of experience. How can an organization adapt an old experience to a new situation? Clearly, learning from experience is more complex than simply adjusting current actions based on previous outcomes. What are the common key issues and processes in experience-based organizational learning? How can one transfer conclusions from an IT experience in one company to another, and is this even necessary? Finally, when and where are the lessons applied and really learned? Such questions remain unanswered in the existing studies.

Organizational Learning

Before introducing our concept, we briefly discuss the main issues associated with organizational learning. This is presented in the literature as a combination of two different approaches: learning as an outcome or “intended product,” and learning as a process. For example, Agyris and Schön (1978) define learning as a process of detecting and correcting error. Kolb (1984) stresses the importance of the transformation of human experience (the process) that leads to new knowledge (the result). It is also recognized that an outcome of the learning process could be a more experienced person, one who might have
a changed self-concept (Jarvis, 1987). Marsick (1987) focuses on learning as acquisition, interpretation, or assimilation of information, skills, and feelings. The learning-as-object approach is still influential. However, of late, there has been an increasing emphasis on learning-as-process (Gourlay, 2006; Tsoukas & Vladimirou, 2001; Walsham, 2005). Learning is increasingly being seen as a process of drawing “distinctions within a collective domain of action, based on appreciation of context or theory” (Tsoukas and Vladimirou, 2001, p. 979). Learning is further considered to take place only within communities, where human performance is articulated through social interaction (Walsham, 2005, p. 10).

This article focuses on the dynamic acting-interpreting learning that is “deeply involved in human processes of communication, and which cannot be divorced from the context” (Walsham, 2005, p. 7).

In this study, in an attempt to bring learning into IT implementation, we define learning as all the interactional processes through which users develop their understanding of a newly introduced technology and that helps them to implement it.

**Experience-Based Learning**

Within learning-as-process concepts, a further refinement is made in the direction of experiential learning (Kolb, 1984) in which the concept of “experience” is central. This provides an opportunity to “begin” the learning process only after the employees get a new technology and start working with it; that is when they gain “experience.”

Learning involves the interplay between two interdependent dimensions of knowledge: acquisition and transformation. Knowledge acquisition requires an individual to resolve the tension between apprehension (concrete experience) and comprehension (abstract conceptualization). Apprehension requires an individual to accept new knowledge through direct experience with the world (feelings and emotions). In contrast, comprehension occurs when an individual obtains knowledge through abstract concepts; in other words, when a person breaks down experience into meaningful events.

Transformation is another dimension of knowledge with a dialectical tension: between intention (reflective observation) and extension (active experimentation). During knowledge intention, a person learns by reflecting upon previously acquired knowledge. In contrast, learning by extension requires an individual to interact with an external environment.

In responding to the dialectical tensions of knowledge, individuals orchestrate their way around the cycle in a continuous process of interactions between personal and environmental demands (Kayes, 2002).

The learning cycle begins when one experiences the world through one’s actions of “doing” (Dixon, 1994). This immediate, concrete experience is the basis for the next stage of “reflecting,” which allows us to learn from our experiences. Observations are assimilated into a theory that makes sense of what we have experienced. The third step is abstract conceptualization, or “thinking.” The final phase is “deciding,” and actively testing the concepts that have been created from a real world experience. Following the fourth step, new implications leading to concrete action can be developed. Thus, one continually cycles through a process of collecting experiences, or a set of conceptualizations (Swieringa & Wierdsma, 1994).

Although there are other models of experiential learning, Kolb’s theory continues to attract attention because of its completeness and generalizability. Since 1971, over 1,500 studies, refereed articles, dissertations, and papers have reflected the work of Kolb, and provided insights into a broad range of learning processes (Kayes, 2002). The basic “wheel” has appeared

Kayes (2002) noted that Kolb had outlined the relationship between individual and social knowledge:

Apprehension of experience is a personal subjective process that cannot be known by others except by the communication to them of the comprehensions that we use to describe our immediate experience... From this it follows that there are two kinds of knowledge: personal knowledge, the combination of my direct apprehensions of experience and comprehensions I use to explain this experience; and social knowledge, the independent, socially and culturally transmitted network of words, symbols and images that is based solely on comprehension. (Kolb, 1984, p.105)

If we understand learning as changing knowledge and behavior through actions with IT, then we should acknowledge the importance of social experience and context in learning (Barrett, Cappleman, Shob & Walsham, 2004; Thompson & Walsham, 2004; Tsoukas & Vladimirou, 2001), and therefore also the importance of interactions among individuals.

**IT Implementation as Experiential Learning**

Although Kolb’s theory is widely acknowledged by academics as a fundamental concept that contributes toward our understanding of human behavior, we propose another view: to see Kolb’s theory as reflecting a kind of IT implementation strategy and suggesting a mechanism for IT adoption in organizations.

Learning begins with the experiences and actions of the targeted employees when a new IT is introduced. It is likely they will have to start operating with the system in order to execute their tasks. This process can develop from operating with the basic system modules in performing their everyday tasks through to searching for new techniques and possibilities present in the system (West, 2000).

The next activity in the learning cycle is reflection and this can occur at various points: after carrying out a few operations with the system, later during implementation, but also even before the system’s introduction as future users discuss technology design issues. Discussions, open dialogue, focus groups, and meetings with a project team might well focus on speaking out about difficulties or perceived difficulties in using the system. Users might express doubts and suspicions, or trust and belief in the existing ways of solving IT-related difficulties, consider the possible reasons for, and the outcomes of, mistakes made when operating the system, or discuss errors that occur in working with various IT functionalities (Schippers, 2003; Stahl, 2000; Tucker, Edmondson & Spear, 2001).

The conceptualization process may also take on a great variety of forms, but will always lead to a shared interpretation of the system among the users (Mulder, Swaak & Kessels, 2002). They will share their understandings of the role of IT in the company and its intentions towards every member of the group, as well as the design.
intentions of the system’s developers (Nelson & Cooprider, 1996; Hendriks, 1999).

Planning, when initiated by the users, aims to establish agreements on improving the use of the system. Employees may take the initiative to arrange additional training sessions, develop further instructions or manuals, or carry out other related activities. Developing policies in order to improve the use of a technology can become a crucial issue, especially if the users have never worked as a group before. For example, this might involve establishing responsibilities for making inputs and schedules for producing outputs. Decisions may also be made about the sorts of documents that should be submitted to the system, or about data traffic and classification (Hettinga, 2002).

We would emphasize that we do not see these steps as necessarily taking place in this order. However, the breakdown of the process into these steps is a logical one, and helps to understand the learning processes.

RESEARCH METHODOLOGY

Having conceptualized IT implementation as experiential learning, we should next justify the choice for interpretive research methods in this study. Firstly, an interpretive view corresponds fully with the theory of learning that we applied to IT implementation. It represents the idea that learners—the users of the technology—do not accept “the truth” about the IT as offered by the managers and project leaders, but actively construct their own views of it through their own experiences. Secondly, when talking about users’ interpretations of a technology, these are seen as reflecting the nonstatic and repeated developments in their communications towards understanding and using a system.

A case study was conducted in order to provide examples to support (or contradict) the theoretical discussion on the implementation of IT as learning, and to clarify the contents of the learning processes. We did not set strict criteria for the company to be involved in this project, but it was important that it had a recently introduced information technology. In terms of the unit of analysis, the investigation focused on the end users within an IT project. The case study techniques, that is, the research instruments, strived to build a platform for interpretive analysis and included document analysis, interviews, and participatory observations.

Collecting Empirical Data

We carried out a six-month case study in a Dutch university that was in the process of introducing SAP_HR. Data was collected using qualitative methods: semi-structured interviews, observations, and document analysis. The 24 interviews each lasted from one to 1 ½ hours. Five university HRM units were investigated in the research: the Service Centre HRM (SC_HRM), the Faculty of Social Sciences HRM (SS_HRM), the Faculty of Arts HRM (A_HRM), the Faculty of Geographical Sciences HRM (GS_HRM), and the Veterinary Laboratory HRM (AL_HRM).

Representatives of three groups of SAP_HR users were interviewed:

• Five employees involved in steering the project in the university, referred to here as project team members. They provided support for end users, carried out help-desk duties, maintained the functional and technical administration of the system, and analyzed on-going use of the system.

• Four leaders from the various faculties’ HRM departments who were responsible for the personnel policy and administration. These were not active end users of the system themselves, but SAP implementation did bring changes to their departments.

• Fifteen end users: four salary administrators from the central Salary Department and eleven HR specialists from five HRM
departments, including five key users who were seen as advanced users of the SAP_HR system. In this way we interviewed HRM specialists whose daily tasks had to be performed through the system.

The questions put during the interviews were in line with the operationalization shown in Table 1.

Transcripts of the interviews were checked and corrected by the respondents involved. Additional information was obtained during informal conversations and through participating in key-user meetings. We also studied relevant documents, namely, the Development Plan of the University “Perspectief2010,” the Project Plan and the Fit/Gap Analysis for the SAP_HR implementation, the plan for the SAP_HR pilot implementation, reports and notes from key-user meetings (04.02.2003, 18.02.2003, 04.03.2003), a special issue of the university newspaper (N26, 2001/02), plus the main manual and 36 sub-manuals covering the use of SAP_HR for the University.

Data Analysis

The collected data were analyzed using discourse analysis. Our primary concern was the social context of the technology use and the discourse that supported it. We distinguished four steps in our interpretation of the data (Van Dijk, 1997; Oevermann, 1996; Titscher, Meyer, Wodak & Vetter, 2000).

The first step involved gaining an overall impression of the views presented in the interviews and linking this to the context that was derived from the documents and observations. Knowledge of the context was crucial in order to understand and feel the implementation of SAP_HR. The second step aimed to describe the learning processes on the basis of text units from the interview transcripts. To achieve this, we had to distinguish and codify the text units from all the interview transcripts on the basis of our operationalization scheme. We used a qualitative approach along the lines indicated in the operationalization scheme (“strong – weak,” “high – low,” etc.).

Table 1. Operationalization of IT implementation as a learning process

<table>
<thead>
<tr>
<th>Learning Dimensions / Range</th>
<th>Components</th>
</tr>
</thead>
</table>
| 1. Learning as acting: task-related operations undertaken with the system by users/ Active - Passive | • operating with basic modules in performing everyday tasks
• searching for new techniques in the system |
| 2. Learning as reflecting: communicating upon the extent to which the system supports task performance/ Strong - Weak | • discussing difficulties in using the system
• comparing with other software experiences
• declaring individual problems in using the system |
| 3. Learning as conceptualizing: the level of common meaning of the system regarding its role and functionality/ High - Low | • clarity about the purpose of the system
• understanding the operation of the modules in the system
• attitudes towards system functionality |
| 4. Learning as planning: activities that aim to reach agreements on on-going use of the system / Strong - Weak | • arranging additional learning activities to improve use of the system
• developing policies
• evaluating intermediate results |
Next, the third step involved identifying the significance and linguistic representation of each text unit. We wanted to reveal a range of semantic features such as vagueness of opinions, doubts, clarity, and hidden meanings, but also the factual representation of the text units for each component. Finally, the fourth step involved refining our conclusions.

**FINDINGS: CONTEXT OF SAP_HR IMPLEMENTATION**

**Background of the SAP_HR Project**

The university had a long history as a knowledge center in the fields of scientific research and higher education. Today, it is one of the largest institutions in the Netherlands, with more than 23,000 students, and 7,000 employees. It has 18 schools and 15 support and administrative units.

By 1994, most of the faculties in the university were using a COMI-P personnel information system that was becoming outdated. The supplier no longer guaranteed updates or further development of COMI-P, and therefore there was felt a need to look for a new personnel IT system. In 1998, the directors of the faculties and other services determined the functional demands for the new system, which had to meet the following basic requirements:

- To have the ability to be integrated with the existing financial and salary administration software packages;
- to have clear and well-designed functionalities in the standard version; and
- to be easily adopted and implemented in the university environment.

On the basis of these specifications, the University Board made the decision in November 2000 to purchase the SAP_HR personnel management system. At that point, the university was already using SAP_Financial, the financial module from SAP®. In choosing SAP_HR, the organization hoped for a painless implementation trajectory based on their existing experience with SAP_Financial, and expected to achieve an easy match between their HR and financial administrations.

**The SAP_HR Introduction in the University**

In the annual university report on IT (2002), under the heading “Administration and IT” one can read the following statement:

*The implementation of the personnel module within the SAP system reveals more outset problems than was expected, especially in management information reports and matching with the salary administration system.*

Problems in matching with the salary administration system” in fact meant delays, mistakes, and other difficulties in the payment of salaries. The university’s weekly newspaper published a small article that highlighted such problems (dated 14 March 2002, # 26):

*Tens of employees have got less salary than they should have... Especially those who had any changes in their contracts since 1 January 2002 and those who had multiple short-term contracts. On the other hand, those employees whose contracts expired on the 1st of January 2002 continued to be paid... According to the project team, the origins of the problems are too complex.*

A historical account of the SAP_HR implementation project is given below.

In December 2000, the university started searching for a consultancy firm to help with the
Successes and Failures of SAP Implementation

In April 2001, a consultancy firm was chosen on the basis of its experience with both SAP® and IPA technologies.

The period April through December 2001 was expected to see a “fast implementation” of SAP_HR. The steering group looked for discrepancies between SAP_HR and the existing systems. Six project groups worked on different aspects of the implementation: realization, salary/IPA, acceptance, technique, conversion, and training.

One unforeseen event which interfered with the project was that the expert from the consultancy firm who specialized in developing an interface with the IPA external salary system left the project. In October 2001, pilots took place in four units: the faculties of biology, pharmacy, and chemistry, and the P&O Service Centre. During November and December 2001, all the future users of the system took training courses. Preparation was carried out on technical issues such as conversion and transportation.

On January 1st 2002, SAP_HR was introduced in 12 faculties and in all the support and administrative services in the university. Two faculties refused SAP_HR, and kept their old personnel systems. In the opinions of the users, the introduction date for the new system was not ideal since it coincided with the introduction of a new Collective Agreement for the Dutch Universities (which had to be processed through personnel administration). Further, some units were restructured requiring further new paperwork.

Documents show that an evaluation of the implementation was already scheduled for March through April 2002, that is, three to four months after the SAP_HR introduction. However, shortly after the introduction, and continuing through to the summer of 2002, unexpected difficulties arose related to inputs and outputs to SAP_HR, and with sending data to the external IPA salary system.

The extent of the drama during the first 7 to 8 months was expressed in various ways. For example, we heard of about 3,000 mistakes being registered in the database with only a third being resolved, 450 e-mails in 6 months from the users reporting problems, 75 “crucial” problems that had to be resolved, 10-20 technical changes/improvements per day, and finally about 300-400 university employees who experienced problems in getting their salaries.

The first months were really terrible. We made inputs in accordance with our experiences and the knowledge we got from the course, but most of the time there were mistakes, and IPA rejected the data. As a result, employees did not get their salary. Sometimes this went on for some months. Mistakes could be very simple and unexpected, but they took a long time to identify. (Roy, A_P&O)

Now I am sure—if they want to do something like this again in the same way—I am leaving. I really mean that! It was just one big disaster from the beginning. People did not get any income for three months. It was terrible and unclear who was responsible for what. Many HRM specialists became sick…. (Erik, SS_P&O)

We did not observe a “happy ending” to the SAP_HR implementation phase during our 6 months of involvement. However, at least the number of employees experiencing problems with their salaries had decreased from 300-400 in spring 2002 to 60-100 by March 2003.

Tasks and Responsibilities of the SAP_HR Users

After SAP_HR was introduced on January 1st 2002, the various HRM specialists were compelled to collaborate with each other. In total, there were about 50 users who worked in six different university units: four HRM departments from the faculties, the Service Centre’s HRM, and the central Salary Department. They were located in
various places: two in the administrative building on the university campus, three in other buildings on the same campus, and one in the historical center of the city. All the users had their own managers, either in their own HRM units or in the salary department as appropriate.

In terms of the SAP_HR implementation, each unit had two types of users: “regular” users and “key” users. Key users were responsible for correspondence with the project team, helping “regular” users, searching for new possibilities in the system, and attending special meetings.

At the time of our research, the personnel administrators were busy processing changes in the personnel files of the university employees. These files were either paper-based or based on SAP_HR. We found about 40 tasks performed using SAP_HR that could be grouped into ten categories: (1) appointment of an employee (subtasks concerning the appointment of a new employee or an external worker, stagier, and those with nil-contracts); (2) modification of basic information, payment information, working time registration and other data; (3) relocation processing; (4) promotion; (5) work time registration; (6) administration of leave (sabbatical, sick, parental, and pregnancy); (7) processing an optional model for employment conditions which is only in part executed through SAP_HR; (8) administration of declarations; (9) vacations; and (10) producing HR statistical reports and information management reports (sick leave reports, HR financial reports, etc.).

We observed some variations among the five units in terms of:

- The number of employees working in the HRM units: SC_HRM (11 employees), SS_HRM (9 employees), A_HRM (9 employees), GS_HRM (5 employees), AL_HRM (1 employee);
- In some of the HRM units, all the employees would perform all the HR administration-related tasks, while in others some were only responsible for communicating with the employees of the faculty while others performed key user tasks with SAP_HR; and
- The functions of key users were assigned differently. For example, in SC_HRM, all employees could represent the unit as its key user, while in others there were strict divisions.

Each faculty had its own special characteristics that influenced the use of SAP_HR in its HR administration. For example, the Service Centre was a special structure within the university that provided HRM services to more than 400 employees including those in three smaller faculties and more than 20 administrative and support services such as the university library, museum, and communication department. Another example is from the “GS” faculty where there were many short-term workers who did not work fixed hours and did not receive a regular salary. Student assistants generally fell within this category (flex workers) in this faculty as they were usually appointed to execute specific tasks within projects. Of about 320 employees, 1/4 were classed as flex-workers.

These examples indicate how the task needs and divisions differed per unit based upon the “idiosyncrasies” of the faculties. As a result, the ways used to process HR information also varied, and these differences needed to be acknowledged in SAP_HR.

Changes Brought by SAP_HR for the Users

The interviews with the SAP_HR users showed that an apparently straightforward technical inten-
tion had brought with it many social changes. We have clustered these into three groups:

1. HRM administrators had increased responsibilities for the transactions they completed; as one of them noted:

   *With SAP we gained extra control, but also more responsibilities. We have to be very careful with all inputs. Earlier everything was on paper, but now we have to concentrate more intensively in order to avoid faults.* (Roy, A_HRM)

2. Task interdependence had changed radically. Instead of being concerned only with internal paperwork within the faculties, all the inputs made by personnel administrators now became interdependent with the inputs of salary administrators, and over time with the IPA Salary Information System that was located outside the organization.

3. Unlike the old situation, online working with personnel and salary documents demanded standardization in the operationalization of the personnel and salary tasks and processes by the entire group of users. Whereas, as we have already discussed, the HRM units all had their own traditions and rules in the pre-SAP situation, the new circumstances required clear definitions of all the terms and processes used. This reinforced interdependency between all the units.

**LEARNING IN SAP_HR IMPLEMENTATION**

We were able to distinguish two distinct periods in the implementation of SAP_HR: the first 6 to 8 months which were described as a “disaster” (time-1), and later when the situation had improved (time-2).

**Learning as Acting**

When they began to work with the system, the users strived to handle basic tasks such as inputting personnel data, sick leave administration, time registration, and applying the right types of contracts through SAP_HR. They expressed the view that they were initially afraid to work with the system because they could not predict whether many of the transactions would be correct or not. In such cases, they preferred to contact a salary specialist or a key user and ask them to execute the task.

The users had to operate the system because it was necessary in order to perform their primary tasks. However, the intensity of use did differ from unit to unit. For example, based upon the interviewees’ estimates, the Salary Department processed about 250 transactions per week and the A_HRM unit about 250 transactions per month, whereas the user in AL_HRM worked for no more than two hours per week with SAP_HR.

Initially, the users sensed a lack of time or motivation to search for new possibilities within SAP_HR but, after 6 months, the situation changed: they could now work with the system without asking for help every time, and they could begin to search for new possibilities in SAP_HR. For example, there was a special application called “Query” through which a user could generate a range of HR reports. The interviewees emphasized that they found it interesting to combine HR and financial data. All the key users had test versions of SAP_HR, with which they could experiment and search out new possibilities and produce reports. However, it was commented that these versions did not indicate any link to IPA, something that was essential for much of the work.

**Learning as Reflecting**

The interviewees expressed the view that, initially, there were no fruitful communications across the
entire group of users. Opinions were expressed that no one wanted to admit their own mistakes and so always blamed others, for example:

*Sometimes it was not only technical difficulties that caused the problematic situation. Correct and timely communication is very important. Even within those groups closely related to the salary administration groups we cannot always find consensus: when anything goes wrong, everybody is sure that they did their own job well, and the problem must be elsewhere. Such communications do not help to improve the situation, and we might face similar difficulties in the future.* (Daniel, SAP technical administrator)

Lack of time was considered as the main reason for the lack of cross-communication, for example:

*We did not communicate with the HRM units about the use of the system. We did not even think about that—there were so many mistakes that had to be corrected; it was easier to do this ourselves instead of talking with the HRMs. It was terrible that we had to correct all the inputs.* (Karen, Salary Administration).

However, within the units, there were active discussions about the problems with the SAP_HR administration system. In the A_HRM unit, meetings took place every two weeks, and in SS_HRM every week. The personnel administrator from GS_HRM described the situation as follows:

*We [the Personnel Department] worked together very well. We discussed difficulties and helped each other with this system. We made reports about mistakes ourselves, and the key-user took these to the regular meetings. In our faculty, we are lucky to have such a strong team. With all these SAP problems we became even closer to each other.* (Tom, GS_HRM)

Gradually, after some months of working with SAP_HR, the users from the various units became more open in the discussions. They expressed enthusiasm for communicating across the entire group in this later phase of SAP_HR use:

*Also we communicate with other HR managers to ask questions and share difficulties. In this way, people from the Service Centre helped us a lot at the beginning. We also found it useful to discuss SAP with the HRMs from the Social Sciences faculty.* (Roy, A_HRM)

Key-user meetings became an important event for information exchange. The key users took the latest news to and from the meetings; and users started sending e-mails across the group with their questions. The meetings of key users became a strong group device; even non-key users attended in order to participate in the communication process. During the interviews, all the respondents acknowledged the importance of these meetings:

*I like communicating with other users. During the key-user meetings we raise a range of questions and exchange our ideas. It is very helpful. Actually I am not a key-user, but I like to attend those meetings (together with the ‘real’ key-user from our unit) to gather all the news and to communicate with others. There, I always meet the Salary Administration people and talk with them. I also visit them after each meeting—to chat face-to-face—otherwise we would communicate only by telephone.* (Marijke, A_HRM)

### Learning as Conceptualizing

All the interviewees were well-informed and understood the goals behind introducing SAP_HR. They gave two main objectives as being behind SAP_HR’s introduction: replacing an outdated system, and matching the SAP modules already
Successes and Failures of SAP Implementation

being used in the university. Those involved in the working project groups were all of the opinion that, by January 2006, the IPA system would be replaced by SAP_Payroll, and thought that SAP functionality would then become even more valuable.

The comment below from one of the interviewees shows the clarity of his awareness of the goals behind SAP_HR:

*The system was introduced in January 2002 because of two reasons. Firstly, there was already SAP_Financial, and the financial department had worked with SAP for some time. I think the management desired to have the university’s ICT from a single supplier. Another reason for the introduction of SAP_HR was that the contract with COMI-P had expired by January 1st 2002. (Roy, A_HRM).*

None of the users however expressed a need for a new system and none of them felt an urgent need to replace the “old” technology. On the contrary, they stressed that the previous technology was reliable enough, simple, and worked correctly. An interviewee from the AL_HRM department gave several reasons why she did not need SAP_HR:

*I think SAP_HR is a good system. You can do many things with it, but I don’t need many things. For example, we have our own system for sick leave administration. The same applies to time registration - there is our internal ATREA system. This contains various special items such as overtime, working during the weekends or holidays, and evening work. It has existed for ten years already. Maybe it can be incorporated into SAP, I don’t know. Therefore, I don’t use the sick leave administration and time registration components in SAP_HR. I don’t use the ‘arrangements’ application either. They do this task in the performance appraisal files and keep them on paper. With SAP, this would be extra work for me. Other examples of useless applications are the ‘previous employer’ field, and the ‘children’ and ‘subscriptions’ fields - I don’t need them. (Monique, AL_HRM)*

During the first 6 months, the users felt that they did not really understand how to operate SAP_HR. All the 24 interviewees commented that they lacked an understanding of the logic of the system. For example, a salary administrator said:

*It was terrible that we had to correct inputs, and that we did not have enough knowledge about the system and how to work with it. We did not even have an image of a good input, and how a correct input should look. It was very confusing for us because one month an input ‘A’ was good and accepted by the IPA system, but the next month the same input ‘A’ was certified as bad and rejected by the same IPA. It was not clear what went on behind the screen. (Karen, Salary Administration)*

The main complaints were about the lack of understanding of what was “behind the screen.” It was not difficult to click the buttons, but they needed to foresee the outputs of the transactions and the connection with IPA which, at the beginning, seemed to be a big black box.

Based on many of the opinions expressed, the situation at the beginning could be characterized as one of high uncertainty. Most problems and their understanding would only come from experience; they could not be predicted in advance:

*The situation at the beginning could, in general, be characterized as one of high uncertainty – COMI-P was very rapidly replaced with SAP_HR. We got a new system, but we did not know sufficiently what to do. The biggest problem, and the highest priority, was to keep to the transaction deadlines. (Sandra, SS_HRM)*
In fact, none of the project leaders realized that we — the HRM specialists — did not know about IPA. We had never worked with it. The end-users in their day-to-day work only see SAP screens. We were often confused because sometimes SAP_HR would allow us to input a number (as a code), but then it was then forbidden by IPA, etc. (Lucie, GS_HRM).

In assessing the users’ attitudes towards the functionality of the system, we note that most opinions were negative. Criticisms concerned both technical and contextual aspects of SAP_HR. We have produced the following summary of criticisms that arose during the interviews:

- making mistakes was “blind”: a user could not understand why an input was wrong;
- some problems were too difficult to solve;
- employee classification in the system was too complex;
- searching for new possibilities was limited as the system was very standardized;
- producing historical overviews was impossible;
- the codes in SAP_HR were different from the codes in IPA, and therefore there was a need to memorize them;
- useless functionalities (such as inputting educational data on the employees and data on their children which was not processed in calculating salary); and
- some issues that are common in a university environment were not incorporated in SAP_HR (conference leave, sabbatical leave, and CAO à la carte).

One of the personnel administrators described her attitudes towards SAP_HR as follows:

In April 2002 I started to hate both the system and working with it. I had a feeling that everything I did went wrong, and that it was all about salaries and bonuses. (Monique, AL_HRM)

At the same time, the functional and technical administrators of the system were of the opinion that SAP_HR was very logical, technically reliable, and easy to use.

**Learning as Planning**

Arranging activities to improve system use became an observable occurrence after several months of practical experience. In the beginning, activities, if any, were initiated by the project team and not by the users. However, since spring 2002, as the interviewees themselves noted, the users have tried to initiate actions in addition to the key-user meetings. Thus, “informal discussions over a cup of tea” were arranged between the SS_HRM unit and the Salary Department. Discussions about certain transactions were also initiated outside of official meetings (e.g., the development of a report for the Executive Board).

We also discovered differences in the policies developed by the users in the various units:

- control over transactions was organized in various ways, from triple control involving the head of the HRM unit, to double checking by the same user in AL_HRM;
- in GS_HRM, there was an agreement that the key user would decide whether to inform regular users about e-mails from the project team or not, in order not to “overload” them;
- each HRM unit had its own time schedule within its faculty for making changes to personnel files, and they agreed a schedule with the Salary Department for providing them with the data that would guarantee timely salary payments; and
- in January/February 2003 (a year after the system was introduced), the Salary Department introduced “report forms” for those HRMs who had questions/problems in order to initiate discussions rather than just correcting the mistakes themselves.
All the interviewees noted that there were no evaluation rounds throughout the project.

**DISCUSSION**

**Success of SAP_HR Implementation and the Role of Learning Processes**

When we started the case study we knew that the SAP_HR implementation had developed many problems at the university. The users had struggled with problems associated with SAP_HR for 6 to 8 months before working with the technology became easier although still not fully enjoyable. After this initial period, the employees became more willing to cooperate with each other in order to develop their work with the technology. How did this develop?

After 8 months of preparation, the technology was introduced to the users on January 1st 2002. Although the users received instructions and participated in workshops about setting up and converting to SAP_HR prior to its introduction, they found that they were not ready to operate the system but lacked the option of rejecting it.

The introduction of SAP_HR was initiated and promoted by the top management in the university, and this choice of technology was never fully supported by the future users. SAP_HR use became obligatory with the objective of replacing what was seen in some quarters as the outdated COMI-P system and so standardizing HRM and salary administration in the organization.

What did the users experience and feel once SAP_HR had been introduced to them? Personnel administrators saw significant changes in their daily tasks: greater responsibilities for making online inputs, and more control over those inputs, the need to become interdependent with the salary administrators, and a need to collaborate with other personnel administrators whom they did not previously know. Salary administrators also gained new tasks: to control the inputs from the HRM departments, to collaborate with them, and to learn how to operate SAP_HR. One additional issue that complicated working with SAP_HR was that the interface with the external IPA salary system often obscured the SAP_HR inputs.

Stress, greater responsibilities, and uncertainty in making inputs, all brought about by SAP_HR, stimulated negative interpretive schemes about the technology among the users. They were unwilling to invest a lot of effort and were disappointed by the technology. Right from the beginning, the users perceived the system as not worth learning about, and in fact, worse than the previous technology. The negative opinions about SAP_HR strengthened daily as the users collected and accumulated disappointments, including seemingly small details and misunderstandings with the project team.

Neither did we see strong user participation in the project. Only the key users actively took part in the preparation and conversion of the system. A pilot for introducing the system took place in four units in the university. Although the users did not agree with the official, positive evaluation of this, their opinions were largely ignored.

Although a negative opinion about SAP_HR grew within the user group, use of the provided technology remained obligatory for the staff. Slowly, after 6 to 8 months, the interpretations of SAP_HR began to move in a positive direction. The employees started to find ways of avoiding or overcoming the major problems they had found with SAP_HR.

The question is how does a group learning perspective help us to explain the developments in the SAP_HR implementation? We saw how group learning among the SAP_HR users developed from an initially low level to moderate after 8 months of using the system. This development was slow and this created difficulties for the users. The qualitative analysis of the transcribed interviews and documents has enabled us to distinguish and grade all the learning processes twice, at the beginning of the SAP_HR implementation and after 6 to 8 months (see Table 2).
The four learning processes all progressed in a positive direction over time although mutual adjustment processes progressed only slowly.

In terms of acting, the users progressed from being afraid to click the buttons at the beginning to attempting to generate a range of HR reports. The key users remained the most active, but the rest of the group also became more active. Everybody found routine administrative tasks easier to execute over time. Reflection among the targeted employees also developed progressively. Initially, discussions about SAP_HR implementation took place only at the microlevel, that is, within the units, and there were no fruitful interunit communications, not even between Salary Administration and the HRM departments. However, later, this developed with e-mail, telephone, and other informal ways of corresponding and discussing SAP_HR taking place across the units. The key-user meetings became especially popular.

The general understanding of the purpose of the system coincided with the reality. All the users were informed about the goals of SAP_HR and could express them correctly. However, they perceived it as useless, and they did not feel there had been any immediate need for a technological change in their tasks. We did not find users expressing needs in terms of SAP_HR, even during the later stages of working with it. Users’ attitudes towards the functionality did not improve during the observed period and remained negative. Only key users appreciated the possibilities of generating reports. We did not discover any activities arranged by the ordinary users in order to improve their work with SAP_HR, in fact there were only two informal meetings and these were initiated by the SS_HRM department. Most policies were developed at the microlevel in the units (such as rules to control the inputs or processing CAO à la carte). There were no evaluation rounds established to assess the system, the project, or cooperation.

We found that, at the beginning of the project, the learning processes had mainly occurred at the microlevel within the units. Further, the interaction processes across the entire group of users were at a very low level during the first months following implementation. We attribute this to the initial lack of shared structural and nonstructural group features.

CONCLUSION

Our case study concerned the implementation of a personnel administration system in a university environment. A six-month investigation
Period allowed insights to be gained into the processes involved in adopting the system by the user group.

Learning among the SAP HR users emerged as soon as the system was introduced. We observed the slow but steady development of all the learning processes over time. Initially, the extent of the learning was not sufficient to handle the system, with interactions mostly taking place at the level of the units. The lack of communication and the misunderstandings across the entire group of users led to mistakes in working with the system when it was first introduced. The system triggered learning by calling for a redirection of all processes towards a new and larger community. After 8 months, learning moved towards stronger cross-unit cooperation and the exchange of users’ experiences.

We began the theoretical discussion with an understanding of IT implementation as a user-centered process in which employees together develop interpretive schemes about a newly introduced technology. In this study, we based the concept of learning on the model of experiential learning by Kolb (1984) in which learning is considered as: (1) a process rather than simply outcomes; (2) a problem-solving process that is always practice-oriented; and (3) a mechanism for everyday activities, occurring both consciously and unconsciously. It is argued that learning within a group of users is more than simply the summation of individual learning processes. The character of group processes becomes more complex as they acquire a social context.

In answering the central research question – What is the role of experiential learning in IT implementation? – we would stress four issues: (a) learning is a process-based activity; (b) it rests on the interaction processes between members of a user group; (c) these processes begin when a new technology is introduced.; and (d) these processes lead to changes in knowledge about the IT and in users’ behaviors (ways of operating the system).

The main role/function of learning processes in IT implementation is that they become a “hidden” mechanism in the IT implementation. Several theoretical components can be added here to articulate the strategic potential of experiential learning in IT implementation. First, there are two learning processes – acting and reflecting – that concern individual behavior. Observations have shown that these occur immediately after a technology is introduced to the targeted employees. Once users are “thrown to chaos” (Weick, Sutcliffe & Obstfeld, 2005), they have to (or choose to) experience it, and their next implicit step will be to judge it. The other two processes—conceptualizing and planning—bridge individual and group learning. These two steps concern “talking a situation into existence” (Taylor & Emery, 2000) and articulating and integrating labels.

We observed that verbally expressing concerns developed more extensively when groups of users established such characteristics as trust, knowing each other, and openness in risk-taking conversations (known as psychological safety) (Edmondson, 1999). These characteristics were seen to develop during the IT project.

Findings elsewhere have shown that group learning processes do not follow a linear sequence, but develop as cycles. Within a group, discussions occur both before and after actions and so it is difficult to distinguish a “point of departure” in an experiential group learning cycle.

Finally, we argue that learning can be considered as a “hidden” mechanism for speeding up or slowing implementation. As Weick et al. (2005) remarked, it is a micromechanism that can bring macro-changes. If a group of users appreciate the technological help provided for their tasks, share positive attitudes, help each other, and attribute growth in performance to the system, they will learn the relevant issues concerning a technology. In so doing, the system will be discovered, “studied,” and better understood, and through this the technology will become more relevant for the job tasks and easier to work with. This can lead to a
Successes and Failures of SAP Implementation

better and quicker acceptance by the users. The opposite scenario was initially observed in our case study when the users only complained about the system, perceived it negatively, and convinced each other of its uselessness. Even small details that would be ignored in other situations received the attention of the group. In such a scenario, employees learn of issues that reinforce earlier negative attitudes. Their views became increasingly negative about the relevance of the system to their tasks, and they saw the technology as too complex to operate. Thus, the technology became “even less relevant” for their work in the opinions of the users, and they learned of issues that discouraged them from accepting the system.

Further research could greatly contribute to the understanding of the origins and differences in learning by taking into account differences in work environments. Insights could be gained by exploring IT implementation in various types of work environments (such as process-based, product-based, logistics-based, and administrative work). Determining whether there is a link between the type of work environment or the type of organization, group learning in IT implementation would add to the current findings.

Practical Implications

Our findings suggest that the main thrust of managerial support during the implementation of information technologies should be in promoting interaction processes geared towards adopting the system. We observed a number of good practices in the case study that did stimulate constructive learning. These were:

- having a help desk or front/back office services on system functionality available for the users at any time;
- creating and distributing a list of experts on the system’s functionality within the group (generally these were the advanced users among the targeted employees) whose experience could be very helpful to others;
- introducing an e-mailing list including all the users (setting up a hot-line chat room would be an alternative);
- scheduling informal meetings (such as during coffee breaks) for the group of users;
- agreeing how to involve new employees in using the system (what to explain to them, who is responsible, etc.);
- distributing special notebooks amongst the users for ideas, proposals, and complaints; and
- accepting proposals that come from the users and reacting to them (negotiating).

This list is far from exhaustive since it includes only those practices that we observed in the implementation of the SAP_HR system at the university. However, we did observe how all the above practices advanced learning in the “right” direction.

The Human Face of E–Business: Engendering Consumer Initial Trust Through the Use of Images of Sales Personnel on E–Commerce Web Sites

Khalid Aldiri

University of Bradford, UK

ABSTRACT
Business-to-consumer (B2C) e-commerce suffers from consumers’ lack of trust. This may be partly attributable to the lack of face-to-face interpersonal exchanges that provide trust behavior in conventional commerce. It was proposed that initial trust may be built by simulating face-to-face interaction. To test this, an extensive laboratory-based experiment was conducted to assess the initial trust in consumers using four online vendors’ Web sites with a variety of still and video images of sales personnel, both Western and Saudi Arabian. Initial trust was found to be enhanced for Web sites employing photographs and video clips compared to control Web sites lacking such images; also the effect of culture was stronger in the Saudi Arabian setting when using Saudi photos rather than Western photos.

INTRODUCTION
The beginning of the 21st century brought rapid development to the field of e-commerce and many enterprises in Western developed countries found success in this area. According to emarketer.com, total online retail sales for 2005 were $144,613 million. In 2001 Internet sales to households from the UK non-financial sector stood at £4 billion;
by 2004 these had increased to over £18 billion (Wallis, 2006). The growth in Internet sales between 2003 and 2004 was over 67%; this clearly shows brisk expansion in the value of Internet sales (Wallis, 2006). In the Asia-Pacific region, sales also grew rapidly, from about $200 billion in 2003 to about $300 billion by 2004 (United Nations Conference on Trade and Development [UNCTAD], 2003). In contrast, the situation in the Arab world is different since the estimated figure for B2C in Africa and the Middle East cannot be compared with those in the US, the EU, or China (UNCTAD, 2004).

Trust in online shopping still represents a significant barrier for Internet users and is crippling the e-commerce environment (Zhang & Zhang, 2005). Trust is a critical component for any business transaction, and is particularly essential in the e-commerce environment because of the paucity of rules and customs in regulating e-commerce and due to the fact that, typically, online services and products are not immediately verifiable. Moreover, online transactions are more impersonal, anonymous, and automated and lack the assurance provided in traditional settings through formal proceedings and receipts. B2C online vendors are particularly challenged when trying to build and attain consumer trust. Indeed, in contrast to face-to-face commerce and to other applications of trust, which encompass a wide range of emotions involving various types of social interaction with humans, there are typically no interpersonal interactions in e-commerce, neither direct nor implied. Such interactions, or even cues relating to them, are notably missing from e-commerce Web sites. Online shopping may be viewed as lacking human warmth and sociability. The social aspect of shopping has been shown to be a major contributor towards positive emotions (Jones, 1999) that have been linked to several important outcomes, such as increased unplanned purchasing, increased spending, and increased time spent in the store (Jones, 1999).

Online vendors face a significant challenge in making their Web sites socially rich (Kumar & Benbasat, 2002).

The aspect of trust has been examined over many years, however, most of the research on consumer trust focuses on consumers in English-speaking countries and newly industrialized countries. Trust in e-commerce research has been conducted almost exclusively in the US or Western Europe. Considering the cultural, economic, social, and political differences between the developed and less developed countries, concerns have been raised in terms of whether research based in the US or Western Europe can be generalized to other countries (Bagozzi, Wong, Abe, & Bergami, 2000). The global nature of the Internet raises questions about the effects of trust across cultures as well. Although trust may be formed in a variety of ways, it depends on the cultural factors (e.g., societal norms, values, etc.) that guide people’s behaviors and beliefs. Despite the differences national culture can cause in e-commerce behavior (Kacen & Lee, 2002), and despite e-commerce becoming global, research on trust in e-commerce has to emphasize the possible effects of national culture. For that, this study attempts to carry out a pilot case investigation of our research objectives in Saudi Arabia; a developing country with the highest growth in Internet users in the Middle East and Africa (www.mcit.gov.sa).

Research Objectives and Organization of the Article

This study researched the effect of adding media cues (video clips, photographs) of a presumed sales person’s face to the home page of an e-commerce vendor, and considered the effect of social presence cues, also known as interpersonal cues, that are implicit in the media cue on users’ initial trust in the vendor (Research Objective 1). The majority of studies of online customer trust focus
on general trust as it develops between customers and online vendors over time and after repeated experiences. While we recognize the importance of the evolving nature of trust, our study focuses on initial trust beliefs that develop after a customer first interacts with the company’s Web site. The difference between the two concepts may be subtle but, as we discuss later, is significant, particularly in the online environment. The study further investigated the effect of culture, as represented by a facial photograph of a Western and Saudi man added to the home page of an e-commerce vendor, on users’ trust in that vendor (Research Objective 2). This experiment was concerned with investigating trust as a dependent variable and other variables as independent variables, as well as how the depth of a user’s exploration of a site (exploration depth) influences the effect of a media cue on user trust (Research Objective 3). On a methodological level, the experiment aimed to overcome part of the limitations of conventionally used trust questionnaires free from financial risk by introducing trust questionnaires that were elicited under conditions of financial risk (Research Objective 4). This article is organized as follows: the second section examines previous work related to e-commerce and trust and reviews the research hypotheses. The third section outlines the methodology of the study, while the data analysis is presented in the fourth section. The results are discussed in the fifth section and in the final section conclusions are drawn.

THEORETICAL BACKGROUND AND HYPOTHESES

Trust

Trust has widely conflicting conceptual definitions; the literature on trust in general, and on trust in e-commerce in particular, is in a state of confusion (McKnight & Chervany, 2001). The confusion in trust terminology is expressed in terms of two kinds of problems. First, similar concepts are given different names and second, the same terms are used for different concepts (Krauter, Kaluscha, & Fladnitzer, 2006). There is no universally accepted scholarly definition of trust (Rousseau, Sitkin, Butt, & Camerer, 1998).

Summarizing the different definitions of trust across various research disciplines, it can be concluded that all trust definitions address one or more of the following perspectives: (1) context characteristics, (2) trustor properties, and (3) characteristics of the trusted object (Krauter et al., 2006). Many definitions also address the interaction or relationships between two or all three of these perspectives. The key concepts of most of the trust definitions are risk (Mayer, Davis, & Schoorman, 1995), vulnerability (Mayer et al., 1995), expectation (Baier, 1986), and confidence (Lewicki & Bunker, 1995). These factors are gathered by the following trust definition, which represent the most common definition of online trust (Mayer et al., 1995):

Trust is the willingness to depend upon another party and be vulnerable to the actions of this other party based on the assumption that the trusted party will deliver without taking advantage of the situation. (p. 711)

As it is very abstract, this definition can be seen as the most common in the human computer interaction (HCI) trust research (Corritore, Kracher, & Wiedenbeck, 2003). It defines trust as an internal state or attitude which entails cognitive and affective aspects (Corritore et al., 2003). Trust, as an internal state, is different from trusting action (e.g., buying online, entering credit card details, relying on advice) or cooperation (e.g., in a team setting), which are observable behaviors (Corritore et al., 2003). Also trust is not the same as trustworthiness; trust is the act of a trustor while perceived trustworthiness is a characteristic of someone or something that is the object of trust (Corritore et
In the e-commerce context, trust has been defined rather narrowly (e.g., Bhattacharjee, 2002, defined trust as trusting beliefs) or more broadly (e.g., McKnight, Choudhury, & Kacmar, 2002, who defined trust as trusting beliefs and trusting intentions). Trusting beliefs (i.e., perceptions of Web vendor attributes), and trusting intentions (i.e., intentions to engage in trust-related behaviors with a Web vendor) are based on the theory of reasoned action (TRA) which was introduced by Ajzen and Fishbein (1980) to analyze the psychological processes that reflect observed relationships among beliefs, attitudes, intentions, and behaviors. The theory asserts that intention to perform behavior is determined by the individual's attitude toward the behavior, and a person's attitude is affected by his/her beliefs. TRA has been widely accepted and applied to a broad range of disciplines and contexts. Existing empirical research has revealed that trust is significantly related to attitude, and attitude positively signifies people's purchase intentions (Chow & Holden, 1997; Macintosh & Lockshin, 1997). TRA is also applied as the theoretical base in recent studies on trust formation (McKnight & Chervany, 2001; McKnight, Cummings, & Chervany, 1998), especially in the context of e-commerce (Jarvenpaa, Tractinsky, & Vitale, 2000). Since trust can be seen as a belief, confidence, sentiment, or expectation about an exchange partner's intention and/or likely behavior, we believe that it is posited to be directly related to the attitudes toward purchasing from a vendor and indirectly related to consumers' willingness to buy through purchasing attitudes. This is how we define trust in this article; this is consistent with how trust has been previously defined in the literature (Gefen, 2002).

Trustors and trustees, that is, objects of trust, can be individual people, groups, organizations, or even societies. This article focuses on the narrow-scale study of trust, where the target is an individual e-business. At this level, the focus is on the process of identifying a trustee's characteristics or his trustworthiness.

The Varying Dimensionality of Trust

Although there is no complete agreement on the meaning of trust, it should be noted that the dimensions that constitute it are context-specific (Lewis & Weigert, 1985). As mentioned previously, the literature does reveal that the concept of trust tends to coalesce around a few key recurring concepts. There must exist, for the trusting party, uncertainty about a potential or existing relationship that leads to a certain perception of risk or vulnerability. This perception of risk is generally based upon the beliefs regarding specific factors of the trustee. Yet, recent research has primarily focused on three specific factors which may parsimoniously capture the concept or the dimensions of trustworthiness—that is, ability, benevolence, and integrity (Jarvenpaa et al., 2000). Ability is the perceived skills, competencies, and characteristics that enable a party to have influence within a specific domain (Mayer et al., 1995). Benevolence is the trustor's belief that the trustee wants to do good toward the trustor. Integrity is the belief that the trustee adheres to a set of principles that the trustee finds acceptable (Mayer et al., 1995). Perceptions of these three characteristics can lead to a willingness of the trusting party to depend or rely upon the trustee in expectation of a certain beneficial outcome or that the trustee will not act opportunistically. These three specific factors can often not be observed directly, but need to be inferred from signals in the Web site interface. In HCI trust research, signals given in the interface of a system that can form the basis of perceived trustworthiness are referred to as surface cues (Fogg, 2002). Certain literatures construct trust from different viewpoints and propose two main components or factors of trust: cognitive and affective or emotional (e.g., Shneiderman, 2000). Feng, Lazar, and Preece (2004) argue that the affective component...
of trust has been to some extent ignored in HCI trust research, in particular in the domain of e-commerce, where research is largely focused on factors that contribute to cognitive trust, such as security, error absence, and trust seals. For retail transactions, cognitive factors can increase the confidence that a transaction will be successfully completed. Affective factors can increase the feelings of attraction and trust.

The distinction between cognitive and emotional trust has received some support in an empirical study on long-term work relationships (McAllister, 1995), and strong support in a face-to-face study that manipulated emotional trust (Johnson-George & Swap, 1982). However, only a few studies have examined affective-oriented factors in an e-commerce (B2C) environment.

This oversight of the affective element of trust does not reflect the increasing consideration that is given to affective processes in multiple disciplines (e.g., marketing, psychology, sociology) (Riegelsberger, Sasse, & McCarthy, 2005). For example, marketing and advertising research are the fields that have the greatest power in investigating affective elements in decision-making processes. In these disciplines it is well-known that a consumer’s purchase decision depends on rational process and on positive affective reactions (Kotler, 2002).

However, as mentioned in the research objectives, this study concentrates on initial trust. The definition of trust previously discussed also applies to initial trust. The difference lies in the temporal context of the development of trust. In this case, initial trust is the willingness to rely on a third party after the first interaction with that party. It is recognized that the development of trust is an ongoing, dynamic process that is influenced by interactions between two parties. However, we believe that initial trust beliefs can also be formed without any prior experience or interaction between the two parties. The initial trust beliefs may change with time and with repeated interactions but they may also determine the extent to which such future interactions will take place (McKnight, Choudhury, & Kacmar, 2002).

In the context of e-commerce, initial trust is very important since Web-based companies must rely on their Web sites to represent them and to show their new customers that they are reliable and trustworthy. Customers visiting a Web site for the first time may rely heavily on Web site cues to form their initial trust beliefs, but they still lack the important information that develops through interaction over time (McKnight et al., 2002). Another important reason for establishing customer trust through the first Web site visit is the possibility of low switching costs for new customers compared with switching costs for expert customers (Reichheld & Schefter, 2000). Since the Web contains vast numbers of alternatives, either in vendors or in products, it has become very easy for customers to switch to a different online store after their first visit. So it has become an essential process for online vendors to try to establish and retain a trusting relationship with first time customers. Therefore, we believe that a thorough examination of the factors that promote initial trust in new customers of online vendors is critical.

**Social Presence and Online Trust**

Applying trust-inducing features to the Web sites of online merchants is the most effective technique for enhancing online trust. Many researchers in HCI have begun to study trust in an online context. Some researchers are focusing on the cues that may affect trust or convey trustworthiness to users of Web sites. In a sense, a Web site with trust-inducing features functions as a skillful salesperson for the company (e.g., Katsikas, Lopez, & Pernul, 2005).

The trust phenomenon represents an ongoing interpersonal interaction with another party, whether a person or organization, over an extended...
period of time. Indeed, trust is typically built gradually through extensive ongoing interactions that enable individuals to create reliable expectations of what the other party may do (Luhmann, 1979). This social context is a key characteristic of trust and trust-building behaviors, since trust, in general, is built through constructive interactions with other people (Luhmann, 1979). So, the perception of a high degree of social presence, implying direct or indirect human contact in the relationship should, arguably, contribute to the building of trust. Extending this logic implies that another way in which trust in an e-commerce Web site may be built is through embedding the Web site interface with a high social presence, such as the perception that there is a medium of communication that represents personal, sociable, and sensitive human contact (Gefen & Straub, 2004).

Social presence has been defined as the extent to which a medium allows users to experience others as being psychologically present (Fulk, Schmitz, & Power, 1987). Social presence theory by Short, Williams, and Christie (1976) describes how the social context affects medium use; they see social presence as a quality inherent in a communication medium. Some researchers characterize the social presence of a medium as its capacity to transmit information about facial expressions, posture, dress, and non-verbal cues (Short et al., 1976). Others focus on the psychological connection, where social presence is concerned with warmth and whether it conveys a feeling of human contact or sociability (Yoo & Alavi, 2001). While others still, focus on its close relationship to information richness theory (Straub, 1994), which concentrates on the interactivity of the media. Related to media information richness theory (Straub, 1994), social presence theory considers the extent to which a medium enables a communicator to experience communication partners as being psychologically present (Short et al., 1976). High social presence is typically found in face-to-face communication. However, medium richness can vary depending on circumstances (Zmud, Lind, & Young, 1990).

A significant difference between online and off-line shopping environments is that the latter involve a wide range of social interactions with humans through multiple sensory channels. Online shopping, on the other hand, primarily tends towards reducing the users’ affective or emotional factors through functional and performance based Web site design. As such, online shopping may be viewed as lacking human sociability, since it is more impersonal and automated than traditional offline commerce. Social responses to computer technology (SRCT) research paradigm proposes that individual interactions with computers and other communication technologies are fundamentally social and natural, and people interact with computers and mediated stimuli using the same social attitudes and behaviors that they apply to other people. The computers are social actors (CASA) paradigm (Nass, , Moon, & Carney, 1999) initiated this field of research and uses theories and experiments derived from psychology, sociology, and communication to develop and validate theories. Granted, online shopping Web sites typically involve no actual interaction with other people, however, Web site interface features have been suggested to help impact the perception of social presence cues, also known as interpersonal cues (discussed in more detail in the next section), that can be embedded in different ways. Higher perceived social presence cues in a Web site may increase online trust through their effect on increased electronic communication since communication is a necessary element of constructive interaction (Gefen & Straub, 2004). Trust may increase when the trusted party shows behavior or other indicators in accordance with one’s expectations; the perception that the vendor is embodying a high degree of social presence cues in the Web site should increase consumer trust to the degree that such indications are expected (Luhmann, 1979).
Social presence cues can convey a sense of personal, sociable, and sensitive human contact, so too should multimedia Web sites. Indeed, recently many online shopping Web sites have used interface features and embedded social presence cues. Advertising research has long relied on imagery of friendly faces to build a positive attitude towards products.

**Social Presence Cues (Interpersonal Cues)**

Social presence cues, also known as interpersonal cues, are the signals that make a person aware of the presence of other people (Short et al., 1976). They are non-verbal and para-verbal communication methods and suggest participant appearance each time a person interacts with another. It may be intentional or unintentional and it is part of the rapid stream of communication that passes between two interacting individuals. Although there are a number of definitions of social presence cues (interpersonal cues), in the broadest sense it is communication that transcends the bare elements of the written or spoken word. The interpretation of this communication has been shown to have a central effect on participants’ perceptions of the event and can give information about individuals’ backgrounds, motivations, and emotional attitudes. They augment spoken messages by helping people express their feelings or thoughts through the use of their bodies, their facial expressions, and their tone of voice and so on (Mehrabian & Epstein, 1972). Psychological studies have concluded that more than 65% of the information exchanged during a face-to-face interaction is expressed through non-verbal means. Fromkin & Rodman (1983) suggest that up to 90% of the communicative process takes place non-verbally. The characteristics of the individuals involved and their response to coding and decoding signals govern the role of social presence cues in any exchange. Three specific variables can be identified as impacting on the nature of non-verbal communication during the exchange; gender, culture, and personal traits. Social presence cues (interpersonal cues) are of relevance in the debate on trust as they can be interpreted as signals for trustworthiness. A trustor can form an impression of perceived trustworthiness of a trustee from the interpersonal cues he/she perceives in a face-to-face situation; it works as inferences (Steinbruck, Schaumburg, Kruger, & Duda, 2002). Interpersonal cues lead to an instant impression formation and thus have an immediate impact on affective trust. The different types of cues differ in their reliability for trust assessments, and in how they are affected by transmission over media (Riegelsberger et al., 2005).

There are many classifications of interpersonal cues (Hinton, 1993); the most common types are:

1. **Paralanguage**: The vocal cues that accompany spoken language
2. **Kinesics**: Body movements
3. **Oculuses**: Eye behavior
4. **Appearance/artifacts
5. **Proxemics**: The non-verbal study of space and distance
6. **Haptics**: The non-verbal communication study of touch
7. **Olfactics**: The non-verbal communication study of smell
8. **Chronomics**: The non-verbal communication study of time
9. **Facial expressions

**Online Trust and Media Cue**

Existing technologies allow for various representations of interpersonal cues that are embodied in different kinds of media cues (e.g., photo, audio, video, embodied agent) to be integrated into one platform. There are many theoretical concepts that classify and explain such media effects. The most common are social presence (Short et al.,
The reduction in the number of interpersonal cues when interacting online is seen as one of the reasons for the lack of trust online (Shneiderman, 2000). This assumption is well supported by many studies (e.g., Hassanein & Head, 2004). These studies found that richer representations result in higher awareness, preference, and interpersonal focus. The most commonly used example of visual interpersonal cues is the smile—this has been identified as powerful in stimulating immediate affective responses, and can form a basis for affective trust.

Thus, Web site interface elements such as photographs, video clips, or synthetic voices can create some level of social presence that may enhance the affective trust compared to Web site interfaces lacking such elements, and can therefore be taken as an indication of the trustworthiness of the trustee.

There is much research on trust in e-commerce vendors, while in contrast there are very few that have specifically tested the effect of interpersonal cues on trust (Al-Diri, Hobbs, & Qahwaji, 2006). Some of the existing studies focused on the effect of synthetic interpersonal cues in avatars (embodied agents); others investigated the effect of displaying facial photos of humans on e-commerce sites. All of these studies tested users’ trust either in the form of quantitative questionnaires or with qualitative interviews, using two mock-ups of an e-commerce Web site, one with and one without a photo or avatar (e.g., Bickmore & Picard, 2005).

Video

In general, video is considered to be a rich media cue and thus is considered to afford high social presence cues as it transmits many visual and audio cues.

In a study by Swerts, Krahmer, Barkhuysen, and Van de Laar (2003), on the effect of social presence cues on the detection of speaker uncertainty, they found the best discriminative ability for video with audio, compared to video only and audio only.

Brosig, Ockenfels, and Weimann (2002) found that video with audio reached levels of cooperation that were close to those reached in face-to-face communication, even though they were reached after a longer time than in face-to-face communication.

Horn, Olson, and Karasik (2002) in a study on lie detection in job interviews found a better performance in discriminating lies from truthful statements in high quality video than in audio only.

The study also compared low resolution video and low frame rate video. They found that low resolution video, which suppresses detailed facial cues gives a performance as high-quality video and good performance in lie detection. Horn et al. (2002) attribute this result to the reduction in truth bias in the absence of recognizable facial cues and the fact that the presence of facial cues may lead to a trusting reaction.

A study by Van Mulken, Andre, and Müller (1999) investigated trust in advice. This study varied the representation of an advisor (video, embodied agent, audio, and text only) and the quality of the advice. Hence, the effect of media representation could be compared to the effect of advice quality. The study found a preference for high quality advice in all representations, but only insignificant indication of a positive effect for video on the behavioral measures.

Photos

Research on the use of personal photos in Web sites are very few and contradictory, with some studies finding such images to be a positive cue (Fogg, 2002; Nielsen, 1996; Steinbruck et al.,
2002), while others found them to be neutral (Riegelsberger, Sasse, & McCarthy, 2002). Urban, Fareena, and Qualls (1999) found that screensized facial photographs of shopping assistants embedded into a shopping Web site interface led to a wide range of reactions as some users liked it, while others considered it unnecessary. In the Fogg et al. (2001) study on the credibility of online news articles, they found that photos of authors increased credibility. Riegelsberger, Sasse, and McCarthy (2003) found that virtual re-embedding had a positive effect on user trust for medium experienced shoppers. Highly experienced Internet users, as well as consumers with a high level of distrust towards online-vendors, benefited little from the provision of social cues in the interface (Riegelsberger & Sasse, 2002). Steinbruck et al. (2002), in an experimental study, investigated whether adding a photo of an employee to the home page of an online-banking site increased user trust in the bank—they found a positive effect on trust. As a result of the foregoing it was hypothesized that:

H-1: Subjects differ significantly on their rating of trust belief and trust intention across vendor’s Web sites.

H-2:

H-2-a. The first rating of a vendor’s Web sites trustworthiness will result for those presenting video clips.

H-2-b. The second rating of a vendor’s Web sites trustworthiness will result for those presenting photos.

H-2-c. The third rating of a vendor’s Web sites trustworthiness will result for those without photos.

Web Site Design and Culture

Understanding how to build trust for diverse consumers in electronic markets is imperative (Grewal, Munger, Iyer, & Levy, 2003). Culture has implications in Internet settings as well and is considered to influence consumer trust (Jarvenpaa & Tractinsky, 1999), Internet diffusion (Ferle, Edwards, & Mizuno, 2002), Internetmarketing (Tian & Emery, 2002), Web site development (Kang & Corbitt, 2001), and Web interface acceptance and preferences. Despite an anticipated large number of consumers from multiple cultures, few studies have examined the Web preferences of users in terms of design characteristics across cultures (Chen & Dhillon, 2003). Cyr and Trevor-Smith (2004) found statistically significant characteristics in Web design for municipal Web sites across cultures. Further, Simon (2001) examined cultural differences related to Web site satisfaction among the residents of Asia, Europe, Latin and South America, and North America based on Hofstede’s model and found different preferences for colors and navigation. Sun’s (2001) exploratory study examining cultural markers focused on language, pictures and graphics, colors, and page layout and found culture to be an important design consideration that increases usability of multilingual Web pages. All of these studies point to one general conclusion—Web sites need to be adapted to the different cultures of the targeted consumers. Singh, Xhao, and Hu, (2003) concluded: “The web is not a culturally neutral medium.” Studies like that of Hillier (2003) emphasized that “building trust on the web requires user interface characteristics appropriate for culturally diverse audiences.” An effective Web site design can engage and attract online consumers’ trustworthiness (Fogg et al., 2001), which is also considered central to trust development (Egger, 2001).
Cultural Photo as a Symbol

Symbols are important elements denoting culture (Marcus & Gould, 2000). One important form of symbolism is multimedia relating to culture, which few researchers have so far examined. Such multimedia elements might include streaming video, sound, and animation. So, the aim was to identify whether the strategy of adding a facial photo representing the users’ culture is beneficial when tested and can bias the trustworthiness of vendor Web sites. Hence the following additional research hypotheses were proposed:

H-3: Across Web sites including human portraits there will be significant statistical differences in trustworthiness between Web sites with local social presence and Web sites with foreign social presence.

H-4: Saudi subjects will trust a Web site with Saudi social presence (photo) more than a Web site with Western social presence (photo).

EXPERIMENTAL METHODOLOGY

This study was designed as a one-factor experiment manipulating three levels of Web site social presence cues (or interpersonal cues). Each of the four specially designed Web sites displayed the same products but each represented different vendors. Only the media cues were manipulated on the sites. Thus, the study attempted to investigate and examine the effects of the interpersonal cues that can be manipulated by facial photographs, video clips, and culture as control variables, which used photos of Saudi and Western people when forming the initial trust toward online vendors. In addition the study set out to measure some auxiliary parameters.

Experiment Participants

The experiment was conducted in an IT training institute in Riyadh, Kingdom of Saudi Arabia (KSA). The number of participants totaled 72 students. Since online consumers are generally younger and more highly educated than conventional customers, student samples are close to the online consumer population (McKnight et al., 2002) and therefore are representative of online shoppers (Gefen & Straub, 2004).

Experiment Material

An initial survey on the most popular online products was carried out and found that laptops came first in popularity. The stimulus experiment material used in this research was carefully selected, having noted that previous studies in online trust used mock-ups of shopping sites to test the effect of interpersonal cues (e.g., Riegelsberger et al., 2002; Steinbruck et al., 2002). This experiment used semi-functional copies of existing vendors’ sites, chosen in consultation with the four most famous reviewer business sites; BizRate.com, ResellerRating.com, Price Grabber.com, and Epinion.com to facilitate the task of rating online shopping sites. These services aggregate feedback from customers of e-commerce vendors based on post service and handling of privacy and security, which represents an aspect of vendor trustworthiness. Western shopping sites were selected as they constitute a realistic scenario with relatively high risk, due to the vendor and the users being in two different countries. The selection was based on the rating of high trustworthiness of the vendors and the number of reviewers of the selected site. Also we made a usability test for the four vendors’ Web sites to check the usability index for each Web site and to make sure that all selected Web sites had almost the same usability criteria. To do that, we asked five participants to use the check list developed by Keevil (1998) to measure the us-
ability index of the four Web sites. The checklist has over 200 questions in five categories, and even though it is not very recent, it is still valid and robust. The results showed that the four Web sites had almost the same usability index.

Semi-functional copies of the Web site including the home page and some subsequent layers depending on the available links in each layer were designed so that participants were able to browse and search general information about the site. Also any certification or reputation seals that were present on some pages were removed.

Photos and the video clip were selected by five professionals in computing and business, who were asked to rate the photos and select the most appropriate based on a realistic image of a customer service representative. The media cues (photo or video clip) were placed in attractive places in the first page of the site showing the selected product (without deleting or hiding anything from the page itself). This page was connected to the entire Web site so the subject could browse and search the site. In addition, each media cue was presented into each vendor Web site based on a predefined Web sites display scenario (see Figure 1).

Data Collection

The research methodology of studies on trust in e-commerce can be categorized into qualitative approaches, using either semi-structured interviews (e.g., Egger, 2001), or qualitative interviews in conjunction with user evaluation.
sessions (e.g., Witkowski, Neville, & Pitt, 2003). The second category entails trust questionnaires in an experiment environment, in this approach the majority of studies used an experiential survey, that is, participants were asked to navigate to a specified or self-selected Internet company and had to perform several predefined tasks and afterwards report on their impressions by filling out a questionnaire (e.g., Jarvenpaa et al., 2000). A second group of studies that used this approach, applied a basic survey approach, that is, subjects were administered a questionnaire or they were pointed to an online-questionnaire form without previously visiting any e-commerce Web site (e.g., Bhattacherjee, 2002). The third category involves social dilemma games, studies in this category measure players’ rate of cooperation and defection to infer media effects on trust and trustworthy behavior (e.g., Brosig et al., 2002).

From a clear review of these approaches, there are distinct advantages and disadvantages. For this study it was decided to use the hypothesis-testing laboratory and experimental quantitative approach. This approach allows a high level of experimental control for independent variables while keeping resource requirements relatively low.

All experimental tasks during this research experiment were performed in a computer laboratory. The research instrument to measure the constructs of interest was developed by adapting existing measures from the literature to the current research context. All items were scored on a five-point, Likert-type scale ranging from (1) strongly disagree to (5) strongly agree (see Appendix 1). As the experiment was conducted in an Arabic speaking country, the questionnaire, originally written in English, was translated into Arabic by a bilingual person whose native language is Arabic. The Arabic questionnaire was then translated back into English by another bilingual person. This English version was then compared with the original version and no items were found to deviate significantly in terms of language. This process was conducted not only because it can prevent any distortions in meaning across cultures, but also because it can enhance the translation quality. The study question items consisted of five sections. The first section included the basic demographic characteristics such as age, gender, education level, and Internet experience. In the second section, respondents were asked to answer questions on their online purchasing experience. In the third section, respondents were tested for their trust propensity or disposition to trust an individual trait, defined as a “general willingness based on extended socialization to depend on others” (McKnight & Chervany, 2001). The questionnaire items were selected based on their high reliability and validity to discriminate the construct and achieve a high Cronbach alpha value; this was adapted from Teo and Liu (2005) and Gefen (2000). In the fourth section, respondents were asked to answer a question adapted from McKnight et al. (2002) regarding their belief towards the Internet as a new medium or as a new environment (i.e., how confident they feel in the Internet system). This item was adapted based on high value of reliability and validity—its Cronbach alpha value was 94%. The fifth section tested respondents on their trust and trust intentions toward the e-commerce vendor. The questionnaire items reflected the most common trust belief dimensions, which are ability, integrity, and benevolence. Also it measured trust intentions—intentions to engage in trust-related behaviors with the Web vendor. All items in this section were adapted from Kammerer (2000), since his questionnaire items effectively discriminate trustworthy from less trustworthy online vendors. Also, Kammerer reports excellent reliability scores with Cronbach alpha values of 0.97%.

Experimental Procedure and Tasks

Previous online trust research has been criticized for relying on measuring trust without inducing any form of risk (Riegelsberger et al., 2003),
which represents an important key related to trust. To overcome these criticisms, this study induced financial risk in a laboratory situation. While it does not fully represent a real-world risk, nevertheless, it allowed combining a laboratory setting with some element of real-world risk by informing participants that the experiment Web site trustworthiness had been assessed and rated by independent business reviewer sites and one of their tasks was to identify the trustworthiness of each shopping site; those whose rating matched the real trustworthiness rate would be entered into a lucky draw with prizes such as a laptop to be offered in a random draw conducted at the end of the study. In this way we induced a slightly higher level of risk thus, increasing the realism of the experiment and encouraging participation.

At the beginning of the experiment a brief introduction and the total estimated time that it would take were given. Then participants started the first part of the experiment by opening the first experiment page, which includes the experiment objectives and instructions, then they started filling out sets of the first four questionnaires sections, which extracted some demographic characteristics, online purchasing experience, disposition to trust, and their belief towards the Internet as a new medium or as a new environment. **In the second part each subject was asked** to look at four Web sites and browse them. This involved looking at the site and then evaluating the e-commerce vendor using the online vendor trust questionnaire. This process was repeated for all four Web sites in the set. However, in order to avoid predictability and the effect of learning by subjects within the scenarios (the possibility that participants exposed to a particular interface or task would do better the next time they were asked to use it), we defined each media cue to a particular vendor Web site since they had almost the same usability criteria. Also, within the experiment software we included a software module with the capability to control the order display scenario of the four Web sites so that different subjects would receive each of the four experimental Web sites in a different order.

When subjects finished, they were asked to move on to the third part which comprised one task. In the first task each subject was asked to search the first Web site seen and imagine that they had enough money to buy a laptop that would serve their needs for the next two years. The subjects were required to indicate the model, price, and certain product specifications of their final laptop choice. Once the participants had found their products and completed their responses on the instruction form, they were asked to fill out the vendor trust questionnaire again.

**DATA ANALYSIS**

All data analysis was conducted using the SPSS Windows software package. A total of 72 subjects participated in this study, all male and between the ages of 18-25 and 26-35 respectively; most (79.2%) held bachelor degrees. As expected, this group was Internet-savvy with over 39% of the respondents spending between 6 and 10 hours online per week. On average, the majority made at least one online purchase per week and 28% of the respondents spent 2000SR (1$=3.75SR) or more per online purchase.

**Testing the Research Hypotheses**

The experiment analysis is based on the well-known statistical test of Friedman. This test is an alternative to the repeated measures analysis of variance (ANOVA), when the assumption of normality or equality of variance is not met. This, like many non-parametric tests, uses the ranks of the data rather than their raw values to calculate the statistic.

This test was chosen because it is suitable for comparing variant vendor Web sites embedded with different media cues when the relative data sample has some characteristics also presented in
this context, including the following ones (Peter & Smeeton, 2001; Sheskin, 2004):

- The experimental data is not parametric, that is, the dependent variables are not normally distributed.
- The number of compared Web sites is two and more. In our context, we typically compared several vendors Web sites embedded with different media cues.
- The same subjects were used to observe different manipulation in vendors’ Web sites.

To test the first hypothesis (H-1), the Friedman test was used. This test was computed for trust belief and trust intention of all Web sites to see if there were any significant statistical differences between the subjects’ answers with regard to the trustworthiness of the four Web sites. Two types of data were used in the analysis, the first was the mean value of each subject answer, and the second was the actual subject answer regarding each questionnaire item. Results showed the subjects differed significantly on their rating of their initial trust and trust intention regarding the four vendors’ Web sites owing to the overall statistical significance (P =.000) at 0.05 levels using the two kinds of data; so, the first hypothesis was supported (see Table 1).

In order to test the second hypothesis (H-2-a, b, c) it was necessary to conduct comparisons contrasting specific conditions with one another. Wilcoxon matched-pairs signed-ranks test was recommended by Sheskin (2004) and Peter and Smeeton (2001) for conducting the three pairwise comparisons (video clip, photo, no photo) with regard to trust belief and trust intention. Table 2 contains the results.

| Table 1. Friedman test for trust belief and trust intention between the four Web sites |
|---------------------------------|----------------|----------------|----------------|
|                                | Trust Belief    | Trust Intention |
|                                | Ability | Integrity | Benevolence | Ability | Integrity | Benevolence |
| N                               | 72      | 72         | 72          | 72      |
| Friedman test Sig at 5%        | Yes     | Yes        | Yes         | Yes     |

| Table 2. Results of Wilcoxon signed rank test |
|---------------------------------|----------------|
| Web site                        | Wilcoxon Signed Rank Test Asymp.Sig |
| With photo                      | Trust Belief   | Rank | Yes   |
| With video clip                 | Trust Belief   | 2    | Yes   |
| With no photo                   | Trust Belief   | 3    | Yes   |
| With video clip                 | Trust Intention| 2    | No    |
| With no photo                   | Trust Intention| 2    | No    |
After reviewing the three analyses, it was found that all pairwise comparisons were significant, with the exception of the video-photo Web site comparison in trust intention. Subjects rated the trust belief and trust intention for the photo Web site the highest, the video clip Web site next highest, and the no photo Web site as the lowest. Thus, the second hypothesis was only partially supported, since the vendor Web site utilizing the video clip came second rather than the expected first position. A possible explanation for this unexpected result is that the video clip was not recorded to professional standards.

The same procedure followed when testing the first, and the second hypothesis was also used to test the H-3 and the H-4 hypotheses, but in this case between two vendor Web sites only, (the Web site with the Saudi photo and the Web site with the Western photo). The Friedman matched samples results are shown in Table 3. The analysis showed that subjects differed significantly on their rating of their trust belief (ability and integrity, although not for benevolence dimension), and also for trust intention in respect of the two vendor Web sites (overall statistical significance of p=.000 at 0.05 levels using the two kinds of data); so the third hypothesis was fully supported (see Table 3).

With respect to the fourth hypothesis (H-4), the Wilcoxon matched-pairs signed-ranks test was conducted for comparison, contrasting specific conditions with one another with regard to trust belief and trust intention. Table 4 contains the results.

From Wilcoxon test analyses, it can be said that pairwise comparison was significant. Subjects rated the trust belief and trust intention for the

Web site using a Saudi photo as the highest; the Web site with a Western photo next. So the fourth hypothesis was supported.

**Analysis of the Exploration Depth**

In terms of investigating the factor depth of a users’ exploration of a site (exploration depth) which influences the effect of media-subject on user trust (Research Goal 3), a superficial exploration of the home page and additional pages with no task browsing was compared to a subsequent in-depth exploration of a vendor’s site, beyond the home page with predefined task browsing. Hence, each participant in this scenario saw the first vendor’s site twice: first only the home page and the additional pages that were linked from it, but with a general browsing task (superficial exploration); then the home page and additional pages, but with the specific task of imaginary purchasing—an in-depth exploration. The introduction of the exploration depth was used for several reasons. Most trust models indicated that browsing time is an essential factor affecting trust. Initial trust in the first encounter depends on factors other than behavioral trust that emerges from a long-standing relationship. Applying this consideration to the initial trust that can be measured in a laboratory experiment, it can be proposed that the level of trust will be based upon factors other than initial trust after a detailed exploration of the site. A media cue might have a strong effect based on a quick look, but might lose its significance once more information (e.g., from a site’s security and privacy policies) is obtainable. On the other hand, it can be expected that the first impression (e.g., influenced by a media cue) can color further information processing and thus have a long-term effect (Baron & Byrne, 2004).

The Human Face of E-Business

The same analysis techniques were used in investigating the data. The analysis confirmed the same finding, that there was a statistical significance between trust of the four vendors’ Web sites, where the Web sites with a facial photo were ranked first and then those with a video clip. Also the vendor Web site with a Saudi photo was trusted more (statistically significant) than that with a Western photo (see Tables 5, 6, 7, and 8).

Finally, many nonparametric correlation tests were conducted to see whether there were any significant relationships between the trust belief; trust intention and participants’ trust disposition; system assurance; age; education level; or Internet usage. Results showed no statistically significant differences between any of these variables.

DISCUSSION

This experiment investigated initial trust in e-commerce vendors. It explored the effect of adding a media cue (video clip or facial photo) to the home page of an e-commerce vendor and the effect of interpersonal cues that are implicit in media cues, on users’ trust in that vendor. It further studied the effect of the culture represented by a facial photo of a Western or Saudi man on users’ trust in that vendor. The factor depth of a users’ exploration of a site (exploration depth) was found to influence the effect of media cue on user trust. On a methodological level, the study aimed to overcome part of the limitations of conventionally used trust questionnaires conducted under conditions of no
financial risk by introducing trust questionnaires that were elicited under financial risk.

The analyses found that there were significant differences in vendors’ trustworthiness. This supports earlier research by Fogg et al. (2001) and Steinbrueck and Schaumburg (2002), and provides support for the first hypothesis. It was found that media cues can manipulate and bias users’ judgments towards vendors’ trustworthiness based upon inspection of surface cues. Thus, this experiment demonstrated that users can perceive the trustworthiness of a vendor from the surface cues that are present in a media cue displayed as part of the user interface.

Results from the Wilcoxon Signed Ranks test for responses given by subjects on the vendors’ trust belief and trust intention showed favor for the Saudi photo first, with the Western video clip as second and the Western photo as third in the superficial exploration task, while after in-depth exploration participants showed more trusting responses to the media cue vendors’ in terms of trust, and in their declared measures of preference.

An interesting and important result is that the effect of trust was improved once users explored vendors’ sites in greater depth, once they had looked further for a specific task in pages beyond the home page. It can be interpreted that the cues that carried reliable information about a vendor’s trustworthiness were perceived, and media cues could easily influence this decision. Hence, a media cue has a long-term effect on user trust and it biases the perception of other site elements (Baron & Byrne, 2004). Rather, the additional information perceived on additional pages improved the relative impact of the media cue.

In contrast to earlier studies on the effect of photos on e-commerce sites, this experiment investigated the effect of two different cultural photos (Western man and Saudi man) across two different e-commerce sites. This experiment found a bias for the presence of the Saudi photo over the Western photo in terms of trust measures in the superficial exploration task, in the-depth exploration task, and in terms of preference.

CONCLUSION

This experiment addressed the main research goals of the study. First, it investigated a media cue’s (facial photo or video clip) ability to influence user trust in respect of e-commerce vendors, based on surface cues that were implemented in the media cue. This goal is of high relevance, because this strategy is now being used by e-commerce vendors (especially facial photographs, but not yet video) in an attempt to increase trust and attract customers. Secondly, this research tested the effect on user trust of adding a facial photo from two different cultures (Western and Saudi) to an e-commerce vendor’s home page. It thus focused on the symbolic use of interpersonal cues. This goal, despite its importance for the development of trust in e-commerce, has not been addressed in previous research. Thirdly, the experiment was concerned with investigating how time, as an independent variable, represented by the depth of a users’ exploration of a site (exploration depth), influences the effect of a media cue on user trust by comparing a superficial exploration of the home page and additional pages with no task browsing to a subsequent in-depth exploration of a vendor’s site beyond the home page with predefined task browsing. Fourthly, most of the previous studies tested the effects of adding one photo to a mock-up of one e-commerce site. This experiment aimed to overcome this limitation by testing several photos on several semi-functional copies of existing vendors’ sites. In addition, this experiment introduced a method for measuring trust that required participants to make decisions under conditions of financial risk.

This experiment found that media cues in the interface are indeed able to affect a vendor’s trustworthiness based on the surface cues it contains.
A clear picture emerged regarding the effect of photos from different cultures. The experimental results found a positive effect of the media cues in the two stages of exploration—a superficial exploration and an in-depth exploration of a vendors’ Web site. These visceral reactions, however, appear to color the subsequent processing of signals, as their effect improved with the perception of additional signals from an in-depth exploration.

From a methodology point of view, this experiment verified that financial risk can be used in a laboratory experiment to enhance the validity of trust research. Analyzing users’ behavior leads to a relevant outcome to e-commerce vendors since they are concerned with users’ purchase decisions.

With respect to investigating the influence of the auxiliary variables on trust, such as trust disposition, system assurance, age, education level, and Internet usage, the experiment did not find any significant evidence that could support any kind of influence.

Finally, based on the findings of the experiment it is suggested that Web designers and e-commerce vendors should keep in mind the following recommendations when introducing e-commerce applications in Middle Eastern countries in general, and in Saudi Arabia in particular:

There is a significant effect of a media cue in B2C e-commerce Web sites. Users arriving at a site home page will decide, based upon their first impressions, whether to explore the site in more depth or leave it and go instead to a competitor’s site. The positive, attractive impressions of a media cue can thus help e-commerce vendors in the process of converting a visitor to a customer. The findings of this experiment underline the importance of the interface as a communicator of trustworthiness.

In B2C e-commerce applications it is very important to take cultural aspects into consideration when designing an e-commerce Web site. It is expected that when Web sites are appropriate and culturally sensitive, then users will have increased access to content and enhanced user experiences. Selecting photos of customer service representatives that relate to targeted markets represent an easy way to enhance the vendors’ trustworthiness.

Section VII
Critical Issues

This section addresses conceptual and theoretical issues related to the field of human-computer interaction. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters address particular algorithms for web personalization, sociotechnical change, and security for ubiquitous computing systems. Overall, contributions within this section ask unique, often theoretical questions related to the study of human-computer interaction and, more often than not, conclude that solutions are both numerous and contradictory.
INTRODUCTION

The individual sense of gendered identity and location are embedded within information technology (IT) usage (Meyrowitz, 1985). Exploring gender in relation to place and IT assists to reveal the impact that cultural knowledge has upon IT usage. This article illustrates the intertwined complex of issues that associate gender and place with IT by examining the currently dominant approaches to research conducted around this topic. The article begins with a presentation of the founding concepts regarding location and the construction of the gendered self, and then discusses investigations of gender, place and IT usage that utilize geographical and bounded constructs and, alternatively the concept of socially occupied space.

BACKGROUND

Situating experience physically—and by implication, locationally—reveals how socio-cultural and socio-technical knowledges play a significant role in the shaping of human action. Maintaining a sensitivity to sociality within IT-oriented research prevents solely technical considerations being interpreted as primary causal factors. Culturally shared knowledge—including media events, physical location, physical sensation and sexual innuendo—is utilized in all IT-enabled exchanges of information. These exchanges serve to strengthen “group” identity and solidarity. Although computer-mediated presence is not a physical environment, the range of possible experiences that can be achieved through engagement with IT-enabled environments are influenced by existing inequalities in the enveloping physical environment. The continual presence of this surrounding physical environment influences knowledge formation to all activities conducted in the IT-enabled environment. IT usage can locate the user—and their actions—simultaneously at many hundreds of machines, creating a physical indeterminacy of presence that challenges the dualisms of physicality, spatiality and the traditional understandings of gender formation (Green,
Owen & Pain, 1994). While gendered examinations of inequality abound (Adam, Howcroft & Richardson, 2002; Wilson, 2004), explorations of the gendered body in relation to technical artifacts are relatively under-represented within IT-based research. By exploring this gap and the intersections of gender, place and technology, it is possible to identify the significance of existing socio-cultural experience and technical knowledge as both barriers and gateways to knowledge acquisition in IT. The conflation of self presence with a “place” makes identity formation a complex phenomenon difficult to isolate or parameterize.

The notion of place and identity are well established in social science disciplines and particularly within geography (Ashkenas, Ulrich, Jick, & Kerr, 1995). “Place” is considered by many (Soja, 1996; Massey, 1994) as primarily a geographic construct providing the individual with a sense of “where” and “when.” However, with few exceptions (see Boland (Jnr), 2001), “modern” organizational forms tend to be analyzed and constructed within traditional and, consequently, physically fixed world views. Predominant discussions (e.g., Gagliardi, 1992) relating to an organization’s physical form reinforce underlying assumptions regarding IT and gender. These positions limit the scope of current analysis in IT research and in relation to gender as self-legitimating arguments that obfuscate critical perspectives.

**IT Artifacts and Human Activity**

The argument presented by this article is indicative of a growing body of research (Gagliardi, 1992) that predominantly combine anthropological and geographical approaches to the examination of human activity and IT artifacts within organizations. Most notably among these approaches is the collection by Gagliardi (1992). These studies critically consider the limits imposed by IT usage on employees’ success in their day-to-day activities. Arguably, the utility and strength of these studies is the parallel considerations of IT artifacts and organizational culture. As Ciborra et al. in Gagliardi (1992) state, “We submit that most recounts overlook the complex interactions between systems as dynamic artifacts and organizational culture.” There is a conscious effort in these works to move away from the causal considerations of computers as tools or control devices towards their role as participatory elements in the organizational environment.

The long history of social constructionist research has tended to look beyond physical form as the primary determinant in the examination of humans and technology. Notions of gender, place, space and even time are seen as social constructs that shape human perspectives of location, boundary and border.

The inclusion of daily lived experience and, specifically, gendered experiences, into the consideration of IT is a significant departure from technologically focused theories associated with implementation and organizational considerations (Ashkenas et al., 1995). Acknowledgement of the significance of cultural roles and everyday life enables an alternative interpretation of the spatiality that is embedded in IT. Geographically focused approaches that consider gender and IT usage, in contrast, utilize physical and observable boundaries (Johnston, 1997), including the spatial limitations imposed by a location. The neglect in explicitly articulating the gendered self of the researcher and the subjects of their research also consequently ignores the socio-cultural aspects of spatial constructions. Examining “place” in relation to the gendered body associates a series of physically bound artifacts, including computers and their intricate ongoing relationship with humans.

**Sense of Place**

Massey (1994, p. 119) describes “place” as a gendered experience that allows individuals to experience “locality” and “inhabitance” along with their own feelings of self-awareness:
So the search after the ‘real’ meanings the ‘self’ in relation to ‘place,’ is the unearthing of heritages and so forth, which is interpreted as being, in part, a response to desired fixity and for security of identity in the middle of all the movement and change. Obtaining a ‘sense of place’, of rootedness, can provide—in this form and on its interpretation—stability and a source of unproblematical identity.

“Unproblematical identity,” which encompasses gender-inclusive identity, is pivotal to the successful inhabitance of IT-enabled places. Inhabitance can be described as the willingness that people have to visit and continue to revisit a space, including IT-enabled environments. This willingness is reflected in the familiarity and closeness that people access and use IT. Anzaldua (1987) offers an example of how familiarity and descriptive closeness can influence relationship and identity formation in relation to “place.” Anzaldua extends her observations of marginalized gendered experiences, providing insight into the intimacy through which she experiences place.

I am a border woman, I grew up between two cultures, the Mexican (with heavy Indian influence) and the Anglo (as a member of a colonized people in our own territory). I have been straddling that Texas-Mexican border, and others all my life. It’s not comfortable territory to live in, this place of contradictions. Hatred, anger and exploitation are the predominant features of this landscape.

However, there have been compensations for this mestiza [a woman of mixed racial ancestry], and certain joys. Living on borders and in margins, keeping intact one’s shifting and multiple identity and integrity, is like trying to swim in a new element, an ‘alien’ element ... [that] has become familiar—never comfortable, not with societies clamour to uphold the old, to rejoin the flock, to go with the herd. No, not comfortable but home. (Anzaldua, 1987, preface)

Massey (1994, p.151) explains that a sense of “place” is established when individuals are able to achieve the combined sense of “locality” and “inhabitance.” The “feeling” of place is achieved through stable identity formation, including and acknowledging one’s gendered identity. In the context of IT-enabled environments, this “feeling” includes identification and familiarity of the IT artifacts being utilized.

Organizations as Bounded Territories and Places

Another way of examining the gendered experience of IT usage within an organization is to employ a spatial perspective. The construction of the organization as a territory, dichotomized between the bounded and unbounded, draws again upon geographic theories as a reference point. Ashkenas et al. (1995) utilize this perspective for their examination of IT. In their example, Ashkenas et al. (1995) emphasize geography in the hierarchical organization that is explored and challenged. The underlying concern in their work is the spatial examination of organizational structure. Spatial understandings of IT simultaneously depict ideas of vastness as well as emptiness. The spatial relativity of objects, such as water and our bodies, are often depicted as extensions of a surface (see Grosz, 1995; Bordo, 1996). The implication implicit in this representation is that extending the surface also incorporates notions of depth and vastness. This understanding of space is also regularly drawn upon to describe and situate human bodies, and therefore, contributes to social constructions of the gendered body (see Grosz, 1995; Bordo, 1996). Density is an aspect of spatial form and is expressed in the popular descriptions of outer space or the depths of oceans. However, spatial notions of depth also incorporate the idea of an inner space. Space conventionally encapsulates a dichotomized position that incorporates the void of an object. Lefebvre’s definition of space is most clearly presented by Molotch (1993).
Space is not simply inherited from nature, or passed on by the dead hand of the past, or autonomously determined by ‘laws’ of spatial geometry as per conventional location theory. Space is produced and reproduced through human intentions, even if unanticipated consequences also develop, and even as space constrains and influences those producing it.

Lefebvre’s understanding of space emphasizes the human requirements for constructing spatial forms. He does this by privileging the subjectivity inherent in the construction of social reality over the object-filled approaches utilized by other spatial analysis and, most particularly, those engaged in studies of geography. These studies are based on Cartesian theory; in other words, the mathematical rules of geometry that extrapolate the socio/temporal relationships of the universe into a manner capable of formulaic manipulation (Woods, 1996). It is Cartesian theory that provides an axis for understanding our “reality” through the duality of time and space. Within this dichotomy, it is time more than space and its impact on work practices, and hence, IT usage that has been, and continues to be, studied (see Boland (Jnr), 2001).

FUTURE TRENDS

Exploring the interaction between humans as gendered beings and objects requires a discussion of “spatiality” and the differing spatial configurations a variety of theorists have presented. “Spatiality” has an association with both time and space. A bodily object is understood in terms of its existence, its connection to “reality” and its mathematical representation (Lefebvre, 1991). The way we spatially position objects in our day-to-day lives is conventionally understood in terms of a human focal point and the relationship between objects and humans. These perspectives are tied closely to Western traditions of Humanism and the absence of the Cartesian object (Jones, 1993). Reality is constructed through existing observable material structures, those “things” that dominate the spaces of daily life. Structures, such as buildings, furniture and other people, can be critically presented as meaning-stabilizing entities (Rosen, Orlikowski, & Schmahmann, 1992). The existence of objects—in “reality”—requires a human physical presence to define its social meaning. When the individual is separated from the social system, it reinforces constructs that assert the presence of an ego “within,” or “inside,” the individual, while society remains “outside” (Elias, 1978). In constrained spatial analysis, such as that of Elias, social systems occupy a boundless space outside the individual and are disjointed from the bounded space defined by the traditionally understood gendered body. A spatial description such as Elias’ is static, placing time and all other social constructs in an arbitrary conceptual opposition to space (Laclau in Massey, 1994). Giddens (1985) as a structuration theorist, and in contrast to Elias’ ideas, interlocks the notions of time and space and, more specifically, time-space compression to interpret the contemporary usage of IT. Utilizing Massey’s theories regarding “place and gender” with spatial theory such as Lefebvre’s allows an analytical shift away from structural and notional time constraints. This shift from the theoretical emphasis found in works such as those of Elias and Giddens is necessary if the conducting of research is to be a determinant of meaning. As Lefebvre (1991) and other spatial theorists argue, it is socially occupied space that can most appropriately be utilized to explore all components of human interaction. In this way, it is arguably one approach that can be drawn upon when interpreting IT usage in a gendered context.
CONCLUSION

Lefebvre (1991, p. 38) defines place as:

... the relationship of local to global; the representation of that relationship; actions and signs; the trivialized spaces of everyday life; and, in opposition to these last, spaces made special by symbolic means as desirable or undesirable, benevolent or malevolent, sanctioned or forbidden to particular groups. We are not concerned here with mental or literary “places,” nor with philosophical topoi [conventions], but with places of a purely political and social kind.

Space in this configuration is the “place” that the individual goes to or chooses not to go to. As an embedded aspect of Western consciousness, space encapsulates all the tensions and oppositions that enable and restrict the individual and the group to interact and conduct their daily lives. Accounting for the gendered place of socially occupied space involves the description of not only the mundane daily visits to the stationary cupboard and canteen but also the quick peek into a fellow worker’s desk drawer to identify those objects associated with gendered identity. Documentary films, ethnographic accounts and the narration of daily activities provide the media for presenting the configurations of place, gender and identity. An understanding of the gritty reality of life and all the limitations and possibilities that unravel in daily life are necessarily presented to the reader once the analysis of a user’s place in relation to IT has been carried out. An example of this theoretical application exists in works, such as Hooper’s (1992) work exploring the production of citizen-bodies in classical Athens, nineteenth-century Paris and Los Angeles through a critical reading of the political emanations from the body of citizen Rodney King. Hooper (1992, p. 50) acts to place disorder at the borderlands of bodies, cities and texts. For example, she writes that:

Body and the body politic, body and social body, body and city, body and citizen-body, are ultimately linked productions ...

The practice of using the individual body as metaphor for the social body, of deploying it as a sign of the health or disease of the social body, develops in the Athenian polis with ideas of the democracy and reason, and continues into the present. Body and city are persistent subjects of a social/civic discourse, of elements and an equally obsessive desire to bring them under control: fear of pollution, contagions, disease, things out of place; desires for controlling and mastering that [become] the spatial practice of enclosing unruly elements within carefully guarded spaces.

The research exploring place, gender and IT echoes Hooper’s (1992) sentiments, as it extends Lefebvre and Massey’s notion of place, gender and identity construction theoretically. “Place” is an avenue from which to explore gender and IT, which, in turn, enables the unraveling of the significance of culture and knowledge acquisition in IT usage. By situating experiences both locationally and, therefore, physically, we are able to show that socio-cultural and socio-technical knowledge play a significant role in shaping the actions of participants. The acknowledgement of “gendered place” in identity formation and IT usage enables sensitivity to sociality not to be subsumed by technical considerations. Considerations of artifacts as they relate to daily experience and identity formation enables an understanding of knowledge acquisition that is IT enabled. The significance of culturally shared knowledge, including gender, physical location and physical sensation, are often neglected when studying users of IT and how they exchange information. Although IT existence is not necessarily tied directly to any physical environment, the range of possible experiences that can be undertaken when engaging with IT are influenced by exist-
ing inequalities in the physical that consequently affect knowledge formation via IT.

REFERENCES

KEY TERMS

**Gendered Body**: Recognition that the physical human body is itself a product of cultural and social forces.

**Gendered Place Experience**: The combined experience of “locality” and “inhabitance” framed within an individual’s own sense of self awareness.
**Knowledge:** Understanding that is actively constructed by the learner; not passively received from the environment.

**Inhabitance:** The willingness of individuals to visit and continue to revisit a space, including IT-enabled environments.

**Place:** Primarily a geographical construct providing the individual with context for the temporal and spatial concepts of “where” and “when.”

**Socio-Cultural Knowledge:** Experiential understanding of the external social world and its forces.

**Spatiality:** The way in which an object is understood in terms of it existence, its connection to “reality” and its mathematical representations.
Chapter 7.2
The Intersection of Gender, Information Technology, and Art

Linda Doyle
University of Dublin, Ireland

Maryann Valiulis
University of Dublin, Ireland

INTRODUCTION

The interdisciplinary field of art and technology is now well established in artistic and academic communities (Wilson, 2001). However, this article will focus on how the combination of technology and art can be used to facilitate the expression of thoughts, the experience of ideas and the explorations of concepts dealing with gender. A research project called the Art of Decision, which focuses on women in decision making, is used as a means of investigating the ways in which creative technologies can illuminate aspects of gender studies.

BACKGROUND

Creative Technologies

In the context of the research presented here, information technology (IT) is defined very broadly as an entire array of mechanical and electronic devices that aid in the storage, retrieval, communication and management of information. It includes all computing technologies and mobile and fixed communication technologies, but it is not restricted to those areas. Smart materials that change attributes on the basis of input stimuli and that can be used to present and display informa-
The Intersection of Gender, Information Technology, and Art

The use of creative technologies with its flexibility, crossing of boundaries, multidisciplinarity and interdisciplinarity lend themselves to feminist inquiry and provide a space to develop feminist...
The Intersection of Gender, Information Technology, and Art

research. At the most basic level, the tools available to us allow material on gender to be presented in a new and exciting way. While this, of course, applies to material of any nature, the use of these techniques in the gender sphere is particularly appropriate.

Gender studies are underpinned by feminist research methodologies. Feminist methodology is interdisciplinary and multidisciplinary, drawing insights from different fields and weaving them together through an understanding of feminist theory. For example, Ramazanoglu’s definition of feminist methodology (Ramazanoglu, 2002) speaks about feminist methodology as being grounded in women’s experience and seeks to analyze connections among ideas, experience and material reality. DeVault, on the other hand, discusses the need for “excavation ... that is to find what had been ignored, censored and suppressed, and to reveal both diversity of actual women's lives and the ideological mechanisms that have made so many of those lives invisible” (DeVault, 1999, p. 30). Reiharz includes in her definition an emphasis on multiplicity of methods and perspectives, of being transdisciplinary, of the effort to create social change, of being inclusive (Reiharz, 1992). Jenkins et al. see “the concept of power as central to feminist research” as well as noting the importance of “how the researcher and the researched have been gendered, sexualized, raced and classed” (Jenkins et al., 2003 p. 2, 4).

Irrespective of the exact definition used, feminist methodologies incorporate the desire to give women an opportunity to tell their stories, express their views and have their voices heard. In essence, it is women-centered. It acknowledges that researcher and researched are “gendered, sexualized, raced and classed,” and both bring these characteristics into the research project (Jenkins, 2002). We consider the interaction of gender with other characteristics of identity as vital to understanding the complexities of research. To summarize very broadly, feminist research methodology: (1) places major emphasis on valuing a variety of viewpoints, (2) is highly concerned with remaining true to the voices of both those who research and are researched, (3) embraces complexity of argument, and (4) incorporates

</table>
elements of social responsibility and a desire for social change. IT and, in particular in this case, the combination of the technology with artistic practices and methods, can play a major role in the first of these three essential criteria, as shown in Table 1.

As can be seen from that table, the negative potential of the technology is also listed. However, the existence of these very obvious negative factors also has a role to play. Often, traditional science and technology have assumed the air of impartiality and objectivity that gave them the veneer of having produced “authoritative knowledge.” In the current world, this is very much not the case. Exploring gender with creative technologies opens the discussion on how knowledge is produced, authorized and imparted. It helps to problematize questions of objectivity, authority and knowledge production.

The Art of Decision

The ideas introduced in this article are illustrated through an example of a research project undertaken jointly by the Centre for Gender and Women’s Studies and the Department of Electrical Engineering at Trinity College in Dublin, Ireland. This project, known as the Art of Decision, was funded by the Irish government through the Department of Justice, Equality and Law Reform and the European Union. The project aims to bring more women into political decision-making. To show how creative technologies and gender can combine in an effective way, a large interactive multimedia exhibition was specially designed and built. The exhibition took place in a Dublin city center warehouse during May 2005 and was open to the public. The exhibition comprised a series of rooms that immerse visitors in situations that invite them to reconstruct their perceptions of political structures and political involvement as women. Fionnuala Conway (artist and technologist) and Jane Williams (gender studies researcher), both from Trinity College, played a major role in the design of the Art of Decision. Figure 1 shows a schematic of the exhibition. Visitors enter the reception area and wander around the space as they please.

DATAmap

This is a large-scale (47x20 meter) interactive map of Ireland designed to present statistical data on the gender balance on Irish State bodies in more than 70 locations around the country. Users walk on the map and sensors embedded in the map trigger the associated area information on surrounding screens. The DATAmap presents information in a visually interesting and memorable way, depicting the statistics on women and men as pairs of symbols from everyday life – knives and forks, matches and flames, while suggesting a gender for each object. The presentation of the information in this manner highlights the arbitrariness of gender categories and opens discussion on gender categories.

Decisions, Decisions, Decisions

This is a short documentary film where nine people present their perspectives on decision-making. The film is screened in three parts, all three parts running concurrently and in the same location. As the user approaches the three
The Intersection of Gender, Information Technology, and Art

screens, a jumble of voices emerges and it is only by standing in the correct location that sense can be made of the film. In many ways, this project reflects the conflicting nature of decision-making, the “messiness” of the process and the fact that neither men nor women have a monopoly on decision-making procedures.

Finding your Voice

These are simple audio pieces that present unedited stories of two activist women. The stories are presented in two small, intimate spaces as audio installations with lighting design that responds as the stories unfold. The actual voices of the women are heard and their stories are told in their own, unedited words.

Rite of Passage

Images of the visitors to the Rite of Passage are digitally captured and their faces are superimposed on a large digital mural of figures from political life in Ireland, using image signal processing techniques. The power that attaches itself to gender, in this case the masculine gender, is evidence from the dominance of white middle-class men. As women’s faces are superimposed, the balance shifts and we are able to see a more gender-balanced picture.

The Art of Decision Daily Post

This is a giant interactive newspaper projected on a large wall of the room. A headline is automatically pulled at random from an online daily newspaper and displayed as the Art of Decision Daily Post headline and is based on technology by Doyle, Conway and Greene (Doyle et al., 2003). Visitors to the room can text their reactions from their mobile phones to the headline and the reactions appear as text of the newspaper. This is particularly relevant for gender concerns, as it can trigger a spontaneous discussion on current issues important to gender studies.

The VIP Room

The VIP room contains interactive pieces that allow visitors to explore power relations through the manipulation of graphical representations of people’s understanding of power. Drawings from participants are converted to digital format and displayed on the walls of the room. The images can be rotated and explored through control with joysticks. This exhibition illuminates the way in which women see the flow of power and the ways in which the power attaches itself to gendered institutions.

PowerHouse

The PowerHouse is a photographic exhibition presented in a set-designed caricature of a home, its garden and street. Seventy anonymous participants were given disposable cameras and asked to take photos that represent their ideas of power and include comments on the photographs. The visitor is invited to find these photos and comments in the PowerHouse. The research participants’ evaluations of how their attitudes to power changed over the course of the project are also presented over speakers in the PowerHouse. The images can be viewed as an online exhibition at www.imagesofpower.net, where viewers are encouraged to contribute their own comments on the photographs. Using photographs to capture ideas of power provides a different way to capture what power means. Having a camera for a period of time to capture the images creates a persistent alertness to the notion of power. The “voices” of women are heard through the images they chose to take. This type of approach allowed a wide range of women to participate without the need to be able to write skillfully or express themselves eloquently. It also meant that the unedited view of the participants, namely, their photographs, could be presented without interpretation by the researchers.
Rant Room

This is the last exhibit in the journey and is intended as a resting space. Visitors can relax here and text or mail their opinion and comment on the exhibition. The comments board is continuously updated in the space and online during the exhibition so that visitors have the opportunity to send their comment from any remote location via text and e-mail and see it on screen in the space. This exhibition simulates discussion on gender issues. It is an excellent mechanism for allowing voices to be heard in an uncensored manner and for collecting data on views about gender.

FUTURE TRENDS

The ability to stimulate thinking and discussion about gender can increase with the growth in creative technologies. This is particularly important among the younger segment of the population. What was quite striking in the Art of Decision project was the appeal it had to second-level students (students in the 12-18-year age group). They responded positively to the presentation of ideas about gender, gender imbalance and the arbitrariness of gender categories. Thus, joining creative technologies and gender in an interactive manner has the potential to revitalize interest in and discussion about gender among younger cohorts of men and women.

CONCLUSION

Using creative technologies to explore gender enables the researchers to design research projects that cross traditional boundaries and create spaces for women to participate in an active and engaged manner. Using the principles of feminist methodologies focuses the research projects on being women-centered and about doing research in the interests of women. They involve the researched in an active and engaged manner in the evolution of the project. Some allow the participants to change the direction of the research by their input. All stress agency. Moreover, these projects are about raising awareness and consciousness, about presenting information in a new and engaging manner. They tackle issues of power imbalance and work towards bringing new faces into a revitalized feminist debate. When feminist methodology is linked to creative technology, the results are powerful and our understanding of the operation of gender is magnified.

On a theoretical level, the joining of gender, feminist methodologies and creative technologies is most exciting. Creative technologies disrupt the traditional notions of authority and the authorization of knowledge. Because it is technology and technology is allied to science, there is an expectation of authority, validity and objectivity. But creative technology problematizes these expectations and instead focuses on issues of subjectivity, of nonlinear thinking, of multiplicities and imaginings. The questioning of traditional authority characteristic of feminist methodology is given added weight when allied to creative technologies. It reinforces one of the beliefs of feminist methodologies that the authorization of knowledge is not an objective process based on a detached analysis. Rather, it stresses the fact that knowledge and the authorization of knowledge is political and provides the mechanism to reveal that this authorization is raced, classed and sexed.

Moreover, linking creative technology to gender provides opportunities for many, especially those not necessarily comfortable with technology, to not only understand the technological dimension to their project, but to take ownership of it. It calls into question the divide that places technology as a “masculine” tool and allows men and women to participate in this field.

By harnessing the power and potential of creative technologies to feminist methodologies, a richer, stronger, more dynamic understanding of gender may emerge.
REFERENCES

KEY TERMS

Ad Hoc Network: A collection of nodes that form a network on an as-needed basis without the need for any preexisting infrastructure.

Blog: This is the short form of Weblog. A Weblog is a personal journal published on the Web. These journals typically contain informal thoughts of the author in the form of posts or short dated entries in reverse chronological order.

Bluetooth: A technology specification for small form-factor, low-cost, short-range radio links between mobile PCs, mobile phones and other portable devices.

Gender: Gender is primarily defined as the interplay between biology and culture in which definitions of femininities and masculinities are developed and dispersed in accordance with their norms. These definitions are neither unity nor static, so that one can speak of hegemonic masculinities or emphasized femininities.

IEEE 802.11: A wireless local area network standard.

Instant Messaging (IM): A text-based computer conference over the Internet between two or more people who must be online at the same time. When you send an IM, the receiver is instantly notified that he or she has a message.

Moblog: This is similar to a blog except in the case of a mobile Weblog (or moblog)—the content is posted to the Internet from a mobile or portable device, such as a cellular phone.

SMS: Short Message Service, or also known as text. SMS facilitates the sending of text messages on mobile phone systems.
**WiMAX**: A standard for delivering point-to-multipoint broadband wireless access. Specifically, WiMAX is an acronym that stands for Worldwide Interoperability for Microwave Access.

**Zigbee**: This is a proprietary set of high-level communication protocols designed to use small, low-power digital radios based on the IEEE 802.15.4 standard for wireless personal area networking.
Chapter 7.3
Gender-Based Attitudes Toward Technology

Konrad Morgan
University of Bergen, Norway

Madeleine Morgan
University of Bergen, Norway

INTRODUCTION

During the past 30 years of investigation into the ratios of males and females using technology (Harrison, Rainer, & Hochwarter, 1997), there have been consistent reports of males being more positive toward technology and being more likely to adopt the use of new technology on a voluntary basis (Volman, & Van-Eck, 2001). This trend has been reported from early school through adult life, and from diverse geographical sources (Broos, 2005; Heemskerk, Brink, Volman, & Ten-Dam, 2005). Although some scientists have argued that this pattern is changing (Colley & Comber, 2003; Durndell & Thomson, 1997), surveys continue to show an imbalance between the sexes favoring males over females (Colley & Comber; Heemskerk et al., 2005).

The authors consider the consequences of this gender bias to be significant not only in terms of maximizing the whole potential workforce, but also because there is some evidence that males design information- and knowledge-based systems in ways that are different from females, and often these differences favor male users in communication and searching methods. The gender imbalance may become of increasing importance as high-technology industries, such as knowledge engineering and Web commerce, become the normal methods of conducting business throughout the global economy.

BACKGROUND

A scarcity of females in computing can be detected from the earliest levels in many educational systems (Durndell & Haag, 2002). It pervades through all levels of education and into industry (Jackson, Ervin, Gardner, & Schmitt, 2001). This trend could not only pose a threat to the economic growth and stability of the global economy, but it
may also reflect a continuing gender inequality in society.

When we consider the individual differences that occur in humans, then gender, along with age, are often considered among the primary attributes that differentiate people from each other. In comparison to many of the differences such as intelligence, cognitive style, or social grouping, the difference of gender is relatively easy to determine; but like racial origin or social grouping, the topic of gender is often sensitive and highly controversial (Morgan, Brebbia, Sanchez, & Voiskounsky, 2004).

Explanations for these reported gender differences have been varied, but include genetic and hormonal sources (Brosnan, 2004), brain chemistry (Bransford, Brown, & Cocking, 1999), cerebral lateralization (Brosnan), and social roles (Morgan, 2005; Morgan, Gibbs, Macleod, & Morris, 1991; Morgan & Morgan, 2000; Morgan et al., 2004).

FUTURE TRENDS

Reviews of the literature of gender and technology show a consistent trend of male domination in the computing industry and education (Volman & Van-Eck, 2001). Although there appears to be no single reason for this domination, social roles and stereotypes are now thought to be of major importance in shaping education and vocational choices (Durndell & Thomson, 1997; Morgan & Morgan, 2000).

There is a growing body of evidence that suggests that there are strong parental influences on the attitudes and behaviors that we develop in later life. These influences include not only our views on appropriate gender-based behavior (Snyder, Velasquez, Clark, & Means-Christensen, 1997; Tidwell, Witt, 1997), but also our attitudes toward technology and even our self-rated proficiency in using technology (Morgan, 2005; Morgan et al., 1991; Morgan & Morgan, 2000; Morgan et al., 2004). It is the authors’ view that in order to redress the gender imbalance inherent in the technological world of the future, greater emphasis should be placed on parental influence and also that of the educators to encourage females to explore and develop a positive technological attitude. Of equal importance is the establishment of more positive female role models, particularly with regard to the representation of women and technology in the media.

CONCLUSION

As yet, there are no universally accepted explanations for the sex differences found in computing. Broos (2005) conducted a large quantitative analysis of previous studies of the gender divide in ICT attitudes and found, in general, females had more negative attitudes toward computers and the Internet than did men. As we have seen, there is some evidence that social and cultural effects play a large role in gender differences. The mass media also can influence people’s perceptions by the way in which they portray sex roles. Currently, males are usually portrayed as being the predominant users and being in dominant roles in any mixed-sex portrayals (http://www.media-awareness.ca/english/issues/stereotyping/women_and_girls/index.cfm).

One other factor that could explain the lack of females in computing is the harassment of females in the typically male-oriented workplace (Rutter, 1996). This reflects a sexist attitude of viewing females as sex objects rather than human beings or fellow workers. The task of addressing such unfair attitudes, stereotypes, and biased behavior will take considerable time, but it can only be hoped that a day will come when such unfair pressures are removed.

**KEY TERMS**

**Cerebral Lateralization:** The theory that the attitude and behavior differences reported as existing between males and females are due to differences in brain specialization. Specifically, left-hemispheric activity is associated with male behaviors, and right-hemispheric activity is associated with female-type behaviors.

**Cognitive Style:** The high-level heuristics or principles that organize mental behavior. Some researchers propose that the natural cognitive style of males and females are not only different, but are responsible for many reported gender differences.

**Gender Roles:** The sets of behaviors and attitudes that a society or culture normally associates with males or females.

**Sexual Harassment:** Unwelcome and unlawful discriminatory behavior or attitudes that are related to sexual or gender roles.

**Technology:** The term technology is used within this article to cover the cluster of technologies that includes all aspects of ICT, networked computers, hypertext, hypermedia, the World Wide Web, and other adjuncts.

**Technology Attitudes:** The views held by an individual with respect to technology that influences not only his or her rate of voluntary use of technology, but also predicts stress levels when faced with situations that involve the use of unfamiliar technology.

INTRODUCTION

Distance education is defined by six pedagogical elements: (1) physical separation of teacher and learner; (2) regulatory function or influence of an educational organization; (3) media to connect teacher and learner; (4) two-way communication exchange between teacher and learner; (5) individualized pedagogy instead of group focus; and (6) “industrialized” facilitators, entailing less individuated instructors (Keegan, 1980). Distance education technologies include video (videotape, satellite delivery, microwave delivery, broadcast video, and desktop video), computers (e-mail, Web-based courses, video conferences, DVD, and CD-ROM), collaborative activity software (chat, discussion rooms, and white boards), voice/audio technology (telephone, voice mail, audio conferences, audiotapes, and radio), supplemental print material (books, study guides, workbooks, and FAX), mobile technology (laptop computers, PDAs, tablet PCs, and cell phones), and blended-learning combining one or more of these delivery methods together, including face-to-face instruction.

Distance education technologies as tools are situated in the larger context of technological and scientific knowledge, economic institutions, including the property and market institutions of capitalism, and social institutions, such as education, which historically has been unequal and exclusionary due to class structure and the system of gender and racial power relationships (Carroll & Noble, 2001). People barred or deterred from regular access to education in various ways have always been users of distance education technologies, starting with its inception as correspondence course education in the 19th century and continuing today in high tech distance education classes with women comprising the majority of enrolled students (Hansen, 2001; Ossian, Christensen, & Rigby, 1968).
The promise of distance education technologies in the 21st century is for empowerment of students through democratization of knowledge, personalized pedagogy, and convenient access. Despite the promise and the current high enrollments in distance education courses, attrition rate is high in North America and Europe (Carr & Ledwith, 2000; Serwatka, 2005), and this is a concern to educators and social policy makers, who search for reasons to account for the discrepancy between promise and practice. While recognizing men students have high attrition in distance education courses, too, the fact is women comprise the majority of distance technology users. If educators and policy makers hope to use distance education technology to reach female students (and garner the interest of more male students as well), then issues of gender in distance education technology need to be addressed. A female gendered perspective on distance education technology reveals a number of variables that explain women’s disengagement and dissatisfaction with online educational delivery systems. Educators, secondary education institutions, and instructional software designers are some of the groups working to create and implement inclusive, constructivist, and rich multi-media instructional design (McLoughlin, 2001) that will accommodate a wide range of learner needs.

BACKGROUND

Educational technology associated with distance education reflects the evolution of human institutions and inventions, starting from mail delivery and evolving to CD-ROMs and PDAs. From its beginning in the 19th century, distance education stemmed from a scarcity of educational resources in an era with more rigid class and gender definitions than in the 21st century (Carroll & Noble, 2001; Gandle & Katz, 2004). Distance education, first known as correspondence education because course materials and lessons were conducted using the postal service, was directed toward nontraditional, under-privileged and disadvantaged groups who did not have economic, geographical, or social access to education. Correspondence course users included people who were poor, rural, intellectually gifted, and female. In the U.S., distance education was modeled after European correspondence education, such as the program started by Isaac Pitman in Great Britain offering shorthand instruction. In 1892, the University of Chicago established a school of correspondence study that raised the reputation of distance education as an institution in the U.S. Most distance education schools in the United States in this time period were not the caliber of the University of Chicago, however. Often advertising their educational programs on matchbook covers, hence the derogatory appellation matchbook colleges, these schools were considered inferior to traditional education and often were second-rate and even charlatan. With the 20th century advent of new technologies, such as radio and television, however, correspondence education in general took on other forms and its respectability began to improve. As technology continued to evolve, using audio cassettes, video cassettes, cable television, and tapes, so, too, did correspondence education. The modern stage in correspondence education began in the 1970s with the creation of Open University in Great Britain, where print instruction was supplemented with audio-visual technology. Within this time frame, teleconferencing and computers began to be used as instructional mediums. In 1982, the International Council for Correspondence Education evolved into the International Council for Distance Education, and the term correspondence course dissolved.

Today distance education is a legitimate and mainstream pedagogical practice in K-16 education and employee training. Many educators, business leaders, and policy makers are firm in the view that, there is no significant difference in asynchronous learning networks (ALNs) from
University (brick and mortar) settings in terms of learning outcomes (Allen & Seaman, 2003). Currently, in the early 21st century, distance education, along with its various technologies, is an integral part of education, specifically, higher education services, which are projected to reach 160 million students by 2025 (Hansen, 2001).

WOMEN AND DISTANCE EDUCATION TECHNOLOGY

Women have taken advantage of distance education from the 19th century, when, in an era of educational rationing, depending on class, sex, and race, people were denied access to higher education and professional education. (Carroll & Noble, 2001). Now in the 21st century, women are the dominant user group of distance education, although they no longer depend on the postal system for delivery of course material. Instead, the computer is the major distance education technology with instructors utilizing various ALNs or course management systems (CMS), such as WebCT, Desire2Learn, and Blackboard, which allow students to access classes anywhere and any time they have Internet connection. Some instructors create their own CMS by placing material on their own individually designed Web sites, often with a la carte features added, such as discussion boards and chat rooms. The computer skills students need to engage with any of these courses are minimal. Orientation to the online environment is a major requirement, but once this is accomplished, a good deal of activity on the computer entails keying in text and handling the mouse. Although technical difficulties may intrude from time to time, most CMS are user friendly and designed to be problem free.

Despite women’s long history as distance education students and user-friendly CMS, female interaction with distance education technology, specifically computers, is problematic. Generally, women lack confidence with computers and are anxious about encountering technical difficulties, although, ironically, they are more successful in completing online course than men, who tend to have greater confidence and proficiency with computers (Parker, 2003; Serwatka, 2005; Taplin & Jegede, 2001). Attrition in online education is high for women, and many express dissatisfaction with their online learning experience. Men students also experience high levels of attrition and dissatisfaction when it comes to distance education; however, given that the majority of distance education students are women, educators, cognitive scientists, and educational software designers are especially interested in determining why women are not more enthusiastic users of distance education technology. Research suggests a number of gender variables influencing women’s attachment and detachment to distance education technology, all of which contribute to an inequitable and unsatisfactory learning experience: computer socialization, which includes diversity issues; tacit discrimination; androcentric dominance online; lack of support structures for successful course completion; and poorly designed online courses.

COMPUTER SOCIALIZATION

In Western middle class educational settings and home life, gender enculturation in terms of computers is evident at an early age. At home, boys are generally given more access to computers than girls, who instead will often watch males in their households use computers. Toys and games also serve to reinforce this gender divide in computer use, especially since computer games typically have been created and manufactured for boys. Although the educational value of computer games is contested, research indicates gaming does accustom boys to online environments, allowing them to become accustomed to navigating through games and online sites and using discussion boards and forums to locate cheat sheets and
build competencies in gaming, programming, Web site development, and technical troubleshooting. Consequently, before adolescence, boys can have keyboard dexterity and technical proficiency that will be helpful in future coursework and computerized instruction.

The socialized gender divide in computer acclimation becomes more evident in middle school and high school, where girls, even though enrolled in more advanced placement (AP) classes than boys, are not active in computer science classes or clubs. In post-secondary education and college, this pattern persists. Computer science (CS) in college and career choice is a largely male terrain with women earning a low percentage of the bachelor’s degrees awarded in CS in the U.S. Women who do take computer courses in college terminate training much earlier than males; women with CS degrees earn fewer advanced degrees. Socialization, social expectations, and cultural metaphors all guide these choices. (Palmieri, 2004; Rajagopal & Nis, 2003). Girls who are not comfortable with computers grow up to be women who are apprehensive about computer use and this attitude affects their experience of distance education courses, even when they enter or exit courses with the required competency in computer use (Fisher & Margolis, 2002).

**DIVERSITY**

Although women in a gendered world have some historical and social experiences in common, there is no uniform female experience, and any examination of women’s interaction with distance education technology must acknowledge the diversity of women’s lives (Carr & Ledwith, 2000). Socialization with regard to computers and computerized instruction, then, is qualified by differences in each woman’s personality, family socialization, class, and ethnicity, (Hayes & Flannery, 2000). Women who have multiple cultural identities, such as Spanish American and Asian Americans, often experience conflicting demands and expectations from two cultures, adding another variable to gender and distance education technology. Some women, for instance, depending on their ethnic backgrounds, find it difficult to provide critical commentary on written texts or written authorities, which makes distance education assignments requiring critical analysis difficult for them to fulfill. When it comes to working poor and underclass women in the U.S. and first world countries, these women, who often have not completed secondary education, have difficulty utilizing distance education technology because of economics and because electronic culture is unfamiliar in their social and educational milieus.

**TACIT DISCRIMINATION**

A more crucial factor involved with women’s attitude and relationship with distance education technology is tacit discrimination that deters women from computerized instruction and computer use in various ways (Palmieri, 2004). The basic tenet of tacit discrimination, derived from feminist theory, is that men and women lead very different lives in patriarchal societies; gender as a system of social organization and social relationships has effects on learning and knowledge acquisition (Hayes & Flannery, 2000) and makes self-realization and functioning in society more difficult for women. Unlike blatant sexual discrimination, which is now mitigated by statute law, tacit discrimination is unconscious and subliminal in terms of its gender discrimination, making it difficult to recognize and surmount.

One example of tacit discrimination in relation to the gendering of distance education technology is educational institutions not providing safe access to campus computer labs at night, which dissuades women from computerized instruction. Another example of tacit discrimination toward women using distance education technology is the
Gender in Distance Education Technology

failure of institutions and instructors when planning educational programs or designing courses to take into account that school work for many women entails a “third shift” in their lives, along with the first shift of childcare and family responsibilities and the second shift of paid employment (Kramarae, 2000). Although some men students also work a “third-shift” in terms of child care and family responsibilities, statistically women in society still perform a majority of third-shift work. The burden of this third-shift creates not only work overload and increased stress but also anxiety about failure. As a result, many women withdraw from distance education courses or do not successfully complete them.

ANDROCENTRIC DOMINANCE ONLINE

Another factor contributing to women’s dissatisfaction with distance education technology and online instruction is the dominance of men in CS and digital culture. Predominantly, computers and the Internet are male terrains, although women use computers and the Internet for e-mail transmissions, social interaction on discussion boards and forums, and e-commerce (Fisher & Margolis, 2002). Computer hardware, software, tech-speak, and online communication comprise an androcentric or male centered world that does not overtly bar women, but it does not always encourage their participation or engagement. For example, in Internet communication, whether forums, discussion boards, or chat rooms, male dominated speech prevails: aggressive, blunt language; harassment; flaming; and combative, sexualized jargon.

This male patois in electronic culture carries over to distance education technology in chat rooms, discussion boards, and class e-mail transmissions where men tend to dominate communication (Jackson, Ervin, Gardner, & Schmitt, 2001). When women encounter male classmates online with these behaviors, similar to traditional classroom dynamics, the learning environment is perceived as non-nurturing and hostile, causing self-doubt and silence. Research shows that male verbal dominance in online class environments takes many forms, all of which make women feel unwelcome: indicative, imperative, and agonistic verb moods; intentional and unintentional patronizing language; dismissive and hostile comments; and vulgar speech. In this verbal environment, women often feel alienated, consider themselves as outsiders, and are disinclined to further their education using distance education technology (Jackson, et al., 2001; Taplin & Jegede, 2001; Vuorela & Nummenmaa, 2004).

LACK OF SUPPORT STRUCTURES

Still another reason for women’s disengagement from distance education technology is lack of support structures for successful pursuit of educational goals. Lack of support falls in to five categories: institutional, occupational, peer, instructional, and familial, all of which men in distance education courses experience as well. Because distance learning differs from conventional learning primarily in terms of student isolation and self-discipline, it is important for students to have support structures that enable them to successfully engage with the course material (Serwatka, 2005; Taplin & Jegede, 2001). Problems develop for students when these support structures, for various reasons, are not in place.

Lack of institutional support results when campuses operate as if they only have traditional students to service, such as when offices and college services are not open in evening hours. Occupational support systems fail when employers, who are generous with oral encouragement and financial support, do not follow through in terms of flexible work hours that would allow completion of class work. Peer support structures founder when students feel isolated from other students in
the class, both in terms of physical presence and communication lines. Although women typically do well with the self-regulation and independent study required in distance learning, the social isolation from other students is difficult for them (Moore, 1993; Parker, 2003; Serwatka, 2005). Lack of instructional support takes the form of unreceptive, unresponsive instructors who do not respond to e-mail in a timely manner. Close contact with online instructors is another crucial factor in whether women gauge their online experience as meaningful and worthwhile (Serwatka, 2005; Taplin & Jegede, 2001). Finally, lack of familial support also hinders women distance education students. Although women generally like the convenience of working from home and not having to commute, home life does not always nurture educational effort, and psychological or emotional support from family members is absent (Kramarae, 2000).

PEDAGOGICAL SHORTCOMINGS

Questions about women’s attachment to and detachment from distance education technology leads to questions about the quality of the pedagogical theory and design informing the technology as well as the quality of teaching by online instructors. How do designs and practices of distance education technology affect women learners’ experiences? Distance education practitioners suggest five criteria for quality distance education instruction and delivery: facility with delivery and access; learner control over the medium, including adequate skills for human-computer interface; a high degree of interaction, not only between teacher and learner but learner and learners; a rich multimedia learning environments, utilizing audio-visual material; and a strong social presence in the course (Short & Christie, 1976).

Examination of these criteria reveals that, the major distance education technology in use, the computer, is not the problem, even though women experience computer anxiety. Distance education course design, content, and teaching practice, however, do fail to live up to the suggested criteria. Traditional pedagogical frameworks, similar to on-site lecture courses, still predominate in online instruction. Too often, course material is nothing more than classroom text and notes transplanted online (Allen & Seaman, 2003; Lee & Owens, 2000). Additionally, many courses are designed using a middle-class male episteme or knowledge framework, which alienates many students (Moore, 1993; Serwatka, 2005; Tisdell, 2000). Online teaching is also lacking. Many online courses lack strong social presence and have low levels of instructor-student and student-student interaction (Hayes & Flannery, 2000; Moore, 1993). Consequently, men and women students both are disenchanted with their online educational experiences.

FUTURE TRENDS

Educators, instructional designers, and educational institutions are aware of the factors impacting women’s experience with distance education technology and online instruction, and, accordingly, they are making efforts to correct weaknesses and deficiencies. Elementary and middle schools are requiring girls to be computer literate as well as literate in digital culture, and educational and recreational software is being designed for girl students and girl gamers. All these efforts will nurture female computer confidence. Educational institutions are offering affordable day care facilities to accommodate women students with children; providing safe access to computer labs in evening hours, including security guard or buddy-system escort service to cars; and adding evening office hours for access to administrative offices and student counseling.

Educational and feminist theorists, aware of the importance in designing online courses to meet
the needs of the target audiences and the needs of those who are at a disadvantage, whether from gender, ethnicity, or socio-economic background, are designing online classes that promote endogenous learning and knowledge construction for all students (Carr & Ledwith, 2000; Hayes & Flannery, 2000; McLoughlin, 2001; Palmieri, 2004; Tisdell, 2000). Emphasis is placed on universal and inclusive pedagogy in instructional design because it requires instructors and designers to place learners’ needs first in the educational process and design courses for diverse student bodies. Implementing constructivist pedagogy in online instruction, which emphasizes the active participation of the learner, is also viewed as key in pedagogical reform (Weigel, 2001).

Online course designers and educators are also striving to take advantage and make use of rich multimedia software and utilities in online material (Billinghurst, Kato, & Poupyrev, 2001; Knemeyer, 2005; Lee & Owens, 2000), which will stimulate all the senses and intellectual faculties. These designers and educators are aware that more innovation is needed in online instruction, such as an electronic teaching theater that takes advantage of hypertext and multimedia and allows “depth education” (Weigel, 2001) that will engage and challenge students. Learning objects (Los), such as those available through Project Merlot—http://www.merlot.org/Home.po—can also be used to enhance online instruction.

Finally, educational institutions and instructors themselves are acknowledging that, distance education instructors, who are the key to making distance education technology and online instruction a positive experience for students, need training and institutional support on how to design stimulating and challenging online content (Allen & Seaman, 2003; Moore, 1993). Accordingly, faculty development training in online instruction and effective use of distance education technology is now the new standard in post-secondary educational institutions.

**CONCLUSION**

Distance education technology has evolved a long way from the 19th century mail delivery correspondence system to computerized instruction. Statistics indicate women, the dominant user group, successfully complete distance education classes more than men; however, women, as do their male student cohorts, experience high attrition in distance education courses and express dissatisfaction with their educational experiences. There is no single factor responsible for female attrition, nonparticipation and discontentment; the reasons are multidimensional and complex: computer confidence socialization; diversity issues of race, ethnicity, and socioeconomic status, which qualify women’s relationships to digital culture; tacit gender discrimination, such as “third-shift demands of childcare and family responsibilities on women; androcentric dominance online; support network absence; and pedagogical shortcomings in instructional content and instructors themselves. Improving women’s experience with distance education technology begins with awareness of these factors and the acknowledgment that a woman-centered, learner-centered perspective by educational institutions, educators, and instructional designers is needed in order to make effective corrections. Approaching distance education technology from an inclusive perspective, along with applying constructivist pedagogy that is highly interactive and rich in multimedia will humanize and enrich online education for all learners—for men as well as women.

Gender in Distance Education Technology

**KEY TERMS**

**Asynchronous Learning Network (ALN):** An online method of instructional delivery that enables students to have the flexibility of learning at anytime from any location over the Internet.

**Constructivist Pedagogy:** A learning theory that contends learning should be an active process, whereby learners themselves construct new ideas or concepts based upon their current/past knowledge. Constructivist instructors encourage students to discover principles by themselves, and the instructor and student engage in highly interactive, Socratic dialogue.

**Inclusive Pedagogy:** See **Universal Design for Instruction (UDI).**

**K-16:** Refers to kindergarten through four years of college or post-secondary education.

**Learning Objects (Los):** Instructional modules that enable and facilitate the use of educational content online. Due to internationally accepted specifications and standards, Los are interoperable and reusable in various learning environments. (http://itdl.org/Journal/Sep_04/article02.htm)

**Personal Digital Assistant (PDA):** A handheld device that combines computing, telephone/fax, Internet, and networking features. Some PDAs can also react to voice input by using voice recognition technologies.

**Social Presence:** One of the most important factors for student engagement, collaboration, and retention in online learning environments. Social presence is the ability of learners to project themselves as real people and relate to the instructor and class peers socially and emotionally online. Formation of social presence for each student is not automatic; it must be nurtured and supported by the online environment and the instructor.

**Tablet PC:** A compact, portable device that incorporates many features of a laptop computer while also allowing learners to write lecture notes and save them electronically.

**Tech-Speak:** The formal technical vocabulary of programming, computer science, electronics, and other fields connected to hacking. (http://catb.org/~esr/jargon/html/distinctions.html)

**Universal Design for Instruction (UDI)/Inclusive Pedagogy:** An approach to teaching that consists of the proactive design and use of inclusive instructional strategies that benefit a broad range of learners including students with disabilities” (UDI Fact Sheet, 2002). Chapter 7.5

Gender Differences in Information Technology Acceptance

Will Wai-kit Ma
Hong Kong University of Science and Technology, China and Hong Kong Shue Yan College, China

Allan Hio-Kau Yuen
The University of Hong Kong, China

INTRODUCTION

Gender differences in computer use has been always a topic of research interest. The understanding of the patterns among gender, including beliefs, intention and use behavior of IT/IS would provide us a better picture to the process of design and implementation, which gives support to IT/IS success. However, published works explaining why and how beliefs and attitudes varied between different genders are still scarce, yet the topic was of widespread relevance.

We direct our empirical work on user’s beliefs, intention and usage behavior. Gender differences in beliefs would likely make a corresponding impact on the intention to use or not to use computer in the future, and hence, the actual usage pattern. Assumed to be behavioral manifestations of users’ gender differences, we infer these gender differences in the beliefs of computer use from their self-reported intention and usage behavior.

Therefore, we aim to explore the factors affecting the intention and usage behavior; and their corresponding strengths in affecting the intention and usage behavior; in order to suggest effective implementation strategies accordingly.

The research questions of this empirical study are:

1. What are the emergent constructs that drive the intention and usage behavior of computer use?
2. Do users’ beliefs regarding IT/IS usage differ among genders?
3. To what extent do these effects differ?

To address these research questions, we applied technology acceptance model (TAM) to a group of pre-service teachers, and measured their beliefs in using computer to explain the gender differences in their beliefs, intention, and usage of computer. The rest of the article proceeds as
follows. The next section starts with a review on gender and technology. The third section explains the model framework TAM. The fourth section describes the instrument construction and validation. The fifth section reports the model testing results. The final section discusses the thrusts of the study and future trends.

BACKGROUND

There have been findings showing that gender differences in computer acceptance are prevailing. Young (2000) found significant gender differences in computer attitudes of 462 middle and high school students. The male domain scale showed that boys were more likely to have claimed computers as a male area. Thus, higher levels of confidence and, for males, the absence of negative teacher attitudes were associated with greater computer skills. Using TAM as the theoretical framework, Venkatesh & Morris (2000) found that, compared to women, men placed a greater emphasis on perceived usefulness in determining behavioral intention. On the other hand, women weighted perceived ease of use more strongly in determining behavioral intention than men did at earlier time frame. A few more empirical studies showed that gender differences in information technology do exist: Yuen and Ma (2002) found significant gender differences in beliefs while applying the technology acceptance model to a group of pre-service teachers; Houtz and Gupta (2001) found that males generally are more interested in information technology; Gattiker and Nelligan (1988) suggested that there is an association between gender and attitudes of information technology. On the other hand, interestingly, in their study of Australian Women in IT, Hellens and Nielsen (2001) indicated gender and IT were socially constructed as they suggested that cultural differences might be more important than gender alone, “Women of Asian background significantly outnumber all other ethnic female students in Australian IT degree studies” (p. 48). However, whether this applied to teachers is still in doubt and further empirical investigation was in need. Thus, the aim of this article was to explore gender differences in teacher computer acceptance in contrast to the studies in other workplaces. To prepare this article for the “Encyclopedia of Gender and Information Technology”, part of the findings were extracted from a previous article of the authors (Yuen & Ma, 2002).

METHOD

Subjects

The study targeted pre-service teachers who were mostly fresh degree holders, joining the one-year full-time teacher education program (Postgraduate Certificate in Education) at a local university in Hong Kong. According to past experience, majority of these graduates would become teachers and work locally. It was believed that a study to these subjects would provide a good understanding of the pre-service teachers, but also shed light to understand the future computer use of in-service teachers. A summary of the 186 respondents who had successfully completed the survey instrument was listed as seen in Table 1.

Technology Acceptance Model (TAM) and Its Measurement Items

In prior studies, there have been extensive investigations on developing computer attitude scale. Attitude was viewed in a hierarchical manner, including firstly the affective responses to attitude, then the cognitive responses to attitude, and the highest level of conative responses to attitude (Ajzen, 1988). Applying this attitudinal process to computer use, it might explain as: (1) firstly an user heard about computers and tried to evaluate them; (2) then, the user got chance to have hands-on experience with computers and
formed perceptions about computers; and (3) finally, the user reflected his or her attitude on computers through behavioral intention and actual usage behavior. How to measure perceptions would become an important process to predict and explain computer use.

TAM was one of the widely validated and applicable model frameworks to measure perceptions on technology use. It was firstly suggested by Davis, Bagozzi, and Warshaw (1989). TAM suggested that perceived usefulness and perceived ease of use as two fundamental determinants to intention and technology usage. Other empirical tests of the TAM (e.g., Adams, Nelson, and Todd, 1992; Hu, Chau, Liu Sheng, & Tam, 1999) had for the most part, been supportive of the model for the last 20 years. Legris, Ingham, & Collerette (2003) conducted a critical review of the technology acceptance model and confirmed the wide applicability of the model towards a wide range of technologies, organizational contexts, and subject domains.

The use of TAM to investigate student-teachers’ computer acceptance was advantageous because of its well-researched and validated measurement instrument. Specifically, the questionnaire was designed to include five items of perceived usefulness (PU1 to PU5), five items of perceived ease of use (PEOU1 to PEOU5), two items of intention to use (ITU1 to ITU2). All items are measured in a 7-point Likert scale, with 1 indicating strongly disagree and 7 indicating strongly agree. The major measurement items were listed in the appendix. Subjects were also asked to report their self-reported usage. Duration of usage was measured in hours per week and was coded into seven categories, namely, “Less than or equal to 4 hours”; “4 to 6 hours”; “more than 6 to 9 hours”; “more than 9 to 12.5 hours”; “more than 12.5 to 16 hours”; “more than 16 to 20 hours”; and “over 20 hours”. The degree of current usage of computer was measured in a 7-point Likert scale. At the same time, subjects were asked to state demographic data in the first

part of the questionnaire, including gender, age range, major teaching areas, access to computer at home and if there was any previous formal computer training experience.

**Procedure**

Data were collected using a user-reported self-assessment approach. It deemed to be appropriate because of considerable literature support for its use in intention-based studies and being the common method used in TAM research (e.g., Collopy, 1996; Davis, 1989). At the beginning of the semester in October, a total of 282 questionnaires were distributed through the various group representatives. Subjects were asked to return the completed questionnaires to their group representatives within a week’s time, just before they left for their school experience. Group representatives collected the questionnaires and sealed in an envelope and returned to the researcher for collection. 186 questionnaires were collected with return rate 66 percent.

**FINDINGS**

**Summary of the Observed Variables and Scale Validation**

The descriptive statistics of the measurement items were shown in Table 2. It showed that all the items showed generally positive perceptions towards computer use, all mean scores over four. The mean scores ranged from 4.60 to 5.79 while the standard deviations ranged from 1.15 to 1.51. All constructs satisfied the criteria of reliability (alpha > 0.80).

Discriminant validity was demonstrated if an item correlated more highly with items within the same factor than with items in a different factor (Campbell & Fiske, 1959). The inter-item Pearson correlation coefficients showed the discriminant validity where the coefficients of inter-item within each measurement construct were much higher than correlations across constructs. The factor components were then analyzed by a principal component factor analysis with varimax rotation method. The components generated confirmed the corresponding constructs as predicted by the TAM model. The EigenValues of the three components are as follows:

Table 2. Summary of descriptive analysis
extracted were 5.436, 1.879, and 1.349 respectively. The percentages of variance explained by the components ranged from 11.245 to 45.302, with a total variance explained of 72.21%.

One-way ANOVA was employed to determine the mean differences between the different gender groups on the major variables (teaching experience, computer training, PU, PEOU, ITU, and Usage). No significant differences were found between gender groups for each variable.

**LISREL Models**

LISREL was a software product designed to estimate and test statistical models of linear relationships among latent and manifest variables. It was an extremely powerful structural equation modeling technique that had been used extensively in research (e.g., Hu et al., 1999). LISREL was then used to analyze the survey data and to perform the analysis towards model testing. Table 3 showed the resulting model testing findings.

For the overall model, the data supported most of the individual causal paths postulated by TAM. Perceived usefulness had a significant direct positive effect on pre-service teacher’s intention to computer use, with standard path coefficient 0.43 (p<0.001). Literally, this coefficient suggested that every unit increment in perceived usefulness would strengthen an individual’s (positive) intention to computer use by 0.43 units. Perceived usefulness also had a direct and significant effect on usage, with standard path coefficient 0.38 (p<0.001). Effect of intention to computer use towards self-reported usage was significant and shown a 0.33 path coefficient. Thus, perceived usefulness had a direct effect, as well as an indirect effect, through the mediating intention to computer use, on usage. Perceived ease of use had positive effects on both perceived usefulness (path coefficient = 0.58) and intention to computer use (path coefficient = 0.15). Although it was a significant direct effect on perceived usefulness (t = 7.41, p<0.000), its effect on intention to computer use was statistically non-significant.

From the R square values, it showed that perceived ease of use explain 33% of the variance in perceived usefulness, while perceived ease of use

Note: * p<0.05; ** p<0.01; *** p<0.001
and perceived usefulness together explained 29% of the variance in intention to computer use. Intention to computer use and perceived usefulness accounted for 38% of the variance in usage.

This finding was consistent with prior research (e.g., Venkatesh & Davis, 2000) that while “the effect of usefulness on usage was significant,” “the effect of ease of use on usage, controlling for usefulness, was non-significant” with the reason that “ease of use operates through usefulness” (Davis, 1989, pp. 331-332).

The LISREL model was then analyzed on male as well as female data in order to examine the gender differences of the effect of each construct to the model. All data segments provided an overall fit of the model postulated by TAM. However, compared to women, men placed a greater emphasis on perceived ease of use in determining perceived usefulness (0.85 for male; 0.47 for female). On the other hand, women weighted perceived ease of use more strongly in determining intention to computer use than men did (0.07 for male; 0.23 for female). The causal path from perceived usefulness to intention to computer use was non-significant for men. For the case of women, the strong direct significant effect of perceived usefulness in determining intention to computer use showed that was hindered by the overall model, which was not consistent to prior research findings of Venkatesh and Morris (2000).

In agreement with what most literature postulates, the two independent variables, perceived usefulness and perceived ease of use, contributed significantly to the behavioral intention to computer acceptance and actual self-reported usage, accounted for 38%, 61% and 36% of the overall, male and female model respectively.

**MAIN THRUST AND FUTURE TRENDS**

**Key Findings**

The research questions of this empirical study were:

1. What were the emergent constructs that drive the intention and usage behavior of computer use?
2. Did users’ beliefs regarding IT/IS usage differ among genders?
3. To what extent did these effects differ?

The empirical findings were that female and male users’ differ in beliefs, intention, and usage. From the testing summary of the models, the beliefs were influenced and differed among different gender. Female users were influenced by both perceived usefulness and perceived ease of use to their intention and usage of computer, in a more balanced manner. Both factors were significant in predicting intention and usage, though perceived usefulness was stronger in effect ($\beta=0.47$ at $p<0.001$ versus $\beta=0.23$ at $p<0.05$). On the other hand, male users were nearly totally influenced by perceived usefulness to their intention and usage of computer. Perceived usefulness was significant and strong ($\beta=0.85$ at $p<0.001$) while perceived ease of use was non-significant and had only an indirect effect through perceived usefulness toward intention and usage of computer.

**Limitations of the Study**

It was believed that the study on a longitudinal perspective would be conducted in order to gain better understanding about the users’ acceptance behavior. Moreover, this study collected pre-service teachers’ view on “computer” acceptance in a general term. This might also limit us from knowing the differences among other technologies or software applications. Therefore, further studies...
on the area of the acceptance towards different technologies and the acceptance differences on a continuous basis would also be recommended.

**Contributions to Practice**

This empirical study had unique contributions for IT/IS practitioners. Successful system implementation required users to effectively use the system while effective management required a better understanding of the beliefs of users toward IT/IS systems. The findings of gender differences in beliefs and their corresponding beliefs’ strengths could assist in the proactive implementation planning of IT/IS (e.g., user training, system support, etc.) for minimizing the impacts while using IT/IS.

**Contributions to Research**

This study attempted to explore the teachers’ computer acceptance and re-confirmed that perceived ease of use and perceived usefulness were the two independent variables towards computer use. It also revealed the gender differences in the application of the TAM. These findings were definitely important to the design of teachers’ professional development. Viewing teacher training as a kind of remedy for teachers’ inadequacy, teachers’ computer training was, still in many cases, unified and one-off. Without a continuous development plan to teachers (e.g., Bradley, 1991), the problem of acceptance would still be an important barrier to the successful use of computers in education. The study had collected the views of pre-service teachers at a given point of time, however, studies found that the factors to pre-adoption and post-adoption might be different (e.g., Bhattacherjee, 2001; Karahanna, Straub, & Chervany, 1999), that was, a factor contributes positively to acceptance might not necessarily contribute to the same extent and degree after adoption. Sometimes, on the contrary, a factor might hinder further computer use.

**CONCLUSION**

In summary, this study extended the applicability of the technology acceptance model over teachers’ computer use. It validated the instrument and the model framework using survey data from a group of pre-service teachers, as well as reflected gender differences in technology acceptance. We suggested that this model could be applied in the teachers’ computer use context and used to explain the use intention and use behavior. We recommended that these findings to be included in future gender and IT/IS research studies.

Davis, F. D., Bagozzi, R. P., & Warshaw, P. R. (1989). User acceptance of computer technology:

**KEY TERMS**

Affective Responses to Attitude: They are the responses that reflect evaluations of, and feelings toward the attitude object.

Attitude: An attitude is a disposition to respond favorably or unfavorably to an object, person, institution, or event.

Cognitive Responses to Attitude: They are the responses that reflect perceptions of, and information about, the attitude object.

Computer Attitude Scale: A composite instrument to measure an overall attitude of an user to respond favorably or unfavorably to computer.

Conative Responses to Attitude: They are responses that reflect behavioral inclinations, intentions, commitments, and actions with respect to the attitude object.

Perceived Ease of Use: The degree to which the prospective user expects the target system to be free of effort.

Perceived Usefulness: The prospective user’s subjective probability that using a specific application system will increase his or her job performance within an organizational context.

Technology Acceptance Model (TAM): A model framework which is composed of two fundamental determinants, perceived usefulness and perceived ease of use, to explain computer usage behavior.

Chapter 7.6
Discourses in Gender and Technology:
Taking a Feminist Gaze

Sheila French
Manchester Metropolitan University, UK

ABSTRACT

The majority of women are not involved in the design, manufacturing or shaping of technology in many Western societies. This is at a time when governments globally see technology as an enabler to economic success. Using feminist scholarship and discourse analysis, this chapter questions why patterns of gender segregation prevail in technology related fields in the United Kingdom. The chapter critically analyses why government policy, and equal opportunities initiatives, have so far largely failed to increase women’s participation. Using examples taken from two educational settings, the chapter uses the narratives of individual’s experiences of technology, their engagement, or lack of engagement with it, to examine the dominant discourses of the field. It is argued that technology discourses, which shape our understanding and identity with technology, are gendered. It is argued that current policies and initiatives, based on giving women equality of access will continue to make little difference. Until gendered dominant discourses of technology are deconstructed and examined; we will not have the tools to address the current situation of gender segregation.

The Connection between masculinity and technology, reflected in women’s under-representation in engineering, and indeed in all scientific and technical institutions, remains strong as we enter a new era of technological change. (Wajcman, 2004)

INTRODUCTION

Globally, governments see new technologies as the enabler of economic success in the global knowledge economy. At the same time the United Kingdom, along with many other Western societies, is experiencing a gender divide in relation to the use, development and design of information and communication technologies (ICT). For sometime it has been recognized that males dominate the use of technologies in all areas of British society (DFEE, 2001; Hellawell, 2001; Wilkinson, 2001) and that gender segregation in ICT occupations persists (EOC, 2004a). Only a few girls are taking
Discourses in Gender and Technology

up computing at an advanced level at school, and universities are experiencing a continued lack of interest in applications by women for computing degree programs (Alexander, 2001b; EOC, 2005). In 1996, 19% of computer science students were reported to be female. Today, there has been little improvement; females account for only 20% of computing graduates in Great Britain (EOC, 2005). In the workplace, women hardly feature in the innovation and production of technology and the computing industry is concerned about the lack of women in the sector. British industry continues to experience major skills shortages of technicians and ICT professionals (DFEE, 2001; EOC 2004b). This is contrary to images in the popular press of women—such as Martha Lane Fox, the co-founder of lastminute.com—who are hailed as heroines of the dot.com industry. In reality men dominate e-commerce start-ups, and there is little involvement of women at the investment level of the industry (Hellawell, 2001). There are signs that women are not involved in the new economy and the new technologies, and “that men are firmly in the driving seat” (Wilkinson, 2001). This has not gone undetected, nor has it been ignored. Over a number of years the lack of women’s participation in science and technology has been addressed in various United Kingdom government policies and initiatives. However, neither the government nor industry has set specific targets in relation to women entering these male dominated industries (EOC, 2004). Gender segregation still prevails and women are still under-represented in the field of technology.

This chapter begins by looking at the emphasis that the United Kingdom government, along with others around the globe, place on the new technologies in relation to the global knowledge economy. The discussion moves on to look at why the current situation of gender segregation is thought to prevail. I present here a critical analysis of government policy and initiatives based on giving equal opportunities to women, most of which have so far largely failed to increase the participation of women. I then introduce feminist theory and discourse analysis to look at “discourses of technology.” Focusing on examples from two educational settings, I use the discussions of individuals’ experiences of technology, their process of engagement, or lack of engagement, with the technology. The aim is to demonstrate that issues of gender and technology are by no means simple. I suggest we should not just focus on giving women equal opportunities to access, training and education in technology, we should instead try to identify and understand more clearly how the dominant discourses around technology come to shape our understanding and identity with technology. It is this I suggest that needs deconstructing before we can address patterns of gender segregation.

ICT AND THE GLOBAL KNOWLEDGE ECONOMY

Technology and innovation feature highly in future economies, and are seen by governments in the United Kingdom and around the globe to be an essential ingredient to becoming internationally competitive (Brooks & Mackinnon, 2001). Training the population in the use of information and communication technologies (ICTs) is seen as a powerful enabler. The lack of access to ICTs does not only lead to exclusion from the new technologies but also to exclusion from the new knowledge economy (Castells, 2000). Training members of society to be computer literate is regarded as essential to participation in the current and future labor market. In government rhetoric about “education” there is a shift in emphasis from being purely concerned with the education of individuals, to a need to ensure the population has the essential skills that will assist with the nation’s wealth creation (Brooks & Mackinnon, 2001; Coffield, 1999). This raises issues about what type of knowledge and skills will be valued by society in the future. It suggests that those
with the knowledge and ability to use the new technologies will be favored for their capacity to contribute to the economy. It suggests that those without the requisite information technology skills will fail to contribute to the economy and, therefore, could be excluded from future prosperity.

UK GOVERNMENT POLICY AND INITIATIVES

The UK government has recognised the gender divide and has proposed a number of initiatives to reverse what they refer to as “the challenge of women’s participation in ICT” (Alexander, 2001b). The aim is to give women access to information technology (IT) in education, the workplace and their social lives. Strategies are being funded to address socially excluded groups, which often include women, to enable them to acquire what are thought to be essential ICT skills for daily life in future economies (DTI, 2004). The aim is to improve the image of IT in education and work; this, it is suggested, will increase women’s participation. Girls will be encouraged to become more enthusiastic about today’s technologies, and it is hoped that they will gain confidence to compete with boys in what the government refers to as the male domination of ICT in the classroom. This is aimed at ensuring that all girls along with other socially excluded groups have the necessary ICT skills to work in and meet the skills demands of the new economy. Female role models will be used to improve the image of IT, to encourage young women to take ICT as a subject at school, and to enter careers related to technology. A change in business attitudes will be promoted in the computing sector to encourage flexible working conditions for parents. This approach is well-meaning, but there are a number of problems with it. Already there is evidence that these policies and initiatives are failing to make little difference.

Firstly this approach treats technology as an artifact that has no political or social values attached to it. This is clearly not the case, as social studies of science and technology have provided strong evidence that technology is not gender-neutral (Adam, 1998; Cockburn, 1985; Wajcman, 1991, 2000). In the home, male members of families still have more access to computers than women do (Richardson & French, 2001). Boys are very often given greater priority of access to computers at home by their parents than girls (Habib & Cornford, 2001; Na, 2001). In education it has been argued that there is a maleness surrounding technology, IT and computing subjects (Woodfield, 2000).

Secondly, there is an assumption that women, if the conditions are right, will want to be involved in the field of technology. However, evidence suggests quite the contrary; women may not want to be involved in computing (Clegg, 2001; Na, 2001). While women are quite able to “do computing,” for many the image of computing and IT is masculine; it is these gendered notions of what “is” technical which lead to girls becoming reticent about taking up computing and technology (Clegg & Trayhurn, 1999; Clegg, Mayfield, & Trayhurn, 1999). Therefore, suggestions that we can use role models to change the image of ICTs lead us to question where the role models will be found if the majority of women in our society remain uninterested in technology. These initiatives presume that given equality of access and the right workplace conditions, women will begin to participate. It suggests that women and men attach the same perceptions and social values to technology—an assumption I believe to be flawed. This approach is misguided in its treatment of technology. Taking this stance is likely to obscure many of the issues related to our social relationship with technology.

In the following discussion feminist theory and discourse analysis will be employed to help us understand the issues involved. We begin by unraveling the existing social and cultural prac-
Discourses in Gender and Technology

practices, which have led to the current situation in the United Kingdom and other Western societies.

TAKING A FEMINIST GAZE

Feminism comprises of one but many different theories and perspectives that have some common understandings and some differences. Feminism is complex, so defining it is controversial. Feminists agree that social and political theory has a history of being “written by men, for men and about men” (Theile, 1986), and that issues of women have been largely ignored or trivialised. Feminists critique any practice where there is an “assumption of male superiority and centrality” in which women’s subordination is taken as a given (Beasley, 1999). However, they do not necessarily agree about how we might bring about changes to any given situation.

Feminists collectively seek to explain women’s oppression and share a belief that women hold an unequal position in society; to use the theories to question the causes for this. The theories do not all suggest the same reasons for oppression or have the same ideals. In their different forms, feminisms collectively “prescribe strategies for women’s liberation” (Tong, 1997). The context in which I will use “discourse analysis” is taken from the critical tradition. Critical feminist work is ultimately political in that it seeks to understand the position of those who suffer most from dominance and inequality. Critical feminists are social critics. They outline their point of view, perspective and their aims, as in this chapter. Often they place their own subjectivity in the research rather than attempting to be neutral observers. The aim is to produce knowledge which might make a positive difference for women. In this case the question being asked is what factors or conditions sustain, legitimise and perhaps condone the current state of social inequality and injustice regarding women’s participation in technology.

DISCOURSE ANALYSIS

Discourse analysis has evolved from a number of theories about how we should study language and text. The way in which I use it here broadly rests on the work of Michel Foucault (1978, 1981). The concept of “discourse” is taken in a quest to understand the relationship between language, social institutions, subjectivity and power. Discourse, as used in a linguistic context, is taken as a system of representation connected to writing or speech. In Foucault’s terms this is not just an analysis of “text” and the spoken word; it is also about how discourses, in his terms, create knowledge or meaning in our social world. Language, in his view, is not necessarily unique to the individual but is shaped by a range of social, political and economic practices. In a way, it places emphasis not only on what one says but also on what one does. Foucault, taking a constructionist theory of meaning and representation, argued that it is “discourse” that gives us meaning, which in turn creates knowledge values or norms in a particular field. There is a range of discourses in society, often overlapping, some of which are more dominant than others. They do not all carry equal weight or power. Foucault argues that the most dominant give meaning to the world and organise social institutions and processes. A dominant discourse in a historical period can then come to be constituted as the norm. Those who hold these beliefs, he argues, have a vested interest in keeping the status quo. This does not mean that individuals cannot contest the discourse, but it may mean that they are perhaps marginalised by what is considered to be the norm in that field. Meaning, therefore, depends on a person’s subjectivity. Subjectivity refers to the conscious and unconscious thoughts and emotions of an individual (Weedon, 1997). In these terms, what we say and what we do are shaped by the discourses we inhabit and the norms and values associated with them. Experiences in the home and at school, such as expectations of the way girls and boys should behave as female
Discourses in Gender and Technology

or male, shape subjectivity. Therefore, if we look at the issues of women’s lack of participation in technology in terms of discourse, it is not only about issues relating to “technology,” “education,” or “careers.” It is also about the context and historical moment in which the discourse resides. In this case the context is also to do with the global knowledge economy and our relationship with technology at this time and the meanings such discourses produce.

To illustrate the complexities and put this work in a historical context I want to return briefly to government policy and initiatives to give an example of such discourses. The following demonstrates how knowledge and power are at work in discourses and how they come to make social meaning.

Consider the following statement made by the UK government, “ensure everyone has the requisite skills for the knowledge economy” (DFEE, 2001). As we read this statement we can see it is about giving the population opportunities to contribute in the workplace. However, it is also linked to the “knowledge economy.” As an educationalist reading this, I would suggest the education of individuals seems to have shifted from pure interest in an individual’s education to securing “economic wealth” for the nation (Brooks & Mackinnon, 2001). Therefore, if we look at the statement in terms of “discourse,” we could question if the statement is perhaps located in a discourse of what we might call “future economic wealth,” or in what Lucey, Melody and Walkerdine (2003) refer to as the discourse of “social capital.” The British government’s political position influences the meaning of this statement, as does my interpretation as an educationalist and feminist. As this discourse of “social capital” is constructed further and propagated by the government in policy and in the media, it becomes a dominant discourse in British society and has the power to shape our norms and values around the new economy.

My argument is that these discourses shape our beliefs and what becomes our “knowledge.” To understand women’s lack of participation, we need to look at norms and values associated with the field of computing and information technology before we can hope to make any difference to women’s lack of participation.

DISCOURSES OF TECHNOLOGY AND GENDER

It is important to define the context in which the terms “computing,” “IT,” and “ICT” are used in this discussion. Computing is a number of disparate and complex practices and technologies where the terms “computing,” “IT,” and “ICT” are used interchangeably. The term “ICT” is relatively new; my interpretation is that it refers more to the “user end” of the technology. The UK government appears to hold a similar interpretation, as the focus is on giving society the necessary “end user” skills for a future economy. In the following discussion, I will use the term “computing” which includes all of these definitions.

Clegg, Mayfield, and Trayhurn (1999) suggest there is not only one “form,” or way, of “doing computing,” and that, this being the case, there is likely to be more than one discourse of computing. They have identified two major discourses; what we can term the “hard end” discourse, dependent on formal methods and mathematical models, and the “soft” or “user end” discourse, in which technology assists or supports organisational systems. Therefore, the meaning of the term “technical” can be different, depending on the context, or frame of reference.

These discourses are reflected in the way we organise “computing,” for example, in education. A computing department in a UK university might place the emphasis of its computing courses on a “mathematical” model of computing (the hard end), whereas a department in a faculty of humanities or business may place more emphasis on
Discourses in Gender and Technology

the human and social dimensions and on the real world uses of computers (the user end). In many academic institutions there is a discourse that suggests that “to do” computing requires superior mental powers linked to those of the mathematician or scientist (Edwards, 1990). In academia, the more traditional view of formal mathematical methods can also be strongly associated with math and “technical machismo” (Mahony & Van Toen, 1990, p. 321). In the disciplines of math and science, there is also a long history of a masculine culture (Hughes, 2001). It has been argued that this association of mathematics and science with masculine culture has turned women away from the subjects. This association suggests a gendered discourse of computing in which women may not wish to participate because it conflicts with their gender identity (Clegg & Trayhurn, 1999). Whilst the field of computing is still defined in this way, it may discourage some, but it cannot solely be responsible for the lack of women’s participation, as women have increased their participation in other seemingly impenetrable “macho” occupations such as medicine. It is also important to note at this juncture that not “all” females are put off by male-dominated occupations; just as not “all” males favour male-dominated occupations only (Hughes, 2001). However, if we look at our lives through the dominant discourses that help us define our identities, we can see that those discourses discussed so far could maintain the status quo in the field of technology.

Through the following two examples, taken from two different case studies carried out in educational settings, I will demonstrate the pervasiveness of these discourses. Both examples are used here to uncover and illustrate the dominant discourses that operate, or serve to maintain how we perceive computing. Both of the studies used are small and are not, therefore, being used to “claim” anything. They are being used to demonstrate the power of discourse in determining what becomes the knowledge, or norm, and values, and, therefore, maintains the current position. The narratives that follow draw on free association techniques (Hollway & Jefferson, 2000), which means that the interviews were unstructured, allowing the individuals to tell their story. The aim was to take a reflective look at what had informed their experiences in relation to their gender identities and their relationship with technology. Using theories of the “gestalt” (Hollway & Jefferson, 2000), I look to the sum of the “whole,” rather than the individual “part”; consequently, the work does not just focus on the subjects’ relationship with technology but also on the influence of the other aspects of their lives and experiences. The students may have constructed their accounts to make sense of the world they inhabit through their subjectivity. I add my interpretation, which I acknowledge is influenced by my own subjectivity and experience (Walkerdine, 1997; Hollway & Jefferson, 2000).

For the first example I use excerpts from the narratives of four university students, two males and two females (aged 18-24) who were studying for a degree in information technology at a British university; this study was carried out in 2003.4

THE NARRATIVES

First we will discuss Simon and Paul. In the following excerpt we can see evidence that for both of them their relationship with technology is embedded in their masculine identities and in several other overlapping discourses around how they played as children and as young adult males. This is not surprising, as there is evidence that the relationship between technology and gender begins in the home where males dominate many of the technologies including computers. When computers first entered the home they were targeted at boys and male hobbyists (Kirkup & Abbott, 1997; Wajcman, 1991). Simon and Paul were not exceptions to this targeting. They had been introduced to computers early in their lives and both of them still played computer games.
Discourses in Gender and Technology

Simon was proud of what he defined as his “technical skills” and how he had recently networked the computers in his home. Simon talked about computers as “something I’m serious at” and explained how, through “trial and error,” he had learnt to build computers.

For Paul the computer is an “object” of some significance in his life. He described how he was comfortable in an environment where there was a computer turned on and how he would leave it on in his bedroom whilst he was working, listening to music or doing other things—“You can click on it and it runs itself... I leave it on in the room and just go back to it.” During the narrative Paul appeared to “confess” to using computers in his leisure time—“It might sound geeky, but yeah, my friends are geeky... I sound like I am always playing games and stuff, but it’s only when I’m sitting in my room and stuff.” Paul appeared to know about the popular images of computing and did not seem to want to be associated with them.

Both Paul and Simon claimed expertise in computing; they said they were “confident,” “good at” computing. Like boys in other studies (Beynon, 1993), they claimed expertise in using computers. I suggest that in their narratives they place themselves in what I have described as the “hard” discourse of computing. For both Simon and Paul, using computers allows them to inhabit a discourse in which they are comfortable. This discourse is located, amongst other issues, in how they played as children, and the way they currently socialise with other males. This promotes personal confidence and a sense of ability with technology, which I suggest is worth preserving. Their interest, as they described it, is fundamental to their identity as males and not just an external interest or passing hobby.

As discussed earlier, boys still have more access to home computing than girls, and there is evidence that parents favour boys over girls in issues of access to computers. It is believed that it is this that has led to girls having less experience of computers than boys before they reach school.

Both Asiya and Karima, the other two students in the study, who are female, both located themselves at the “user end” or “soft end” of any computing discourse. They were very explicit about the “usefulness” of computers in the workplace; neither of them used computers in their leisure time. Both of them expressed how their interest in the computer was gained in their experience at school or at work. “With computers I don’t like the hardware, the technical side of it as much. I understand I need to know about it. I find the technical side difficult, it doesn’t interest me. I would rather be sitting at a PC designing a database than looking inside a PC” (Karima).

Their choice, as with the males, was based around feeling they were good at something. Asiya had found she was “good at using computers” in her secretarial position; she had found time in her position as a secretary to “open program files and discover the PC.” They used the same sort of terms as Simon and Paul—something they were very “interested in,” “good at”—and in Karima’s case she had studied IT at her secondary school and was very enthusiastic—“I absolutely loved it, loved it” (meaning as a subject at school).

Neither of them continued to play computer games or appeared to see much use for the computer outside their university work or in the workplace. They had both developed an interest in computers in their teens, later than Simon and Paul. Both females identified a “use” for computers, but did not perceive that using computers was part of their social activities. This is very much in contrast to Simon and Paul. Simon linked his interest in what he referred to as “building computers” directly to how he played as a boy. We can see in the following how Simon’s “interest” in computers is linked to his identity as a child—“It (computers) are generally like Lego... then it’s like slotting everything in... then it’s setting it up.”

This demonstrates how the gendered attitudes of how Simon played as a child and also gen-
Discourses in Gender and Technology

...dered preferences for toys may have influenced his computer usage. Mead and Piaget have said that children develop a sense of “self” through their play and games (Crossley, 2000). Studies have found that girls and boys play differently and this has implications on the development of their self-identity as girls and boys (Gilligan, 1982). Children’s choices of toys are different. Males are associated with mechanical toys and construction toys such as Lego, which encourage technical confidence (Wajcman, 1991). Girls play with toys such as dolls and stuffed animals (Rheingold & Cook, 1975). All four students were introduced to computers through play, though the females lost interest as they matured. We know that most computer games are targeted at young males and it is likely that most computer games that are available are more popular with boys than girls (Griffiths, 1997). Karima explained she had “grown out of it” and Asiya stated, “I don’t really play, not in the last few years.” The females in this study were no longer motivated to use a computer to play games. Thus they rejected the computer as a toy, changing their view of it in adulthood to that of a useful tool. Computing is something both these female students have an interest in, but I suggest it is not strongly linked to their gendered identities.

What I have shown in this small example is that discourses around technology can extend into the home and other parts of our social lives, including in this case our gender identities as young children and young adults. How we play as children and what are acceptable interests for boys and girls in the home contribute to our gendered identities. All four students have been influenced by childhood and teenage experiences of using computers in the home. I have suggested that both of the male students located themselves in the “hard” end of computing, which in their case is intrinsically linked to them as males and bound up in their masculine identities. Both females were very interested in computers but located themselves in what could be described as the “soft end” or “user” discourse in computing. They could clearly see a use for technology in their lives, but the computer has little to do with their gender identity. The males and females in this study inhabit different discourses; we can identify these are open to interpretation and do not have clear borders.

In the next example, I want to demonstrate how these discourses are perpetuated in another area of education and how they can then influence decision-making of young women when it comes to choosing subjects, courses and careers. We know that educational experiences have the power to influence our perceptions of who we are. Research has identified that “education has a mammoth part to play in gendering social worlds, not only through what is taught but also through how it is,” and therefore perpetuates a society’s norms and values (Evans, 1994, p. 52). There is a great deal of research in the field of gender and education which expands on these issues. In schools and colleges computing and the skills associated with it are still perceived in gendered terms. There are good reasons for this. Early school computers were usually bought and controlled by male teachers in the math and science subject areas. This perpetuated the “hard” discourse and further marginalised girls as the boys showed more interest. A reluctance of girls to embrace the computer was seen early on as a problem of girls’ confidence, rather than rooted within the way technology is perceived (Clegg, 2001). Today there are still only a few women lecturers and teachers in computing and IT at all levels of education in the UK, which may reinforce the idea that it is an area of study most suitable for males. This of course raises the question as to where the government will find their role models.

The following abstracts are taken from a study of 16-18 year old female students studying in two colleges of further education in an inner city area in Manchester, UK. This second study took place in 2004 (French & Saxon, 2006) and was initiated...
Discourses in Gender and Technology

by a number of colleges. They were concerned about the lack of participation of women in their technology courses and the lack of progression of the young women to university and technology industries. The following demonstrates with a few examples how the discourses we have already discussed manifest themselves in this educational setting. Twenty-five female students between the ages of 16 and 18 were interviewed. The narratives demonstrate how the discourses around technology in this study influenced the students’ and teachers’ perceptions of what is a suitable subject for girls to study.

Even before joining their course these female students encountered a gendered discourse around the information technology courses they were interested in—“I couldn’t believe that people said IT was a lad’s (boy’s) course... There were a lot of girls being interviewed at the same time as me, but they didn’t come on the course” (Female, 16 years). She was referring to the course tutor’s remarks during her interview for the course. In light of the description of the course as a course for boys, it is not surprising that so few young women enrolled.

The girls were asked why they thought girls did not enroll in technology courses. There were many duplications of this type of remark; I include only three examples here.

“I think girls prefer hairdressing and girlie type courses.”

“Maybe they think it’s a boy’s thing.”

“A lot of girls think it’s too technical and that they wouldn’t be able to do it.”

We can see a gendered discourse prevails not only through the way the course tutor describes the courses but also around some girls’ perceptions of information technology courses. The EOC recently reported (Fuller, Beck, & Unwin, 2005) that there are still strong gendered perceptions of what are suitable careers for “boys” and “girls” in the UK. Girls are still over-represented in childcare fields, while males are over-represented in subjects related to engineering, motor vehicles and construction. This is despite the fact that as early as 1984, Women into Science and Engineering (WISE) (Henwood, 1996) was launched to encourage women to enter these careers. WISE influenced policy and practice as many small and large-scale initiatives were designed to encourage females to join science, engineering and technology courses. Henwood (1998) has criticised the WISE project for taking an equal opportunities approach based on women’s choice.

In this study, none of the 16-year-old female students said that they were interested in pursuing a career related to technology. Only the female students whose ages ranged from 17-18 years old stated that they were intending to pursue a career associated with their course and technology. There were only 11 females in the 17-18 year age group, out of a total cohort of 83 students; seven were interviewed; all of them were intending to take up a career in computing. It is unlikely that the choices of the younger students had anything to do with their academic achievement. In the UK girls have shown they have ability in the subject area. In 2001-2002 girls achieved 62% of passes at grade C or above in General Certificate of Education – Advanced level (GCE A level) computer studies, whereas the achievement rate for boys was 56% (EOC, 2003). Despite their success in the subject, young women continue to shun technology subjects at the higher levels. In 2004-2005 around half the number of total students in England who took GCE A level in ICT were female. There were 4,510 females compared to 8,370 males, which is an improvement on 2003-2004. However, the numbers of students taking computer studies are a stark reminder of the gender division in this subject area; a total of 5,336 males, but only 493 females took the GCE A level subject (DFES, 2005). It has been shown that there is a direct correlation between
the number of women entering IT or computing degrees at university and those taking the subjects at school and college (Symonds, 2001). In this study, the courses these 17-18 year olds attend are also “feeders” into university degree courses. Whether they can “do” technology is not the issue, they just are not choosing it.

Female tutors and course leaders were in the minority in the two colleges who participated in this study. Several students commented about the male tutors—“The male programming tutor is a bit strange” (15 year old). Most of their personal tutors were male, and another student said “I would rather have a woman to talk to” (15 year old).

Working with male students presented “problems,” or “perceived” problems, some of which had consequences on the course choices as this comment identifies—“I could have gone straight onto the advanced course, but there were no other girls on the course that year. So I did an extra year on my previous course so that I would have some female company” (17 year old). This student’s perceptions had influenced career choice and academic progression. Young men were the dominant group on the IT courses she had studied. Most of the girls interviewed reported they did not like working with the boys. Other students were initially put off by boys, but got used to working with them. Some, as in that quote, had asked to stay in groups with other girls on the course. Having another female in the class made a difference—“If I didn’t have Julie in the class, I would have felt a bit intimidated” (16 year old).

One student had noticed that several girls had started the course with her but did not complete the course. It could be that the thought of a class of mostly male students was worse than the actual experience for some of the students. For some it clearly put them off the course; it meant them having to “fit in.” Some had compromised their career choices and, in other cases, it led them to leave the course before completion. Therefore the dominant number of males on the courses, and the gendered attitudes of the tutors, influenced their experiences.

From the narratives of the university students and the college students we can identify a dominant gendered discourse in computing which is linked to the use of technology in the home, as well as to education. In the previous examples we can see that this discourse is linked to gendered notions of how we view and experience technology. It is this I would argue, which needs deconstructing. I suggest that gendered perceptions of technology started early in life are further perpetuated as women mature. This discourse is pervasive, as it is not just isolated to the field of computing but extends into many other social spheres.

Clearly, if we want to change the current situation, we need to challenge this gendered discourse around technology. This is not easy because it is so pervasive. However, it is possible. We need to look very closely at our gendered identities and our relationship with technology and how, as parents, educators and government, we perpetuate these images. We need to challenge the current values and norms regarding technologies in our society.

**CONCLUSION**

I have shown evidence of a gendered digital divide with regard to technology in British society. I have discussed and criticised government policy. Throughout this discussion, feminism and discourse analysis have been used to unravel the issues and complexities concerning the lack of women’s participation in technology. Through the narratives of these two small studies I have identified gendered discourses around computing and technology. These gendered perceptions relate to our identity and our experiences with technology. These two case studies have shown how this discourse manifests itself in the home and is further perpetuated through our education.
and leads to choices in education and careers. I suggest we need to study this further to enable us to deconstruct this discourse before there is any possibility for change. Gender segregation in ICT is not just an issue of equality; it is also about tackling gendered attitudes and identities in relation to technology. Clearly, it is this we need to address before we can challenge gender segregation and gain women's participation in the future development and use of technology.

ACKNOWLEDGMENT

I would like to thank Diane Saxon, fellow author and research colleague, for her permission to use some of our co-authored work in this chapter. Finally, I would like to thank Helen Richardson for raising my political awareness in our early work together about government policy in relation to gender and technology issues.

INTRODUCTION

A fundamental consideration when attempting to understand the complex factors leading to the underrepresentation of women in IT is the choice and use of theory. Theories about women and their relationships to information technology and the IT profession guide the conceptualization of the research problem, the methods of data collection, the basis for analysis, and the conclusions that are drawn. However, a criticism of gender and IT research is that the topic of gender and IT is currently undertheorized (Adam, Howcroft, & Richardson, 2001, 2004).

This undertheorization takes on several different forms. First, there are cases in which there is no theory in evidence to guide the conceptualization of the research project or to inform the data collection and analysis. Rather, the focus is typically on compiling and representing statistical data regarding the differences between men and women with respect to technology adoption, use or involvement in the IT profession. This form of undertheorization can be labeled pre-theoretical research. Second, other research, while not explicitly articulating a particular theory, nevertheless, is guided by a theory-in-use. For example, quite often a theory of inherent differences between males’ and females’ relationships to IT is used implicitly to guide data collection and analysis. This form of undertheorization can be labeled implicit-theoretical research. This approach is considered to be a type of undertheorization in that the lack of explicit discussion of a theory makes it difficult for others to discuss, challenge or extend the research. Finally, the body of research that reflects explicit theory-in-use has been shown to have gaps in the theoretical landscape (Trauth, 2002). That is, an argument has been made that current theories about gender and IT do not fully account for the variation in men’s and women’s relationships to information technology and the IT field. This form of undertheorization can be labeled insufficient-theoretical research. It is this third condition that is addressed in this article: the need for new theoretical insights to guide our effort to understand the underrepresentation of women in the IT profession.
Two dominant theoretical viewpoints are currently reflected in the majority of literature about gender and IT: essentialism and social construction (Trauth, 2002). Essentialism is the assertion of fixed, unified and opposed female and male natures (Wajcman, 1991, p. 9). The existence of biological difference between the sexes has led to a tendency to assume that other observed differences between men and women are due to biological determinates as well (Marini, 1990). When applied to the topic of gender and IT, the essentialist theory presumes the existence of relevant inherent differences between women and men with respect to information technology. It uses the observed differences in the participation of women and men in the IT field as evidence of this view. Thus, the causes of gender underrepresentation in IT are attributed to biology. It turns to observed differences in men’s and women’s behavior for explanations of what are believed to be inherent, fixed, group-level differences that are based upon bio-psychological characteristics.

Essentialism underlies research on gender and IT that views gender as a fixed variable that is manipulated within a positivist epistemology (e.g., Dennis, Kiney, & Hung, 1999; Gefen & Straub, 1997; Venkatesh & Morris, 2000). Adam et al.’s (2001) analysis of this perspective points out that focusing on a background literature of psychology, alone, places too much emphasis on individual gender characteristics where a form of essentialism may creep in. Looking only to psychological explanations of observations without giving attention to the influence of context results in a determinist stance with respect to gender.

One inference that could be drawn from an essentialist approach to gender and IT research is that women and men should be treated differently. For example, Venkatesh and Morris (2000) recommend that trainers adopt different approaches toward men and women and that marketers design different marketing campaigns for men and women. Trauth’s critique of essentialist approaches to gender and IT research suggested that one logical extrapolation from this line of thinking to IT workforce considerations would be the creation of two different workforces: a “women in IT” workforce and a “men in IT” workforce. Thus, policies for addressing the gender imbalance would focus on differences between women and men and the equality issue would focus on “separate but equal,” something that was rejected in the arena of racial equality decades ago (Trauth, 2002; Trauth & Quesenberry, 2005; Trauth, Quesenberry, & Morgan, 2004).

The other dominant theoretical perspective focuses on the social construction of IT as a male domain. According to this theory, there is a fundamental incompatibility between the social construction of female identity and the social construction of information technology and IT work as a male domain. This explanation for women’s relationship to information technology looks to societal rather than biological forces. Thus, the causes of gender underrepresentation can be found in both the IT sector and in the wider society.

The literatures of gender and technology in general (e.g., Cockburn, 1983, 1988; Cockburn & Ormrod, 1993; Wajcman, 1991) and that of gender and information technology, in particular (e.g., Adam et al., 1994; Balka & Smith, 2000; Eriksson, Kitchenham, & Tijdens, 1991; Lovegrove & Segal, 1991; Slyke, Comunale, & Belanger, 2002; Spender, 1995; Star, 1995; Webster, 1996) look to social construction theory (Berger & Luckmann, 1966) rather than biological and psychological theories. According to this view, the social shaping of information technology as “men’s work” places IT careers outside the domain of women.

Recommendations for addressing this situation vary. One school of thought based on a multi-year investigation of female underrepresentation in both academe and the workplace in Australia explores the development of strategies to help women fit in to this male domain (e.g., Nielsen, von Hellens, Greenhill, & Pringle, 1998; Nielsen,
von Hellens, Pringle, & Greenhill, 1999; Nielsen, von Hellens & Wong, 2000; Pringle, Nielsen, von Hellens, Greenhill, & Parfitt, 2000; von Hellens, von Hellens, Nielsen, & Trauth, 2001; Pringle, Nielsen, & Greenhill, 2000). Another school of thought focuses on the need to reconstruct the world of computing to become more of a “female domain.” For example, Webster (1996) focuses on the social shaping of female gender identity and the implication for women’s relationship to workplace technologies. Based on analysis of women as a social group in cyberspace, Spender (1995) predicted an influx of “female values” into the virtual world that would accompany increased female presence.

Wajcman’s (1991) analysis of the social constructivist perspective on gender and technology reveals several issues. For example, there is no universal definition of masculine or feminine behavior; what is considered masculine in one society is considered feminine or gender-neutral in another. Further, while gender differences exist they are manifested differently in different societies. Hence, addressing the gender gap in IT employment based upon an assumed “woman’s perspective” is problematic. This analysis suggests a gap in current theory and motivates the articulation of new theory to help us better understand the underrepresentation of women in the IT field.

**MAIN THRUST OF THE ARTICLE**

The need for an alternative theory to account for the underrepresentation of women in the IT workforce emerges from consideration of the assumptions underlying the two prevailing theories discussed in the previous section. The initial work on the Individual Differences Theory of Gender and IT resulted from an analysis of this theoretical gap and used empirical data from a study of gender and IT in Australia and New Zealand (Trauth, 2002; Trauth, Nielsen, & von Hellens, 2003) to make the case for an alternative theory to occupy the space between essentialist theory and social constructionist theory. Subsequent work has focused on greater articulation of this theory (Trauth & Quesenberry, 2005, 2006; Trauth et al., 2004, 2006) and empirical testing of it (Morgan, Quesenberry, & Trauth, 2004; Quesenberry & Trauth, 2005; Quesenberry, Trauth, & Morgan, 2006; Trauth, Quesenberry & Yeo, 2005).

The Individual Differences Theory of Gender and IT addresses the undertheorization of gender and IT by offering an alternative theory that focuses on individual differences among women as they relate to the characteristics of IT work and the IT workplace. This view finds the causes of gender underrepresentation in the varied individual responses to generalized societal influences. Thus, it represents the middle ground between the essentialist and social constructionist theories. In doing so, it investigates the individual variations across genders as a result of the combination of personal characteristics and environmental influences in order to understand the participation of women in the IT workforce. Hence, the focus is on differences within rather than between genders. The theory also views women and men as individuals who possess different technical talents and inclinations and respond to the social shaping of gender in unique and particular ways that vary across cultures. This individual differences theory takes into account the uniformity of social shaping messages conveyed in a culture. However, it also takes into account the varied influence of individual background and critical life events that result in a range of responses to those messages.

The individual differences theory is comprised of three general constructs that, together, explain women’s decisions to enter and remain in the IT field. The individual identity construct includes both personal demographic items (such as age, race, ethnicity, nationality, socio-economic class, and parenting status) and professional items (e.g., industry, type of IT work, etc.). The individual influence construct includes personal character-
istics (e.g., educational background, personality traits, and abilities) and personal influences (e.g., mentors, role models, experiences with computing, and other significant life experiences). The environmental influence construct includes cultural attitudes and values (e.g., attitudes about IT, about women in IT), geographic data (e.g., about the geographical location of one’s work) and economic and policy data (e.g., about the region/country in which one works). The Individual Differences Theory of Gender and IT posits that, collectively, these constructs account for the differences among men and women in the ways they experience and respond to characteristics of IT work, the IT workplace and societal messages about women and men and IT.

CONCLUSION

It is ironic that coincident with a documented need for a deeper understanding of the gender imbalance in the IT field, there is insufficient attention being paid to theorizing gender and IT. Given this need, greater theorization in gender and IT research can contribute in several ways to a better understanding of women’s relationship to information technology. First, it can lead to more theoretically-informed treatments of gender in IT research. Wajcman (2000) has observed that gender is seldom considered a relevant factor in socio-technical studies of IT in context. Second, much of the published work that does focus on gender places emphasis on data analysis rather than theoretical implications and linking these results to the existing body of gender, and gender and IT literature (Adam et al., 2001). Hence, greater explicit use of theory can strengthen the existing body of gender and IT research. Finally, insufficient attention has been paid to the differences among women rather than between women and men with respect to information technology adoption, use and work. The development of the Individual Differences Theory of Gender and IT is intended to address this need by providing additional theoretical insights to help us to better understand the individual and environmental forces that account for the underrepresentation of women in IT. It accomplishes this by focusing on women as individuals, having distinct personalities, experiencing a range of socio-cultural influences, and thus exhibiting a range of responses to the social construction of IT. This, in turn, can facilitate more nuanced studies of gender that explore the multiple identities of women—for example, race and gender, or sexual orientation and gender, or age and gender—and their relationships to information technology.

One stream of future work will explore the role of epistemology and methodology in conducting gender and IT research using the Individual Differences Theory of Gender and IT. Another stream of research will explore the contribution of organizational factors to the underrepresentation of women in IT by focusing on the articulation of workplace factors that enhance and inhibit women’s participation in IT work and women’s varying responses to them. A third stream of research will apply the individual differences theory of gender and IT to an examination of differences in Internet search behavior across a variety of uses.

REFERENCES

**KEY TERMS**

**Essentialism:** The assertion of fixed, unified and opposed female and male natures (Wajcman, 1991, p. 9). This theoretical perspective is used to explain the under representation of women in the information technology field by arguing the existence of “essential differences” between males and females with respect to engagement with information technology.

**Individual Differences Theory of Gender and IT:** A social theory developed by Trauth (Trauth, 2002; Trauth et al., 2004) that focuses on within-group rather than between-group differences to explain differences in male and female relationships with information technology and IT careers. This theory posits that the under representation of women in IT can best be explained by considering individual characteristics and individual influences that result in individual and varied responses to generalized environmental influences on women.

**Social Construction:** A theoretical perspective articulated by Peter Berger and Thomas Luckmann (1967) that focuses on social processes and interactions in the shaping of actors. This theoretical perspective is used to explain the under representation of women in the information technology field by arguing that technology—socially constructed as a masculine domain—is in conflict with socially constructed feminine identity.

INTRODUCTION

Humans have learned to cooperate in many ways and in many environments, on different tasks, and for achieving different and several goals. Collaboration and cooperation in their more general sense (and, in particular, negotiation, exchange, help, delegation, adoption, and so on) are important characteristics - or better, the most foundational aspects - of human societies (Tuomela, 1995). In the evolution of cooperative models, a fundamental role has been played by diverse constructs of various kinds (purely interactional, technical-legal, organizational, socio-cognitive, etc.), opportunely introduced (or spontaneously emerged) to support decision making in collaborative situations.

The new scenarios we are destined to meet in the third millennium transfigure the old frame of reference, in that we have to consider new channels and infrastructures (i.e., the Internet), new artificial entities for cooperating with artificial or software agents, and new modalities of interaction (suggested/imposed by both the new channels and the new entities). In fact, it is changing the identification of the potential partners, the perception of the other agents, the space-temporal context in which interaction happen, the nature of the interaction traces, the kind and role of the authorities and guarantees, etc.

For coping with these scenarios, it will be necessary to update the traditional supporting decision-making constructs. This effort will be necessary especially to develop the new cyber-societies in such a way as not to miss some of the important cooperative characteristics that are so relevant in human societies.

BACKGROUND

Trust (Ganbetta, 1990; Luhmann, 1990; Dasgupta, 1990), in the general frame described above, might be considered as a socio-cognitive construct of main importance. In particular, trust building is always more recognized as a key factor for using and developing the new interactional paradigm.

Trust should not be made indistinct with security. The latter can be useful to protect – in the electronic domain - from the intrusiveness of an unknown agent, to guarantee an agent in the identification of its partner, to identify the sender of a message (for example, by verifying the origin of a received message; by verifying that a received message has not been modified in transit; by preventing that an agent who sent a message might be able to deny later that it sent the message [He, Sycara & Su, 2001]). With sophisticated cryptographic techniques, it is possible to give some solution to these security problems.

However, more complex is the issue of trust, that must give us tools for acting in a world that is in principle insecure (that cannot be considered 100% secure), where we have to make the decision to rely on someone in risky situations. (Consider the variety of cases in which it is necessary or useful to interact with agents whose identity, history or relationships are unknown, and/or it is only possible to make uncertain predictions on their future behaviors.)

Trust should not be made indistinct with reputation, too. In fact, communicated reputation (Conte & Paolucci, 2002) is one of the possible sources on which the trustier bases its decision to trust or not.

The more actual and important example of the usefulness of trust building is electronic commerce, but we must also consider other important domains of Multi Agent Systems and Agent Theory such as Agent Modeling, Human-Computer Interaction, Computer Supported Cooperative Work, Mixed Initiative and Adjustable Autonomy, Pervasive and Ubiquitous Computing.

In fact, today many computer applications are open distributed systems (with many autonomous components that are spread throughout a network and interacting with each other). Given the impossibility to rule this kind of system by a centralized control regime (Marsh, 1994), it becomes essential to introduce local tools in order to choose the right partnership and at the same time reduce the uncertainty (deriving from the nature of an open distributed system) associated with that choice.

TRUST IN THE NEW TECHNOLOGICAL SCENARIOS

In fact, various different kinds of trust should be modeled, designed, and implemented:

- Trust in the environment and in the infrastructure (the socio-technical system)
- Trust in personal agents and in mediating agents
- Trust in potential partners
- Trust in sources
- Trust in warrantors and authorities.

Part of these different kinds of trust have a complementary relation with each other, that is, the final trust in a given system/process can be the result of various trust attributions to the different components. An exemplary case is one’s trust in an agent that must achieve a task (and more specifically in its capabilities for realizing that task) as different from one’s trust in the environment (hostile versus friendly) where that agent operates, or again as different from one’s trust in a possible third party (arbitrator, mediator, normative systems, conventions, etc.) able to influence/constrain the trustee and representing a guaranty for the trustier (Castelfranchi & Falcone, 1998; Falcone & Castelfranchi, 2001).

Therefore, the “sufficient” trust value of one single component cannot be established before
Socio-Cognitive Model of Trust

evaluating the value of the other components. In this regard, it is very interesting to characterize the relationships between trust and (partial) control (Castelfranchi & Falcone, 2000).

It is important to underline how trust is in general oriented towards not directly observable properties. It is, in fact, based on the ability to predict these properties and to rely or not to rely on them. Thus, it is quite complex to assess the real trustworthiness of an agent/system/process, not only because - as we have seen - there are many different components that contribute to this trustworthiness, but also because the latter is not directly observable (see [Bacharach & Gambetta, 2001] about signs of trust). The important thing is the perceived trustworthiness that is, in its turn, the result of different modalities of the trustier’s reasoning about direct experience; categorization; inference, and communicated reputation.

SOCIO-COGNITIVE MODEL OF TRUST

The Socio-Cognitive model of trust is based on a portrait of the mental state of trust in cognitive terms (beliefs, goals). This is not a complete account of the psychological dimensions of trust. It represents the most explicit (reason-based) and conscious form. The model does not account for the more implicit forms of trust (for example, trust by default, not based upon explicit evaluations, beliefs, derived from previous experience or other sources) or for the affective dimensions of trust, based not on explicit evaluations but on emotional responses and an intuitive, unconscious appraisal (Thagard, 1998).

The word trust means different things, but they are systematically related with each other. In particular, three crucial concepts have been recognized and distinguished not only in natural language but also in the scientific literature. Trust is at the same time:

- A mere mental attitude (prediction and evaluation) toward another agent, a simple disposition;
- A decision to rely upon the other, i.e., an intention to delegate and to trust, which makes the trustier “vulnerable”(Mayer, Davis, & Schoorman, 1995);
- A behavior, i.e., the intentional act of trusting, and the consequent relation between the trustier and the trustee.

In each of the above concepts, different sets of cognitive ingredients are involved in the trustier’s mind. The model is based on the BDI (Belief-Desire-Intention) approach for modeling mind that is inspired by Bratman’s philosophical model (Bratman, 1987). First of all, in the trust model only an agent endowed with both goals and beliefs can “trust” another agent. Let us consider the trust of an agent $X$ towards another agent $Y$ about the ($Y$’s) behavior/action $\alpha$ relevant for the result (goal) $g$ when:

- $X$ is the (relying) agent, who feels trust; it is a cognitive agent endowed with internal explicit goals and beliefs (the trustier)
- $Y$ is the agent or entity that is trusted (the trustee)
- $X$ trusts $Y$ about $g/\alpha$ and for $g/\alpha$.

In the model $Y$ is not necessarily a cognitive agent (for instance, an agent can - or cannot - trust a chair as far as to sustain his weight when he is seated on it). On the contrary, $X$ must always be a cognitive agent: so, in the case of artificial agents we should be able to simulate these internal explicit goals and beliefs.

For all the three notions of trust defined above (trust disposition, decision to trust, and trusting behavior), we claim that someone trusts some other one only relatively to some goal (here the goal is intended as the general, basic teleonomic notion, any motivational representation in the agent: desires, motives, will, needs, objectives, duties,
Socio-Cognitive Model of Trust

utopias, are kinds of goals). An unconcerned agent does not really “trust”: he just has opinions and forecasts. Second, trust itself consists of beliefs.

Since Y’s action is useful to X (trust disposition), and X has decided to rely on it (decision to trust), this means that X might delegate (act of trusting) some action/goal in his own plan to Y. This is the strict relation between trust disposition, decision to trust, and delegation.

The model includes two main basic beliefs (we are considering the trustee as a cognitive agent, too):

- **Competence Belief**: a sufficient evaluation of Y’s abilities is necessary. X should believe that Y is useful for this goal, that Y can produce/provide the expected result, and that Y can play such a role in X’s plan/action.

- **Willingness Belief**: X should think that Y not only is able and can do that action/task, but Y actually will do what X needs (under given circumstances). This belief makes the trustee’s behavior predictable.

Another important basic belief for trust is:

- **Dependence Belief**: X believes -to trust Y and delegate to it- that either X needs it, X depends on it (strong dependence), or at least that it is better to X to rely on it, rather than not to rely on it (weak dependence). In other terms, when X trusts someone, X is in a strategic situation: X believes that there is interference and that his rewards, the results of his project, depend on the actions of another agent Y.

Obviously, the willingness belief hides a set of other beliefs on the trustee’s reasons and motives for helping. In particular, X believes that Y has some motives for helping it (for adopting its goal), and that these motives will probably prevail -in case of conflict- on other motives, negative for it. Notice that motives inducing adoption are of several different kinds: from friendship to altruism, from morality to fear of sanctions, from exchange to common goal (cooperation), and so on. This is why, for example, it is important to have common culture, shared values, and the same acknowledged authorities between trustier and trustee.

Another important characteristic of the socio-cognitive model of trust is the distinction between trust “in” someone or something that has to act and produce a given performance thanks to its internal characteristics, and the global trust in the global event or process and its result, which is also affected by external factors like opportunities and interferences.

Trust in Y (for example, “social trust” in strict sense) seems to consists in the first two prototypical beliefs/evaluations identified as the basis for reliance: ability/competence (that with cognitive agents includes knowledge and self-confidence), and disposition (that with cognitive agents is based willingness, persistence, engagement, etc.). Evaluation about external opportunities is not really an evaluation about Y (at most the belief about its ability to recognize, exploit and create opportunities is part of our trust in Y). We should also add an evaluation about the probability and consistence of obstacles, adversities, and interferences.

Trust can be said to consist of or better to (either implicitly or explicitly) imply the subjective probability of the successful performance of a given behavior a, and it is on the basis of this subjective perception/evaluation of risk and opportunity that the agent decides to rely or not to rely on Y. However, the probability index is based on, and derives from those beliefs and evaluations. In other terms, the global, final probability of the realization of the goal g, i.e., of the successful performance of a, should be decomposed into the probability of Y performing the action well (internal attribution) and the probability of having the appropriate conditions (external attribution) for the performance and for its success, and of not having interferences and adversities (external
**Socio-Cognitive Model of Trust**

The degree of trust is used to formalize a rational basis for the decision of relying and betting on $Y$. A “quantitative” aspect of another basic ingredient is relevant: the value or importance or utility of the goal ($g$). In sum, the *quantitative dimensions of trust are based on the quantitative dimensions of its cognitive constituents.*

If we call $DoTXY\tau$ the degree of trust of an agent $X$ about $Y$ on the task $\tau=(a,g)$ we have:

$$DoTXY\tau = DoCX[OppY(a,g)] \cdot DoCX[AbilityY(a)] \cdot DoCX[WillDoY(a,g)]$$

Where:

- $DoCX[OppY(a,g)]$, is the degree of credibility of $X$’s beliefs about $Y$’s opportunity of performing $a$ to realize $g$;
- $DoCX[AbilityY(a)]$, the degree of credibility of $X$’s beliefs about $Y$’s ability/competence to perform $a$;
- $DoCX[WillDoY(a,g)]$, the degree of credibility of $X$’s beliefs about $Y$’s actual performance;
- $DoCX[WillDoY(a,g)] = DoCX[IntendY(a,g)] \cdot DoCX[PersistY(a,g)]$
  (Given that $Y$ is a cognitive agent)

In any circumstance, an agent $X$ endowed with a given goal, has three main choices:

i) To try to achieve the goal by itself;
ii) To delegate the achievement of that goal to another agent, $Y$;
iii) To do nothing (relatively to this goal), renouncing.

Considering the simplified scenario in which only (i) and (ii) are the possible choices we have the Figure1.

Where if $U(X)$ is the agent $X$’s utility function, more specifically:

---

**Figure 1.**

```
To do by itself
  \[ U(X) \]
Failure
  \[ U(X) \]

Delegation
  \[ U(X) \]
Success
  \[ U(X) \]
Failure
  \[ U(X) \]
```

**attribution**. This decomposition is important because:

a. The trustier’s decision might be different with the same global probability or risk, depending on its composition (for example, for personality factors);

b. Trust composition (internal vs. external) produces completely different intervention strategies: to manipulate the external variables (circumstances, infrastructures) is completely different from manipulating internal parameters.

The idea that trust is gradable is usual (in common sense, in social sciences, in Artificial Intelligence). However, since no real definition and cognitive characterization of trust is given, the quantification of trust is quite *ad hoc* and arbitrary, and the introduction of this notion or predicate is semantically empty. On the contrary, in the socio-cognitive model of trust there is a strong coherence between the cognitive definition of trust, its mental ingredients, and, on the one side, its value, on the other side, its social functions. More precisely the latter are based on the former.

A degree of trust of $X$ in $Y$ is grounded on the cognitive components of $X$’s mental state of trust. More precisely the *degree of trust is a function of the subjective certainty of the pertinent beliefs.*
Socio-Cognitive Model of Trust

- $U(X)p^+$, the utility of the $X$’s success performance;
- $U(X)p^-$, the utility of the $X$’s failure performance;
- $U(X)d^+$, the utility of a successful delegation (the utility due to the success of the delegated action);
- $U(X)d^-$, the utility of a failure delegation (the damage due to the failure of the delegated action).

In the previous scenario, in order to delegate we must have:

$$DoTXYτ * U(X)d^+ + (1 - DoTXYτ) U(X)d^- >\]
$$DoTXXτ * U(X)p^+ + (1 - DoTXXτ) U(X)p^-$$

where $DoTXXτ$ is the selftrust of $X$ about $τ$.

More precisely, we have:

$$U(X)p^+ = \text{Value}(g) + \text{Cost}[\text{Performance}(X)],$$

$$U(X)p^- = \text{Cost}[\text{Performance}(X)] + \text{Additional Damage for failure}$$

$$U(X)d^+ = \text{Value}(g) + \text{Cost}[\text{Delegation}(X Y)],$$

$$U(X)d^- = \text{Cost}[\text{Delegation}(X Y)] + \text{Additional Damage for failure}$$

Where it is supposed that it is possible to attribute a quantitative value (importance) to goals and where the costs of the actions (delegation and performance) are supposed to be negative.

CONCLUSION

The Socio-Cognitive model of trust analyzes the basic elements on which trust is founded in terms of the cognitive ingredients of the trustier. In fact, the richness of the referred model (trust is based on many different beliefs) allows us to distinguish between internal and external attributions (to the trustee) and for each of these two attributions it allows us to distinguish among several other subcomponents such as: competence, disposition, un-harmfulness, and so on.

The model introduced a degree of trust instead of a simple probability factor since it permits us to evaluate trustfulness in a rational way.

In other words, if we understand what precisely the basic ingredients of trust are, we would be able to better model and build artificial systems in which this attitude should be present.

FUTURE TRENDS

One of the main aspects that should be analyzed in the next few years is the dynamics of trust and the possibility of introducing all the dynamic aspects in the computational setting in which humans and machines will work together. Trust is a dynamic phenomenon in its intrinsic nature (Falcone & Castelfranchi, 2001). Trust changes with experience, with the modification of the different sources it is based on, with the emotional state of the trustier, with the modification of the environment in which the trustee is supposed to perform, and so on. But, trust is also influenced by trust, itself, in the same specific interaction: for example, how trust creates a reciprocal trust; how the fact that $A$ trusts $B$ can actually increase $B$’s trustworthiness; and so on. In other words, in a computational model of trust relationships we have to consider all the dynamical aspects of the trust phenomenon.

Socio-Cognitive Model of Trust

**KEY TERMS**

**Cyber-societies:** The set of natural, artificial, and virtual agents connected and interacting with each others through natural and artificial infrastructures within virtual institutions.

**Reputation:** the estimated trustworthiness in an agent as derived from the communicated opinions of other parts (directly or indirectly received); the resulting and emergent “common opinion” about the agent’s trustworthiness.

**Task:** An action and/or a goal an agent has to realize as delegated by another agent; thus – in the opposite perspective - the couple action/goal that an agent intentionally delegates to another agent; where at least the delegating agent knows one between the action and the goal.

**Trust:** The attitude of an agent to delegate a part of its own plan/goal to another agent and rely upon it in a risky situation (possible failure) on the basis of its own beliefs about the other agent and on the environment in which it operates.

**Trustee:** the trusted agent in the trust relationship.
**Socio-Cognitive Model of Trust**

**Trustier:** the trusting agent in the trust relationship.

**Ubiquitous Computing:** The trend of the technological development to integrate into any kind of object information processing and communication capabilities.

ABSTRACT

This chapter is on cultural aspects of information-communications systems embedded into new media environment and invisible e-technologies, and on a new age of social responsibility for information technology professionals. Besides the key issues in information technology development that create smart environment and ambient intelligence, the chapter also discusses digital e-culture and the new media role in cultural heritage. From the viewpoint of information technology, the current information-communications systems converge with media. This convergence is about tools-services-content triangle. Thus, we are confronted with a new form of media mostly presented with the term digital, reshaping not only media industry but also a cultural milieu of an entire nation on a regional and global basis. The discussion follows on the World Library idea that is rebuilding with new form of World Memory (World Brain), the shift from visible culture domination to the domination of invisible culture in the world of e-technologies predominance. From this scenario, information technology professionals coping with information systems projects, e-services development, and e-content design have more cultural responsibility than in the past when they worked within closer and inner cultural horizons and when their misuse of technologies had no influence on culture as a whole.

INTRODUCTORY REMARKS

The information society is, above all, an economic concept but with important social and cultural implications. The new forms of direct access to information and knowledge create new forms of e-culture. E-culture is a part of a culture. It not
only concerns users but the community of information professionals as well. When one speaks of information technology, it is always from the Western point of view, whereas e-technology (especially its applications) takes place throughout the world, and every culture has a different understanding of it. The shift to an e-culture at the level of society in general is translated to the individual level, enabling cultural change to be described empirically. The term e-culture refers to the diffusion of new technology, its application for various purposes (especially information and communication), and shifts in related attitudes, values, and norms. E-technology may not be gnawing at the roots of our culture, but those roots are gradually absorbing it. As with all innovation, cultural or otherwise, this technology will reinvigorate, transform, and inspire older cultural forms. We are living in the era of globalization, the information economy, with borderless communities and multiple citizenships. E-culture literacy and attainment will require serious attention to new infrastructure, to the building blocks and platforms for e-culture. These are critical issues for the pursuit of information professionals’ excellence, for creativity in an information society, as well as for fundamental imperatives for commerce and trade in a new media environment.

The main notion of the following text is on cultural aspects of information-communications systems embedded into a new media environment, on invisible technologies, and on a new age of cultural responsibility for information technology professionals. The key issues in information technology development that create invisible e-technologies and smart environments are under e-culture influence. From the viewpoint of information technology, the current information-communications systems converge with media. This convergence is about tools-services-content triangle. Thus, we are accepting a new form of media mostly presented with the term digital, reshaping not only media industry but also a cultural milieu of an entire nation on a regional and global basis. The discussion follows on the new e-technology and information-communications systems convergence as the basis for defining pervasive computing and positive e-technologies. The findings at the end of this chapter explain the process of a fundamental cultural shift from the computer-based information technology to the computerless (invisible) e-technologies in which the e-culture is the essential factor of the success. The discussion section is about the role of information technology professionals coping with information systems projects, e-services development, and e-content design. They have more social responsibility than in the past when they worked within closer and inner cultural horizons and when their misuse of technologies had no influence on culture as a whole.

**BACKGROUND ON INFORMATION COMMUNICATIONS SYSTEMS AND NEW MEDIA**

One of the most valuable and essential processes that humanity can engage in and which is, therefore, essential to look at in terms of information technologies, is the process of self-determination. The principal of self-determination of people was embodied as a central purpose of the United Nations in its 1945 charter. The purposes of the United Nations are to develop friendly relations among nations based on respect for the principle of equal rights and self-determination of nations, and to take other appropriate measures to strengthen universal peace. Resolution 1514 (XV) of December 14, 1960, containing the Declaration on the Granting of Independence to Colonial Countries and Peoples, stated that all nations have the right to self-determination; by virtue of that right, they freely determine their political status and freely pursue their economic, social, and cultural development (United Nations, 1960). In the 1990s,
these issues continued to be highly relevant as numerous people around the world strove for the fulfillment of this basic right of self-determination. The UN General Assembly in 1995 again adopted a resolution regarding the universal realization of the right of nations to self-determination. Thus, the General Assembly reaffirmed the importance for the effective guarantee and observance of human rights and of the universal realization of the right of nations to self-determination (United Nations, 1995). By this, we see that self-determination is tied to all aspects of life: political, economic, social, and cultural. It is ultimately about how we choose to live and allow others to live together on this planet. Furthermore, information technology plays a key role in current economic and social affairs, so the information technology specialists/professionals have much more social responsibility than other professions. Information and communication technologies and networking infrastructures are playing an expanding role in supporting the self-determination of people and emergent nations. Access to information and the facilitation of communication provides new and enhanced opportunities for participation in the process of self-determination. It gives the potential to enhance political, economic, social, educational, and cultural advancement beyond the scope of traditional institutions and forms of governance.

The next step in recognizing cultural and social dimensions of information technology on the international scene is regarding the Council of Europe document, Declaration of the Committee of Ministers on human rights and the rule of law in the information society (Council of Europe, 2005). The Declaration recognizes that information and communication technologies are a driving force in building the information society with the convergence of different communication media. It also stressed that building societies should be based on the values of human rights, democracy, rule of law, social cohesion, respect for cultural diversity, and trust between individuals and between nations, and their determination to continue honoring this commitment as their countries enter the Information Age.

Vannevar Bush (1945) predicted that the advanced arithmetical machines of the future would be (a) electrical in nature, (b) far more versatile than accounting machines, (c) readily adapted for a wide variety of operations, (d) controlled by instructions, (e) exceedingly fast in complex computation, and (f) capable of recording results in reusable form. The new computer devices as smart devices, linked through communications systems, are creating new forms of information-communications systems. Thus, the new form of information appliances and ubiquitous information technology creates the basis for the concept of an information-processing utility. Based on interactive and ubiquitous carriers of information, the first generation of new information systems evolved to provide easy communication over time and space barriers. Thus, the new information systems are media. They are virtual communication spaces for communities of agents interested in the exchange of goods and knowledge in a global environment. Further promising technologies are pervasive computing and augmented reality. The vision of pervasive computing is, to some extent, a projection of the future fusion of two phenomena of today: the Internet and mobile telephony. The emergence of large networks of communicating smart devices means that computing no longer will be performed by just traditional computers but rather by all manners of smart devices. From these notions, it is evident that information-communications systems open the way to information society development. The information society is based on the new (digital) media that provides vast opportunities for information/content networking. New organizational networks are built, cutting across national borders and interests. The networks themselves increasingly may take precedence over nation-states as the driving factor.
Information-Communications Systems Convergence Paradigm

in domestic and foreign affairs. At the same time, native communities have been actively engaged in creating and utilizing such networks with increasing participation and sophistication.

We are entering the era of new media. New media are tools that transform our perception of the world and, in turn, render it invisible or visible. Information technology (IT) professionals must understand new problems, considering the role of e-technologies in the integration and interaction between cultures. It is apparently true with tera architecture of the sensor networks that will transform business, healthcare, media, and e-culture itself. A new form of information-communications systems boosts intelligent networks with the majority of computers that are invisible and disposable. The IT professionals have the challenge in turning all that data into useful and meaningful information and in resolving cultural and privacy issues that accompany pervasive networked computing and ambient intelligence. IT professionals are confronted with the stage when e-technologies extract analytic values from social networks turning information issued by sensors and other data sources into knowledge management systems.

Defining new media is hard work. If we begin to use voice or books in an innovative fashion, we have just made old media into new media. Whatever we define as new media now would be old media as soon as we add innovations. We cannot define new media strictly based on the use of new technology for distance communication, since technology is always changing. What is new media today will be passé tomorrow. If we try to define new media by process rather than by structure, we are still in trouble. Whatever we define new media as today no longer will be valid tomorrow as technology changes the structures and processes. Trying to define the limits of change is a futile effort due to the very nature of change. This means that the regulation of new media is also an exercise in utility. The experiences with first-generation media platforms showed that in order to take advantage of the potentials and chances offered by new media, we need to explore their features and learn how to use them effectively and to build them efficiently. In short, we need to develop innovative concepts, frameworks, and methodologies for the design, realization, and management of the new media. The new media offer unprecedented opportunities and potentials for positively changing almost any aspect of our lives. The growing importance of new media and the demand for appropriate platforms have given rise to the development of innovative technologies and components for such media. Consequently, we can now observe the first generation of media platforms and the first management approaches for such platforms.

The evolution in convenient, high-capacity storage of digital information is one of the enabling technologies for new media. Disk drives that allow local storage, retrieval, and manipulation of digital content are increasing in capacity and falling in price. The current TV experience will evolve into a highly personalized process. Consumers have access to content from a wide variety of sources tailored to their needs and personal preferences. New business models and opportunities for the various providers in the value chain will evolve in an organic market focused on addressing individuals directly with new services. This will allow content providers to respond more effectively to audience needs. Digital media and the emerging communication technologies have created an overabundance of programs and information available from which each consumer can choose. The consumer will need new solutions enabling smart and active decision making over viewing preferences, such as a personal filter for the multitude of choices, dynamically adapting to changing needs and preferences.

Communications technology is available for the support of highly complex interenterprise service networks that support new services (Negroponte, 1996). Altogether, this creates a new view on the product, emphasizing the utility of
the package (product and services) instead of the product itself. Analyzing the lifecycle of a product is crucial for synthesizing and specifying new types of benefits for a customer. Therefore, modern manufacturers have to provide benefits to customers. Questions are what could be the benefits and what kind of utility may be beneficial for the customer. Based on that exercise, they have to come up with appropriate business concepts based on new media e-culture.

THE CULTURE AND INVISIBLE CULTURE

To cope with the new culture space in the context of information-communications systems embedded into new media environment, there is a need for basic definitions on culture, new media, and digital e-technologies. The great advances in culture come not when people tried to impose the values of one culture to the exclusion of all others, but rather when modern individuals try to create structures that are more exciting by combining elements from different cultures. The current information technology is capable of recording universal standards and particulars around the world, and it opens new ways and sources for creativity and global cultural heritage. Hence, information technology must reflect the full range of human existence, the values, the culture, and the entire knowledge. At the same time, the new e-culture is born interacting with e-technologies, and it exists in new cultural ecology. This new cultural ecology stimulates the development of a new trio (triple convergence) consisting of e-technologies, e-culture, and e-society.

The culture is a shared set of manifest and latent beliefs and values (Sackmann, 1991). It helps people to categorize and predict their world by teaching them about habits, rules, and expectations from the behaviors of others. Culture also molds the way people think—what their motivations are, how they categorize things, what inference and decision procedures they use, and the basis on which they evaluate themselves. Most of other definitions are too narrow. Sociologists have focused on behaviorist definitions of culture as the ultimate system of social control. In this system, people act appropriately and monitor their own standards and behaviors. Thus, the culture consists of the learned ways of group living and group responses to various stimuli; sociologists describe the content of the culture as the values, attitudes, beliefs, and customs of a society. Media theorists have explored the interplay of culture and technology, which has led to an emphasis on some aspects of culture. The new approaches are considering cultural ecology as consisting of new media in which various types of media are translated into a common digital form that is accessible within a single framework.

Today’s networked media allow each user to participate actively in the creation of cultural expressions, which we perceive simultaneously and with immediate proximity. The new culture is emerging due to the use of digital technology (e-technology). At the same time, there is a strong relation between values promoted by the new digital e-culture and the traditional moral values created by the major world cultures. These notions open the new contextual approaches on culture in the information society. The culture related to the information society is about three contextual elements (Figure 1.)

The forces of globalization and technology development are paradoxical by nature, offering both threats and opportunities for cultural diversity. Yet, the information society is currently perceived only as an economic imperative in a new environment shaped by rapid information technology developments, based on visions shaped primarily by technologist and business concerns and priorities. The prevailing options embedded in these visions, such as globalization based on cultural homogenization, are questionable not only from a political and social standpoint but also in economic terms. Citizens around the world
are becoming increasingly concerned about the way accelerating processes of globalization and technological innovation are leading to cultural homogenization and immense concentrations of financial power. Globalization generally is seen to be a phenomenon driven primarily by economic interests. As such, it has neither moral content nor values. Therefore, it could be independent from culture.

**Cultural Diversity and the Information Society**

Cultural diversity potentially can become a key asset in the information society, despite the fact that the culture could be defined as an obstacle. It is clear from the previous discussion on globalization that the economic forces of globalization pose a serious threat to cultural identity.

---

*Figure 1. Triple context of culture in information society*

*Figure 2. Tools-services-content triangle as the basis for information society*
Information-Communications Systems Convergence Paradigm

Information technologies are not only the tools that accelerate the pace of globalization, but they are also becoming the key means of access to any good or service. One could thus argue that cultural diversity is an obstacle. Cultural diversity is essentially a question of communication, both internally to one’s own culture and externally with distributed cultures. Thus, one of the central issues is not only access to new e-technologies but also the capability of manipulating new media in order to participate actively in communicational exchanges.

Technology literacy is needed to operate IT effectively. Cultural literacy refers to the ability of an individual (or community) to relate to the services made by one’s own cultural heritage and with access to another culture in a positive way. This means learning from both similarities and differences, being able to reject some aspects, and accepting others. Cultural literacy thus lies at the heart of the possibility of communication in a context of cultural diversity. Content is about Creativity. Creativity is the factor lying at the intersection of motivation and competence, and it covers both the individual and the collective levels. Collective creativity is of greater importance if we are aiming for a shift toward an information society in which a given community will depend on the collective creativity of its social and economic individuals and organizations (with accepting collective memory and brain).

Visible Culture

Western culture has had a strong bias toward the so-called fine arts, such as painting and sculpture. These expressions of culture, which are continuously visible, were more significant than the performance arts (theatre, film, music), which are only visible when they are being played. One of the key elements of great visible culture is uniqueness. Thus, the challenge of universal standards has brought the question of uniqueness back to the fore. To communicate internationally, we need global standards that bring the risk of reducing everything to one mode of expression.

The world of telephony offers an interesting case in point. We clearly need standards and uniform rules for telephones, yet every conversation on those telephones still can be different (Veltman, 1997). In this imperative to record the particular as well as the universal, creativity is only one essential element. The major cultures of the world owe much of their greatness to the fact that they have a recorded tradition, which stabilizes the corpus but also ensures the possibility of a cumulative dimension, which is reflected in terms such as cultural heritage. Even so, there are many skills in the craft tradition relating to culture that remain oral and invisible.

Invisible Culture

Many people favor material culture because it is visible and easily recognized. Culture is about more than objects in visible and tangible places. For example, many computer users are accustomed to thinking of computers as tools for answering questions. We need to think of them as tools for helping us to understand which questions can be asked, to learn about contexts when and where questions are not asked, of knowing that there are very different ways of asking the same thing. If software continues to be dominated by one country and if the so-called wizards of those programs all rely on the questions of that single country, then many potential users of computers inevitably will be offended, and it is likely that they will not use the programs.

The base assumption is that culture for us is invisible (invisible culture). As workers do not know that they are participants accepting entire organization values, the culture of an organization is invisible (Cooke & Lafferty, 1989). Yet, it is all-powerful. Therefore, this assumption is important for invisible e-culture. We are working in organizations that actually drive our behavior and performance in a way that most of the time is
Information-Communications Systems Convergence Paradigm

A definition of culture includes the way we do things. A way to look at culture is actually to have some outside expert or outside person come in and question the way things are going, which can begin to give some insight to the people inside the organization about their own culture (Cleary & Packard, 1992). However, the culture is also considering exchange of ideas, thoughts, and beliefs, and it helps people realize that things can be done differently somewhere else. The success in one culture does not mean success in another culture, and there are actually many ways to succeed, change, and live. People realize that they can act on some other level of culture and act on their own culture.

E-Culture

We could define culture as the beliefs, behaviors, languages, and entire way of life of a particular time or group of people. Culture includes customs, ceremonies, art, inventions, technology, and traditions. The term also may have a more specific aesthetic definition and can describe the intellectual and artistic achievements of a society. The new world economy develops in e-culture and characterizes with the fast, open access to information and the ability to communicate directly with nearly anyone anywhere (Kanter, 2001). This sets e-culture apart from traditional environments.

In a first approximation, one could say that an e-culture is emerging from the convergence of communication and computing along with globalization and the penetration of e-technology in the smallest corners of our lives. The advent of information and communication technology goes hand in hand with changes in attitudes, skills, and behaviors that play a central role in daily life. The advent of an e-culture is correlated with terms of a broad definition of culture. This concerns the culture of a society with both invisible and material characteristics. E-technology as a part of the cultural information may be classified as e-invisible culture, but the outputs of that technology (information appliances) may range among the material (visible) cultural products.

The shift to an e-culture at the level of society is translated to the individual level enabling cultural change to be empirically described. The term e-culture refers to the diffusion of new technology; its application for various purposes (especially information and communication); and shifts in related attitudes, values, and norms. The human thinking and behavior are changing gradually by information and communication technology. E-technology may not be gnawing at the roots of our culture, but those roots gradually are absorbing it. As with all innovation, cultural or otherwise, this technology will reinvigorate, transform, and inspire older cultural forms. We are living in the era of globalization, the information economy, with borderless communities and multiple residencies. E-culture literacy and attainment will require serious attention to new infrastructure and to the building blocks and platforms for e-culture. These are critical issues for the pursuit of information professionals’ excellence, for creativity in an information society, as well as for fundamental imperatives for commerce and trade in new media environments.

E-TECHNOLOGIES AND UBQUITOUS INFORMATION (DIGITAL) APPLIANCES

The Internet is without precedent because of two key features: its interactive and communicative natures. It is not a commodity in the sense that you can go out and buy a TV. You cannot go out and buy a net. The key word here is interactivity. Interactivity implies a dialogue of some kind, a changing response based on changing stimuli. There is much talk of interactive Web sites, but even the best of these choose from a preprogrammed set of possibilities in order to give the
illusion of being interactive. You have interactivity over the telephone, and you have interactivity in a face-to-face dialogue. However, you do not have interactivity in traditional analogue television. The prosperity of the net is that it permits simultaneous interactivity with thousands and, perhaps, millions of people worldwide. This is a first in the history of humankind.

With the new and upcoming information-communications systems with pervasive and personal appliances, there will be a huge number of networked intelligent devices and information appliances functioning as self-organizing and managed networks (Figure 3).

In the near future, information communications systems with invisible networked devices, sensors, and appliances will transform businesses, public administration, public services, and the way we communicate within digital networks. Digital networks through the new form of information transport by ultra wideband and WiMax technologies will boost the intelligent networks development around the entire globe. The computer is becoming invisible and everywhere simultaneously. This is the beginning of the invisible computer era.

Parallel to this development is that of networking, which conceivably could result in all the invisible computers in the world being networked into a single virtual computer. This would lead to the evolution of a computer that would be everywhere and nowhere at the same time. Technology itself and on its own is not a cultural determinant. Technology is the invention of a particular culture—a cultural expression. The relationship between culture and technology is not linear and monodirectional but rather multidimensional and hyperspatial. Ten years from now, the computer as we know it today will be an anachronism, a device consigned to museums. Instead, the digital information and services once delivered via conventional computers will be available through almost everything we touch. At the heart of this next generation of computing is the network. It will be pervasive and personal. Looking out a decade or two, every person and thing could be instrumented with sensors that feed data into the content base and take actions on behalf of the client.

The new term, speckled computing, goes in that way. It offers a radically new concept in information technology that has the potential

---

**Figure 3. Scenario of universal personal information appliance**

[Diagram of a universal personal information appliance with labels for calls, clock, calculator, calendar, games, location, player camera, remote controller, always on—always online, computer, browser, email, map wallet, ID, key, multi-modal user interface, control of life(style).]
to revolutionize the way we communicate and exchange information (Arvind, 2005). Computing with Specknets will enable linkages between the material and digital worlds, and it is the beginning of truly ubiquitous computing. As the once-separate worlds of computing and wireless communications collide, a new class of information appliances will emerge. Where once they are used regularly, the post-modern equivalent might not be explicit after all. Rather, data sensing and information processing capabilities will fragment and disappear into everyday objects and the living environment. At present, there are sharp dislocations in information processing capability—the computer on a desk, the PDA/laptop, the mobile phone, smart cards, and smart appliances. However, Speckled Computing, the sensing and processing of information, will be highly diffused. The person, the artifacts, and the surrounding space become computational resources and interfaces to those resources. Surfaces, walls, floors, ceilings, articles, and clothes will be invested with a computational activity for rich interactions with the computational resources.

The information appliance is the natural outcome in the evolution of information processing. That is why they were foreseen a long time ago. Digital computers started out as expensive mainframes accessible to a few. The next step was the personal computer that individuals could own, and it was incorporated into everyday human activities. Thus, it was essential to have as much functionality in the personal computer as possible. Information technology is making feasible small and inexpensive devices that are smart. This helps to push intelligence closer to the people, the ultimate customers of information technology that accept some of the hidden cultural attributes of the entire community.

In a smart environment, the interaction endpoints simply could not be cognitively or physically visible. In essence, the user may have no idea that they are engaging in a computer-mediated communication. A smart environment is a composite space made from many individual objects. These objects are either fixed or mobile. The term invisible means that a technology has become so natural (common) and so comfortable that we use it all the time without ever thinking of it as a technology or a number of linked technologies. These invisible technologies are taken for granted. Since they are no longer technological, we can afford to think of them as customary, as the day-to-day workings of our world. As it continues to become more acceptable and as people come into the any-information system more proficient with these new tools, computer technologies will become increasingly invisible.

The exact example of the ubiquitous e-technologies environment is under way through the ubiquitous city in South Korea. New Songdo City (U-city), being built on a manmade island, will feature pervasive computer technology throughout, driven by RFID tags and CDMA wireless communication. Although many Western observers would find the lack of privacy disquieting, Asian countries are more interested in the technological potential of such environments. U-life will become its own brand, its own lifestyle. Residents will enjoy full videoconferencing calls between neighbors, video on demand, and wireless access to their digital content and property from anywhere in Songdo. At the same time, privacy is also encountered: all information services will be anonymous, and they will not be linked to user identity.

INVISIBLE E-TECHNOLOGIES’ INTERACTION WITH INVISIBLE E-CULTURE

Our relationship with the manmade world is dominated by the paradigm of the device. This paradigm creates an illusory separation between the technological means (the machinery, the medium) and the technological ends (the commodity, the message). Technological progress generally is
devoted to increasing the availability of technological goods, to make them everywhere available instantly without risk or hassle. At the same time, we want the machinery to become invisible. For various reasons, we repress ourselves from seeing the machinery and our dependence upon it. Our conscious awareness focuses on the message, and we refuse to acknowledge the medium (Pribram, 1971). Our perception of the world and our place in it are inextricably mediated through technology and the device paradigm. Our discovery of ourselves (identity through self-determination) is technical and complicated.

We are entering a new era of computing, often referred to as ubiquitous or pervasive computing. Ubiquitous computing consists of information appliances, specialized and easy-to-use devices that avoid the complexity of the computer. The future belongs to information appliances. When technology changes rapidly, greater ease of use serves to attract more users and developers, creating new frustrations. The most we can do is ameliorate the spread of the information appliance products and services. To do this, it appears necessary to recognize that flexibility and ease of use are in an unavoidable conflict and that the optimal balance between those two factors differs among users. Therefore, systems should be designed to have degrees of flexibility that can be customized for different people. Information appliances will be popular, since they will provide many new services for which the desktop computer is ill-suited and will do so in user-friendly ways. However, they will introduce their own complexity, and the level of frustration with information technology will not decrease. This is a result of the conflict between usability and flexibility. The information appliance market will be anything but mature for a long time to come. The emphasis in information processing has been and is likely to continue to be on development of novel applications. When the available information is stored on computers, it is important for information management applications to be able to model users’ interpretations of their data and to capture the possibly different meanings, semantics links, and relationships with which users associate the information units available. This is in correlation to one’s personal culture. For this purpose, various Personal Information Management tools are being developed to assist the user with navigation/browsing over various forms of personal digital data. As an example of capturing, organization, and archiving new media content, the MyLifeBits project is very explanatory. MyLifeBits has the aim to store in digital form everything related to the activities of an individual, providing full-text search, text and media annotations, and hyperlinks to personal data (Gemmell, Aris, & Lueder, 2005).

Information technology should mature to the humane technology of appliances in which the technology of the computer disappears behind the scenes into task-specific devices that maintain all the power without the difficulties. This could be explained by the technology of radio. Thus, computers should evolve the way radio receivers did (Norman, 1998). However, there is a problem of motivation, beliefs, knowledge, and frustration dealing with the information technology. This is considering culture (dominantly invisible culture). The problem is that with information appliances and by invisible technologies, we are confronted with the services that must be well-understood and stable. We will not see this scenario with information appliances, not for a long time. In a world with a huge potential in services, content, and navigation, we cannot know how people will want to use information appliances.

Careful design that is focused on human factors and incorporates powerful processors and software can provide information appliances that are a delight to use. However, once the number of devices to be connected increases and wireless communication with WiFi networks expands, the difficulties will increase. Building complicated systems that work is hard. Building ones that work and are user-friendly is much harder.
Further, it is necessary to balance the demand for user friendliness with the demand for more features. A tradeoff between flexibility and ease of use is unavoidable. The problem is that we should not be thinking just of individual information appliances. We have to be concerned with the whole system, which is likely to be complex. The problem is also how to balance flexibility and ease of use in a way that can be customized for people with different needs. This problem is especially focused on multimedia home systems. The home information appliance environment is likely to be more complicated than the office environment today. In addition, many users will be less knowledgeable about information technology than the typical office worker will (Ronfeldt, 1992). Therefore, it will be essential to outsource the setup and maintenance of home computing and electronics to experts. This notion opens new ways for information technology professionals that are accessing information appliances environment (this environment asks for new interface design, navigation methods, and computational power over networked appliances). Hence, there is convergence of culture and technology in use, be they visible or invisible.

Positive E-Technologies

Rheingold (2000) argues that the technology that makes virtual communities possible has the potential to empower ordinary citizens at a relatively small cost. E-technology potentially can provide citizens and professionals advantage and power, which is intellectual, social, commercial, and political. At the same time, civil and informed people must understand the advantages that e-technology provides. They must learn to use it wisely and constructively, as it cannot fulfill its positive potential by itself. Thus, the positive e-technologies should be developed as reduction technologies that make target behaviors easier by reducing a complex activity to a few simple steps. One of the most explicit theories that attempts to describe our natural inclination to do a cost/benefit assessment is expectancy theory. This theory posits that behavior results from expectations about what alternatives will maximize pleasure and minimize pain. E-technologies also should be self-monitoring technologies to perform tedious calculations or measurements, helping people achieve goals or outcomes. Ideally, these technologies work in real time, giving users immediate feedback on a performance or status. When people can take immediate action on a persuasive message, psychologists have found the message more persuasive than when presented at other times. The recent effort on real-time speech translation is an obvious example of these notions. Researchers from the International Center for Advanced Communication Technologies (interACT), a joint venture of Carnegie Mellon and the University of Karlsruhe, have developed a wearable system that allows real-time speech translation. The system consists of sensors that detect mouth muscle movements, translates that to a spoken language, and then retranslates that into other languages. It will make communication and cultural learning more likely, since people using this technology will be empowered to come together when they otherwise would not interact.

Culture is omnipresent in all technological advancements over the course of history, whether it is the result of intrinsic societal dynamics or the extrinsic factors of the environment. As history clearly documents, whenever technology changes, some pressing force of culture has had an effect on it. Moreover, there is a sort of invisible complimentary system between culture and technology; that is, whenever technology changes, the culture will adapt its way of life to fit the technology. For example, with the invention of the technology necessary for agriculture, cultures worldwide changed their hunting and gathering way of life in order to use the new technology and expand its horizons. This would be expected with the information technology, too. In essence, culture indeed influences human technology, but
technology also simultaneously molds the way in which cultures function.

**PERSUASIVE AGENDA**

Like human persuaders, persuasive interactive technologies can bring about positive changes in many domains, including health, business, safety, and education (Dillard & Pfau, 2002). With such ends in mind, the new area of information technology development is created under the term *captology*. Captology focuses on the design, research, and analysis of interactive computing products created for the purpose of changing people’s attitudes and behaviors. The fact that people respond socially to computer products has significant implications for persuasion. It opens the door for computers to apply a host of persuasion dynamics that are described collectively as social influence. These dynamics include normative influence and social comparison as well as less familiar dynamics such as group polarization and social facilitation.

Just as the term *software* shifts the emphasis from media/text to the user, the term *information behavior* also can help us to think about the dimensions of cultural communication, which previously went unnoticed. These dimensions always have been there, but in an information society, they have rapidly become prominent in our lives and, thus, intellectually visible. Today, our daily life consists of information activities in the most literal way: checking e-mail and responding to e-mail, checking phone messages, organizing computer files, using search engines, and so forth. In the simplest way, the particular way people organize their computer files, use search engines, or interact on the phone can be thought of as information behavior. Of course, according to a cognitive science paradigm, human perception and cognition, in general, can be thought of as information processing. While every act of visual perception or memory recall can be understood in information processing terms, today there is much more to see, filter, recall, sort through, prioritize, and plan. In other words, in our society, daily life and work largely revolve around new types of behavior activities that involve seeking, extracting, processing, and communicating large amounts of information. Information behaviors of an individual form an essential part of individual identity. They are particular tactics adopted by an individual or a group to survive in information society. Just as our nervous system has evolved to filter information existing in the environment in a particular way that is suitable for information capacity of a human brain, so we evolve particular information behaviors in order to survive and prosper in an information society. In today’s world of information, people suddenly are shifting their attention to the Web for their computing needs.

Levy (1998) contends that communication in the virtual world can cultivate collective intelligence, which can encourage the development of intelligent communities. He states that sharing of information, knowledge, and expertise in e-communities can promote a kind of dynamic, collective intelligence, which can affect all spheres of our lives. He contends that the virtual world can foster positive connections, cooperation, bonds, and civil interactions. In e-groups or e-communities, which are flexible, democratic, reciprocal, respectful, and civil, this collective intelligence can be enhanced continually. Researchers in science, education, business, and industry are pooling their collective intelligence, knowledge, and data in collaborative memories. These are virtual centers in which people in different locations work together in real time, as if they were all in the same place. Science, education, commerce, and industry have become increasingly global. Collaboration, which is efficient, maximizing, and timesaving among distance researchers in these fields, has become more critical.

This new e-culture paradigm within the Web users’ community opens the ways for Web 2.0
Information-Communications Systems Convergence Paradigm

e-technologies platform comprising the set of principles and practices based dominantly on the user behavior and cultural values of collaboration. Most users find that Web 2.0 sites are extremely useful, because they are always available (whenever they need it and anywhere they go) with their information. Web 2.0 is the network as platform, spanning all connected devices. Web 2.0 applications are those that make the most of the intrinsic advantages of that platform:

- Delivering software as a continually updated service that gets better, the more people use it.
- Consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others.
- Creating network effects through architecture of participation.
- Going beyond the page metaphor of Web 1.0 to deliver rich user experiences.

One of the key aspects of Web 2.0 is that it connects people so that they can participate effortlessly in fluid conversations and dynamic information sharing. At the same time, information appliances and computing devices are giving people permapresence on the Web. Before now, the user consciously had to go to cyberspace by sitting at a desktop computer and looking at it through a display. Web 2.0 applications will become invisible as they become more popular, and there also would not be such a phrase as “going on the Web.” Moreover, if the network is omnipresent and invisible, we do not need the term cyberspace anymore. Web 2.0 is also more human and a social one labeled with social interactions like conversation, sharing, collaboration, publishing, which could be supported by the corresponding processes (blogging, tagging, sharing, publishing, networking) and content formats (blogs, wikis, podcasts, folksonomies, social software). In addition, Johnson and Kaye (2004) stated that the Web would become a trustworthy place and the users would take it with much more reliance and credibility.

Computers Influence our Thoughts and Actions

Although culture is mostly learned, it is bound by necessity to a particular setting or context of its behavioral and material articulation. Culture is both conservative and adaptable. Culture is articulated symbolically and has the function of symbolically integrating the diverse moments and spaces of culture into a coherent sense of order. This format is emerging throughout the social field as a format of technology (the point-to-point Internet, file sharing, grid computing, blogs), and as a third mode of production producing hardware, software (often called open sources software) and intellectual and cultural resources (wetware) that are of great value to humanity (GNU/Linux, Wikipedia).

Cognitive scientist Clark (2003) believes that we are liberating our minds, thanks to our penchant for inventing tools that extend our abilities to think and communicate, starting with the basics of pen and paper and moving on to ever more sophisticated forms of computers and e-technologies. He declares that we are, in fact, human-technology symbionts, or natural-born cyborgs, always seeking ways to enhance our biological mental capacities through technology. The persuasive e-technologies are in front of us to solve the problem of difficulties in utilization of the computer, which complexity is fundamental to its nature. We have to start over again to develop information appliances that fit people’s needs and lives (Norman, 1998). In order to do this, companies must change the way they develop information system products. They need to start with an understanding of people: user needs first, technology last. Companies need a human-centered development process, even if it means reorganizing the entire company.
People are more readily persuaded by computing technology products that are similar to them in some way (Fogg, 2003). Although people respond socially to computer products that convey social cues, in order to be effective in persuasion, hardware and software designers must understand the appropriate use of those cues. If they succeed, they make a more powerful positive impact. If they fail, they make users irritated or angry. With that in mind, when is it appropriate to make the social quality of the product more explicit? In general, it is appropriate to enhance social cues in leisure, entertainment, and educational products, especially with smart mobile devices (Rheingold, 2002). Users of such applications are more likely to indulge, accept, and perhaps even embrace an explicit cyber social actor. When perceived as social actors, computer products can leverage these principles of social influence to motivate and persuade.

**DISCUSSION ON NEW FORMS OF CULTURAL RESPONSIBILITY OF IT PROFESSIONALS**

Culture and ethics are a very important part of our everyday life in information society. The invention of new e-technologies tends to bring many different dilemmas into the lives of the creators and the people who use them. Some technologies have been created without choice, and we must make sure we fully understand how to use them properly. The introduction and use of new technologies require a check against the moral structure of the society and the ethical beliefs of the individuals that will feel the effects of such an addition to their lives (Postman, 1992). This belief should be the foundation of innovation so that members of the society can have a strong, viable, and ethical solution to satisfy their wants and needs and to extend their capabilities. Ubiquitous computing and smart environments will be characterized by massive numbers of almost invisible miniature sensing devices that potentially can observe and store information about our most personal and intimate experiences. The new forms of direct access to information and knowledge create new forms of e-culture. It concerns not only users but the community of information professionals as well.

Technology can be a powerful tool for change, especially when used responsibly. Responsible IT management should be an important part of any socially responsible enterprise’s strategies, policies, and practices. Users should have information technology choices that can and should reflect organizational, community, and national values and social responsibility. These notions are considering IT professionals’ activities; they should create applications that guarantee accessibility. Accessibility to information via the information-communications systems should not be inhibited by disability or resource limitations, and the design solutions should be for the user experience. Usability of information technology solutions requires attention to the needs of the user (information consumer). The information-communications systems create new psychological demands from human. They ask us to bring a greater capacity for innovation, self-management, and personal responsibility. They also demand social responsibility of information technology professionals. Information technology is the wave of today and the future. Society must adapt to it by creating responsible rules, norms, ethics, and knowledge workers that will enhance its rapid growth.

Many firms acting on the global scene via information-communications systems are committed to incorporating socially responsible projects into their policies and activities. Corporate social responsibility is a development that is here to stay for the long term as a part of corporate policy influencing the company’s involvement in the well being or development of local as well as global communities (Furnham & Gunter, 1993). Information technology firms are in a unique
position to distribute their high-tech expertise and cultural values in development projects. The new information society environment poses a new relation between values promoted by the new digital civilization and the traditional moral and cultural values created by the major world civilizations. Computer technology and ethical egoism are the products of secular research within a free market capitalist society. The majority of non-Western societies and some Western, as well, follow ethical rules created within traditional culture. These rules are centered on guiding the individual in properly fulfilling his or her role within the society, which means the superiority of the society over the individual. The changes that information technology is bringing to people’s lives are revolutionary, and one of the features of every revolution is that it is at the same time both a process of creation and of destruction. The revolutionary process itself is a very rapid one, which means that there is little or no time for a methodical and deep reflection on it while the process is actually in progress. These points ask for more attention from information technology professionals to cope with the culture exposed through the visible objects. They also should implement invisible culture elements when designing new information services. One possible way of minimizing the harm could be through incorporating the experiences of the process of intercultural dialogue into the process of creating a global e-culture of the information society.

IT Artefacts as Socio–Pragmatic Instruments: Reconciling the Pragmatic, Semiotic, and Technical

Pär J. Ågerfalk
University of Limerick, Ireland, & Örebro University, Sweden

ABSTRACT

There are many attempts to explain success and failure in information systems. Many of these refer to a purported sociotechnical gap. In this article we develop an alternative approach that does not impose such a strong dichotomy, but regards social and technical rather as dimensions along which to study workpractices. The developed theory involves not only the “social” and “technical” constructs, but also other generic ones, namely “instrumental,” “semiotic,” and “pragmatic.” We call this theory socio-instrumental pragmatism. To illustrate the theoretical concepts introduced, we use an example brought from an extensive action research study including the development of an information system in eldercare, developed through a participatory design approach.

INTRODUCTION

Development and implementation of an information system (IS) is a very demanding task, and many times the expectations from such endeavours are not met. Unexpected negative effects often arise, while anticipated positive effects fail to appear. There are many attempts to explain IS failure (and, indeed, success) in general terms. Some of them refer to a sociotechnical gap — a gap between what is socially required and what is technically feasible (e.g., Ackerman, 2000). Such explanations tend to make a sharp differentiation between the social and the technical. For example in the sociotechnical tradition represented by Mumford and Weir (1979), there are discussions about balancing the technical system and the social system. This is built upon a view that
computerised information systems are technical systems with social and organisational effects—a view that seems almost entirely to permeate mainstream IS research (e.g., DeLone & McLean, 1992, 2003; Benbasat & Zmud, 2003). This is also in line with the soft systems view that there is a “serving system” to support a “system to be served” (Champion & Stowell, 2002). There are criticisms toward such a conceptualisation. For example Nurminen (1988, p. 82) writes: “By removing the social dimension from the systems entity, we imply that the technical system is basically non-social.” In the same spirit, Goldkuhl and Lyytinen (1982) suggest that the traditional view of information systems as “technical systems with social implications” should be inverted to “social systems, only technically implemented.” As pointed out by Mead (1934):

“Language does not simply symbolise a situation or object which is already there in advance— it makes possible the existence or appearance of that situation or object, for it is part of the mechanism whereby that situation or object is created.”

Since every IS uses language for purposes of communication and understanding (Goldkuhl & Lyytinen, 1982), what Mead claims about language also counts for information systems.

Instead of a separation into a social realm (humans acting in the IS environment) and technical realm (the IS), another approach is proposed here: using “social” and “technical” as dimensions along which to study workpractices. The theoretical way to proceed is to articulate a common theory for both the IS and its organisational context. The concepts of social and technical are however not found to be sufficient. The purpose of this article is to outline a theory appropriate for interpretation, description, explanation, and evaluation of the interaction between information systems and their organisational context. The developed theory involves not only the “social” and “technical” constructs, but also other generic ones, namely “instrumental,” “semiotic,” and “pragmatic.” As we shall see below, these constructs are “generic” in the sense that they are not specific to any particular empirical setting, but are high-level categories useful in describing and discussing social action in relation to information systems in general. We call this theory socio-instrumental pragmatism, aligning with the work of Goldkuhl and Ágerfalk (2002) and Goldkuhl and Röstlinger (2003).

The article proceeds as follows. In the next section we briefly introduce some concepts of socio-instrumental pragmatism. To illustrate the use of socio-instrumental pragmatism as a theory of information systems, we use a simple example of an IS in the subsequent section. The example is brought from an extensive empirical study. This study involves an action research endeavour, including development of an IS in an eldercare setting. The IS and its supported workpractice were developed through a participatory design approach. We do not describe this case study in any detail, but use part of the developed system and the workpractice to illustrate our theoretical endeavour.

We then condense our conceptualisation of the IS and its organisational context in the following section, where important concepts are clarified and related to each other. Our contribution should be understood as a way to conceptualise the information technology (IT) artefact and its context. Hence, this article can partly be seen as a response to the requests for theorising the IT artefact as espoused by Orlikowski and Iacono (2001) and Benbasat and Zmud (2003). Those papers have given rise to quite a debate (e.g., Alter, 2003; Galliers, 2003). It is beyond the scope of our article to directly engage in this debate, although near the end, we comment on our contribution as a response to these requests for theorising the IT artefact. The article concludes with a brief summary of the main points.
SOCIO-PRAGMATIC PRELIMINARIES

Every attempt to theorise on information systems and their organisational uses relies on some ontological assumptions. Are there any fundamental entities and processes in the social and artificial world that should direct our conceptualisations? The basic stance taken here is pragmatic. Blumer (1969, p. 71) states “that the essence of society lies in an ongoing process of action — not in posited structure of relations. Without action, any structure of relations between people is meaningless. To be understood, a society must be seen and grasped in terms of the action that comprises it.”

With inspiration from Blumer and his pragmatic forerunners Dewey (1931) and Mead (1934), we will let actions appear as the ontological core in our analysis. In the IS field, such a position has been argued by Goles and Hirschheim (2000), guided by discussions on the “new pragmatism” (Wicks & Freeman, 1998).

The kinds of actions we are interested in are social actions — that is, actions performed in a social context. Weber (1978, p. 4) made a classical definition of social action: “That action will be called ‘social’, which in its meaning as intended by the actor or actors, takes account of the behaviour of others and is thereby oriented in its course.”

Our interpretation of this definition is that a social action (performed by an actor) has social grounds (“takes account of the behaviour of others”) and social purposes (“thereby oriented in its course”).

In communication and other direct interaction between actors, the social character is obvious. A communicative act (e.g., a question) functions as an impulse or initiative for a subsequent act (presumably an answer), which then is seen as a response to the first act (Sacks, 1992; Linell, 1998). Talk and other social interaction are seen as such chains of initiatives and responses.

The social grounds not only comprise the direct intended influence toward the actor; when acting, the actor may use immaterial and/or material instruments. These instruments usually have a social origin, and hence the instrumental use in action implies a social influence on the actor (Vygotsky, 1962; Wertsh, 1998). This is obvious when people use language. All use of language is social in the sense that it uses the social instrument of language. The actor’s thinking, speaking, and writing are shaped by the socially constructed categories of the world manifested in language or other sign systems (Berger & Luckmann, 1967). This also means that the use of an IS must be social, since there can be no such use without the exploitation of signs.

People intervene into the world through their actions. Actions are intended to make a difference (Dewey, 1931). When one usually talks about actions, such intervenient actions are implied. However, all human action is not intervenient and overt. There are covert actions, which are not intended as external changes. The perception and interpretation of the world is also seen as actions, although as covert ones (Schutz, 1970; Strauss, 1993). This also involves thought and conscious deliberation through reflection. Such covert actions (interpretation and reflection) do not aim at external change, rather a change to the actors themselves in their knowledge about the world. Social interaction consists of related intervenient and receptive actions. An ordinary communicative situation with a conversation between two actors consists of continual acts of speaking (i.e., intervening) and listening (i.e., receiving) (e.g., Clark, 1996). The production of an utterance is followed by an interpretation of that utterance by the other actor. Conversation consists of such reciprocal pairs of intervention and interpretation (Goldkuhl, 2003), which are embedded in “adjacency pairs” of communicative actions (Sacks, 1992), for example a question and a corresponding answer (mentioned above).

Such acts in communication processes are semiotic acts, since they specifically are dealing
with signs (i.e., producing signs and interpreting signs). People perform other kinds of acts as well. They act toward material objects with the intent to accomplish material changes in the world. Most material actions are also social actions, since they have social grounds and social purposes as stated above (also see Goldkuhl, 2003). Material actions are often parts of social interactions, and as such they are intertwined with semiotic acts (Goldkuhl, 2003; Andersen, 1990). Vološinov (1985) expresses this in a clear way:

“Verbal communication can never be understood and explained outside of this connection with a concrete situation...In its concrete connection to a situation, verbal communication is always accompanied by social acts of a nonverbal character, and is often only an accessory to these acts, merely carrying out an auxiliary role.”

In material actions, people often use external instruments (e.g., IT artefacts) to enable or facilitate their actions. Also, in communication, instruments are often used to improve the transfer of messages. Instruments such as telephones, fax machines, and computers make communication possible over time and distance. Instruments play different roles in action and interaction; they can also be more or less advanced. Goldkuhl and Ågerfalk (2002) and Goldkuhl and Röstlinger (2003) have distinguished three levels of instruments:

1. Static tool (artefact-supported human action)
2. Dynamic tool (human-artefact cooperative action)
3. Automaton (human-defined artefact action)

A human must use a static tool directly in order to make a difference. For example, an axe is used to chop wood. A human uses a dynamic tool in a cooperative way. For example, a car must be manoeuvred when driven. Automatic machines can perform work independently according to its programme, after being initiated by a human. When started, a washing machine works by itself.

The most central of these socio-pragmatic preliminaries are summarised and visualised in the generic model of social action depicted in Figure 1. More elaborated descriptions can be found in Goldkuhl and Ågerfalk (2002) and Goldkuhl and Röstlinger (2003).

When acting through and by means of an IS, the IS is used as the instrument by which intervening actions, and possibly also receptive...
actions, are performed. In the next section, this socio-pragmatic view of sociotechnical action is elaborated further by means of examples from a case study.

**ACTIONS AND INSTRUMENTS IN WORKPRACTICES: AN ELDERCARE CASE STUDY**

For the purpose of illustration, we will use material from a case study — a longitudinal action research-based case study — on the development of a municipal eldercare unit. The action research project consisted of integrated workpractice and information systems development. A new IS was developed in a participatory design setting, where researchers and eldercare personnel participated in a co-design endeavour. Data generation in the case study has been pursued with different qualitative research methods: interviewing directors and nursing assistants, observing their work, collecting and analysing several documents, and participating in development seminars. A closeeness to the empirical phenomena was necessary in order to gain reliable data. Experiences from the case study have been reported previously by Cronholm and Goldkuhl (2002) and Goldkuhl and Röstlinger (2002).

Let us start the discussion with the eldercare practice before computerisation. The eldercare practice consists of nursing assistants giving care to elderly people living in their own residences. The elderly people need assistance with ordinary tasks like hygiene, dressing, and cleaning, as well as simple medical attention on a daily basis. A nursing assistant visits each client on one or more occasions each day. The visits are regulated by daily schedules, which inform the nursing assistant what tasks to perform. There exist different schedules depending on the kinds of tasks to perform and the time of day. There are typed contents on the schedules, but they also consist of handwritten annotations. Besides the schedules, there are also more informal communication between the nursing assistants, such as handwritten notes and verbal interaction. Quality assurance problems were encountered in the eldercare practice which gave rise to the development of an IT system to support communication and documentation. Schedules are nowadays mediated by the IT system, and this has improved the quality assurance and the individualisation of the eldercare which are important objectives of the workpractice.

In order to understand what the new IT artefact does, we need to understand its role in the workpractice. In order to do this, let us focus on three different types of actions in the workpractice:

1. production/reproduction of daily schedules,
2. reading of the schedules before home care visits, and
3. care service provided to the elderly clients.

Based on the socio-pragmatic perspective outlined above, we focus on actions as a kind of basic unit of analysis. A workpractice consists of actions, actors, signs, and material artefacts related in meaningful ways (Goldkuhl & Röstlinger, 2002, 2003). The way social practices appear as meaningful to an inquirer is through making their constituent actions become visible — what people do in the workpractice.

The first two kinds of action (creating and interpreting the schedule) are two inter-related parts of a communication process. One nursing assistant may, for example, annotate something to the schedule at one occasion as a message to her colleagues (“remember to take out the laundry”). Another nursing assistant reads the note when she is about to visit an elderly resident. And she takes this into account during her visit to the resident (taking care of the laundry). The first two actions are actions dealing with language (writing and reading) and are thus parts in a communication
process. The last action is not a linguistic action. It is a material action—changing physical objects in the world. This reasoning may be illustrated by the model of social action depicted in Figure 1.

We distinguished above between intervenient and receptive actions. Actions 1 and 3 in the examples are intervenient actions. Action 2 in the example is an interpretive action. All three actions are social actions, although they might all be performed in solitude without any direct interaction with another human. All actions described have social grounds and social effects. The first nursing assistant might write her note without any other colleague around her, but the communicative action is, of course, directed toward and intended for another human—that is, asking the (other) nursing assistant to visit the elder. The second nursing assistant may perform the second act—the reading of the schedule and the accessory note—in solitude. As an interpretive act it is a typical social act. It certainly has social grounds through the written communication directed toward her. This act also has social purposes. The nursing assistant reads the message in order to arrive at an informed readiness on the eve of her visit to the elder. The third act—the material act of taking out the laundry at the elder’s residence—may also be performed in solitude. This material act is however also a social act, since there are obvious social grounds and social purposes. There was a request directed to her from her colleague (i.e., social grounds). She is taking out the laundry in order to help the elder and fulfill the obligations of the eldercare centre (social purposes).

All these genuinely social actions are performed by use of different tools, or instruments. The reading of the schedule requires the schedule being presented in a readable form, and annotating it requires a writable form. Both the “pen and paper” used initially and the subsequently introduced computerised IS afford these actions. In both cases, the instrument is used for interpreting and expressing semiotic results as a basis for and as a result of social action. The first nursing assistant is guided by communicative intent. She wants to say something to her colleague on the next work shift. The computerised schedule is an instrument for her to perform this communicative action. The second nursing assistant wants to be informed before she embarks on her visits to the elderly people. She uses the computerised system comprising schedules in order to become informed. Thereby she becomes capable of performing subsequent knowledgeable actions for the clients. The nursing assistant manoeuvres the IT system in order to arrive at a specific schedule (a specific client at a specific date and work shift). This kind of manoeuvring of the IT artefact implies both technical and semiotic knowledge. The nursing assistant must of course also have relevant organisational knowledge. She must be aware of the obligations of the eldercare centre and herself in her organisational role. She must know the institutionalised way of communicating expected tasks (i.e., the work schedule), which now is included in the new IT system.

One of the main driving forces of this computerisation was to ensure the quality of the communication and documentation around the care of the elderly. The directors of the eldercare centre wanted the new IT system to be the main medium for communication. Earlier there was a mix of several different handmade forms, small handwritten messages, and oral communication. The idea was now to channel most of the communication through the IT system. The work schedule should describe all planned (desired) measures to be taken for a particular elder at one visit. This includes both standard measures generally performed for this elder and specific measures needed at one or a limited amount of occasions. This means that the work schedule in the IT system is a collection of several communicative acts performed by several persons in the eldercare staff. One role of the IT system is thus to collect and integrate these different communicative acts in a proper way—that is, to enable communications
IT Artefacts as Socio-Pragmatic Instruments

from many persons to the one nursing assistant to perform a particular visit.

Even if the IT system is considered to be the main medium for communication of work tasks, there will of course remain informal channels beside the system. There will be situations when it is more appropriate to still communicate in an informal way. The system will not hold a complete description of the elders and their different needs. Unanticipated discourses concerning the elders will be required, which are not suited for channelling through the IT system. Also, the system cannot communicate all necessary measures to be taken. The nursing assistants must of course be attentive during their visits and, based on observations and demands from the elderly, perform appropriate unplanned measures.

As shown above, the role of the IT system is to facilitate communication. The system must support and enable the eldercare staff to perform important communicative actions through the system, like work schedule planning. There are other communicative tasks not yet mentioned which are important in the workpractice. Important incidents regarding the elderly must be reported into the care journal of each elder. The IT system supports the reporting of incidents into the care journal. The system must automatically manage the care journal and on request present parts of it to those privileged to read the journal. The organisational role of this care journal is to be part of a workpractice memory. Actors in the workpractice must be able to remember what has happened and what actions have been performed. The IT system gives institutionalised support for recollecting things that occurred and were performed.

In general, workpractices are equipped with a diverse range of instruments for actors to use in their social endeavour. These are often technical instruments, such as computers and washing machines. The usefulness of these instruments within a practice is contingent upon the meaning attached to them by the actors. From this perspective, computers are mainly means to improve communication (Flores, 1998). Indeed, IT artefacts are technical instruments. Their main functioning within a workpractice, such as eldercare, however, is as instruments for social action.

This means that we can view IT artefacts in a workpractice as: 1) technological artefacts with physical properties, 2) semiotic artefacts affording communication and interpretation, and 3) social instruments used to responsively express actors’ beliefs, values, and intentions. These three aspects of IT artefacts may be analytically distinguished. It is important to see, though, that IT artefacts are not simply isolated technical systems related to a social practice, in whatever intricate way. Rather, their physical properties are what enable and restrict possible semiotic interpretations and expressions required to form the social practice at hand. To paraphrase the quotation from Mead (1934) above: they are not simply objects which are there — they make possible the existence or appearance of that situation, for they are part of the mechanism whereby that situation is created.

With this theoretical and empirical backdrop, the following two sections explore how information systems (as IT artefacts) can be conceptualised following socio-instrumental pragmatism, and how such a conceptualisation contributes to our understanding of IS theory in general.

CONCEPTUALISING SOCIO-INSTRUMENTAL ACTIONS AND SOCIO-PRAGMATIC ARTEFACTS

Information systems (as IT artefacts) are technical systems. This is obvious. They consist of hardware and software. They are technical instruments, usually not aimed for direct support of material action. Instead they support communication and other types of information handling. As such
they are communicative and semiotic devices. Information systems consist of representations such as texts and other signs.

This means that an IS is not just a restricted technical tool. An information system is a socio-pragmatic instrument. As such an instrument, it is utilised to perform social actions. These social actions are communicative in nature. An IS must thus be a semiotic instrument. It must have capabilities to process signs. In doing this in a sophisticated way, information systems rely on advanced technical equipment. This technical equipment needs to be managed by a human being who wants to utilise its semiotic capabilities. An IS is an instrument for producing messages to other people and an instrument to be informed by other people. The technicalities of an IS are necessary material bases of its functionality as a socio-pragmatic instrument. Without hardware and software, one could not write and read through an IS. The material nature of an IT artefact can make it instrumental for social purposes.

Usually, an IS has a pre-defined set of communicative possibilities as defined by its functionality and vocabulary (the latter usually defined by its database schema); not everything can be said. An IS is also an instrument for getting informed by others; otherwise it would not be a communication instrument. It must support both parts of the communication process — to express and to interpret. Information systems have the capability to execute communicative actions according to its predefined action repertoire (determined by its programmmed software). The action repertoire includes affordances for communicating and interpreting. An IT system as a communicative instrument supports writing and reading; in other words, it is a mediator of communication. IT systems usually have advanced capabilities of a mediating agent. Such a system does not only mediate one message from one person to another person. It has capabilities to mediate communication from many persons to many persons in intricate and sophisticated

Figure 2. An information system as a socio-pragmatic instrument in a workpractice
ways, including the maintenance of appropriate workpractice memory (i.e., a database). An IS as part of an organisational context is depicted in Figure 2. This figure is based on the general model of social action (Figure 1). In this socio-pragmatic view of information systems, the most important property of such artefacts is referred to as their actability. In order to be socially useful, information systems must be actable for their users (Goldkuhl & Ågerfalk, 2002; Cronholm & Goldkuhl, 2002; Ågerfalk, 2004).

Such capabilities make the IT system an organisational agent. An agent is someone who does something on behalf of someone else. Humans working in an organisation are agents for that organisation. They act as representatives for that organisation, on behalf of the organisation (Ahrne, 1994; Taylor & Van Every, 2000; Goldkuhl & Röstlinger, 2003). An IT artefact (being an organisational agent) does possess some action capabilities, but lacks typical human attributes (consciousness, intention, emotion, social awareness, empathy). In some situations it is appropriate to view the IT artefact as a mere instrument (a static or dynamic tool) to be used by humans. In other situations it may be appropriate to bring its agent capabilities to the fore — and hence its possibilities to interact with humans as other organisational agents.

One key feature of this theory (socio-instrumental pragmatism) is that it should be used both for understanding the IT artefact and its human and organisational workpractice, which it is part of. This is a kind of seamless theorising, where we do not shift theoretical perspective when moving between the artefact and its human and organisational context (Goldkuhl & Röstlinger, 2003). According to this theory, actions are multifunctional; performing an action does several things. An action can at the same time be:

- a response to an action made by someone else (i.e., socially responsive);
- an expression of subjectivity, a utilisation of immaterial instruments (such as knowledge and language);
- a utilisation of external instruments (e.g., technical artefacts);
- a compliance to organisational norms (e.g., role expectations);
- a production of action results (semiotic or material objects);
- a realisation of values and intentions; and
- an attempt to influence someone else (i.e., exerting power).

Being multifunctional, actions are also multi-dimensional. Actions performed by a human user, when acting through an IT artefact, can be described as social (social grounds and social purposes), semiotic (using and producing signs with communicative intent), and technical (managing some technical device) at the same time. When we talk about an IS as a socio-instrumental pragmatic system, we emphasise its pragmatic features and purposes. Instrumental (in “socio-instrumental”) should be read as both semiotic (language as instrument) and technical (material artefact as instrument). It is thus not sufficient to talk about an IS as a sociotechnical instrument. If we do that in a restricted way, then we may forget its primary role of being a semiotic device for organisational communication. Socio-instrumental pragmatism provides IS designers with a pragmatic view to direct attention to the whole of the workpractice and to its constituent parts of human, organisational, communicative, and technical characters.

A WAY TO THEORISE THE IT ARTEFACT

Based on a review of the complete set of 1990-1999 articles published in Information Systems Research (N = 188), one of the leading IS scholarly
journals, Orlikowski and Iacono (2001) issued a general call to “theorising the IT artefact.” The reason for taking such a measure was that a stunning 25% of the reviewed articles focused on other aspects than IT, referring to IT only incidentally or as background information. This should be understood in light of an ongoing quest for the identity and legitimacy of the field of Information Systems that started in the 1980s (e.g., Banville & Landry, 1989) and recently culminated in a sometimes heated debate caused by Benbasat and Zmud’s (2003) already famous paper on “defining and communicating the discipline’s core properties.” The question underlying these efforts of organising the IS field seems to be threefold.

First, as pointed out by Benbasat and Zmud (2003), there is the issue of what to include in IS research — what are the core properties that must be considered in order to understand the role of IT in social settings? Second, the flip-side of Benbasat and Zmud’s (2003) coin is the question of what should be excluded from IS studies — that is, what properties of social life are not directly related to IT and thus better left to other disciplines to scrutinise? Finally, we need to understand the very concept of IT — to theorise the IT artefact. We must not regard IT as a technical black box, but recognise what specific properties of this technology contribute to our understanding of its role in everyday life; “We will need to stop taking IT artefacts for granted and begin to take them seriously enough to theorise about them” (Orlikowski & Iacono, 2001).

It is generally believed that IT must be understood within a surrounding social context (e.g., Benbasat & Zmud, 2003). It is also generally believed that a fruitful analytic approach is to separate IT from non-IT, technical from social, and then to study how the two entities interact. This preferred separation of concerns is obvious from Benbasat and Zmud’s (2003) model of the “IT artefact and its immediate nomological net,” which includes the three core IS properties: the IT artefact, usage, and impact. It is also obvious from DeLone and McLean’s (1992) IS Success Model, which includes the corresponding variables of system/information quality, use, and impact.

We argue that in order to seriously theorise the IT artefact, we need to develop theories that are useful in describing IT artefacts, in describing IT artefacts’ social context, and in describing IT artefacts contextually. We need theories that let us see the social in the technical and the technical in the social. Obviously, this view is not too far from that of the actor-network theory or ANT (as in Latour, 1991), where technology and people are both seen as social actants. However, as pointed out by Orlikowski and Iacono (2001), being concerned specifically with IT, we cannot accept general sweeping notions of technology. We must acknowledge the specific characters of IT, which include their symbol processing (semiotic) properties, their tool (instrumental) properties, and their social (agency) properties. The socio-instrumental theory of IT artefacts outlined in this article allows us to use one theoretical lens to study information systems in concert with humans, without losing our focus on core IS properties and without black-boxing technology, seen as something that is simply a cause or effect of something else. It enables us to view both humans and IT artefacts as organisational agents, and to do this without losing sight of their fundamental differences in agency. This prevents us from falling into the trap of a too symmetrical view of humans and IT artefacts, which is one main criticism toward applications of the actor-network theory within the field of IS (e.g., Walsham, 1997). The symmetrical view of ANT should thus not be confused with our ideal of seamless theorising mentioned above.

Orlikowski and Iacono (2001) conclude their research commentary by offering five premises for theorising IT artefacts. In short, they argue that:
IT Artefacts as Socio-Pragmatic Instruments

1. IT artefacts are always value based, since they are designed and used by people with different interests, values, and assumptions.
2. IT artefacts are always embedded in a historical and cultural context.
3. IT artefacts are usually made up of several components, and generic terms such as “the Internet” and “the Technology” should generally be avoided.
4. IT artefacts are not fixed and independent, but co-evolve with the workpractice in which they are embedded.
5. IT artefacts are subject to changes in technology.

Arguably, these premises go well with the proposed socio-instrumental pragmatism, which may thus be regarded as an instance of the sort of theorising called for by Orlikowski and Iacono (2001). On the other hand, we think that Orlikowski and Iacono (2001) might be overly discouraging when stating that: “Given the context-specificity of IT artefacts, there is no single, one-size-fits-all conceptualisation of technology that will work for all studies.” Indeed, any workpractice-related theory is by definition localised to that specific workpractice. On the other hand, we would like to argue that there are generic conceptualisations and units of analysis, such as those put forth in this article, that are general in nature but pragmatic enough to be applicable in most studies. There are a set of “core properties,” or aspects, of IT in workpractices that we should pay attention to in order to understand any IS in practice. We have termed these aspects the social, the technical, the instrumental, the semiotic, and the pragmatic. These properties, in turn, are by nature situational and can as such assist in eliciting important aspects embedded in particular research settings.

CONCLUSION

It is generally agreed that in order to understand IT and its functioning in workpractices, the surrounding social context must be seriously taken into account. A common view of conceptualising IT and its use is to make a sharp distinction between the technology as such on the one hand, and social prerequisites and effects on the other. Contrary to this popular belief we have articulated and illustrated a theoretical perspective that allows for conceiving of technological aspects and social aspects of workpractices in an integrated way. The perspective, which we have termed socio-instrumental pragmatism, is founded in pragmatic theories of social action, and the main unit of analysis is that of mediated social action. By viewing the use of information systems as the performance of technologically mediated social actions, we can distinguish between three important roles of IT: as an affordable technological base, as mediator of semiotic signs, and as a social instrument to responsively express actors’ beliefs, values, and intentions. Instead of separating a social realm from a technical realm, we use “social” and “technical” as dimensions along which to study workpractices. This way of reconciling the pragmatic, social, semiotic, and technical allows for a uniform approach to studying and understanding the relationship between IT and humans by directing attention to humans’ social actions performed through and by means of IT. This approach goes beyond sweeping general notions of technology as part of socially constructed reality, and allows us to explore and exploit the genuine character of IT as part of an organisational agency.

Chapter 7.11

Ignorance is Bliss: The Effect of Increased Knowledge on Privacy Concerns and Internet Shopping Site Personalization Preferences

Thomas P. Van Dyke
The University of North Carolina Greensboro, USA

ABSTRACT

Studies have shown that people claim that privacy matters to them but then they often do things while browsing that are risky in terms of privacy. The seeming inconsistency between professed privacy concerns and risky behavior on the Internet may be more a consequence of ignorance rather than irrationality. It is possible that many people simply don’t understand the technologies, risks, and regulations related to privacy and information gathering on the Web. In this study, we conducted an experiment to determine the answer to the following question: If people understood the risks and technology, would that knowledge alter their level of privacy concern and their preferences concerning e-commerce Web site personalization? Results indicate that increased awareness of information gathering technology resulted in significantly higher levels of privacy concern and significantly reduced preferences for Web site personalization. Implications of the findings are discussed.

INTRODUCTION

Individuals are willing to participate in diverse activities online—from e-mailing friends and looking up personal medical information to purchasing a wide variety of goods and services. While consumers benefit from their activities online, businesses also benefit from information gained while consumers browse. The Internet environment allows businesses to collect and analyze more personal information with greater ease and efficiency than ever before. Firms can use several methods to collect information about visitors to their sites. These include overt methods, such as registration forms, Web surveys and order forms, as well as covert methods including spyware, Web bugs and cookies. The information gathered serves...
as an important input into marketing, advertising, customer service and product-related decisions by online firms. The information gathered also allows firms to offer personalization (i.e., mass customization) to the Web site. This has the potential to benefit both the customer, through added convenience and options, as well as the firm by encouraging increased sales.

However, the consequences of information gathering are not all positive. The ability of firms to gather so much information creates the risk of possible misuse and generates concerns over information privacy among users. These privacy concerns impede e-commerce. The Federal Trade Commission estimates that online retail sales were reduced by $18 billion due to privacy concerns in 2002 (Gellman, 2002).

Users claim that privacy is important to them (Westin, 2003). However, they are constantly taking actions that are risky in terms of privacy. Internet users are often required to make tradeoffs, taking actions that sacrifice privacy in return for convenience, such as Web-site personalization. These actions often appear to be in contradiction of their professed attitudes regarding their personal privacy.

For example, Internet users have consistently indicated that they did not want firms to track their Web surfing habits (Westin, 2003). However, people routinely accept cookies through their Web browsers by default. According to one study, users rejected fewer than 1% of cookies in over a billion page views (Websidestory, 2001).

There are several possible explanations for the seeming contradictions between user attitudes and actions. According to Kristol (2001) these include:

- Users know how cookies can collect information and track them but are unconcerned.
- Users don’t know how cookies can be used to track them.
- Users have inadequate means to select which cookies to accept so they just give up and select them all.
- Users assume that the firms collecting the information will protect it and use it discreetly (not true in all cases).
- Users assume (incorrectly) that that they are protected by governmental regulations that will prevent Web sites from misusing information about them.

Determining which of these explanations are true regarding users has important policy implications. Companies and interests groups that benefit from the information collected on the Net back self-regulation, and that is the current model used in the United States. Research by authors such as Westin (2003) can be used to support self-regulation on the grounds that people are free to make a choice. According to surveys, the majority of Internet users fall into group that Westin refers to as privacy pragmatists. These people make informed cost-benefit decisions regarding Internet privacy (Westin, 2003). However, such reasoning presupposes that respondents accurately assess their level of knowledge and understanding. It is possible that many who believe they are making informed, rational decisions are, in fact, making irrational decisions based on an unrecognized ignorance of the technologies, laws, and data flows related to online information gathering. If people do not understand the technology, regulations, and so forth, then it is unrealistic to expect them to make an informed choice. Such findings could be used to argue for increased government regulation.

Unfortunately there is evidence that many people do not understand the technology, risks, or regulations related to information gathering on the Web. For example, research shows that “many individuals are unaware of the extent of the personal data stored by government and pri-
Ignorance is Bliss

vate corporations” (Roddick, 2001). In addition, the Pew Internet & American Life project found that 56% of Internet users could not identify a cookie and that even those who claimed to have knowledge of cookies seem confused about the technology (Fox, 2000). If people understood the type of information collected, the technology used to gather the information and the potential uses of the information, how would this alter their level of privacy concern and their desire for e-commerce Web site personalization?

In this article, we examine the effect of increased knowledge on privacy concerns and desire for mass customization (Internet shopping preferences). In the following sections, we first review the literature on privacy risks, Web site personalization, also known as mass –customiza-

- tion, and consumer attitudes towards privacy. Next we present a series of hypotheses based on previous research. Then we describe an experiment used to test the hypotheses. Data analysis results are presented. Finally we will discuss the results in the context of earlier research and attempt to explain the implications of our findings.

REVIEW OF THE LITURATURE

Privacy Concerns on the Internet

Since its inception in the mid-1990s, the growth of B2C e-commerce has been phenomenal. According to the Department of Commerce, online retail sales grew from $36.4 billion in 2000 to $54.9 billion in 2003 (http://www.census.gov/mrts/www/current.html). These sales figures could have been many billions of dollars higher except for the fact that many consumers simply refuse to make purchases online. One important factor restraining the growth in Internet sales is the increase in privacy concerns among Internet users (Hoffman et al., 1999). In a survey by AC Nielson, consumers rated the disclosure of personal information and comfort in using a credit card online as the biggest barriers to online purchasing (AC Nielsen, 2001). The Federal Trade Commission estimates that online retail sales were reduced by up to $18 billion due to concerns over privacy (Gellman, 2002). Considerable progress has been made in the development of technological mechanisms for secure payment. Unfortunately while these advances have indeed improved online security, they have done little to alleviate privacy concerns.

Privacy concerns are not merely psychological constructs. There is ample evidence that privacy concerns actually alter consumer behavior in a number of negative ways. According to a survey by AT Kearny, 52% of respondents reported abandoning an online purchase transaction due to privacy concerns (Ragnathan & Grandon, 2002). Total avoidance of online shopping, refusal to provide information and abandoning transactions are not the only responses to privacy concerns. Polls show that 30-40% (Hoffman et al., 1999) of Web users provide false information online. Reasons given include the desire to remain anonymous, avoidance of spam e-mail, and concern about how the Web site will use the information. A consequence of this online lying is that much of the information collected by Web sites is wrong. This both increases the cost and decreases the value of the data collected (Gellman, 2002).

Electronic commerce has increased people’s concerns about privacy because the Internet environment allows business to collect and analyze more personal information with greater ease and efficiency than ever before. “Enormous amounts of consumer data have long been available through offline sources such as credit card transactions, phone orders, warranty cards, applications and a host of other traditional methods. What the digital revolution has done is increase the efficiency and effectiveness with which such information can be
collected and put to use” (Adkinson, 2002). Studies have shown that the amount of data collected is truly vast. A March 2000 Federal Trade Commission survey found that 97% of sites collected some form of personal information. However, only 20% implement the fair information practice principles of notice, choice, access, and security (FTC, 2000).

Firms use several methods to collect information about visitors to their sites. These methods include registration forms, Web surveys, order forms, spyware and cookies. The information thus gathered serves as an important input into marketing, advertising, customer service, and product-related decisions made by online retailers. However, the collection of this information creates the risk of possible misuse and generates concerns over information privacy. In a report to Congress the FTC cited a survey showing that 92% of households with Internet access stated that they do not trust online companies to keep their personal information confidential (FTC, 2000).

Smith et al. (1996) suggest several dimensions of concern related to information privacy. Collection is a general concern that large amounts of personally identifiable data are being collected and stored. Unauthorized secondary use (internal) is the concern that information collected for one purpose could be used for another, unauthorized purpose by the same organization. Unauthorized secondary use (external) is the concern that information collected for one purpose could be used for another, unauthorized purpose after disclosure to an external organization. Improper access is the concern that personal data are available to people not properly authorized to view the data. Errors names the concern that the protections against deliberate or accidental errors are not adequate. One concern that Smith et al. listed as tangential to the privacy issue, but which seems relevant in an e-commerce setting is combining data. This is the concern that several seemingly innocuous pieces of information in disparate databases may be combined to create personally identifying information that the user does not wish to disclose.

Even though all of these specific concerns have been identified, most consumers cannot articulate specific threats to privacy but rather speak of a vague feeling that there is too much information about them “out there.” Unstructured interviews with Internet users show that many have a vague fear that unspecified people unknown to them will have access to personal information. Interviews also indicate that many Web users have little understanding of technology. For example, they don’t really know what a cookie is or how it works. There is also evidence of confusion over privacy rights. Many consumers mistakenly believe that they are protected by “the privacy act” (Gellman, 2002) or that privacy statements are mandated by law.

Whether specific or vague, there is evidence that consumer’s concerns about privacy risks associated with e-commerce are justified. In January 2000, the merger of the online advertising company DoubleClick and the database marketing firm Abacus Direct started a federal investigation when it was revealed that the company had compiled profiles of 100,000 online users, without their consent, and intended to sell the information (Kristol, 2001). More recently, the FTC reported 214,905 instances of identity theft in 2003. This represented 42% of all complaints, up from 40% in 2002 (FTC, 2004). Clearly, some threats to privacy and security related to Internet shopping and online information gathering are real.

Web Site Personalization

E-commerce retailers are increasingly utilizing personalized features on Web sites, also known as mass-customization, in order to build relationships with customers and increase the number of purchases made by each customer (Cranor, 2003). Web site personalization has been shown to be popular with customers and effective at increasing sales (Manber et al., 2000; Personalization...
Consortium, 2000, 2001). However, e-commerce Web site personalization adds new risks that can contribute to an increase in privacy concern. Cranor (2003) suggests four dimensions that can be used to differentiate between types of personalization systems.

Explicit vs. Implicit Data Collection

In explicit data collection systems personalization is based on demographics, preferences, ratings or other information explicitly provided by the user. In implicit data collection systems, personalization is based on information inferred about a user from such things as purchase history, browsing habits, or query history.

Duration

Task or session focused personalization systems make recommendations based on actions taken by the user during the current session. Profile-based personalization systems utilize profiles of users that are updated each time the user returns to the site. These systems often use cookies to recognize customers and retrieve their stored profiles. Logins may also be used to identify the customer and retrieve the corresponding profile.

User Involvement

Personalization may be either user initiated or system initiated. Some systems allow the users to customize their own Web page while other sites attempt to customize for every customer whether they request customization or not.

Reliance on Prediction

Prediction-based personalization systems use explicit or implicit ratings to build a profile that is then compared to others. If similar profiles are found, it predicts that they will have similar preferences and makes recommendations accordingly. Content-based personalization systems also provide customization or recommendations. However, they are based only on the actions of the user, not on profiles of others deemed similar (Herlocker, 2001).

Risks Related to Personalization

Personalization systems can create or exacerbate a number of risks to user privacy. Unsolicited marketing and the possibility of a firm selling information to a third party are generic concerns associated with Internet use. However, these risks are heightened by the fact that personalization systems can collect and store detailed profiles containing considerable amounts of information that go beyond the type of single-purchase information collected by less sophisticated sites.

Another privacy risk associated with personalization systems is fear of prediction. Many people are uncomfortable with the concept that computers are able to make predictions about their habits and interests (Cranor, 2003). Interestingly some users fear that the predictions are too accurate and that the system can figure out information about the user that they would normally be unwilling to divulge. On the other hand, some fear that inaccurate predictions may cause the system to draw incorrect and possible damaging conclusions about the users (Zaslow, 2002).

Personalization systems also increase the risk of inadvertently revealing information to others who use the same computer. Persistent cookies stored on the machine can be used for authentication and provide access to the user’s profile. Through this technology, others using the computer could have access to information such as purchasing records, health queries, and so forth. Profiles often include passwords that then might be used to gain unauthorized access to a user’s other accounts (Cranor, 2003).

In addition, highly detailed profile information could be accesses by third parties, hackers, or e-commerce company employees. It is also possible
that profile information could be subpoenaed in court or used by the government in profiling of surveillance activities. The risks from online profiling led the Federal Trade Commission to recommend that Congress enact legislation to ensure consumer privacy online (FTC, 2000).

Consumer Attitudes Towards Privacy

Alan Westin has been surveying consumers about privacy since 1967. In 1995, the Harris-Westin survey segmented the public on consumer privacy issues into three groups. Privacy fundamentalists rejected consumer benefit claims for data uses and sought legal and regulatory protections. The privacy unconcerned group on the other hand were generally willing to supply their personal information to business and government and were largely unconcerned about privacy risks. Between these two extremes were the privacy pragmatists. According to Westin (2003) this group holds a balanced privacy position. They examine the benefits to them or society of the data collection and use. They wanted to know specific privacy risks and how organizations proposed to control those. Armed with this knowledge the privacy pragmatists would then decide whether to trust the organization or seek legal oversight.

Responses to some of the individual questions used to segment the population can be compared over time to show a trend toward increased public concern about privacy issues. Respondents concerned about threats to personal privacy jumped from 64% in 1978 to 84% in 1995 and had risen to 94% by 1999 (Louis Harris & Associates & Westin, 1999). Surveys in 2000–2002 recorded a dramatic shift in public attitudes (Westin, 2003). By 2002, a majority of consumers (56%) felt that most businesses did not handle the personal information they collected in a confidential manner. This number was up from only 34% in 1999. Sixty-two percent responded that they did not believe that existing laws and organizational practices provided a reasonable level of privacy protection, up from 38% in 1999 (Westin, 2003).

Along with the changes in attitude, the segmentation of consumers has also moved in the direction of increased privacy concern. The privacy unconcerned group dropped from 22% in 1999 to only 8% in 2001. Privacy fundamentalists rose from 25% to 34%. Privacy pragmatists remained the majority at 58%. Policymakers have followed the change in opinion by passing hundreds privacy related laws at the state level and several at the national level. There is an ongoing debate as to the best method to protect privacy while at the same time facilitating electronic commerce. The ability of users to make informed decisions regarding Internet privacy is at the center of that debate.

HYPOTHESES

It is clear that privacy risks exist. It is also apparent that some users do not fully understand the technology or specific risks associated with information gathering on the Internet. This ignorance may explain why users claim that privacy is important but continue to perform activities that put their privacy at risk. In order to investigate if an increase in understanding would alter users’ level of privacy concern or their preferences for Web site personalization, we developed two sets of hypothesis.

Pre-Demonstration Hypotheses

Based on the results of previous research, we tested for between group differences in privacy concern and preferences for Web site personalization prior to the experimental treatment. An Annenberg Public Policy Center survey by Turow & Nir (2000) found that teenagers are more likely to give away personal information than their parents. However, a study by Garbarino & Strahilevitz (2002) indicated that age did not
Ignorance is Bliss

have a significant effect on perceived risk of online shopping. We sought to clarify what effect, if any, that age had on privacy concern or preferences for web-site personalization.

- **H1a**: The level of privacy concern associated with Internet use is affected by age.
- **H1b**: The proportion of users who prefer a Web site to remember them is affected by age.
- **H1c**: The proportion of users who prefer that a Web site make recommendations based on previous visits is affected by age.

Mayer (2002) found difference between Internet users based on education level. As the education level of participants rose they were more likely to say that a promise of confidentiality would make a difference in their decisions, that there were risks associated with a lack of confidentiality, and that there was no guarantee associated with a promise of confidentiality. We developed three hypotheses to test for the effect of education.

- **H2a**: The level of privacy concern associated with Internet use is affected by education level
- **H2b**: The proportion of users who prefer a Web site to remember them will be affected by education level.
- **H2c**: The proportion of users who prefer that a Web site make recommendations based on previous visits is affected by education level.

According to Fernandez & Miyazaki (2001), those who use the Internet frequently have a low perceived risk about the associated technologies. Those who purchase online infrequently will consequently have less knowledge of online technologies, and may be shocked by their capabilities. In 2001, Fernandez & Miyazaki found that “higher Internet experience...[is] related to lower levels of perceived risk toward online shopping, which in turn results in higher online purchase rates.” They also state that “experience gained through simple usage of the Internet for non-purchase purposes such as information gathering and noncommercial communication will lead consumers to discover that privacy and security risks are often exaggerated.” Three hypotheses were developed to test for the impact of Internet usage levels.

- **H3a**: The level of privacy concern associated with Internet use is affected by the level of Internet usage.
- **H3b**: The proportion of users who prefer a Web site to remember them will be affected by the level of Internet usage.
- **H3c**: The proportion of users who prefer that a Web site make recommendations based on previous visits is affected by the level of Internet usage.

Multiple studies have shown that trust is a significant antecedent of customer’s willingness to transact with an online vendor (Gefen, 2000; Jarvenpaa et al., 2000). Jarvenpaa et al. posit that the mechanism by which trust affects one’s willingness to transact is by reducing the perceived risk of doing business with the vendor. Perceived risk is a person’s belief in the likelihood that they will be harmed as a consequence of taking a particular action. Gefen (2000) found that an increase in customer trust resulted in a decrease in the perceived risk associated with doing business with an online vendor. The two most widely cited risks associated with online shopping are privacy risk and security risk. Given the demonstrated relationship between trust and overall perceived risk, it is logical to assume that a similar relationship holds between trust and the level of privacy concern. If this relationship does not hold, we might need to re-evaluate the way that we operationalize the construct of privacy concern.
H4: Those who are more trusting of people in general will tend to have lower levels of privacy concern.

Post-Demonstration Hypotheses

The post-demonstration hypotheses are the focus of this article. They are designed to investigate the impact of the experimental treatment, education concerning information gathering on the Internet through a demonstration, on the dependent variables of privacy concern and two questions related to Internet shopping/personalization preferences. The hypotheses also focus investigation on the possibility of differential impact across various groups.

H5a: The demonstration of privacy risks associated with Internet cookies will increase the level of privacy concern.

H5b: The demonstration will have a greater impact on the privacy concerns of older voters.

H5c: The demonstration will have a greater impact on the privacy concerns of those with lower levels of education.

H5d: The demonstration will have a greater impact on the privacy concerns of those who demonstrate lower levels of Internet usage.

H6: The demonstration of privacy risks will decrease the proportion of people preferring Web sites remember.

H7: The demonstration of privacy risks will decrease the proportion of people preferring to receive recommendations from Web sites.

METHODOLOGY

To test whether or not incongruities could be based upon lack of knowledge, we asked respondents a series of questions to measure their level of trust, online privacy concern and Internet shopping preferences. Basic demographics were also collected.

After a respondent answered questions as described above, we attempted to educate them. On one page of an Internet site, we displayed information about that respondent including their IP address, domain name, and computer information.
tion (see Figure 1). The following is the text that accompanied the information:

The information below was collected from you in just a few short moments without your permission. This is only a simple example. Online companies have the capability to collect much more detailed data. Each time you visit a Web site in fact, you are leaving a 'virtual footprint.' Your information may be actively collected and aggregated by third party companies that can then re-sell your profile.

After the respondents viewed the collected information, they were asked to re-answer the questions pertaining to online privacy concerns and preferences for mass customization. In order to ensure participant privacy, the capture of data was kept confidential. Information stored was limited only to responses and did not include any identifying information.

**Measures**

Several demographic questions were included so that respondents could be categorized by age, education, level of Internet usage and general level of trust. The study utilized two dependent variables, privacy concern and preferences for Web site personalization. The level of privacy concern was measured using a two-item, Likert-type scale. The scale demonstrated a reliability coefficient of .861. Two binary response (Yes/No) questions were used to capture the respondent’s preferences toward e-commerce Web site personalization.

1. Do you prefer for Web sites you visit to remember you?  
2. When you visit a site, do you prefer recommendations based upon your previous visits?

**Data Collection**

The investigation was conducted via an Internet survey. The survey instrument was initially reviewed by three experienced industry professionals to help ensure content validity. A Web site containing the survey was developed. We utilized a convenience sample. The sample included employees from five different companies in the southeast United States as well as undergraduate and graduate students from a southeastern university. Of the 124 useful responses collected 70% were employees of various regional firms and only 30% were students.

**Data Analysis**

Several different analytical techniques were used to analyze the data. Simple T-tests were used to test between-group differences in privacy concern. Z-tests of proportion were used to test for differences in the proportion of respondents answering the binary response format (yes/no) questions related to Internet personalization preferences. ANOVA (SPSS General Linear Model) was used to test for differences between pre-test and post-test scores for privacy concern and for interaction effects. In order to test for differences in the proportions related to the binary response questions from before and after the treatment, McNemar’s test for significance of changes in bivariate nominal scale data was used.

**RESULTS**

**Demographics**

In analyzing our sample, we found that most of the respondents were heavy Internet users. In fact, 54% claimed to spend 10 or more hours per week on the Internet and the majority, 83%, had
purchased more than one item online during the last year. Furthermore, respondents were also mainly college graduates with 72% having a bachelor’s degree or above.

**Age**

In order to determine if age did in fact affect respondent’s reactions to our questions, we broke our sample into two age groups – 18 to 30 and 30 and above. Results indicate no significant difference in the level of privacy concern between the two groups (Table 1). Analysis of results utilizing the Z test of proportion indicate no significant difference between the age groups related to preferences for Internet shopping site personalization (Table 2). These results are consistent with the findings of Garbarino & Strahilevitz (2002) that indicated that age did not have a significant effect on perceived risk of online shopping.

**Education Level**

Respondents were divided into two groups based on education level. One group included those with a bachelor’s degree or higher and the other group include those with less than a bachelor’s degree. Results indicate no difference in privacy concern between the two groups (Table 3). These findings are inconsistent with the findings of Mayer (2002), who found difference between Internet users based on education level. Mayer reported that as the education level of participants rose they were more likely to say that there were risks.

associated with a lack of confidentiality. Although there was no difference between the two groups in the proportion that preferred Web sites remember them, there was a difference in the proportion that preferred recommendations from the Web sites. 43.8% of those with a bachelor’s degree or higher preferred recommendations based on previous visits compared to only 22.9% of those with less than a bachelor’s degree. This difference is significant at the .05 level (see Table 4).

Internet Usage

Our sample was split into two groups—those online more than 10 hours per week (heavy Internet user) and those online less than 10 hours per week. Results indicate a significant difference (p = .011) between the two groups in their level of privacy concern. Interestingly, the heavy Internet users displayed higher levels of privacy concern than the less frequent users (see Table 5). There were no significant differences in preferences for personalization between the two groups (Table 6). The findings related to level of privacy concern may be inconsistent with the findings of Fernandez & Miyazaki (2001). According to Fernandez & Miyazaki (2001), those who use the Internet frequently have a low perceived risk about the associated technologies. The difference in findings may be accounted for by the slightly different de-
Ignorance is Bliss

Fernandez & Miyazaki (2001) used “perceived risk” as opposed to our construct of “privacy concern.” Given that perceived risk is a more general construct that includes both privacy concerns and security concerns it may be possible for experienced users to have a higher level of privacy concern while still perceiving a lower level of overall risk than less experienced users. While little has been done to address privacy risks, security technology, encryption, e-wallets, and so forth have made financial transactions on the Net much more secure over the last few years. It is possible that experienced users’ knowledge of security technology and the low risks related to online use of credit cards might account for the lower level of perceived risk. If experience is related to knowledge of the technologies and risks associated with e-commerce then these experienced users may be more aware of the privacy risks associated with persistent cookies, data miners, spyware and other information gathering technology. If true, this would be consistent with our findings. Likewise, the lower level of privacy concern reported by those who used the Internet less supports the idea that ignorance is bliss. Those with the lowest level of use, and presumably a lower level of understanding, report the lowest level of privacy concern.

Level of Trust

- **H4:** Those who are more trusting will tend to have lower levels of privacy concern.

To determine if trust affects the level of privacy concern, our sample was split into two groups—high and low trust consumers. Those who answered that they tend to trust people were placed within the high-trust category whereas those who did not tend to trust people were placed in the low-trust category. Results of a t-test indicate that low-trust individuals exhibited higher levels of privacy concern. Since privacy concern is related to a fear of potential harm from others, it is consistent that those with low levels of trust would report higher levels of privacy concern. Given the similarity of the two constructs, this finding could be interpreted as evidence of convergent validity of the privacy concern scale.

**Post-Treatment Results**

Hypothesis 5a represents the main focus of this study. The results of the paired samples t-test indicate a significant difference for all users between pre-test and post-test scores. Analysis shows that educating users about the technology of information gathering resulted in a significant (p < .000) increase in the level of privacy concern (see Table 8 and Figure 2).

ANOVA SPSS (general linear model for repeated measures) indicates a significant main effect of the treatment but no significant interaction effect between treatment and age (see Table 9).

Results indicated no interaction effect between the treatment and the user’s education level (see Table 10).

An analysis of the results indicates a differential effect of the treatment based on the level of Internet usage (see Table 11). The treatment had a significantly greater effect on those with lower levels of Internet usage (see Figure 3).

The non-parametric test known as McNemar’s test for significance of changes was used to evaluate the data for hypotheses H6 and H7. The test is used to determine the significance of the proportion of respondents that change their preferences after the treatment.

- **H6**: The demonstration of privacy risks will decrease the proportion of people preferring Web sites remember them.

The contingency table above indicates that 25 people responded yes both before and after the treatment. 24 people responded YES before and changed to NO after treatment, 4 people answered no before and yes afterwards, and 71 people answered no both before and after the treatment (see Table 12). The results indicate that a statis-
tically significant number of users altered their preferences after being educated about information gathering technology online. The direction of change was consistent with the hypothesis. A significant proportion of those who initially preferred to be remembered by Web sites chose NOT to be remembered after the demonstration.

- **H7:** The demonstration of privacy risks will decrease the proportion of people preferring to receive recommendations from Web sites.

  The results shown in Table 13 indicate that a statistically significant number of users altered their preferences regarding receiving recommendations from Web sites based on previous visits after being educated about information gathering technology online. The direction of change was consistent with hypothesis H7. A significant proportion of those who initially preferred to receive recommendations from Web sites chose NOT to receive those recommendations after the demonstration.

**DISCUSSION AND CONCLUSIONS**

**Demographic Differences**

Table 14 presents an overview of the pre-demonstration results. Several hypotheses were tested for between-group differences prior to the demonstration. There was no difference in the level of privacy concern between groups based on age or education level. Although others have found significant differences, our failure to discover many differences in the level of privacy concern based on age or education level is consistent with the findings of Ackerman et al. (1999). The demographic variable that did result in a difference between groups was the level of Internet usage, with heavy users (>10 hours/week) displaying a higher level of privacy concern.

Preferences toward e-commerce Web site personalization were also relatively invariant across groups. The proportion of users that preferred for Web sites to remember them was invariant across age, education, and Internet usage levels. The only significant difference was for those who preferred that Web sites make recommendations based on the results of previous visits between groups divided by educational level. Those with
a bachelor’s degree or higher were more likely to prefer the recommendations than those with less education.

The overall paucity of between-group differences based on age and education level simplify the interpretation of the results and improve the generalizability of the post-demonstration findings. It is not age or education level but how much the respondent uses the Internet that has the greatest impact on the level of privacy concern.

Post-Demonstration Differences

The main focus of this research can be found in the pre-test, post-test results (see Table 15). Notice that the direct effect of the treatment was significant on all three dependent variables, (see hypotheses 5a, 6, and 7 in Table 15). An increased awareness of the types of information collected, information gathering technology, and the potential uses of that information significantly increased the level of privacy concerns of users. Such increased awareness

also significantly reduced the proportion of users who prefer e-commerce Web site personalization. It significantly reduced both the proportion that wished for Web sites to remember them and the proportion that preferred recommendations from the Web sites based on previous visits.

When it comes to the level of privacy concern, it appears that ignorance is bliss. It is clear from these results that many users do not understand the amount or types of information that are collected about them on the Internet. It also suggests that many have little understanding of the technologies, such as persistent cookies, that are used to collect personal information. It is this pre-existing lack of understanding that makes the effect of the treatment in this experiment so significant in its impact on the level of privacy concern and preferences for Web site personalization. It is logical to assume (although not proven by this experiment) that those who are heavy Internet users would have a better understanding of information gathering technology such as cookies than those who use the Internet much less. Even before the treatment, the heavy Internet users demonstrated higher levels of privacy concern than the light users. Those who used the Web the least had the lowest levels of privacy concern (see Figure 3). Although the treatment increased the level of privacy concern for both groups, the effect was significantly greater for the light users than for the heavy users. The two groups began with significantly different levels of privacy concern. However, after the treatment, both groups showed increased levels but the two groups were no longer significantly different from each other. Those with the least experience seemed to have been the most shocked by the information in the treatment and therefore they made a significantly greater change in their perceptions.

**CONCLUSION**

These findings have implication for consumers, e-commerce firms, and policy makers. On the consumer side, it is essential to protect one’s own
Ignorance is Bliss

privacy. Our results indicate that consumers do not in fact fully understand online data collection and the related privacy issues. Therefore, consumers should begin by educating themselves about Internet privacy risks and technology. Those consumers who are concerned about online privacy should be meticulous in reading privacy policies in order to establish what information is collected and how it will be employed. If a consumer is uncomfortable with the information that will be collected and/or how that information will be employed, they have the opportunity to visit another site or eschew the risky transaction. Consumers should also be aware of the technology available to help protect privacy. Browsers can be configured to block offending cookies. Sites such as bug-me-not.com can be used for anonymous registration. Encryption technology can also be used to help protect personal privacy. In addition, consumers must become aware that an inherent trade-off exists between the convenience of mass customization and privacy risks online. Consumers must weigh the potential benefits versus the potential risks and make an informed choice regarding preferences for Web site personalization.

These finding also have implications for e-commerce firms. Our findings showed increased levels of privacy concern as consumers were made aware of information gathering technology. Olivero & Lunt (2004) found that an increase in privacy risk awareness reduces the level of trust and increases the demand for control over information use, thus complicating the relationship between the retailer and consumer. Other studies have shown that trust is related to the willingness to transact business with an online firm (Jarvenpaa et al., 2000). Firms should not become complacent and assume that consumers trust them and choose to participate in surreptitious information exchange simply because consumers fail to block their cookies. Our findings indicate that it is ignorance, not acquiescence that causes people to allow cookies. If knowledge of Internet information gathering increases, consumers are likely to lose confidence in the online marketplace. Businesses must understand consumers’ concern about these issues and aim to build consumer trust.

At a minimum, an online company should attempt to instill trust in consumers through contracts, such as privacy policies and/or disclosure agreements, that adhere to the FTC’s fair information privacy guidelines of notice, choice, access and security (FTC, 2000).

Policy makers will also have to deal with the issue of online privacy in the coming years. According to the Center for Democracy & Technology (2004), there were at least twelve bills introduced in the 108th U.S. Congress related to privacy and the Internet. We find the number of people that claim to be concerned about privacy is increasing (Turow, 2003); yet people continue to perform activities that are risky in terms of privacy. There is a debate as to the best method to protect privacy while at the same time facilitating electronic commerce. Some researchers and interest groups argue for self-regulation on the grounds that consumers are free to make a choice with respect to participating in online information exchange (Turow, 2003). Their argument is bolstered by the findings of Westin (2002), who submits that the majority of Internet consumers are “privacy pragmatists.” His description of these users suggests that they make informed cost-benefit decisions regarding Internet privacy risks. Our findings dispute this assertion. The results of this study suggest that a significant number of people do not understand the technology and risks associated with surreptitious information collection on the Internet. If people do not understand the fast-changing technology, regulations, and privacy laws that govern Internet privacy, it is unrealistic to expect them to make an informed choice. Our findings support the need for further regulation and increased consumer education concerning surreptitious data collection on the Internet.

Chapter 7.12
The Function of Representation in a “Smart Home Context”

Mats Edenius
Stockholm School of Economics, Sweden

ABSTRACT
In our society, we seem almost completely engaged in a variety of representational processes. By rendering events and processes “still”, they can be more easily manipulated and transferred into a stock of movable resources which can provide the possibility to control. It is in that context information technology can give us power. In this article it is argued that in order to understand information technology we must begin with representation. I will illustrate such a perspective by a case study that puts a smart home-technology in focus and exemplifies how it may let us deeper our knowledge about IT, how that knowledge is constructed, what actors are involved, what drives them and what kinds of issues are at stake.

Antiquity had been a civilization of spectacle. “To render accessible to a multitude of men the inspection of a small number of objects”: this was the problem to which the architecture of temples, theatres and circuses responded. With spectacle, there was a predominance of public life, the intensity of festivals, sensual proximity. In these rituals in which blood flowed, society found new vigour and formed for a moment a single great body. The modern age poses the opposite problem: “To procure for a small number, or even for a single individual, the instantaneous view of a great multitude”. (Foucault, 1977, p. 216)

INTRODUCTION
We utilize different tools to represent the world and relevant information and knowledge in order to run our lives and make strategic choices. In our contemporary life, we seem almost completely engaged in different representational, fixation — “still” making — processes. A three-dimensional world is reduced to a two-dimensional representation, a lot of reproduced events and objects in a curtailed form (cf. Cooper, 1992; Latour, 1987; Edenius & Borgerson, 2004; Bloomfield & Vurdubakis, 1997; Kallinikos, 1996).

By rendering events, processes and happenings
The Function of Representation in a “Smart Home Context”

“still”, their manipulation and transference into a stock of movable resources can be facilitated. Thus understood, representation provides the possibility to maintain control by expected reactions to the changes made in and through the representations. By representation, I mean a symbolic codification, an operative scheme; “something for something else” (Castoriadis, 1987) like texts, documents, models, or statistics. A commander of a battlefield, for example, needs a map (representation) of the ground to lead his troops, a manager needs an organization chart to manage the company, we create budgets, Internet-home-banks, timetables, and so forth. Variant technologies of representations exist in almost every facet of our lives, not the least of which are our homes. We not only use different representational practices in our homes that are linked to videos, cellular phones, cameras, and so on, but also for cooking facilities, home computers, e-mailing, heating switches, laundry booking, and more.

During the last 10 years or so, a variety of technologies have come into our homes. Many of these could be said to be an application of the intelligent building concept of residential property. When diverse technologies of representations are consolidated in one place in our homes, we use the epithet “smart homes”. Smart (home) services technology was originally developed for the automation of commercial buildings, and has subsequently gained widespread acceptance (Peterson, Williams, & Mills, 2001). Chapman and McCartney (2002) stress that the “smart home” is comprised of everything from “an intelligent building that provides a comfortable and productive environment through automated control systems such as fire safety, security and energy/lighting management” to claims about the “smart home project that allows individuals using it in their daily lives to use their intelligence and think and act for themselves” (Stelcner, 1998; Woodnutt, 1998) to different unobtrusive monitoring systems that support people (Bowes & McCollan, forthcoming; Fisk, forthcoming).

In conventional research about the smart home, a number of epistemological questions are put forward about the world we have attempted to capture. A few of these questions are: Is it well described? What details have been missed? Do we have the necessary features that are required to run the home efficiently? Have we found an acceptable solution for people with restricted mobility? In what way has the smart home improved the user’s life? What kinds of activities do we need to monitor in order to successfully meet our objectives (Graham-Rowe, 2004; Glascock & Kutzik, 2005; Fisk, forthcoming; Kinder, 2000)? Beneath the surface of these studies, we can see structurational perspective posit technology as embodying structures (which may become appropriated by the users during their use of the system, Orlikowski, 2000). The residents’ actions play a crucial role in explaining the consequences associated with the use of new information technology. However, the conventional studies in the field of smart homes leave the analysis on a more or less instrumental level. A more structurational perspective, which is inherently dynamic and grounded in continuous action, is hitherto lacking or is barely discernable.

I will argue that by not examining the epistemological questions posed in the conventional research, there is a potential risk of comprehensively overlooking where the technologies used in a smart home may lead and what the overall results will be. In other words, I would like discuss what a smart home is as much as what it does.

This article is written in the spirit of Sotto (1997) when he, in his ambition to explore what is inherent in information technology, argues that it “can only be undertaken from the point of its ‘essence’ not that of its use. Only then is it possible to perceive its intrinsic qualities and what modes of actions it provides. An adequate investigation of this cannot be carried out, of
course, by a single researcher. It requires the effort of many and familiarization with a quite new viewpoint and its attendant vocabulary”. This paper’s aim is to contribute towards achieving Sotto’s objective.

A smart home could be said to be the outcome of the function of representation, in other words, “something for something else”, and the opportunity for close packing and the reduction of size and mass. This paper will highlight some specific features of the concept of representation and thereby discuss a phenomenon by illuminating parts of its “essence”. My intention is no just to be theoretical, so I will relate different features of representation and discuss how various codifying processes work in practice. I will do this by illustrating my argumentation with a case study.

Let me return to the subject of what a smart home system has to do with representation. The answer is, to a large extent, that a smart home is built based on charts. These charts have their own instrumentally linked questions; do we have the figures we need in order to represent the world? Are we using the proper key figures that are relevant to running our flats? Do we have organized pictures that correspond to our reality? We are confronted with many different choices for how to represent the world so that the representations enable us to run our homes in an efficient way. It is therefore no surprise that the main purpose of employing these technologies is to make it easier for us to maintain control and order (Chapman & McCartney, 2002).

On the basis of a broader historical evaluation of technology (Mumford, 1934; Winner, 1993) it is possible to assert — in general terms — that the “home” involvement of IT accomplishes much more than the sheer transferring of information and knowledge. According to Heidegger (1977), representation could be linked to modernity and the emergence of the industrial world. Heidegger argues that representation differs from previous modes of knowing in that it is not simply concerned with the duplication of the symbolic coding of the world in its diversity, but rather with the selective objectification of things, states and processes (see also Kallinkos, 1996, p. 118). We can say that in the context of the smart home, representation produces a particular brand of reality and functions as a kind of “world-making” (Goodman, 1978). This world is continually working to structure our thoughts and our thinking and acting processes.

By saying this, I am following the line of thinking in which representation is a matter of intervening and reshaping the social by means. Representation needs to be understood not only as the embodiment of a particular technique or sets of techniques but also “...as a world view whose overall orientation permeates all techniques and defines the social and intellectual territory upon which the very modern notion of the technical can emerge” (Kallinikos 1996, 2004).

What the conventional instrumental discussion about the smart home seems to underestimate, is how the smart home in action works as a dynamic configuration of forces and finalities that also produces knowledge. A smart home intervenes and reshapes knowledge via diverse modes of representation. The “smart home”, instead of being a container-like tool where knowledge is imagined to reside as a kind of stable entity or stock of fixed information, becomes a complex system of discursive practices. A smart home, with all its different discursive practices, can thereby be given an active role, central to instances of new knowledge clusters and new categories of significance (See also Bateson, 1973; Power, 1997; Kallinikos, 1996; Chia, 1996; Bloomfield & Vurdubakis, 1997).

To summarize, one function of representation is to give order and direction and make it easy for the mind and body. From conventional research based on this view, we can regard many applications about smart homes in successful terms, but, at the same time there are further processes going on in the light of the way information is
The Function of Representation in a “Smart Home Context”

represented. These processes seem as important as the first one, but, ironically, their constitutive ordinariness seems to have led to their neglect in the analyses of smart home technologies.

From this background, the overall aim of this chapter can be formulated: to highlight and illustrate how features of representation, with their potential world-making and structuring of our thoughts and actions, can give further meaning to what is occurring when a smart home system is used. My aim is not so much to show that using information technology will generate new knowledge clusters and new categories of significance, rather it is to illustrate how new knowledge is constructed, what actors are involved, what drives them, and what kind of issues are at stake.

The remainder of the paper is organized as follows: the next section discusses the method being used and the case from which the illustrations are generated. This is followed by various illustrations of how a smart home is used in daily life situations. The last part brings together the various claims of the chapter and ends with concluding remarks.

CASE ILLUSTRATION AND METHOD

The empirical material in this article is not intended to be viewed as an endeavor to conceive of a clear order from different observations, like a “pure” induction or a complete “case study”. Verifying clear theories or hypotheses in not the primary goal. The method is therefore to be regarded as abductive (see Hanson, 1958; Eco and Sebock, 1983).

The abductive method encapsulates the kind of uncertainty that is present in my research strategy. Based on an abductive mode of thinking, I assert that my inquiries about the research subject are a “reasonable hypothesis”. I am aware that the validity of my supposition — the relevance of features of representation in this matter — could be called into question. However, I am following the vein of Pierce (1935-1966, 2.663 f) (see also Tsoukas, 1989) who say that making a reasonable guess is the only way of getting closer to attaining new and fruitful knowledge. I will argue that the proposed features of representation, with their potential for world-making and the structuring of our thoughts and actions, can give further meaning to what the smart home is as well as provide us with an understanding of what it does.

By saying that I would like to indicate that in this paper the main ambition is the search for fruitful knowledge and richness of good points, rather than trying to reach “full” reliability in my conclusions. Such a standpoint is not odd in social science (see for example Alvesson and Sköldberg (2000) in general social science and Charniak and McDermott (1985) in computer science) — but is not so frequently made explicit in texts.

I will base my argumentation on a variety of illustrations, with the ambition to demonstrate that features of representation are adequate to use in the context of smart homes. The empirical material is based on a building that has used a smart home system for almost three years. There are 59 flats in total and they range in size from 46 to 181 square meters. The material and furnishings are of a rather high standard. The first occupants moved into the building in February 2002.

In Sweden, there is a special type of residential housing where one pays a lump sum and acquires membership in a housing association which owns the building. The right to occupy a specified flat comes with this membership. The daily running of the building is controlled by a board that consists of elected members of the housing association.

The smart home solution encompasses energy use, lighting and heating control, weather forecast, home-security, reception boxes, a family calendar, e-notes, e-mail, “security lock”, the booking of common facilities, lighting control and heating control, and more. The whole system is controlled by a screen/portal in every flat.

I know this building very well because my
family and I (my wife and two children) moved into a 147-meter flat in the building in Spring 2002. One part of the flat has a separate exit door and bathroom, so it is actually two flats. My illustrations are based on my firsthand experiences of living in a smart home building.

The illustrations are not generated by a robust completed Action research project -Action research is much more demanding (cf. Argyris, Putnam, & MacLain, 1985). My research is grounded on a more micro-action level, but it could contribute to scientific research nevertheless. As Gloster (2000) outlines, the Action research method is differentiated between micro Action research, which improves the practical affairs of a particular social system, and Action research, which, in addition, contributes to social scientific research, where all micro-action research can become Action research. The illustrations presented below are based on my own experiences and on a number of discussions between our neighbors. Despite this, I cannot ignore my preunderstanding and my background in the academic field. This chapter is based on empirical material from my experience of moving into a smart home building. Coming from the academic field, it is natural for me to translate my experience into a theoretical framework.

I will present my illustrations as short stories and short descriptions. I am thus following the line of thinking in which narrative knowledge is a major bearer of knowledge in our society (Lyotard, 1984). A common research method is to follow a logic-scientific type of strategy. Nevertheless, when such a strategy is boiled down to grasp knowledge, we realize that even the most “scientific” paper could not be written without stories about how to write, what scientific knowledge is about, and so forth. Narratives are a common and natural mode of communication; people tell stories when they are together, to convince other people, to learn, and to teach. I will tell short stories which are based on my intentions and actions, but they are not just stories. I will mix objective and subjective aspects of a phenomenon; I will occasionally look for causal connections, and by doing this — in the spirit of scientific knowledge — also suggest general laws — but not prove them scientifically. Such narratologi puts the reader in focus, a reader that is able to see how a text was made, not because she divines the writer’s intentions or comprehends universal human natures, but because reader and writer are both producers and consumers of the same set of human institutions (see for example Czarniawska [1998, 2000] who has brought such a perspective into social science).

**KNOWLEDGE PROCESSES WHEN GAIN DOES NOT COME AGAIN**

Cooper (1993) asserts that information theory begins with the construction of a representation (pattern, picture, model) of some aspect of the world. Information is then defined as that which adds to a representation; it is a gain because it tells you something you did not previously know. The function of a gain (or advantage) is echoed in the prefix of the representations. Representation is simply a device for realizing gain and ensuring that the gain comes again (cf. a timetable). The problem with the portal and information technology in our building was that representation did not always occur. The gain did not come again. The information technology was supposed to provide control, but the control was soon quite limited. Those of us who lived in the building had bought a pilot system without knowing it. The technology was very unstable. But stability — in terms of a technique of representations (here the interval by which representations occur) — was not just about having a screen and different functions that switched off occasionally: its effects were more profound in the space of representation.

The occupants of the building soon realized
The Function of Representation in a “Smart Home Context”

that they could not trust the IT solution. People started to talk about how frequently the system was closed down and what to do about it. This discourse became one of the most repeated by the people living in the building. Different discursive formations appeared. One was about what was responsible for causing the problem and what to do about it. Another was about people being angry about what they had bought. It did not stop in terms of discourses; different knowledge processes appeared and they handled the problem.

The occupants began to adapt to the new situation and started to organize their lives according to a smart home that they could not rely on. I will start with one example of my own way of handling an unstable system. We used electronic keys to open the door to the entrance hall and common spaces, and the door to our flat. The locking system was also linked to the smart living concept. We could activate a security system by “secure locking” the door with the electronic key. The key could be used in combination with a personal code and this could activate the security system. This security system included fire, flooding, and burglar alarms. It also locked the door more securely from the inside as well as the outside. When the alarm was activated, it sent a SMS message to a number that could be specified in advance via the terminal.

In the beginning, we trusted the smart living technology. The first summer we lived in the flat we lent a part of it to some friends. What we did not realize was that both doors were activated by the secure lock. When we secure locked our door we also locked the other one. Our friends had to phone us — we were on vacation in Finland — in order to get out of our flat because the door could not be opened from the inside. Our friends threw the key out of a window, and it was picked up by a friendly neighbor who went up and deactivated the system so the door could be opened. From this experience we realized that the system was linked to both doors of the flat. We never used the security locking after that, and I do not know if electronically separating the flats is even possible. What I do know is that because of this glitch we decided to install a separate, analogue (ordinary mechanical) lock into both our front doors.

Another illustration of the same phenomenon could be linked to the reception boxes which could be booked from the portal. The initial test of the system was successful. To get into the main entrance, we simply had to punch in a special pin-code in front of the building. The same code could be used for getting into one of the reception boxes. It is important to note that we could only book the reception boxes when the portal was in steady mode.

A year ago, I accidentally left my keys at home. My wife — who also has a key — was away, and I had to pick my children up at school and take them home for dinner. How was I to get into the flat? Fortunately, I had given a set of spare keys to one of my neighbors in the building. I phoned them and they said they had my keys, but that they would be gone by the time I got home. I thought this was the right time to use the reception boxes, but I was suddenly struck by a feeling of mistrust. I found myself asking my neighbors to give the keys to a shop owner nearby whom I knew quite well. I picked up my keys from the shop owner, felt secure, and the problem was solved.

A third illustration is our possibility to see our consumption of electricity, gas, and water on a daily basis, and to compare our use to the average use in the building. We occasionally tried to use this service in the beginning, but we soon realized that the figures could not be accurate. After a while, we were informed that there were some weaknesses in the hardware, and that the problem would be solved. Despite this, we never used this function again.

We can certainly speculate about why many of the services in the smart home were never used again. We can link this phenomenon to cognitive capacities, interests, and an ocean of human weaknesses. Just the realization that we did not use it again is enough for me. We could
argue that it is important that a smart home is “smart” from the beginning. We could say that smartness is a function of representation, and when representation does not give clarity and direction we seem to adapt to the new situation in a quite pragmatic manner. I am not claiming to be an extraordinarily pragmatic person, but I have been confronted with an unstable system. We are reversibly stuck.

Another significant aspect of the smart home was how we became organized thanks to the possibility to see (much more clearly) what was happening in the building. Of course I am talking about the effects of the opportunity of close packing, the reduction of size and mass, and the ease with which we can see much more clearly. Here we see the importance of representation again.

To see and to see much more clearly. To represent the world in an abbreviated mode is not an innocent project. To be able to see “everything” not only makes it easy for the mind and body, but it provides the possibility to rule/manage the world and make things happen, and generates a controlling mechanism. Undoubtedly, the visual has been dominant in modern Western culture in a variety of ways. Maybe the most quoted author in this field is Foucault (1973, 1977, 1980). His works are largely concerned with representation, vision, and control. He has illuminated the role of the gaze in institutions such as the School and the hospital. Foucault’s (1977) attempts to establish the link between how we represent things and their effects find their highest expression in the notion of Jeremy Bentham’s Panopticon.

The Panopticon consists of a large courtyard with a tower in the center and a set of buildings, divided into levels and cells, on the periphery. In each cell, there are two windows: one brings in light and the other faces the tower, where large observatory windows allow for the surveillance of the cells. The cells are like “small theatres in which each actor is alone, perfectly individualized and constantly visible” (Foucault 1977, p. 201). Rather than depriving the prisoner of light, enclosing and causing physical pain, the Panopticon fully exposes the prisoner. By using this method, disciplinary effects are not achieved through threats and the execution of physical torture and punishment; rather, discipline is achieved through the prisoners themselves; the “prisoner is totally seen, without ever seeing” (Foucault 1977, p. 202). Power, or its corollary control, is distributed. It does not reside within a locus; for “…he who is subjected to a field of visibility, and who knows it, assumes responsibility upon himself; he inscribes in himself the power relation in which he simultaneously plays both roles: he becomes the principle of his own subjection” (Foucault 1977, p. 201). The Panopticon as a form of visibility has led the prisoner to internalize the external constraints associated with control; such constraints now operate from the inside of the body in order to control it and shape it in prescribed ways. Thus there is no need for arms, physical violence, material constraints. Just a gaze. An inspecting gaze, a gaze which each individual under its weight will end up interiorizing to the point that he is his own overseer, each individual thus exercising this surveillance over, and against, himself. Traditional forms of control pale in comparison to this superb formula which is more cost-efficient and operates from a distance.

The panoptic schema, without disappearing as such or losing any of its properties, was destined to spread throughout the social body; its vocation was to become a generalized function…has a role of amplification, although it arranges power; although it is intended to make economic and more effective, it does so not for power itself, nor for the immediate salvation of a threatened society: its aim is to strengthen the social forces — to increase production, to develop the economy, spread education, raise the level of public morality; to increase and multiply. (Foucault, 1977, pp. 205-206)

What Foucault is really describing here — al-
though in metaphorical terms — is the common and well articulated reason for implementing a smart home. The panopticon is also the kind of formalization of a smart home that makes structures clear. The whole neighborhood is potentially represented, visible and transparent. The residents were put into an architectural and administrative space in order to apply classes, numbers and names. The architecture of the smart home system also served the discourse and a kind of formal organization (cf. Cooper, 1993). Division created vision.

Likewise, offices and factories have always been designed with the efficiency of the gaze in mind. We can see it in Taylor’s idea in Scientific Management and Hawthorne’s experiments of how design affects behavior. This ambition to see and control is often embedded in the architectural design of places (Duffy, 1997). It lies at the heart of the ordering of space, tools, and people. It is a gaze that arrests the flux of phenomena, which in turn makes manipulation as well as surveillance possible.

With this background in mind, I will tell one story about the lack of the gaze and its results. Thereafter, I will return to what occurred when we began to use the system to see (much more clearly) what was taking place. By doing this, it was possible to identify different phenomena.

When they built and programmed the smart living system, they decided to keep the people who used the booking functions anonymous. The reason for doing this was to maintain the integrity of everyone living in the building. Again, we can see how a social term, a social epithet, is closely connected to representation.

After just a few weeks of moving into the flat my — at that time — four year old daughter forgot her teddy bear in the laundry room. Unfortunately, our laundry time had run out and we could not get into the laundry room. Who was the person who had booked the laundry room after us? We did not know. The system had backfired. In older houses that have a “smart living” system it is possible to book a time in the laundry room by writing your name on a sheet of paper on the door of the laundry room. By using this type of information technology — old-fashioned representational technology — everyone knew who had signed up to use the laundry room. We, who live in the most sublime IT-house, did not have access to this information. We had to wait outside the laundry room door for someone to come down or we had to leave a note on the door with our phone number. Paradoxically to the IT-definition-discussion above, we had to move in order to get information. We could not control our life solely from the portal. Our power was limited. From this perspective, we could say that the remote control was pulling our strings. We had almost no control in this situation. The mobility function materialized into the shape of a physical guard, waiting outside the laundry room. However, we learned our lesson. We found ourselves becoming disciplined, in other words, making sure we did not forget anything in the laundry room. Another way to view this is to say that the potential control mechanism of the smart living system was decentralized by sitting in front of the laundry room waiting for someone to come and open the door.

The possibility of transparency also affected us in other ways. Everyone who lives in a housing association flat — in Sweden anyhow — knows that there is one main source of agitation, and it is the laundry room. The system helped us to organize when each person in the building could do his/her laundry. When you have done your laundry you are expected to clean up and all the cleaning tools are in the laundry room. Unfortunately, not everyone does this cleaning. This is not a big problem in our building because some of the residents do their duty and the laundry room is quite clean, but it is always an issue that creates annoying discussions among the people in the residence.

Knowing who did not clean up after themselves would increase the frequency of the laundry room getting cleaned. I would venture to say that almost
The Function of Representation in a “Smart Home Context”

everyone who lives in the building would prefer a system in which it is possible to know who is occupying the laundry room at any given time. The transparency would most likely start to discipline the residents, and without anyone having to tell their neighbors to do their duty. This type of power would work automatically. The knowledge that someone could locate you would probably be enough to keep you in line (like in a Panopticon). Thanks to the portal, people could be divided and easily inspected, thus enabling classification and counting, which are the rudiments of representation. A large number of people could be represented in the small space on the screen and inspected at first glance.

It is not true that it is impossible to locate people in the smart living system. It is possible to find such data by delving deeper into the IT-system. However, this is only possible for people who have permission to do this. In our case, certain housing association board members have this kind of permission. This was an opportunity we began to take advantage of and appreciate. During the first year, we realized that it was difficult to find an available time slot when booking the laundry room. This was due to the fact that it was overbooked. How come? We used the possibility to locate people and discovered that three families were using the laundry room extremely frequently. One evening some of the board members went around and asked these families why they booked the laundry room so often. No one wanted to have to tell someone else how often they should use the laundry room, but we noticed that just by asking these questions — or by letting them know that they were being watched — that their way of booking the laundry room changed. We also installed a kind of IT-police. We programmed the IT-system to make it impossible to book more than two time intervals in advance.

Another example is the building where there is a parking area. To get into the garage you need an electronic key-card. Every flat-owner has their own card and their own parking spot. After a while we realized that one resident was using the parking area for other vehicles than his/her own. This was not allowed. Some of the board members started to take a closer look at who the owners of the cars were. We confronted the person who had misappropriated the parking spot, with these facts, but without any real results. It was difficult to find clear evidence and it is irritating to have to take on the role of a policeman in your own building. Suddenly, something occurred that turned the whole situation around. We realized that the person who had misused the parking area also started to use a card that belonged to another resident. The “smart living” system provided us with evidence that enabled us to confront the owner of the residence. It is easier to present evidence that is generated from a system than to say you have been spying on someone in a garage. The link to the perpetual gaze in the IT-system made this relationship more abstract, and, paradoxically, easier to present.

A last example of the effects of transparency is a story about how our sauna was used one day in December 2004. One evening a neighbor of ours smelled smoke coming from the sauna/relaxation room. He knocked on the door to the sauna, but nobody responded. He knocked again because he heard voices coming from the sauna, but no one opened the door. My neighbor — as a board member — picked up a special key which was programmed to open all doors belonging to common facilities (one board member has permission to have this type of key). When he opened the door he saw four young boys who were very drunk. The atmosphere was in no way threatening and the young men said that a friend of theirs who lived in the building had booked the sauna, but that he had gone to pick something up. It was potentially easy to locate the flat from which the sauna was booked. Again, we can see how the entire system facilitates the ability to see what is transpiring. The point I would like to emphasize is that the transparency in the system is not always — separate from its ability to inspect — a significant.
thing by itself, but its power is amplified when it is combined with other IT-applications. This was a Friday evening in December. The man who had thrown the four young men out of the sauna sent an e-mail at 10:49 a.m. the day after and told the other board members about what had happened. Just a few minutes after he had sent the e-mail, another board member was able to tell everyone else that they knew who was in charge of booking and letting the young men into the sauna. She could also tell the others that this was not the first time the young men had had a drinking party in the sauna. Just a few hours after this e-mail arrived, another board member sent an e-mail that confirmed the story and stressed the importance of communicating what was going on in the sauna to the owner of the flat (the parents of the young men). At 5:45 p.m. another board member could tell the others that he had contacted the parents, that they were upset and that they promised that this would not happen again. This kind of rapid action was effective.

**CONCLUDING REMARKS**

The article has provided several illustrations where representations have been put into focus. I have furthermore illuminated different knowledge processes that have resulted. It is argued that in order to understand what information technology is about, we have to start with a discussion about its “essence”, rather than its use.

The discussion in this article does not aspire to reach any clear specified closure, but perhaps it will be a starting point for further discussion of the features and functions of representation and thereby the inherent “economy” in smart homes at work. The technique of representations exemplified in the text is, of course, not unique to smart homes. It could also be applied to many other technologies. However, the smart home could be regarded as one technology where the power of representation has been exaggerated and hyperbolized by different techniques of representations. I have stressed how important it might be to regard a smart home as something that is not preformed by pre-existing agents. Instead, I have stressed that users in a smart home context are organized as they participate in a smart home.

Representation is a key to understanding what is happening in this type of process. If we begin to think in these terms instead of in “what happens” terms to generate theories about smart homes and ICT in general, we might better understand how we develop deeply entrenched thought patterns which unnecessarily can circumscribe the possibility for action; and by that the theory could also become instrumentally usable (Chia, 2000). By being aware of the power of representation in smart homes solutions we can organize the way we run our residential housing in better ways. For example, we should be aware of that the possibility of using the system to locate individuals will probably be used. Secondly, and therefore, it may be a good idea to let everybody living in residential housing know about this possibility in advance and that it may be used (or not). This could be done by writing down clear rules about this matter. Another important thing to be aware of is to be sensitive to instability in smart home systems. Instability will create knowledge, and change the routines and the way we use the system, and routines are hard to break.

Hence, one of the essential implications of this study is the significance of broadening the research criteria for studying the smart home. Traditionally, researchers focus on different kinds of interviews, or text-based material that arrests what people do in a smart home context and how the technology could be developed in tune with the users’ wishes. A fuller understanding of the smart home requires one not to overlook the fact that people know what they do and why they do it, nor to suggest that the conventional studies are not productive. Instead, it would perhaps be beneficial to go beyond the conventional parameters that are found in conventional research about smart
homes, by also discussing what effect peoples' actions have. Does the smart home generate trust or mistrust by its controlling mechanisms? People who live in a smart house, do they really want to adapt to new ICT-solutions once the they have been confronted with solutions linked to instability or even worse; when they have been aware of its real benefits in real situations?

If we return to the perspective of regarding information technology and the smart home system as representations of control in one’s life, we are back at Mumford’s (1934) well-known example about the man trying to split the stone, but not into larger pieces that he can carry. The knowledge that the practices surrounding the smart home generate, and what it demands from us seems to be a reminder not of the user’s physical, but rather his or her cognitive limits, or will to control/manage. However, those of us who live in a smart home are not necessarily more rational, cognitively gifted or clumsy than others, or more stuck by managing our life and neighborhood. Our advantage, or occasional disadvantage, is that we have a screen on the wall and the others do not.

ACKNOWLEDGMENT

I am very grateful for the insightful comments made by the reviewers and the Editor on previous versions of the paper. I am also thankful to Jan Wallander’s and Tom Hedelius’ Foundations for Social Science Research.

*When the entrance door is locked, the water is automatically shut off two hours after locking, as well as gas or electricity to stove, sockets above the worktop, lighting, and heating. When the resident comes home the lamp in the hall lights up and the main water supply, the gas, sockets, ventilation, lighting, and heating are switched on automatically. The light in the hall is on until the resident manually turns it off.*

Chapter 7.13
Towards a Meta-Model for Socio-Instrumental Pragmatism

Peter Rittgen
University College of Borås, Sweden

ABSTRACT

We claim that a general conceptual framework for the IS field should provide some kind of common upper-level ontology to describe and explain artifact-mediated social interaction. Such an ontology, socio-instrumental pragmatism (SIP), has been suggested. Our aim is to refine and formalize this ontology by providing a meta-model in the form of a unified modeling language (UML) class diagram. We discuss the implications of such a model as well as its relation to other ontologies. The meta-model is validated by using it in the evaluation of an existing business modeling language.

INTRODUCTION

The rise in the use of information systems (IS) is undeniable, and every day IS become a more important part of organizations. But far from being perfect, the design and implementation of IS in organizations is still a very problematic task that is often fraught with failure (Ågerfalk & Goldkuhl, 2006). There is a need for a better understanding of IS, organizations, and their relation to come up with a framework capable of integrating these two concepts. For the past two decades, theories of communication have been imported into the IS field and the language action perspective (LAP) has been proposed as a way to understand IS and organizations based on communication (Goldkuhl, 1982; Winograd & Flores, 1986). Later on, an ontology to capture the social world was proposed and described in Goldkuhl (2001), Goldkuhl, Röstlinger, and Braf (2001), Goldkuhl (2005), and Goldkuhl and Ågerfalk (2002). This ontology was named “socio-instrumental pragmatism” since it aims at human actions which are supported by instruments and performed within the social world (Goldkuhl,
Towards a Meta-Model for Socio-Instrumental Pragmatism

Socio-instrumental pragmatism (SIP) presents a generic framework which allows for the analysis of the social world. Within this world there are six ontological categories:

1. Humans
2. Human inner worlds
3. Human Actions
4. Signs
5. Artifacts
6. Natural objects

Since SIP was intended as a generic framework which can serve as a base to analyze the social world, it is not aimed exclusively at the IS field. We think that a meta-model based on the SIP ontology but with a focus on the IS field is needed. This meta-model has its foundations in both LAP and SIP and presents a model that will allow us to view organizations and IS together with a focus on actions.

The model consists of the basic categories actions, actors, and objects. In addition to this we also consider other important aspects of organizations that are related to their functioning.

**TOWARDS A META-MODEL SOCIO-INSTRUMENTAL PRAGMATISM**

As mentioned before, there is a need for a framework that allows us to describe social systems in a clearer and more thorough way. Our work is based on the SIP ontology. Within the SIP ontology there are six ontological categories (Goldkuhl, 2002):

- **Humans** are the most important participants in the social world described by the SIP ontology; they act in the world based on

![Figure 1. Realms of the world within the SIP ontology (Goldkuhl, 2002)](image)
meanings and perceptions that they derive from the world.

- **Human inner world** represents the knowledge that a human being has acquired over time about themselves and the external world; this inner world is intended to be seen as part of the human being.

- **Human actions** also form a part of the human being; they can be overt, which means that the actions are intended to intervene in the external world, thus trying to change something about it. And they can be covert when they are aimed to change some human being’s inner world; covert actions try to change knowledge that is present in the human inner world.

- **Signs** are the result of communicative actions; for instance, when write a note saying, “I will be at the store”, the writing of the note is by itself a communicative action but the note created is a sign which will mean something to the person that will read it.

- **Artifacts** are things which are not symbolic and not natural but which are material and artificially created. Examples of artifacts are cars, clothes, a knife, and so forth. The difference between signs and artifacts is that while signs are intended to mean something to someone (symbolic), artifacts perform material actions. For instance, a human might use a knife (artifact) to cut some carrots, that is, artifacts are needed to perform material actions.

- **Natural environment** are the objects present in the environment that are not artificially created by humans (e.g., trees).

Figure 1 shows the different realms of the world according to the SIP ontology.

**META-MODEL**

Our model is divided into three main categories:

- Actions
- Actors
- Objects

Although we do not see Agent as a category; we do acknowledge the importance of agency and describe it as a special element in the model.

**Actors**

Actors are the main entities in our model, and they can perform either as locutor or addressee within the communicative context. When actors perform actions that are directed towards another actor we speak of social actions. They can be performed either in a human-human relation or in a human-artifact-human relation. When performing as locutor the actor is trying to change some aspect of the world by means of his/her actions. For instance, when a person pays the phone bill she is trying to avoid the interruption of her phone service. When performing as addressee the actor receives and interprets an action directed to him and can act himself as a consequence of that action. Taking our example the addressee will be the phone company, which at the moment of receiving the payment will not make any attempt to interrupt the customer’s phone service.

Besides locutor and addressee we can distinguish between organizational actors and human actors. The former is an actor that performs as an agent on behalf of the organization, the latter performs an action on behalf of herself.

**Objects**

An object may be physical or conceptual and it may be formed by other objects or related to
Towards a Meta-Model for Socio-Instrumental Pragmatism

them, but every object is unique (Embley, Kurts, & Woodfield, 1994). Under the object category we have artificial and natural objects. Artificial are those that are created by human beings; natural objects are those created by nature and found in the environment. Among the artificial objects, we have artifacts (material objects) and signs (can be material or immaterial). Artifacts are created to extend actors’ capabilities. An artifact is seen as a tool. Signs on the other hand are not tools but messages in a static phase waiting to be interpreted by actors or artifacts. A message can take either a physical form (a written text) or a non-physical form (an utterance) (Goldkuhl, 2002).

We can distinguish between four different types of artifacts: static, dynamic, automated, and multi-level. Static artifacts are those that cannot perform any operation by themselves, for example, a stone, a knife, or an axe. Dynamic objects are those capable of performing some operations by themselves but they need constant control by a human being to function properly, for example a car or a drill. Automated artifacts are those that can operate entirely by themselves and only need to be started by an actor. Here we can mention a washing machine as an example (Goldkuhl & Ågerfalk, 2005).

Multi-level artifacts are those that have a mix of capabilities and can perform either as static, dynamic, or automated artifacts depending on the circumstances. Multi-level artifacts have an important property which is the capability of creating and interpreting signs. They lack consciousness and are ruled by a predefined set of instructions that serve as a guide to perform the predefined actions they do. IT systems are an example of multilevel artifacts. Signs can be created either by human beings or artifacts, and every sign can be interpreted by human beings only, by artifacts only, or by both (Goldkuhl, 2005). A written note is a sign, an utterance performed by an actor is another example of a sign as well as a ticket printed by a system in an electronic store.

Actions

The objective of human actions is to change something in the world. They can be communicative or material. The main difference between these two types of actions lies in the fact that communicative actions are intended to change knowledge. Knowledge is implicitly meaningful to someone; and knowledge handling is an exclusive characteristic of actors within an IS. On the other hand, material actions are aimed at material conditions and aspects of the world which are meaningful to someone. They are intended to change something physical among the external world. Winograd and Flores (1984) stated that language is prior to consciousness and we might add that consciousness is prior to actions performed by actors. As a human characteristic, knowledge can be learned through actions, either communicative actions (for instance, a conversation) or material actions (e.g., when studying an object). Knowledge is the result of the actor’s interpretation of both communicative and material actions, and it can be acquired in a social context (from other actors transferring knowledge, for example, in a classroom) or in a non-social context (a person reading a book on her own) (Goldkuhl, 2001).

We can divide actions into i-actions (intervening actions) and r-actions (receiving actions). I-actions are those intended to make a change in the external world, for example, the action of opening a window is intended to change a particular aspect of the external world (the window will move from closed to open). R-actions are those executed covertly, for example when two people are going out and person A tells B “It’s cold outside” (communicative i-action). Then person B listens and interprets the message (r-action) and maybe after that person B will take a jacket on the way out (material i-action) (Goldkuhl, 2001). Among i-actions and r-actions we have indefinite and predefined actions.
Towards a Meta-Model for Socio-Instrumental Pragmatism

Indefinite actions are those performed by humans and we call them indefinite since it is not certain how they will be performed by the actor. The same action can vary from actor to actor. When two employees are ordered to clean a shelf, they will both do it but not in the same way; one can do it better or faster than the other one. Indefinite actions can be either r-actions or i-actions. On the other hand we have predefined actions which are performed by artifacts. These actions will always be performed in the same way following previously programmed instructions (Goldkuhl, 2005). Predefined actions are i-actions, since they are intended to change an aspect of the external world. Among indefinite and predefined actions we find both communicative and material actions.

Both types of actions are aimed at changing an aspect of the world surrounding the actor or artifact but we can see communicative actions as a two-phase action (at least) where the actor A performs a communicative action that is intended to change an aspect of the world but is directed toward another actor or artefact B in the first phase. In the second phase B (if A was successful) executes the action that A desired. Although material, the last action can sometimes be performed without an initial communicative action.

Organizational actions can be either internal or external, and material or communicative. Material and communicative actions within organizations form patterns. Although human beings perform the actions within organizations, we can say that an organization can act. An organizational action has human origins and purposes and is done through humans, by humans, or by artifacts that act on behalf of the organization (Goldkuhl et al., 2001). We will consider organizational actions that constitute an interaction of two or more elements from the organization (actors or artifacts) within an organizational context. We can say that a worker at a clothing factory using a sewing machine to manufacture clothes is performing an organizational action. He is acting to perform an organizational objective (to produce clothes). But, for instance, a man on a farm that goes to the forest to chop wood using an axe, although using an artifact to perform the action, is not performing an organizational action since there is no organizational purpose if he merely burns the wood to warm up his house.

When performing actions by means or with the help of IT systems, we can distinguish between three different types of actions: interactive, automatic, and consequential actions. Interactive actions are supported by and performed through IS and they consist of one or more elementary interactions. Elementary interactions (e-actions) consist of three phases: a user action, an IT system action, and a user interpretation (Goldkuhl, 2001). Let us take the example of an online bank transfer done by the user online. The user will initially introduce his username and password to access the bank system (phase 1), after this the IT system will check in the database if the information is correct and if it is it will grant access to the user and display a welcome screen (phase 2). The welcome screen is interpreted, and the user now knows that he can start his transaction. This is the end of the elementary interaction. Later on the user inputs the data to make the bank transfer, such as account number, amount to be transferred, and so forth (phase 1 of a second e-interaction), and so on.

Automatic actions are performed by IT systems that produce messages for the actors or other systems. They are done entirely without human intervention. Let us take the banking system again: after logging on, a message pops up in telling the customer that the due date for the credit card payment is very close. The system will execute this operation by itself and present it to the user.

Consequential actions are those performed as a consequence of a message. Taking the bank example again, when the customer sees that his payment is due he might proceed to execute the
Towards a Meta-Model for Socio-Instrumental Pragmatism

payment, or he might decide not to do it and wait for the final day.

Based on these types of IS actions, IS are seen as information action systems. This perspective is called actability. Actability is supposed to reinforce the concept of usability within the IS framework and focuses on action and communication. IS actability is the information system’s ability to perform actions, and to permit, promote, and facilitate the performance of actions by users, either by means of the system or based on information provided by it in a business context (Sjöström & Goldkuhl, 2002). An IS is said to be actable when it has the following characteristics (Cronholm & Goldkuhl, 2005):

- Clear action repertoire
- Good communication satisfaction
- Easy to navigate interface
- Action transparency
- Clear feedback
- Easy access to action log
- Personalized information
- Familiar vocabulary
- Good support for business actions
- Capability to understand different communicative intentions

The components of the IS are the IT system, the actor, and the e-action. IT systems are social systems that are technically implemented and have an action memory which stores the past actions and some future actions. Actors can play the role of communicator, performer, or interpreter in the IS.

Agents

Agents are a special type of object; we can position agents between objects and actors. They are created by actors, and perform actions to help them complete their tasks. They can be seen as servants of actors, but they have a level of communicative capabilities that allow them to act as communicative mediators, and they are also capable of creating signs for the actors or other agents to interpret. Agents have a transformative capability, a property that human beings have as well. The difference between agents and human beings lies in the fact that human beings can perform both socially aware actions (such as a conversation) and nonsocially aware actions (such as a blink) while agents can only execute the latter (Rose & Jones, 2004).

IT systems can perform as agents, but describing an IT system can be a very tricky task due to the versatility that these artifacts have. An IT system can either be seen as a static artifact (e.g., when we are reading an e-mail), it can be seen as an automated artifact (e.g., a payroll system from a bank that executes the payments for the employees automatically every 15 days), and it can be a dynamic artifact (e.g., a sales system used by a sales person in an electronics store) (Goldkuhl & Ågerfalk, 2005). In all three cases there is a common denominator: communication. In the first case the IT system is acting as an intermediate device between the sender and the receiver of the e-mail. In the second case it can also be seen as a communicative mediator between the employer and the employee, that is, by executing the payments it communicates to the employees that their employer is paying them. In the third case the system acts also as a communicative device between the salesperson and the customer. The IT system gives information about the products to the salesperson which is transmitted to the customers and it also prints a ticket of the sale which is taken by the customer. This ticket communicates to the customer what she bought and how much it cost. The IT system in this case executes other tasks which may turn into communicative actions. It decreases the inventory of the article sold and if the article inventory is low it will communicate to the inventory manager that the article is running out.

Communication is seen as a kind of action that IT systems can perform and by doing so they
Towards a Meta-Model for Socio-Instrumental Pragmatism

become communication mediators. IT systems as well as actors have the capability to create signs and process them (in the case of the IT system) and to interpret them (in the case of actors) (Goldkuhl, 2001). The relation between the signs and the interpreters/processors of them is called pragmatics. Messages are a product of communication and are also an important prerequisite of it. Within IS pragmatics, actions are divided into those that occur within the sign transfer and consequential actions that are performed in response to the transferred sign (Goldkuhl & Ågerfalk, 2002).

Organizational Actions

Roughly, we can say that within an organization every actor acts to fulfill organizational objectives; hence, they are agents helping to accomplish organizational actions. Let us take the example

Table 1. Sales process for an electronic store

<table>
<thead>
<tr>
<th>Actor</th>
<th>Action</th>
<th>Type of action</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Salesperson</td>
<td>Utterance: May I help you?</td>
<td>Communicative i-action</td>
<td>S performs an i-action</td>
</tr>
<tr>
<td>Customer</td>
<td>Utterance: Yes I would like to buy some batteries</td>
<td>R-action; followed by a Communicative i-action</td>
<td>C interprets the utterance performed by S (r-action) and makes an utterance (i-action)</td>
</tr>
<tr>
<td>Salesperson</td>
<td>Utterance: Which type of batteries?</td>
<td>R-action; followed by a Communicative i-action</td>
<td>SP interprets the utterance performed by C (r-action) and makes an utterance (i-action)</td>
</tr>
<tr>
<td>Customer</td>
<td>Utterance: Rechargeable AA batteries please</td>
<td>R-action; followed by a Communicative i-action</td>
<td>C interprets the utterance performed by S (r-action) and makes an utterance (i-action)</td>
</tr>
<tr>
<td>Salesperson</td>
<td>Take the batteries and pass them through the bar code reader</td>
<td>R-action; followed by an Interactive i-action</td>
<td>S interprets the utterance performed by C (r-action) and performs an interactive i-action</td>
</tr>
<tr>
<td>IS (Agent)</td>
<td>Reads bar code and gets the information for the product from database</td>
<td>Automatic action</td>
<td>IT system performs an automatic action and displays articles details on the screen</td>
</tr>
<tr>
<td>Salesperson</td>
<td>Gets information of product and tell it to the customer</td>
<td>R-action; followed by a Consequential i-action</td>
<td>S interprets the message on the screen (r-action) and makes an utterance (i-action), telling the customer about the details</td>
</tr>
<tr>
<td>Customer</td>
<td>Pays for the batteries</td>
<td>R-action; followed by a Material action</td>
<td>C interprets the message of S and performs a material action (payment)</td>
</tr>
<tr>
<td>Salesperson</td>
<td>Receives payment and give receipt</td>
<td>R-action; followed by an Interactive i-action; followed by an Automatic action; Material action</td>
<td>S receives the payment and closes the sale in the IT system, IT system executes the automatic actions of modifying the inventory and printing the receipt, S hands the receipt to C (material action)</td>
</tr>
</tbody>
</table>
Towards a Meta-Model for Socio-Instrumental Pragmatism

of an electronics store. A customer (C) comes into the store and the following dialog with the salesperson (S) develops.

(S): “May I help you?”
(C): “Yes, I would like to buy some batteries.”
(S): “Which type of batteries do you want?”
(C): “Rechargeable AA batteries please.”
(S): “We have X and Y brands.”
(C): “I would like X.”
(S) passes the batteries over the bar code reader and says “$10, please.”
(C) pays.
(S) completes the sale in the system and hands the receipt to the customer.

When we analyze this business interaction according to our meta-model we arrive at the results shown in Table 1. We will see organizational actions as those actions performed to fulfill an organizational objective. In Table 1, this objective is to sell batteries. We can also notice that many of the actions are multi-functional, that is, one “surface” action corresponds to a number of implied, “hidden” actions. When the salesperson asks for the type of batteries, he performs an implicit r-action by correctly interpreting the request “I would like to buy some batteries”. At the same time he also responds appropriately by performing the i-action of asking for the type of batteries.

As a result of the contemplations in the previous sections we have developed a meta-model (see Figure 2) that covers the most important aspects of socio-instrumental pragmatism as discussed in the relevant literature. Technically the meta-model takes the form of a UML class diagram with generalization/specialization and association.
OTHER ONTOLOGIES

In the literature, we can find a number of competing ontologies that are also potential candidates for a general conceptual framework for the IS field. We look at three of them and discuss their role in such a framework and their relation to SIP.

Social Roles

This theory emphasizes the importance of social roles among the social concepts. Social roles are concepts that can be played by certain entities when they interact with other entities. Examples of social roles are money, professor, and president. The premises behind roles are (Masolo et al., 2004):

- Roles are properties and can be predicated of different entities. This means that different entities can play the same role.
- Roles are anti-rigid; this aspect regards the temporal nature of the relation between roles and their players.
- Roles have a relational nature, being properties, and they have different types of dependencies to other roles/entities. Notional, identificational, and definitional dependence are some of them.
- Roles are linked to contexts; roles are described as determined by external factors (context).

But as mentioned by Masolo et al. (2004), social roles theory “makes use of a simplified ontology, and therefore only partially characterizes social entities.” (p. 5). With the social roles framework we can only partially describe social aspects. We can get a good description of social actors (a professor, a president, an employee) and objects, but we cannot get a description for other important aspects of social concepts such as actions. Another point to highlight is the fact that there is no explicit distinction between actors and objects, since they are both seen as endurants with the difference that objects lack intentionality.

Intentional Collectives

Collections are seen as social objects which depend on member entities and concepts. Several types of collections are distinguished: simple collections (e.g., a collection of stamps), organized collections can be conceived as characterized roles played by members of the collection and that relate among them through social objects. For instance, in a collection of senators, although all of the members have the same role (senator), one of them can be the president of the economic commission, another one can be the secretary of the agricultural commission, and yet another one can be the vice-president of the senate.

Collectives are considered to be something more than collections (Bottazzi, Catenacci, Gangemi, & Lehmann, 2006). Collectives are built around the concepts of intentionality, agent, and plan, the latter being the most important concept within collectives. Intentionality can be seen as the feature by which agents are directed to something. An agent is considered to be intentional and it is oriented towards producing results. An agent function is also to conceive plans. By plan we refer to a description that represents an action schema. Another concept described within the framework of this theory is that of a task, which is a course that is mostly used to sequence activities or other processes that are under the control of a planner. Collectives are a collection of agents. In collectives roles are played by agents and they actively participate in plans and roles.

This theory presents a more detailed conception of social concepts based on social roles. We can find some similarities with our perspective:

- Tasks represent actions within our perspective
• Agents represent actors within our perspective
• Plans can be seen as organizational objectives that lead to the execution of organizational actions

**Actor Network Theory**

The actor network theory (ANT) describes a world containing both human and nonhuman entities but at the same time it makes no difference in the importance of the elements within the network. Instead of separating the social from the technical, ANT analyzes the world in a sociotechnical manner by arguing that a merely technical or a merely social relation is not possible. Instead of actors, the term actant is used in ANT which can be used to refer either to human or nonhuman elements within the network. ANT’s objective is not to analyze the nature and features of the entities in the network, but to study the relations that compound the network, the mechanics of power between the elements, and how the network relations are built (Tatnall & Gilding, 1999).

The ANT approach appears as radical, and the main issue with it is the symmetry between humans, non-human objects, and natural objects. Within our model, the distinction between all these elements is very important in order to understand the functioning and communication within organizations.

For the ANT theorists, the elements of the network relay and prolong collective actions, and no element is considered as the source of the actions. Therefore, instead of being actions, they are seen as events. As we can see, events can be mapped to organizational actions within our perspective. Organizational actions are collective actions performed by one or more actors, agents, or artifacts within organizational boundaries and with a common goal. Thus, events are described in the same way as being collective actions that have no source but that are performed by the actants of the network (McLean & Hassard, 2004).

**EVALUATING A BUSINESS MODELING LANGUAGE**

To validate the completeness and correctness of the meta-model, we investigated an existing business modeling language. We have chosen the language of SIMM (situation-adaptable work and information systems modeling method), Goldkuhl (1996), because we have considerable experience with this language in action research projects. The analysis proceeded in the following way. First we have extracted the constituting concepts from the diagrams. The diagrams are: collaboration graph, interaction graph, process graph, and action graph. These concepts can be found in the left column of Table 2.

In the second step, we have related the concepts of SIMM to the categories of SIP as formalized in the meta-model. For this step we have thoroughly analyzed the documentation of SIMM (Röstlinger & Goldkuhl, 2006). The result of this step is presented in the middle column of Table 2. The right column contains a textual description of the respective concept.

In the third step, we have analyzed the table to identify deficiencies of the meta-model and the language SIMM. We found that all business concepts of SIMM could be captured accurately by some category of the meta-model. Only concepts originating from a different domain (knowledge) or belonging to general upper-level ontology (time and place) could not be represented.

On the other hand, we discovered some minor shortcomings of SIMM. One is that of construct (or concept) overload where one concept takes on different meanings in different contexts and is therefore mapped to several ontological categories. An example of that is *Initialization*, which can be both an actor and an object/sign.

Another issue is that of construct (or concept) redundancy where one and the same ontological category can be expressed by several concepts of the modeling language. An example of this are *directly related actions* and *Indirectly related actions*.

actions. Both concepts cannot be distinguished ontologically which can be seen as a case of over-specification from the point of view of the ontology. In the latter it is not considered to be relevant whether actions follow each other immediately or not.

CONCLUSION

We started our chapter with the assumption that socio-instrumental pragmatism might contribute towards the development of a general conceptual framework for the IS field. We then set out to capture both the breadth and depth of the SIP literature with a suitable meta-model. This process consisted of uncovering the central concepts and their (often implicit) relations and making them explicit in a clear and concise way. We did this with the help of a UML class diagram, a modeling language which is well established and documented and can therefore be expected to support the communication of and about the meta-model among a large group of IS researchers.

We are well aware of the fact that such a meta-model is not, and cannot be, the ultimate solution to a general conceptual framework for the IS field. But we think that it can stimulate a fruitful discussion about the vital components of such a framework. We do not know of any other meta-models that cover the breadth of IT-mediated social action with similar stringency.

ABSTRACT

If a caller is placed on hold when they call a business, about half will hang up before the call is answered. Of those that hang up, only half of those will call back (Staino, 1994). Optimizing the on-hold experience has the potential to reduce hang-ups and make being put on hold more palatable to the caller. The current study assessed the influence of the opportunity to make a music choice and the length of pre-music announcement duration on perceived on-hold durations and customer satisfaction. Subjective assessments of on-hold times were significantly shorter with longer announcements, but satisfaction did not change. The chance to choose music improved satisfaction, but did not significantly reduce subjective time estimates. To test if multiple within-subject trials might have led to prospective time judgments, a between-subjects design replication was conducted, with each participant estimating only one time interval. A similar pattern of results was obtained.
INTRODUCTION

Many companies provide one or more customer support phone numbers for customers to call when they wish to get information, solicit technical assistance, lodge a complaint, or otherwise make contact with the company. The call to customer support is one contributor to the consumer’s overall user experience, and research shows (Tax, Brown, & Chandrashekaran, 1998), is a major factor in brand loyalty.

The provision of good customer support is therefore an important concern of companies. Along with the quality of information received in the call (defined roughly as the ability of that information to lead to a successful resolution of the consumer’s problem or completion of the consumer’s task), one key variable influencing the consumer’s judgment of the call is the time spent on hold. One way to minimize the consumers’ time spent in the hold queue is to oversupply the call center with customer support representatives. Of course, this is costly, and will ultimately influence the cost of the services and products passed along to the consumer. Therefore, companies attempt to optimize the size of the customer support force, in hopes of keeping the force maximally utilized, while at the same time minimizing the cost to the consumer, in terms of time spent on hold.

The correlation between the length of a time segment and a person’s estimate of the length of that segment is less than +1.0. Put another way, human beings’ perception of the length of time segments is not determined solely by the length of that segment. Rather, many other variables influence the perceived length of time, including variables in the stimuli that fill the time span, variables in the context of that time span, and variables in the person who is perceiving the time span (Block, 1990).

Because time is a limited resource, most people view it as valuable (Feldman & Hornik, 1981). Considering this view, a lengthy hold time may result in customer dissatisfaction regardless of the level of service a customer ultimately receives. There is considerable interest in the telecommunications industry in identifying methods to reduce caller dissatisfaction due to long hold queues for consumer call centers. Telephony and software experts are employed to maximize the efficiency of the call center applications and minimize the average actual time on hold. For times when it may not be possible for a call center to reduce the actual length of time that consumers are placed on hold, it is still possible to change the content presented in the hold time interval so as to reduce the perceived length of the hold time. Two experiments are reported here that advance the understanding of: 1) the role of the caller’s ability to choose content while in the hold queue; and 2) the length of the automated announcement before being placed on hold on the person’s judgment of the length of time they are on hold.

Related Research in Cognitive Psychology

The topic of time perception is one that has been of interest to experimental psychologists and others interested in human information processing for a long time. Researchers have shown that, ceteris paribus, time spans that are filled with content (such as music) or a task to occupy a person’s attention are judged to be shorter than time spans with nothing filling the time (Predebon, 1996). Research on time perception suggests that an individual’s estimate of the duration of a time interval is altered by various attributes of stimuli presented in a given interval. Several studies have shown that the apparent duration of a time interval decreases as the cognitive processing demands increase (Brown, 1985; Chastain & Ferraro, 1997; Fortin & Rousseau, 1987; Fortin, Bourque, & Kirouac, 1993). Qualities of that content that have been shown to influence the perceived time duration include the amount of information memorized during the time period (Zakay, 1989), the complexity of the stimulus (e.g.,
The Effect of Choice and Announcement Duration of the Estimation of Telephone Hold Time

Macar, 1996), the tempo or periodicity of the stimulus (Macar, 1996; Polkosky & Lewis, 2002), the hierarchical nature of the tasks performed (Tractinsky & Meyer, 2001), how interesting passages to be read are (Gray, Gray, & Loehlin, 1975; Hawkins & Tedford, 1975), and the size of the visual display on which information is presented (Bobko, Bobko, & Davis, 1986). Liu and Wickens (1994) found that “Time estimation appeared to be sensitive to the presence of perceptual/cognitive demands, but not to response related activities to which behavioral automaticity has developed” (p. 1853).

Participant variables shown to affect duration estimation include gender (Vercruyssen & Rodenburg, 1992), body temperature (Hancock, 1993), the person’s affective state (e.g., Fiedler, 1988; Hornik, 1993; Thayer & Schiff, 1975), and whether or not the participants know that they will be asked later to estimate the duration of the time segment (Zakay, 1993). Even context of the time interval being estimated, such as time of day (Pfaff, 1968) and length of an immediately preceding time interval (Sasaki, Seutomi, Nakajima, & ten Hoopen, 2002) have been shown to influence duration estimations.

The effect of cognitive complexity on time estimation has been explained in terms of demands of certain stimuli on attentional resources. For example, individuals may track the passage of time with an internal counter and as more attentional resources are allocated to nontemporal stimuli over a time interval, fewer resources may be available for the internal timing mechanism (Thomas & Weaver, 1975; Zakay, 1989). Thus, lower duration estimates result as more attention is allocated to external stimuli.

Various models have been proposed to account for the variations in time segment estimation. Ornstein (1970) proposed a storage size model in which apparent duration depends on the size of the storage space in memory required for storing information about an interval. The model predicts that the more events in a particular time interval, or the greater their complexity, the longer the interval seems.

Attentional allocation models (e.g., Hicks, Miller, Gaes, & Bierman, 1977; Zakay, 1993) maintain that time estimates are based on the output of some sort of cognitive timing device. If a person is engaged in a task that has high attentional demands, the attention that can be allocated to the “timer” is limited, and the interval seems shorter.

A third model, the change/segmentation model (e.g., Block, 1990; Fraisse, 1963; Poynter & Homa, 1983), offers that the number of discrete changes in an interval determine the perceived duration of that interval. Events, that may be external or internal (mental events), segment a time interval, and so durations are judged according to the number of segments, with more events thus leading to a longer estimated duration.

Relevant Applied Research

Beyond the ken of cognitive theory, the topic of time perception has immediacy for designers of call centers, developers of software install programs, amusement park managers, and any number of other practitioners; there are many situations in the business world where it is beneficial for a business entity to reduce the amount of time a customer perceives during the wait for a particular service. The reduction in perceived wait time is not the end goal itself, of course. The reductions in perceived wait time typically result in higher satisfaction ratings from the customer, and higher satisfaction ratings can translate into a number of tangible, positive results for the business. With clear incentives to reduce perceived customer wait time, the goal is to alter the environment and thus the customer experience in such a way that the customers walk away from the transaction happier than they otherwise would because they perceive that the time they had to wait for their service was smaller than it actually was.
Although it might seem appropriate to focus solely on the measure of customer satisfaction as a proxy for reduced perceived wait time (when the assumption is made that lower perceived wait times result in higher customer satisfaction ratings), customer satisfaction ratings alone do not account for all of the dimensions customers use when they are making an assessment of a service. For example, even if a person reported having a magnificent time at Disneyland, that person is also likely to report (and retain the perception) that the wait times for some of the rides tended to be very long. This perception will likely be factored into future decisions about whether or not to visit the park again. As such, both customer satisfaction and perceived wait time must be measured when making assessments of the goodness of a service for which the customer must wait.

While the practice of the manipulation of time perception is evidenced across a wide range of activities where consumers must wait for a product or service, of primary interest here is the ability to minimize the perceived length of time while callers are on telephone hold, and there is ample evidence that this can be accomplished. Sold on Hold, a company that sells advertising systems for on-hold interactive voice response (IVR) systems, conducted a study in which 30,000 callers were placed on hold for 1 minute and then asked how long they had been holding. Three conditions were used: silence, music, and messages. Their data showed that all of the callers exposed to silence estimated that they had been on hold for over 1 minute (with 27% estimating they had been on hold for over 5 minutes). The music and message conditions showed 28% and 17% of the customers overestimating their wait time, respectively (Sold on Hold, 2004). Importantly, the amount of overestimation changed based on what the listeners heard during that wait. It would seem, intuitively, that users might underestimate time more if they are enjoying the music or message that is heard during the wait interval, thus supporting the old adage that “time flies when you are having fun.” Kellaris and Kent (1992) showed that this is not necessarily the case. In their study they presented two kinds of music to users who were on hold: positively-valenced music and atonal music. In contrast to the conventional wisdom, participants exposed to the atonal music underestimated the amount of time on hold more than those callers who were exposed to the positively-valenced (normal) music.

Sometimes the perception of time manifests itself as the time people are willing to wait for a service before they abandon the telephone queue and hang up. In one such study, different types of music were played to people who were on hold for a protective services abuse hotline. Each type of music was used as the hold music for 2 different weeks in a 10-week study. The authors then performed an analysis to see if there were differences in the number of calls that were abandoned (people who hung up before an attendant answered), based on the type of hold music that was played. Five types of music were used: jazz, country, classical, popular, and relaxation. There were significant differences in the number of abandoned calls for the various types of music, with relaxation music resulting in over double the number of abandonments as jazz (Ramos, 1993). Speech-based IVR systems appear to yield similar results. In an experimental situation, telephone users were asked to get a speech recognizer to route them to a particular section of a telephone service. This was a ruse, and no participants were ever routed. During the wait intervals, half the participants heard silence and the other half heard music. At the end of the experiment (5 minutes) the participants were asked how long they had been on the telephone trying to get the system to work. Those who heard music overestimated the time by 5%, while those who heard no music overestimated by 39%. Further, when asked how much longer they would have waited before they hung up, callers who had music indicated that they would have waited, on average, about 20% longer than the users who heard silence.
The Effect of Choice and Announcement Duration of the Estimation of Telephone Hold Time

(Gueguen & Jacob, 2002). In a study conducted by North, Hargreaves and McKendrick (1999), callers responding to an ad in a newspaper for research volunteers were placed on hold with either recorded messages, original Beatles music, or renditions of Beatles music made with pan pipes. The results showed that music that listeners said they liked led to the longest times before they would abandon the queue. Their findings are in opposition to the findings of Kellaris and Kent (1992), suggesting that the mechanisms controlling time estimation and call abandonment, while related, are different.

Of course, the stimulus presented to the user during the telephone wait does not have to be music or messages. IBM used the rate of change of an auditory cue (a ticking sound) to give users information about the response time of a speech-enabled telephone application. They found that increasing the ticking rate of the auditory stimulus increased users’ perceptions of the system’s response time (as well as the user’s feelings of anxiety, stress and impatience). The slower ticking rates produced underestimations of the length of the system response time, but it made the users unhappy (Polkosky & Lewis, 2002). Kortum, Peres, Knott and Bushey (2005) found a more complicated relationship between nonmusical auditory cues and perceived wait time, where the arrangement of the stimulus tones acted differentially on participants’ perception of time. Like Polkosky and Lewis (2002), Kortum et al. (2005) also found that users were generally unsatisfied with the stimuli.

The real cost in dollars of waiting can also impact users’ perception of time. In a simulated banking situation an experimenter had users put on hold while waiting to conduct a financial transaction. Half of the participants were told that the call was to a 900 number (where the caller must pay a per-minute charge) and that their compensation for doing the study would be reduced by the amount of the per-minute charges associated with the 900 call. For short waiting conditions (30 seconds and under), both the free and toll call participants overestimated perceived wait time by nearly 100%. As the wait time increased, overestimation was greatly reduced, but the wait time in the toll condition was overestimated by about 14% more than in the no toll condition (Antonides, Verhoef, & Aalst, 2002).

As all of these studies collectively show, there is ample evidence to indicate that the perception of time can be altered based on the environment to which the user is exposed. The key is to find variables that: a) change the perception of time in the desired direction; b) change the user satisfaction in the desired direction; c) are robust across a wide range of populations; and d) have effects that are large enough to justify the trouble and cost of implementing them.

Motivation for the Current Studies

A study of hold queue content demonstrated the positive impact of implementing an Interactive Voice Portal (IVP) within a call center hold queue (Knott, Pasquale, Joseph, Miller, & Mills, 2003). Specifically, the authors found that when callers used an IVP while waiting on hold, their satisfaction with the wait time was high and they made relatively short wait time estimates compared to several other content conditions (i.e., Silence, Music, and Advertisements). Two explanations were offered by the authors for the results. First, the IVP condition was an active condition when compared to the other more passive content conditions. Research has shown that individuals who are cognitively active underestimate time, compared to less active individuals who tend to overestimate time (e.g., Burnside, 1971; Troutwine & O’Neil, 1981). Second, the IVP shifted the locus of control from the system to the user. First described by Rotter (1966) and then later by Schneiderman (1987) specifically for human-computer interaction, the locus of control describes how much control users feel they have over the system and its operation. An internal locus of control means...
that users believe that their actions have direct impact on the function of the system, whereas an external locus of control means that users believe that input provided does not directly influence system operation. The IVP gave callers a choice over the hold queue content, enhancing an internal locus of control. An internal locus of control can result in a more positive emotional state, leading to higher customer satisfaction. Research has shown that emotional or affective state influences perceived time duration (Hornik, 1993) and the acceptability of a wait time (Chebat & Genlinas-Chebat, 1995). A third explanation for the advantage of the IVP is possible. The IVP included a relatively lengthy hold queue announcement. The hold queue announcement is a brief message that informs the callers that they are being placed on hold. In recalling the amount of wait time, callers may have discounted the time during which the announcement was being played.

The study described here attempts to answer the questions raised in Knott et al. (2003) by determining if the users’ ability to select on-hold music (internal locus of control) and the length of the opening announcement can positively affect both the users’ perception of time and their subsequent satisfaction ratings.

**METHODS: EXPERIMENT 1**

**Participants**

Twenty-four individuals, 13 females and 11 males, were paid (50 USD) to participate in a 1½ session. The mean age was 37, and ages ranged from 23-58 years. Participants were recruited from the general population of a major metropolitan area in the south-central United States. The selection criteria required only that the participants had used a phone before. Because being placed on telephone hold is a rather ubiquitous experience in the United States, this criterion was sufficient to garner a representative sample.

**Apparatus**

The study was conducted in a small laboratory room furnished with a couch, and a coffee table with a Western Electric 2500 Series telephone on it. Calls were placed to an IVR system running on a personal computer through a Dialogic Telephone Interface card. The IVR was programmed using VBVoice.

**Procedure**

Participants were given a brief overview of the study upon arrival and were given time to read and sign an informed consent form. Participants were asked to remove their watches and place them in a drawer in the testing room “so they would focus on the study and would not be attending to the time to see when their session would end.” They were told that this was a standard procedure used for all usability studies. To conceal the purpose of the study, the participants were told that they were there to evaluate several automated systems by placing phone calls to the systems and answering a usability questionnaire. They were also told that they might experience some delay in reaching the automated systems because the systems were currently undergoing heavy testing.

Participants were given a testing packet with instructions, 16 task scenarios, and customer satisfaction questionnaires for each call. The tasks are listed in Appendix A. For each call, participants heard a brief hold queue announcement. They were then placed in the hold queue where they listened to music while they waited to be connected to the customer service system. After waiting on hold, participants were connected to an automated system that asked them for the purpose of their call. Participants were instructed to ask the question provided in their task scenario and to write down the answer they received from the automated system. A different task was used for each call and the tasks were presented in random order. After each call, participants were

asked to estimate the amount of time they had to wait before reaching the customer service system, in minutes and seconds. They then completed a customer satisfaction questionnaire consisting of 11 statements on a five-point scale (Strongly Disagree to Strongly Agree). Eight of the questions were distractors and related to system usability. The remaining relevant questions appear in Appendix B.

The study used a repeated-measures design in which all participants made 16 phone calls. The experimental conditions were presented in random order for wait time (30, 60, 120, or 240 seconds), music choice (music choice or no-choice conditions) and announcement duration (long or short). For calls in which participants could choose the music type, four options were presented: country, classical, classic rock, and jazz. For the no-choice trials, the type of music that was played was automatically selected by the system and was counterbalanced across calls. The actual music selections played for the users within each type of music were identical for both the choice and no-choice conditions.

The four experimental conditions created by the two choice conditions and the two announcement length conditions are represented in Figure 1. The long and short hold queue announcements for the choice and no-choice conditions are shown in Table 1.

Hypothesis

It was hypothesized that:

1. When callers can choose the music type, time estimates will be shorter and customer satisfaction will be higher.
2. Longer announcements will result in shorter time estimates and higher customer satisfaction.

RESULTS: EXPERIMENT 1

Estimate error is defined as the difference between the actual and perceived wait time, such that positive numbers indicate an overestimation of the actual wait time and negative numbers indicate an underestimation of the actual wait time. As can be seen in Table 2, on the average participants overestimated the wait time, but estimate error was smaller for the long announcement condition (M = 1.05 sec) compared to the short announcement condition (M = 13.9 sec).

A 2 × 2 repeated measures ANOVA was conducted to evaluate the effect of music choice and announcement duration on estimate error. There was a main effect for announcement duration on estimate error (F(1,23) = 4.4, p < .05) (see Figure 2). One-sample t-tests were used to compare participants’ estimates with the actual wait times. Estimate error was significantly greater than zero when the short announcement was used, t(191) = 2.37, p = .02. The difference was not significant for the long announcement condition, demonstrating that participants did not overestimate the wait time for this condition. The main effect of music choice on estimate error was not significant (p = .11).

A customer satisfaction measure was created by taking the average score for the three customer satisfaction questions and converting to a percentage score. A 2 × 2 ANOVA was conducted to evaluate the effect of music choice and announcement duration on customer satisfaction scores. The main effect for music choice was significant, (F(1,23) = 19.3, p < .001) with customer satisfaction higher for the choice conditions (M = 75%) compared to the no-choice condition (M = 64%). The effect of announcement duration on customer satisfaction was not significant, F(1,23) = 3.1, p = .09 (M = 71% and M = 67% for the long and short announcements, respectively). Customer satisfaction is significantly correlated with estimation error (r(382) = -.35, p < .01). Table 3 and
The Effect of Choice and Announcement Duration of the Estimation of Telephone Hold Time

Figure 3 show the customer satisfaction data for experiment 1.

After each trial participants were asked how much they liked the music selection (the actual piece of music played during the hold interval) they had just heard, on a 5-point scale. It was thought that the degree to which people liked the specific music selection might be important, so a Pearson correlation was conducted between Statement 4 (‘I liked the music selection I heard.’) and Estimate Error or Customer Satisfaction scores. The more people liked the music selection played, the lower

the estimation error and the higher the customer satisfaction ($r_{(382)} = -0.22, p < .01$ and $r_{(382)} = 0.48, p < .01$). The correlations are both significant.

DISCUSSION OF EXPERIMENT 1

Table 4 summarizes the pattern of results from experiment 1. As Meyer, Shinar, Bitan and Leiser (1996) stated, “Factors that influence duration estimates may or may not influence preferences and vice versa” (p. 47), and the results of experiment 1 certainly bear out the assertion.

The purpose of the study was to test the effect of two variables on the subjective experience of time for participants waiting in a hold queue for a simulated consumer call center. The hypothesis concerning music choice (that wait time estimates

</table>

The prediction that the ability to select the music type would result in a different subjective time experience than the no-choice condition was partially supported by the data. Participants indicated a higher level of satisfaction with the wait time when they were offered a choice of music types in the hold queue. However, contrary to the prediction, the effect of being able to choose a particular type of music on a participant’s estimates of the wait time was not significant.

The hypothesis concerning the duration of the hold queue announcement was also partially supported. It was predicted that a longer announcement would result in a shorter perceived wait time and higher customer satisfaction. The data show that participants significantly overestimate the wait time for the shorter announcement, but do not overestimate wait time for the longer announcement.

Table 4. Pattern of results from experiment one. IV = independent variable, DV = dependent variable
as well is some indication that the callers were perceiving, at some level and to some deleterious effect on the user experience, the longer duration announcements.

**EXPERIMENT 2: BETWEEN SUBJECTS TEST**

**Motivation for Experiment 2**

After experiment 1, there was some concern that the repeated-measures design, requiring as it did each participant to estimate times in 16 trials, may have led to artifactual effects that would not occur in the real world, where a customer support call is a relatively rare event. Zakay (1993) proposed that time could be assessed in two ways. In prospective mode, participants know in advance that they will be making a judgment of time for some event. In retrospective mode, participants do not know that they are going to make a time estimate until after the event occurs. Zakay postulated that prospective estimates would be subjectively longer because people devoted more attention to them.

Clearly, in experiment 1, after the first or first few tasks, the participants were in prospective time estimate mode. From this it can be inferred that, if Zakay (1993) was correct, time estimate errors would be less than they would be in the situation where the person does not go into the task expecting to estimate times. What is the real-world situation like? In a single, relatively rare call, are people typically NOT in prospective time estimate mode? Or could it be the case that, given how common it is to be put on hold, might many people be in prospective time estimate mode when dialing customer support, expecting to time the too-long wait for the impending call? In response to this concern, a between-subjects design was employed, where each participant had only one trial.

**METHODS: EXPERIMENT 2**

**Participants**

One-hundred twenty-eight individuals were paid (25 USD) to participate in a half-hour session. Age and gender distributions were similar to those of experiment one, as was the recruiting criteria.

**Apparatus**

The apparatus used was identical to that described in experiment 1.

**Procedure**

Experiment 2 was a partial replication of experiment 1, conducted as a between-subjects design. Each of 128 participants received one trial, with one of two levels of music choice (choice or no choice), and one of four levels of wait duration (30, 60, 120, and 240 sec); thus, there were eight conditions with 16 participants per condition. A trial was identical to that described in experiment 1.

**RESULTS: EXPERIMENT 2**

Table 5 summarizes the estimate error data (the difference between actual hold duration and participant’s estimates) for experiment 2. Across all four wait times, participants averaged 16.7 seconds overestimation, although they consistently underestimated the longest (240 seconds) condition. The trials on which participants were given no choice of music were overestimated by 0.8 seconds more, on the average.

A $2 \times 4$ (Choice $\times$ Hold Duration) between-subjects analysis was conducted for estimation error. There is a significant effect for hold duration only ($F_{(3, 120)} = 16.02, p < .0001$).

Figure 4. Experiment two customer satisfaction data, showing the interaction between choice and ‘liked/didn’t like’
The customer satisfaction data are summarized in Table 6. There is a monotonic erosion of satisfaction across the four wait times. The choice condition yielded a higher average satisfaction score than the no-choice condition, 4.61 to 4.16.

A 2 × 4 (Choice × Hold Duration) between-subjects analysis was conducted for customer satisfaction. There is a significant main effect for hold duration \( F(3, 120) = 45.23, p < .0001 \) and no effect for choice \( F(1, 120) = 3.591, p = .061 \).

A 2 × 4 × 2 (Choice × Hold Duration × Like) between-subjects analysis was conducted for customer satisfaction (score from 1 to 7). The “Liked” variable is based on the questionnaire item that asked participants to rate the following statement: “I liked the music selection that I heard while I was on hold,” on a scale from 1 to 7. Only the effect of hold duration reached significance \( F(3, 112) = 26.56, p < .001 \). Plotting the interaction of Choice X Hold Duration (see Figure 4) shows an interesting result; those who got to choose their music were slightly more satisfied with the wait period when they did not like the music chosen, whereas those who got no choice were less satisfied with the wait period when they did not like the music. This could be interpreted as the propensity of people to take some of the blame for a negative experience on themselves when they get to choose.

**DISCUSSION OF EXPERIMENT 2**

The results found in experiment 2 were identical to those found in experiments 1. This means that experiment 2 failed to find a difference between prospective and retrospective assessments of time estimation in this variety of on-hold experiment that one would expect to see based on the work of Zakay (1993). The explanation assigned to this result is that because callers have significant experience with the delays associated with making calls to customer service, they are likely predisposed to be in a prospective mode when they make the call. That is, because they typically expect to be put on hold, their internal timers have already started when they make the call, in anticipation of the wait. For this task, it would seem that only naive callers would be able to use retrospective estimation in their first call. In a practical sense, however, it does not matter if retrospective estimation could be found in a subset of naive callers; the fact is that the data indicate that a majority of callers do have this expectation, and so designs (and the experiments to help determine those designs) must conform to the natural reality.

**GENERAL DISCUSSION**

Earlier studies (see the introduction for a comprehensive list) have clearly shown that the content of the wait time can influence the estimated duration. Some content is better than no content, at least when it comes to expressed customer satisfaction, but the effects on perceived length are more mixed. An Interactive Voice Portal is better than music or advertisements. The current work extends these findings along two important fronts. First, the length of the introductory announcement reduces apparent hold times, at least for the parameters specified in the current study. Second, providing a choice, even a minimal choice like the selection of music genre, increases caller satisfaction (but does not influence perceived wait time).

Memory load models would predict lower estimates for silence, and that has not been found in the vast majority of applied studies. The attention allocation model predicts that complex, interactive conditions would lead to shorter estimates. This was true for the Interactive Voice Portal (IVP), but not true for choice. A segment model predicts that more segments lead to longer estimates, but this was decidedly not so for the choice conditions, in which the opportunity to make a choice creates at least two additional segments. What do the results mean in the implementation
of real IVRs? Giving people a choice may not reduce the perceived duration of the wait, but people like it better anyway. Providing choice is a simple way to increase customer satisfaction in on-hold situations with a minimum of investment. Up to some yet-to-be-determined limit, using a longer recorded message does not count against the perceived wait time. Although there is likely an upper limit, the use of appropriately long announcement can reduce the time callers perceive they have been on hold.

Future research will need to identify the limits of announcement length as a means of reducing apparent wait time, as represented in Figure 5. Additionally, an attempt should be made to identify the effects of segments during the wait, rather than have that confounded with choice. For example, a choice/no choice study could be conducted where the no-choice condition has some additional segment (e.g., “You will hear some music. Tap the ‘M’ Key to continue.”) Finally, an attempt should be made to identify the additivity of the various factors. There were no significant interaction effects in the studies, suggesting that there should be a gain in additive effects by offering pleasant, choice-driven, interactive experiences, after long announcements.

CONCLUSION

While satisfaction with the wait period is just one component of the call center customer experience, any dissatisfaction due to on-hold delays can be mitigated by offering well-chosen content within that hold time. Offering users a choice of content and picking an optimal-length automated announcement can serve to reduce the apparent length of wait times and increase customer satisfaction. Finally, participants in these kinds of studies appear to be making time estimates using prospective memory for every trial, most likely due to previous experience with on-hold telephone situations.

**ABSTRACT**

The flexibility and dynamism of ubiquitous computing systems have a strong impact on the way their security can be achieved, reaching beyond traditional security paradigms like perimeter security and communication channel protection. Constant change of both the system and its environment demand adaptive security architectures, capable of reacting to events, evaluating threat exposure, and taking evolving protection needs into account. We introduce two examples of projects that contribute to meeting the challenges on adaptive security. The first focuses on an architecture that allows for adaptive security in mobile environments based on security services whose adaptation is guided by context information derived from sensor networks. The second addresses engineering aspects of secure ubiquitous computing systems through making security solutions accessible and deployable on demand and following emerging application-level requirements.

**INTRODUCTION**

A major challenge in securing ubiquitous computing systems is to cope with the increased flexibility and dynamism these systems show: the actual structure and behavior of a system at a particular point of time during its operation is not known in advance and depends on the physical and application context at that time. Consider
Towards Adaptive Security for Ubiquitous Computing Systems

a service-oriented architecture (cf., the chapter “Ubiquitous Services and Business Processes”), where a business service providing access to a resource—for example, performing a transfer to a bank account—is used in two applications being composed on demand and referring to a different business environment—for example, invoicing in a supply chain management application, and monthly employee payment in a human resources application. Otherwise, in a spontaneous interaction scenario (cf., the section “Ad-Hoc Interaction” of the chapter “Security for Ubiquitous Computing”) the number of participants in a communication as well as their roles change over time, with the particular type of interaction depending on the location of an entity, the networking capabilities available, and the particular features of the devices being used.

The flexibility of ubiquitous computing systems has a strong impact on security. The constant change of characteristics of both the system and its environment leads to different protection goals and exposure to threats over the system lifespan. Security thus needs to be adaptive: the security architecture, comprising both policies and mechanisms—as explicated in section “Sample Solutions” of the chapter “Security for Ubiquitous Computing”—needs to react to events, to evaluate the current threat exposure, and to take the actual protection needs into account. For example, the bank transfer service, being used in the human resources application environment, is likely to be subject to privacy regulations and confidentiality requirements protecting the information about an employee’s salary, whereas the same service, in a supply chain management environment, is probably required to provide strong traceability of transfers and to enforce the four-eye principle on their approval. The service might only be permitted to run on a mobile device in cases where the transferred amount does not exceed a given threshold, due to the increased vulnerability of wireless communication and the mobile environment to eavesdropping, unless it deploys strong authentication and encryption mechanisms.

The challenge of security solutions adapting to the system’s context occurs in development, deployment and operation of ubiquitous computing systems. In a service-oriented architecture, applications are designed on demand in a composite manner through orchestrating services, while taking advantage of the reuse of services in different application contexts. This asks for the application designer to specify the individual protection needs and security policies, and the service ecosystem (cf., the chapter “Ubiquitous Services and Business Processes”) and infrastructure to support the selection and the set-up of the appropriate security architecture as well as its configuration, all being accessible to an application designer not assumed to be a security expert. Such an effort needs to take into account that the system as well as its environment and protection needs might change over time; thus, events indicating a security relevant change—for example, change of a physical condition or location—need to be identified, the actions to be taken upon detection of the event—for example, the modification of the access control policy or the strength of encryption—need to be specified, and the monitoring of the events as well as the execution of the appropriate actions need to be enforced.

The remainder of this chapter introduces two examples of projects that contribute to meeting the challenges on adaptive security. The first focuses on an architecture that allows for adaptive security in mobile environments based on security services that—like application services in a service ecosystem—can be composed on demand to meet individual security requirements, and whose adaptation is guided by context information derived from sensor networks. The second addresses engineering aspects of secure ubiquitous computing systems through making security solutions accessible and applicable—in terms of integration and operation—on demand and following emerging application-level requirements.
MOBILE WORKERS’ SECURE BUSINESS APPLICATIONS IN UBIQUITOUS ENVIRONMENTS: THE MOSQUITO PROJECT

Background

The aim of a European research project—MOSQUITO (Mobile Workers’ Secure Business Applications in Ubiquitous Environment) (MOSQUITO, 2007; Wrona & Gomez, 2006)—was to provide a secure, trusted and ubiquitous access to business applications. The project developed an easy-to-use and flexible technical infrastructure, required so that mobile workers and their clients can perform daily business processes in a secure and collaborative manner. A particularly important segment of the teleworking market is mobile professionals, such as medical personnel, social workers, insurance agents, technicians, traveling executives, consultants and sales representatives. In today’s businesses, sensitivity to the needs of customers, closeness to their demands and tight relations with customers’ daily operational business processes is essential for success. This is why marketing, sales and production companies send out their mobile work forces in order to be as close to their customers as possible, if not permanently on their sites. However, this world is still characterized by obstacles such as inadequate communication facilities, incompatibilities between applications, and system boundaries that actually hinder interoperability between clients’ and customers’ systems more than they support it. This is equally true for security mechanisms that are insufficient, meeting neither the requirements of business users nor those of their clients—for example, when data is being used on systems that do not belong to the owner of the data.

MOSQUITO Architecture

Figure 1 gives an overview of the MOSQUITO architecture. The platform provides basic security functionalities like protecting key material, authenticating a user connected to a device, or ensuring the integrity of the sensitive data. The platform also gives access to local context information through sensors. The heart of the MOSQUITO architecture is a middleware including a set of security services. Finally, applications are either written on top of the middleware or, in case of legacy applications, are adapted to use this middleware. Application-specific policies are defined to configure the middleware.

At a high level, the developer of a MOSQUITO-based system may be confronted with the assembly of a workflow together with some basic initialization of the MOSQUITO components.

Figure 2 depicts the interactions taking place between the various components that implement this workflow behind the scenes and how they have to be set up to properly interoperate with a service-based application. The interface to the MOSQUITO framework from the application developer’s point of view consists of the message filters, Context Information Acquisition and Trust Service (CATS) and the discovery service.

Figure 1. The MOSQUITO architecture
MOSQUITO Scenario

In the following, we describe a typical scenario for how the MOSQUITO framework is used in the healthcare application domain, in particular, elderly care. A patient Bob, who suffers from restricted mobility and stays more or less at home, has subscribed to a monitoring service that ensures assistance in case of illness. Bob’s health status is monitored by several sensors, for example, temperature or pulse sensors. A monitoring application analyzes the data and in case of irregularities (high temperature or high pulse rate) a workflow is initiated to schedule a house visit to the patient and provide medication if necessary.

The first step of the triggered workflow is to select physicians who are able to make a house visit. The selection is based on the patient’s preferences and needs such as language and location. The first physician gets a notification via mobile phone about the house visit to make, which he has to accept. If he refuses the next doctor is notified. Once a doctor has accepted the notification, he is responsible for scheduling an appointment with the patient and for making the house call on time.

The physician visits the patient and conducts an examination of the patient. The physician may require access to the patient’s medical data. The patient’s data are stored on a Medical Information Portal (MIP). The physician uses a Web application on his laptop or his mobile device (PDA) to view the medical data. Access to the medical data is controlled on a context-aware way. In particular, the physician gets access to the patient’s data only when he has accepted the house call notification (workflow is in the examination state) and when he is close to the patient. Proximity is evaluated based on the physical distance (GPS-based) between the patient and the physician. Both patient and doctor are equipped with a mobile phone that can provide the GPS location.

The examination may end with the prescription of a drug. The prescription is issued electronically via Web application and is sent automatically to the nearest pharmacy. A pharmacist will take care
of the medication and prepare or order the drugs if necessary. As soon as the medication is ready for dispatch, the pharmacist uses a Web application to confirm and the workflow continues.

In the next step, a social worker is selected (based on availability) and gets a notification via mobile phone. The notification includes information about where to pick up the drugs and their delivery address. The social worker has to explicitly accept the notification and, by doing so, he commits to carrying out the required tasks.

A special case is the reassignment of the doctor who has already agreed to perform the house call. In our scenario we assume that the doctor gets an emergency call and is therefore unable to make the house visit in time. During this scenario the issued workflow task is reassigned to the next available doctor.

**Pervasive Workflow**

The demonstrator that has been developed throughout the MOSQUITO project outlines the collaboration between actors from the healthcare application domain. As part of the MOSQUITO framework, we also developed a workflow management system—so-called pervasive workflow (Montagut & Molva, 2006a; 2006b)—easing the dynamic collaboration of partners across organizational boundaries. The pervasive workflow engine deployed on each site involved in a distributed collaboration is in charge of orchestrating the overall process execution. Compared to usual agent-based solutions, this model lowers the risk of malicious code hidden in messages exchanged during a workflow instance. As opposed to centralized workflow management systems, the distributed execution of workflows raises security constraints due to the lack of dedicated infrastructure assuring the management and control tasks of workflow instances. As a result, basic security features such as compliance of the workflow execution with the predefined plan are no longer assured. We categorize the security requirements we identified for distributed workflow systems into three main categories: authorization, proof of execution and workflow data protection. In order to achieve the enforcement of these security requirements, we capitalized on security mechanisms ranging from onion encryption in the specification of execution proofs to ID-based cryptography for the workflow policy enforcement. At workflow design phase, a workflow policy is defined to specify the credentials required by prospective business partners, who could be assigned to the workflow tasks. The transactional model we designed for the pervasive workflow model was implemented using Web services (WS) framework. On one hand an extension of an OWL-S matchmaker integrating the theoretical results was proposed. On the other hand, we implemented a proof of concept of the suggested transactional protocol capitalizing on the WS-Coordination specification. Use of contextual information during the workflow execution was demonstrated by including doctor’s availability as one of the parameters.

**Evaluation**

Basic security mechanisms, for example, integrity, confidentiality, and availability, are common grounds for any business scenario. However, healthcare applications introduce specific security requirements such as non-repudiation or accountability. Our work towards the integration of security mechanisms to match these requirements included two aspects. First, our demonstrator makes use of the special security component (CryptoTerminal) in order to assign business partners to workflow tasks and in order to enable signing of relevant workflow documents. This is, for instance, the case for electronic prescriptions that are exchanged throughout the healthcare workflow. This enables, on the one hand, to gather commitments from business partners during the partner discovery procedure as soon as they accept to be involved in a given workflow instance, and, on the other hand, to identify the issuer of
Towards Adaptive Security for Ubiquitous Computing Systems

critical documents, as those are digitally signed. Second, we have designed security mechanisms to ensure both runtime and “a posteriori” verification of compliance with the actual plan of execution by means of a policy-based approach. The solutions that we currently provide are basic mechanisms that partially answer the required security mechanisms, which are accountability and non-repudiation. Designing and implementing mobile and secure logs would have been a perfect means to solve the limitations of our current solutions yet this research effort was outside of the MOSQUITO project main focus.

Context-awareness is a key feature in MOSQUITO that comes in several flavors. Context may be used directly by applications that want to adapt to their environment, in which case its accuracy has an impact on the correct operation of an application. However, context may also be used by security mechanisms, in particular at the access control level, in which case accuracy is fundamental to prevent security breaches that may threaten the availability of services or the confidentiality or integrity of their data. This in particular requires the context acquisition process to be able to check how trustworthy the acquired context information is. The integration of context information into MOSQUITO framework relies on two components: the Context Information Acquisition and Trust Service (CATS), and the Context Information Service (CIS). The CATS is used in order to figure out where to acquire the CI among a set of available CIS servers. The CATS may either select an appropriate CIS out of a static list of known and reliable services, or rely on the Secure Discovery Service to locate CI Services based on a dynamic and semantically rich profile. The CATS also provides basic algorithms for evaluating the trustworthiness and reliability of the context information acquired before providing it to interested applications. The prototype implementation of the CATS and the CIS was equipped with two trust evaluation methods: a PKI-based validation of context information, and a voting-based validation of context information, based on the comparison of context acquisition from a set of redundant CI Services.

The MOSQUITO framework supports a wide range of underlying communication technologies and execution platforms, including wireless networks and mobile devices. Nevertheless, implementing a service-oriented architecture, and heavily relying on Web services has twofold consequences: on one hand, it ensures an easy integration with existing service ecosystems and enterprise systems and makes the framework easier to use for developers familiar with standard Web services technology. On the other hand, it puts higher requirements regarding the communications bandwidth and computing power of end-user devices. In particular, it is currently not possible to execute the full MOSQUITO framework on a small mobile device. In our demonstration and experiments we have relied on laptops and tablet PCs, limiting the use of the phone to personal authentication and signature. However, high-end mobile phones and PDAs already support Web services, and we believe that in the near future, the execution of a complete MOSQUITO framework on much smaller devices should be possible. The bandwidth requirements of the MOSQUITO applications are compatible with most of the existing technologies, including GPRS, 3G, and WLAN. The delay induced by the processing and communication is noticeable in our demonstrator, but we believe that it could be significantly reduced by optimizing the implementation and deployment configuration.

The MOSQUITO framework provides a robust and innovative middleware concept for context-aware business applications in mobile environments. Although it does support the dynamic formation and execution of a workflow, the implemented interaction scheme is however not fully spontaneous—that is, although it does permit dynamic utilization of WLAN or mobile
Towards Adaptive Security for Ubiquitous Computing Systems

networks, currently it does not support fully ad hoc communications. In every ubiquitous environment, a significant amount of implementation work is currently related to the development of an interface between middleware (i.e., CIS) and the physical sensor or sensor network. An easy and seamless integration of sensors and sensor networks with services is still an open issue.

Conclusions

The MOSQUITO project investigated into a middleware supporting secure, collaborative, and ubiquitous access to applications for mobile workers. Key features of MOSQUITO include the support of context-awareness through sensor networks and pervasive workflows that allow distributing workflows across a set of devices without central control. MOSQUITO has been validated by means of a prototype supporting an elderly care scenario, where context information is used to control access to medical data through a mobile device, and a pervasive workflow facilitates the coordination of the actions of the different stakeholders being involved.

SYSTEMS ENGINEERING FOR SECURITY AND DEPENDABILITY: THE SERENITY PROJECT

Background

There is a common understanding that security solutions built into systems after the fact (of design decisions made and system development done) turn out to be ineffective or even inappropriate. Security needs to be designed into a system from the very beginning, leading to a discipline of security engineering supporting all phases of secure system construction from security requirements analysis to security mechanisms design, and stretching out to system deployment and operation. While there is a rich body of design principles, building blocks, and case studies available, for example, Anderson (2001), their integration in development and deployment environments is still immature. The systems engineer is, thus, required to be security aware, and the assessment of the security contribution of a mechanism and its appropriateness for the requirements at hand are left to the security experts.

The engineering challenge is amplified when considering ubiquitous computing: flexibility and dynamism demand adaptive security architectures, as motivated in the introduction, and new security solutions have to be deployed on the fly. Thus, a designer or developer needs an immediate link between emerging security requirements and implemented solutions to satisfy them. The highly distributed nature of and decentralized control in ubiquitous computing systems demand the consideration of interoperability and the heterogeneity of infrastructures. For instance, in a service ecosystem, a security mechanism protecting a service or a resource needs to interact with other security mechanisms owned by different entities, taking interoperability, consistency of security properties, and potential side effects into account. Still, dynamic behavior does not allow evidence to be provided that a security architecture effective at one point of time will still be appropriate at some future point of time, thus requiring continuous monitoring of the security status of the running system.

The Serenity Approach

Following the above, ubiquitous computing demands the dynamic application of security expertise (Mana et al., 2007). The Serenity project (Serenity, 2006) provides a framework to support this goal through:
Towards Adaptive Security for Ubiquitous Computing Systems

- Systematic capture of security expertise in terms of enhanced security and dependability (S&D) patterns and integration schemes, linked to ready-to-integrate implementations of security solutions, for example, in terms of security services.
- Access to expertise through a S&D library integrated into the development and run-time environment.
- A monitoring framework, able to capture context information and triggered by events being specified in the S&D patterns.
- Deployment support for S&D solutions based on S&D patterns and integration schemes, taking information about the system architecture and its context into account.
- An end-user interface, allowing the specification of S&D requirements and their mapping to solutions and implementations through the S&D library, and a system interface allowing retrieval of context and interaction across Serenity-enabled systems.

Figure 3 shows the framework architecture resulting from this approach (Sánchez-Cid et al., 2006). The Serenity framework has to be instantiated each time it has to be applied to a concrete scenario, for example, an application, a device, or a security domain. After specifying the security requirements by the user (i.e., a designer, a developer, an administrator, or an application user), the framework, based on the context information retrieved, suggests appropriate security solutions through S&D patterns and integration schemes, allowing reasoning about alternate options, constraints, and interdependencies. This investigation leads to a final selection of a set of security solutions comprising the system’s security architecture and its deployment. Note that the framework is aware of the deployed architecture through a model describing the actual security configuration, allowing exploitation of this information upon monitoring the system at run-time or even exchanging it with other framework instances.

Patterns and Integration Schemes

The notions of S&D patterns and integration schemes are crucial to the approach, since they contain the information about an S&D solution’s effects, the link to satisfied requirements and implementations, as well as the specification of potential interferences when combining different solutions.

Patterns were first introduced in software engineering (Beck & Cunningham, 1987; Buschmann et al., 1996). This approach was then adopted to schematically describe security solutions in an informal way, for example, in Fernandez (2000; 2004), Schumacher (2003), and Schumacher et al. (2006). Security patterns describe a security solution in terms of the problem context (an abstract description of assumptions made and not to be confused with the use of the notion of “context” above), a problem statement, a solution description and implementation advice. They explicitly
Towards Adaptive Security for Ubiquitous Computing Systems

Serenity significantly extends the notion of patterns in several dimensions:

- Serenity patterns refer to properties that are provided upon deployment of the pattern (assuming all specified constraints are met, or enforced by the framework). This allows us to link user requirements to patterns, since they are expressed in terms of properties as well.
- Serenity patterns, in general, refer to an implementation, that is, program code, that is ready to be integrated into a given system implementation through a defined interface.
- Serenity patterns include obligations on the run-time of the system in terms of events to be monitored and controls to be imposed. The obligations are enforced through the framework.
- Serenity patterns are parameterized and can be hierarchical, thus increasing their flexibility and applicability.
- Security solutions in Serenity patterns are verified, preferably through formal methods. This asks for much more precise specification of a solution than the standard pattern approach does.
- A particular type of Serenity patterns, called integration schemes, allow capturing potential interference in case of patterns being combined, as well as imposing constraints with respect to their deployment.

Figure 4 shows the modeling artifacts used in Serenity. In addition to patterns, properties and implementations, the figure introduces classes as an additional abstraction level. This allows consideration of the fact that security requirements are often given in terms of general notions (like confidentiality, integrity, non-repudiation),

Figure 4. Serenity modeling artifacts: Classes, patterns, and implementation
Towards Adaptive Security for Ubiquitous Computing Systems

with these notions then being refined according to individual interpretations.

Evaluation

The Serenity idea is ambitious and likely to change the way secure systems are developed, deployed and operated. The Serenity library of patterns and integration schemes facilitates a systematic approach to accessing security expertise, based on specifications of security properties covering different layers of abstraction, from business level to network and devices level. The Serenity framework provides means to monitor and reason about a deployed security architecture and to adapt it if necessary. Thus, major requirements on security in ubiquitous computing systems are met: accessibility of security solutions to the non-expert developer, and automated support for adapting security solutions to system evolution.

The key success factors for the Serenity approach include the coverage and quality of the library entries, the integration of the specification means across the abstraction levels, the control of security architectures through the framework, and the interoperability of the security solutions. The latter is particularly challenging in heterogeneous infrastructures that are characteristic to ubiquitous computing. To ensure the feasibility of the approach, Serenity is evaluated through a number of case studies, including such varying domains as e-business, sensor networks, mobile communications, e-government, and air traffic management.

Conclusions

Serenity addresses the problem of security engineering for ubiquitous computing systems through capturing security expertise by means of enhanced patterns and integration schemes as well as providing a framework for components and devices supporting the systematic development, deployment and control of security solutions. Since the framework is aware of the deployed security architecture, feedback from security monitoring can be used to adapt the architecture according to new requirements or system evolution. Serenity’s feasibility critically depends on meeting the challenge of interoperability of the solutions made available through the patterns of the Serenity library.

Trusting Computers Through Trusting Humans:
Software Verification in a Safety-Critical Information System

Alison Adam

Paul Spedding
University of Salford, UK

ABSTRACT

This article considers the question of how we may trust automatically generated program code. The code walkthroughs and inspections of software engineering mimic the ways that mathematicians go about assuring themselves that a mathematical proof is true. Mathematicians have difficulty accepting a computer generated proof because they cannot go through the social processes of trusting its construction. Similarly, those involved in accepting a proof of a computer system or computer generated code cannot go through their traditional processes of trust. The process of software verification is bound up in software quality assurance procedures, which are themselves subject to commercial pressures. Quality standards, including military standards, have procedures for human trust designed into them. An action research case study of an avionics system within a military aircraft company illustrates these points, where the software quality assurance (SQA) procedures were incommensurable with the use of automatically generated code.

INTRODUCTION

They have computers, and they may have other weapons of mass destruction. Janet Reno, former US Attorney General

In this article our aim is to develop a theoretical framework with which to analyse a case study where one of the authors was involved, acting as an action researcher in the quality as-
This involved the production of software for aeroplane flight systems. An interesting tension arose between the automatically generated code of the software system (i.e., ‘auto-code’—produced automatically by a computer, using CASE [Computer Aided Software Engineering] tools from a high level design) and the requirement of the quality assurance process which had built into it the requirement for human understanding and trust of the code produced.

The developers of the system in the case study designed it around auto-code—computer generated software, free from ‘human’ error, although not proved correct in the mathematical sense, and cheaper and quicker to produce than traditional program code. They looked to means of verifying the correctness of their system through standard software quality assurance (SQA) procedures. However, ultimately, they were unable to bring themselves to reconcile their verification procedures with automatically generated code. Some of the reason for this was that trust in human verification was built into (or inscribed into [Akrich, 1992]) the standards and quality assurance procedures which they were obliged to follow in building the system. Despite their formally couched descriptions, the standards and verification procedures were completely reliant on human verification at every step. However these ‘human trust’ procedures were incompatible with the automated production of software in ways we show below. The end result was not failure in the traditional sense but a failure to resolve incommensurable procedures; one set relying on human trust, one set on computer trust.

Our research question is therefore: How may we understand what happens when software designers are asked to trust the design of a system, based on automatically generated program code, when the SQA procedures and military standards to which they must adhere demand walkthroughs and code inspections which are impossible to achieve with auto-code?

The theoretical framework we use to form our analysis of the case study is drawn from the links we make between the social nature of mathematical proof, the need to achieve trust in system verification, the ways in which we achieve trust in the online world, the methods of software engineering, and within that, the software quality movement and the related highly influential domain of military standards.

In the following section we briefly outline the social nature of mathematical proof. The next section discusses the debate over system verification which encapsulates many of the ideas of mathematical proof and how such proofs can be trusted by other mathematicians. The article proceeds to consider ‘computer mediated’ trust, briefly detailing how trust has been reified and represented in computer systems to date, mainly in relation to the commercial interests of e-commerce and information security. Trust is particularly pertinent in the world of safety-critical systems, where failure is not just inconvenient and financially damaging, although commercial pressures are still evident here, but where lives can be lost. The model of trust criticised by e-commerce critics is more similar to the type of trust we describe in relation to safety-critical systems, than one might, at first, expect. Understandably, we would like to put faith in a system which has been mathematically proved to be correct. However computer generated proofs, proofs about correctness of computer software, and automatically generated code are not necessarily understandable or amenable to inspection by people, even by experts. The question then arises of whether we can bring ourselves to trust computer generated proofs or code, when even a competent mathematician, logician, or expert programmer cannot readily understand them.

Following this, we describe the evolution of software development standards and the SQA movement. We argue that the development of quality assurance discourse involves processes of designing human ways of trusting mathematical evidence into standardisation and SQA. Military
standards are an important part of the SQA story, having consequences far beyond the military arena. Standards are political devices with particular views of work processes inscribed (Akrich, 1992) in their design. We note the way that military standards, historically, moved towards formal verification procedures only to move back to rely more on ‘human’ forms of verification such as code walkthroughs and inspections in the later 1990s. The story is shot through with a tension between finding ways to trust the production of information systems and finding ways to control them. Formal methods, based on mathematical proof offer the promise of control, but only if we can bring ourselves to trust a proof generated by a machine rather than a proof constructed by another person. We present the background to the case study in terms of a description of the complex ‘post cold war’ military and commercial environment. This is followed by a description of the action research methodology employed in the project, an outline of the case study and an analysis of the case study findings in terms of our theoretical framework. In the conclusion we briefly note that mathematicians and others are gradually finding ways of trusting computers.

THE SOCIAL NATURE OF MATHEMATICAL PROOF

At first sight, the concept of mathematical proof appears to be relatively simple. The idea of a logical and rigorous series of steps, leading from one or more starting positions (previous theorems or axioms) to the final conclusion of the theorem seems to be the basis of mathematics. The concept of mathematical proof leading inexorably to true and incontrovertible truths about the world is very compelling. It is not surprising that we would like to apply the apparent certainty and exactness of mathematical approaches to computer programming. However if we consider briefly how agreement on mathematical proof and scientific truth is achieved by communities of mathematicians, then the social and cultural dimension of proof, as an agreement amongst trusted expert witnesses, reveals itself.

With the epistemological and professional success of mathematical proof, many of the cultural processes which go into making a proof true sink from consciousness and are only rendered visible in times of dispute; for example as in claims to the proof of Kepler’s conjecture or Fermat’s last theorem (Davies, 2006; Kuhn, 1962; Singh, 1997). Only on the margins then do we call into question our ability to trust these people when a mathematical proof cannot be agreed to be true by an expert community of mathematicians, as sometimes happens.

The apparently pure and abstract nature of mathematical proof fairly quickly breaks down when we inspect it more closely. In particular, when there is disagreement about a proof, the nature of proof is revealed as a social and cultural phenomenon; the matter of persuading and convincing colleagues. DeMillo, Lipton, and Perlis (1977, p. 208) wrote

Mathematicians talk to each other. They give symposium and colloquium talks which attempt to convince doubting (sometimes hostile) audiences of their arguments, they burst into each others’ offices with news of insights for current research, and they scribble on napkins in university cafeterias and expensive restaurants. All for the sake of convincing other mathematicians. The key is that other mathematicians are inclined to listen!

This traditional approach towards mathematical proof, which could be described as one of persuasive rigorous argument between mathematicians leading to trust, is not the only way to address the idea of proof. A quite different approach appeared in the 1950s and was based on the work on logic developed by Bertrand Russell and others in the 1930s and used the newly invented electronic computer. This new
logic-based approach was not dependent on the computer, but the computer’s speed and accuracy had a major impact on its application to the proof of theorems in replacing the persuasive rational argument of competent mathematicians with a formal approach which sees any mathematical proof as a number of steps from initial axioms (using predicate logic), to the final proof statement (based purely on logical inference) without the requirement of a human being.

Many proofs can be completed by either method. For instance, many persuasive rigorous argument proofs can be converted to formal proofs (MacKenzie, 2004). It should be emphasised, however, that there is a real difference between the two types of proof. We are not simply talking about a machine taking on the role of a competent mathematician. Some proofs which are readily accepted by mathematicians rely on arguments of symmetry and equivalence, analogies, and leaps of imagination, which humans are very good at understanding but which a formal logic approach cannot replicate. Symmetry and analogy arguments of this type cannot be established by formal methods based on logical progression because symmetry relies on understanding semantics and cannot be gleaned from the syntax of a proof.

Whereas the persuasive rigorous argument, the ‘human’ approach, has been used for thousands of years, the formal or ‘computer generated’ approach has been in use for only about half a century. Clearly, the two methods are not treated in the same way by the expert community of mathematicians. With a rigorous argument type of proof, although one may expend much energy convincing one’s colleagues of the validity of the proof, the potential for coming to agreement or trust of the proof is there. Essentially, in trusting that a mathematical proof is correct, mathematicians are demonstrating their trust in other competent mathematicians. However, expert mathematicians clearly have trouble bringing themselves to trust computer proofs, for good reason, as a computer cannot explain the steps in its reasoning (Chang, 2004).

COMPUTER SYSTEM VERIFICATION: TRUST AND THE SOCIAL

The preceding section contrasted the use of computer technology in a claimed proof: the formal method and the human ‘rigorous argument’ approach to proof. Although this is not the same thing as the proof or verification of a computer system itself, in other words the formal, computer generated proof that the computer system matches the specification, the question of whether we can trust the computer is exactly the same.

The idea of proof or verification of a program is quite different from simply testing the program. Typically, a large suite of programs might have thousands or millions of possible inputs, and so could be in many millions or even billions of states. Exhaustive testing cannot be possible. If a computer system is to be used in the well-funded and high-profile military field to control a space craft, aeroplane, or a nuclear power station, it is highly desirable if the system can be actually proved to be correct, secure, and reliable. Since testing, although vital, can never prove the system’s correctness, more mathematical methods involving the notion of proof became of great interest in the late 1960s and have remained so ever since.

In fact the history of the verification of computer systems echoes that of mathematical proof, with basically the same two approaches: those who support the rigour of formal methods and those who believe that the purely formal, mechanised proof lacks the crucial element of human understanding (Tierney, 1993). In a paper to an ACM Symposium, DeMillo et al. (1977) argued that the two types of proof were completely different in nature, and that only the persuasive rigorous argument proof with its strong social aspect will
 ultimately be believable and capable of earning trust

COMPUTER-MEDIATED TRUST

In ethical terms, trust is a complex phenomenon and is essentially a human relationship (Nissenbaum, 1999; Stahl, 2006). We think of trust in terms of a trustor who does the trusting and a trustee who is trusted. The trustee does not of course have to be human, but Nissenbaum (1999) suggests that the trustee should be a being to whom we ascribe human qualities such as intentions and reasons, what might be termed an ‘agent.’ Trust allows meaningful relationships and a vast range of intuitions to work. Nissenbaum (1999) argues that when we are guaranteed safety trust is not needed: ‘What we have is certainty, security, safety—not trust. The evidence, the signs, the cues and clues that ground the formation of trust must always fall short of certainty; trust is an attitude without guarantees, without a complete warrant.’

Intrusive regulation and surveillance are attempts at control and bad for building trust.

This generalised definition of trust clearly maps onto our description of mathematicians trusting proofs. They may not have complete certainty over the correctness of a mathematical proof, but they have good reason to trust a competent member of the community of expert mathematicians. Therefore they can trust the proof supplied by such a person.

Understandably, there has been much interest in trust in the online world, both in terms of online security and trust in e-commerce transactions. Nissenbaum (1999) suggests that excessive safety controls, say in e-commerce, may encourage participation but they limit experience: ‘Through security we may create a safer world, inhospitable to trust not because there is distrust, but because trust cannot be nourished in environments where risk and vulnerability are, for practical purposes, eradicated.’

Stahl’s (2006) take on trust in e-commerce shows another example of the intangible human nature of trust, which has become reified and commodified, so that it can be measured and exchanged in machine transactions. Like Nissenbaum (1999), Stahl points to the way that a trustor does not have complete control over a trustee; vulnerability and uncertainty must be accepted in a trusting relationship. This of course includes business transactions, and is especially important in e-commerce as many of the traditional ways of developing trust are absent from online transactions. Trust becomes a way of generating profit; small wonder that trust, including technological ways of creating trust and maintaining it, has been of so much interest in e-commerce. In the world of e-commerce research, trusts lose its relational aspects and becomes a form of social control. ‘If trust is limited to calculations of utility maximisation in commercial exchange, then most of the moral underpinnings of the mechanisms of trust become redundant. Trust changes its nature and loses the binding moral quality that it has in face-to-face interaction.’ (Stahl, 2006, p. 31)

Although, on the face of it, Nissenbaum’s and Stahl’s arguments on the problems of online trust in e-commerce are not the same as the issue of trust described in the body of this article, there are important congruencies which are very directly applicable to our characterisation of trust. Whether it is a human trusting another human or an expert mathematician trusting another expert mathematician to supply an accurate proof, the same relationship between trustor and trustee obtains.

For Nissenbaum and Stahl, the issue is what happens to trust when it is commodified within an online relationship. In other words, what happens when the human-trusting-human relationship is mediated by technology? In this article we also consider what happens when the human-trusting-human relationship—in terms of a human trusting another human’s mathematical proof, or computer program—is replaced by a human
having to trust a machine. Of course, in this truster-trustee relationship, the trustee, that is, the machine, cannot be understood in the way that another person can be.

The pressure to create computer-mediated trust is completely bound up with commercial pressures. The maximisation of profit drives the reification of trust in e-commerce. Similarly in the world of military avionics we describe, it is the commercial pressure of building systems more cheaply and faster which provides the impetus to turn over proofs, testing of programs, and automatic generation of code to a machine.

A third aspect of similarity between Stahl’s and Nissenbaum’s view of computer-mediated trust and ours relates to the tension between trust and control. This is clearly present in the debate over trust in e-commerce. But it is also present in software quality discourse as we discuss below.

In the following section we briefly discuss some of the ways in which human trust has traditionally been built into procedures designed to verify program correctness, and how this can be seen to mirror an ideal group of mathematicians agreeing upon a mathematical proof.

**BUILDING TRUST INTO A COMPUTER SYSTEM**

We argue that, historically, much of the development of the software engineering discipline can be understood in terms of the development of procedures, through which we can convince ourselves to trust, and control, the development of information systems and the production of software. For instance, Myers’ (1979) classic book on software testing explores the topic of human testing in detail, justifying methods such as formal code inspections and code walkthroughs. The differences between the two methods depend on different usages of the terms ‘inspection’ and ‘walkthrough,’ but the important point is that both involve a small group of professionals carefully reading through code together. We argue that this can be viewed as an imitation of the social (persuasive rigorous argument) form of proof described earlier where ‘mathematicians talk to each other’ in symposia and colloquia and so on (DeMillo et al., 1977). The original programmer should be in the group, analogous to the mathematician demonstrating a proof or principle to expert colleagues. The aim (as originally suggested by Weinberg [1971]—an ‘egoless’ approach) is to discover as many errors as possible rather than to try to demonstrate that there are none. So the team is to act as an idealised group of ‘Popperian’ scientists looking for ‘refutations’ (Popper, 1963). Under such an approach, one can never be entirely sure that the code is correct. But, as the walkthrough proceeds, the original programmer and the code inspection team can gradually come to trust the code as bugs are weeded out and fixed.

Myers claims positive advantages of code inspections and walkthroughs, including the value of the original programmer talking through the design (and thus spotting the errors). He also notes the ability of human testers to see the causes and likely importance of errors (where a machine might simply identify symptoms) and also the likelihood that a batch of errors will be identified simultaneously. Also the team is able to empathise with and understand the thought processes of the original programmer in a way which a machine arguably cannot. Importantly, the team can be creative in its approach. In working together they also, inevitably, form something of a sharing and trusting community (even if it is disbanded after a day or two).

The lesson gleaned from human verification techniques, such as walkthroughs and code inspections, is that these have been regarded, for some time, as reliable, if not exhaustive, ways of ensuring reliability of software.
SOFTWARE QUALITY ASSURANCE AND MILITARY STANDARDS FOR SOFTWARE

The software verification techniques of code walkthroughs and inspections are important parts of the armoury SQA. Effectively, we argue that SQA is a branch of software engineering which formalises and standardises the very human methods of trust, and ultimately control outlined above, which we need to build into software engineering procedures. The SQA movement is an important part of the story of the growth of software engineering because of its quest for rigour and control of potentially unruly programs and programmers.

First of all, SQA offers a promise of rational control over software, the software development process, and those who produce software. Software quality criteria include features for directing, controlling, and importantly, measuring the quality of software (Gillies, 1997). ‘Qualification’ is achieved when a piece of software can be demonstrated to meet the criteria specified in these quality procedures. An important aspect of SQA involves demonstrating that software meets certain defined independent standards.

The development and adherence to software standards is a very important part of the story of SQA. Generic industry standards are available, but also of much interest—particularly for the case study set out later in the article—are military standards. Indeed, the defence industry is so influential that Tierney (1993) argues that military standards influence software engineering far beyond applications in defence. Hence military standards are a very important part of SQA, and ultimately are important in formalising ways in which designers of computer systems can come to trust the systems and the production of correct software.

A number of military standards have been developed to regulate and control the use of software in defence applications. For instance, US standards DOD-STD-2167A (1988), MIL-STD-498 (1994), and ISO/IEC 12207 (1995) respectively established the requirements for software development and documentation in all equipment to be used by the US military (and effectively that of all Western armed forces), introduced object oriented development (OOD) and rapid application development (RAD), then broadened the scope of international standards to include acquisition and maintenance. (DSDM Consortium, 2006).

The relevant UK standard 00-55, (MoD, 1997) Requirements for Safety Related Software in Defence Equipment, was published in 1997 and echoes much of MIL-STD-498, but moves the discussion on provably correct software in a particular direction. At first sight, this seems highly significant to the current argument, because it clearly expressed a preference for formal methods, in other words mathematical procedures whereby the software is proved to be correct by a machine (MacKenzie, 2001).

Tierney (1993) argues that the release of UK Defence Standard 00-55 in draft in 1989 had the effect of intensifying the debate over formal methods in the UK software engineering community. It devoted as much space to regulating and managing software development labour processes as the techniques and practices to be used for formal designs. This reinforces our argument that SQA is concerned with control of work processes and those who perform them, the software developers. On the one hand, many argued that mathematical techniques for software development and verification could only ever be used sparingly, as there simply was not enough suitable mathematical expertise in most organisations and it increased software quality at the expense of programmer productivity. On the other side, those from a more mathematical camp argued that there was commercial advantage in proving software correctness as errors could be
trapped earlier in the software development cycle (Tierney, 1993, p. 116).

Designed into the MoD (UK Ministry of Defence) standard was a view of safety-critical software as an important area of regulation and control. Some of the reason for this was a change in its own organisation from the 1980s. The UK government sought to open up work traditionally done in-house by the MoD in its own research establishments to private contractors (Tierney, 1993, p. 118). Given that it had to offer its software development to the private sector, it built in ways of controlling it within its defence standards (Tierney, 1993, p. 118). Further political impetus was offered by the introduction of consumer protection legislation in the UK in the late 1980s which required software developers to demonstrate that their software had not contributed, in the event of an accident enquiry, and that they had demonstrably attended to safety. Thus we can see that in Def Stan 00-55, politics, in the shape of the MoD’s need to open up software development to the private sector and also to avoid being held responsible for inadequate software in the event of an accident, played an important role.

However, more significantly, this document has itself been superseded in 2004 by (draft) standard 00-56 (MoD, 2004). Def Stan 00-55 has now become obsolete. The changes involved in Def Stan 00-56 are of great interest, in that the preference for formal method is lessened. In the new standard, it is accepted that provably correct software is not possible in most cases and that we are inevitably involved in a human operation when we attempt to show that code is reliable in a safety-critical environment. Without a more detailed consideration of the history of formal methods in the UK over the last decade, which is beyond the scope of the present article, a strong claim that the move back to more human methods of verification might be difficult to sustain. Nevertheless it is interesting to note the way that Def Stan 00-5, with its emphasis on formal approaches and attendant onerous work practices, has been consigned to the history books with a clear move back to human verification.

**CASE STUDY CONTEXT**

The case study relates to a large European military aircraft company (MAC) with which one of the authors was engaged as a researcher in a joint research project, lasting around three years, during the mid to late 1990s. A high proportion of the senior management were men and its culture was masculine in style, particularly emphasising an interest in engineering and technical mastery (Faulkner, 2000). Indeed there was much interest, pleasure, and admiration for elegant products of engineering (Hacker, 1991). When one of their fighter planes flew over (an event difficult to ignore on account of the engine noise), offices would clear as employees went outside to admire the display of a beautiful machine. A certain amount of military terminology was used, sometimes ironically, in day-to-day work. A number of employees had links with the armed forces. MAC was exclusively involved in the defence industry, with the UK’s MoD being its largest customer and other approved governments buying its products.

As a manufacturing company in an economy where manufacturing was in steep decline and with its ties to the defence industry, if a major defence contract went elsewhere, jobs would be on the line. Despite the ‘hi-tech’ nature of its work, MAC had a traditional feel to it. The company had existed, under one name or another, right from the beginning of the avionics industry. The defence industry, and within that the defence aerospace industry, faced uncertain times as the UK government was redefining its expectations of the defence industry in post-Cold War times. It quickly came to expect much clearer demonstrations of value for money (Trim, 2001). Therefore, the ‘peace dividend’ brought about by the end of the Cold War meant uncertain times for the defence aerospace industry as military
spending was reduced significantly (Sillers & Kleiner, 1997). Yet, as an industry contributing huge amounts to the UK economy (around £5 billion per annum in export earnings Trim (2001, p. 227)), the defence industry is hugely important in terms of revenue and employment. Defence industries have civil wings (which was the case with MAC) and it was seen as important that the defence side of the business did not interfere with civil businesses. For instance, BAE Systems is a partner in a European consortium and was pledged £530 million as a government loan to develop the A3XXX aircraft to rival the USA’s Boeing 747 (Trim, 2001, p. 228).

Although not strictly a public sector organisation itself, its location in the defence industry put MAC’s business in the public sector. However, in the UK, views of public sector management were undergoing rapid change in the mid 1990s and it was seen as no longer acceptable that the taxpayer should underwrite investment (Trim, 2001). Such firms were required to be more competitive and to be held more accountable financially. Hence, quality management and value for money were becoming key concepts in the management repertoire of the UK defence industry from the mid 1990s onwards. As we discuss in the preceding section, this was at the height of the UK MoD’s interest in formal approaches to the production of software. In a climate where post-Cold War defence projects were likely to demand a shorter lead time, there was considerable interest in speeding up the software development process.

Computer technology and related activity clearly played a central role in MAC. One division of MAC, the Technical Directorate (TD), developed most of the airborne software (much of it real-time). This software clearly has a central role in ensuring aircraft performance and safety. Around 100 people were involved in developing systems computing software. It was in this division that Software Development System (SDS), a safety-critical airborne software system for flying military aircraft, was developed.

Research Methodology

The methodological approach of the research was based on action research (Myers & Avison, 2002). As several successful participant observation studies in technology based organisations have been reported in the literature (Forsythe, 2001; Low & Woolgar, 1993; Latour & Woolgar, 1979), an ethnographic approach holds much appeal. However, a strict ethnographic approach was neither feasible nor desirable in this study. As someone with technical expertise, the researcher could not claim to be the sociologist or anthropologist, more typical of reported ethnographic studies of technological systems (Low & Woolgar, 1993; Forsythe, 2001). This also meant that he was not ‘fobbed off’ by being directed into areas that the participants thought he wanted to look at or where they thought he should be interested in as happened in the Low and Woolgar (1993) case study. Based in the Quality Assurance Division (QAD) in the SQA team, early in his research, the researcher proved his technical credentials by helping run a workshop on software metrics and this helped to gain him full inclusion in the technical work. Although as a technical researcher, rather than a social researcher, it was arguably difficult for him to maintain the ‘anthropological strangeness’ which ethnographers look for in explaining the common sense and every day logistics of working life. In any case, he had been invited, through this research, to make a contribution to the improvement of SQA procedures. Therefore the research can be characterised as a form of action research (Baskerville & Wood-Harper, 1996), where potential improvements to SQA were to be seen as the learning part of the action research cycle.

Although action research receives a mixed press from the IS research community (Baskerville & Wood-Harper, 1996; Lau, 1999), it is nevertheless seen as a way of coming to grips with complex social settings where interactions with information technologies must be understood within the context of the whole organisation.
Baskerville (1999) notes the growing interest in action research methods in information systems research. Two key assumptions are that complex social settings cannot be reduced for meaningful study and that action brings understanding (Baskerville, 1999). The culture of MAC was extremely complex, as we characterise above and discuss again in what follows. Arguably, key elements would be lost were the researcher to have adopted a more distant role, relying on interviews and questionnaires rather than becoming fully immersed and contributing to the detail of the project. The researcher adopted an interpretivist approach, looking to the interpretations of the other participants of the research. But by allowing for social intervention he became part of the study, producing shared subjective meanings between researcher and subjects as coparticipants in the research (Baskerville, 1999).

For a period of over one year out of the three that the whole project lasted, the researcher spent, on average, one day per week working with MAC staff with access to a variety of staff across the organisation, and was therefore able to participate in a range of meetings and workshops and to gain a familiarity with the individuals concerned. This could not easily have been gained from interviews or surveys. These events included meetings where software quality staff considered quality policy, such as the implication of international standards, to broader meetings where technical staff were considering development methods in detail. Free access was allowed to relevant policy and development documents. This permitted an overview of the detailed practices and culture of this large and complex organisation.

**Analysis of Case Study Findings**

The initial remit of the researcher was to work with staff to optimise the use of software quality assurance within the organisation. The use of cost benefit analysis was originally suggested by senior management. Given our characterisation of the UK defence industry’s particular focus on management of quality and value for money, as described above, it is entirely in keeping with the industry’s changing needs that the researcher was initially directed into these areas. The researcher viewed it as problematic to assign monetary cost to SQA activities, and even harder to assign monetary benefits. However, these concerns were never addressed directly in the project as it soon emerged that there was greater interest in a new approach to software development being pioneered by MAC.

Ince (1994, p. 2-3) tells the story of a junior programmer’s first day in a new job. A senior programmer shows him around, advising him where to buy the best sandwiches at lunchtime, where to find the best beer after work, and other similarly important matters. Then the senior colleague points to a door. ‘Whatever you do don’t go through that door, the people there have been given the job of stifling our creativity.’ The door, of course, led to the quality assurance department.

The staff of MAC’s Quality Assurance Division expressed some similar feelings, albeit less dramatically. They wanted to act as consultants, offering a measure of creativity to the technical development process, although safely wrapped in appropriate quality assurance processes, but all too often they felt like the police. The strong awareness of the safety-critical nature of software development, and the related fairly advanced organisation of quality assurance in MAC, thanks in no small measure to the necessity to adhere to MoD standards, meant that SQA was never going to get quite the negative press that it attracted in Ince’s (1994) anecdote. Nevertheless, there was still some feeling that the Quality Assurance Division could be brought on board in a project some time after the Technical Division had time to do the creative part.

Hence, TD had been prototyping the new SDS system for about a year when they decided to bring in Quality Assurance Division. As we explain
below, the newness of the style of development in SDS made it unclear how it was to be quality assured. Unsure of how to proceed, the SQA manager turned to the researcher for suggestions. The researcher now became involved in investigating the use of the new software development approach, which would involve the inclusion of computer generated program code (’auto-code’) in safety-critical airborne software systems, leading to the approval of the new approach and its incorporation into MAC’s software quality assurance systems.

Although there has been a long tradition of using computers to aid the process of software engineering itself, such CASE tools (Pressman, 2005) have not generally been used to generate safety-critical code (this was always written by human programmers). The new MAC SDS was an ambitious system whose targets were principally to reduce avionics systems development time by 40% and the cost by 30%, whilst maintaining the very high quality standards necessary for computer-based system which fly—and therefore can crash—military aircraft.

A key aspect of SDS was process integration using an integrated modeling environment. There was consequentially a heavy reliance on automated methods. A specification was developed in a formal modeling language and this generated programming code automatically. In particular, automatic code generation was eventually to lead to aircraft flying ‘auto-code’ in safety-critical systems. Two aspects of SDS stand out in the climate of defence spending of the mid 1990s.

First, there was pressure to reduce costs and show value for money. Second, the use of formal methods in computer programming received a huge boost in the mid-1990s through the Defence standard DEF Stan 00-55 which mandated the use of formal methods base approaches in safety-critical software. It is not surprising that there was considerable interest in a system which offered the promise of considerably reduced software production times.

MAC invested a great deal of money and time in SDS in the hope that the improved time-scales which SDS promised, together with reduced costs, could keep major current aircraft developments on course. This was particularly important in an environment of political intervention and considerable public interest and concern over escalating costs and delivery times in the public sector, including the defence industry. These benefits could only accrue to MAC if the quality, that is, correctness of the software, could be assured.

SDS was heavily dependent on software (CASE) tools. MAC had used these for many years, and had procedures in place for their qualification (i.e., acceptance) in certain circumstances. However, these applied to mission-critical rather than safety-critical systems. Furthermore, the movement towards auto-generated code led to a different environment than one where tools improved and speeded up the design process, but where failure would show up and be merely time-wasting. There was seen to be a need for a major improvement/update of these procedures, a quantum change, before they would be acceptable for safety-critical applications.

Some tools being used had major world-wide user communities, associated academic conferences, and came from supposedly secure and reliable suppliers. Others might not be so well supported, both intellectually and commercially. (For instance, it might be no use having an ideal tool if the supplier was small and unlikely to survive for many years.) Methods already existed for supplier qualification. These methods were undertaken by software quality staff. However, the qualification of these suppliers could be a crucial issue in the qualification of the tool and ultimately the integrity of the avionics system. The issue was not merely one of qualification, it was also one of demonstration of qualification to customers. Ultimately, the need in some sense to prove the new methods became paramount. Hence we can see that quality procedures did not just involve procedures, such as code walkthroughs through
which software teams could persuade themselves to trust program code, they also applied to the question of choosing and trusting suppliers.

A number of meetings took place with members of the SDS team. This discussion was very useful for an understanding of SDS and gave the researcher a richer understanding of the SQA needs. It soon became apparent that the necessary fundamental problems with SQA in SDS were going to be difficult to answer.

The difficulties were centred around two conflicting ideas. The first of these was that for the persuasive rational argument approach to be successful there would be a need for a group of professionals to participate in code walkthroughs, with consequent discussion and persuasion. On the face of it, this was simply not possible, since the computer which wrote the auto-code could not take part in such a discussion. Alternative approaches were considered. Clearly there would be a stage before the auto-code (at the requirements specification level) where human agents were involved, but this was found to be too high level to meet the relevant military standards (the US MIL-STD-498 [1994] and the UK standard 00-55 [MoD, 1997]). Both standards are very specific about the exact conduct of the necessary walkthrough. It had to be a code walkthrough.

On the other hand, for the formal proof approach method to work, there would first need to be such a formal proof. This did not seem within the capability of the QAD itself, despite the division being quite well resourced. MAC referred back to the auto-code tools suppliers, but once again there was no such proof and no realistic possibility of achieving such a proof. Although MAC was an important customer for the auto-code tool suppliers, they were not prepared to expend the necessary resources. Furthermore, a ‘weakest link’ argument demonstrates a fundamental flaw with the formal approach in computer systems. If the auto-code tool itself could be formally verified, it would then become necessary also to consider the operating system on which the tool would run and the hardware systems involved. Potentially this could involve a seemingly infinite regression of hardware and software systems having to be proved correct, where the system is only as good as its weakest link. Frustration grew as no solution was forthcoming and ultimately SDS was shelved indefinitely.

We have argued that mathematical proof is essentially a human achievement between members of the expert mathematical community who are persuaded of the correctness of mathematical proofs because they trust each other. These processes of trust are replicated in the procedures that have been developed in software engineering, and within that, software quality assurance. As part of the defence industry, developing safety-critical systems, MAC had highly developed SQA procedures which were obliged to follow international military standards. Their code walkthroughs, which are analogous to the ways mathematicians achieve trust in a proof, were an important part of such quality procedures. Formal methods offer the promise of an attractive certainty and control over software production and hence control over the work processes of human programmers. They also offer the promise of automatic verification of software systems which, potentially, could be much cheaper than traditional human based approaches to the verification of software through traditional SQA procedures.

SDS achieved very little despite the huge efforts put into it by the many people working for MAC. Although it was not, at the time, formulated in such stark terms, success was elusive because an attempt was being made to achieve the impossible: namely using auto-code whilst being held to quality assurance procedures which demanded code walkthroughs which could not possibly be achieved in an auto-code system. Attempts were made to consider formally proving the correctness of the auto-code. In addition to supplier reluctance, this raised the spectre of the infinite regress. If
one looks to proving the auto-code correct, then
the operating system must be proved correct, the
hardware platform and so on.

This was at the height of interest in formal
methods for safety-critical systems for defence,
a view embodied in Def Stan 00-55. The rise
of formal methods is crucially linked to the de-
fence industry. The interest in formal methods
and automated approaches arrived as pressure
mounted on Western governments to prove cost
effectiveness due to the changing nature of defence
developments after the end of the Cold War and
the need to avoid litigation for software that might
be implicated in an accident. Yet the difficulties of
applying formal methods in systems of any level
of complexity and the need to trust the program
code acted as a spur to maintain complex human
centred software quality assurance procedures.

CONCLUSION:
TRUSTING COMPUTERS

There is much evidence that we already do trust
computers in many walks of life without formal
proof or other formal demonstration, even to the
extent of trusting safety-critical systems such as
the ‘fly by wire’ software in the Boeing 777
airliner, two million lines of code which have not
been fully proved (Lytz, 1995). Expert mathemati-
cians have begun to accept computer generated
proofs, albeit in qualified ways (Chang, 2004).
entrepreneurs’ of computerised risk ensure that
warnings about computerised risk are heeded
so that safety-critical software is avoided and,
where it is unavoidable, much care is taken over
its development. Military standards, so detailed
about the use of formal methods in software design
and attendant work processes in the 1990s, have
moved a decade later to be much less prescriptive
about the work methods of ensuring software
quality, thereby allowing for the crucial element
of human inspection in order that the software
may be trusted. As Collins (1990) notes, we are
remarkably accommodating to computers, mak-
sing sense of them and involving them in our social
networks, and will continue to find imaginative
ways of doing so. This echoes Nissenbaum’s (1999)
view that we may trust computers if we can treat
them as ‘agents.’ We may meaningfully ascribe
intentions and reasons to them.

In this article we have sought to tell a story of
trust, in particular how software may be trusted
when it is not produced by a human programmer.
This involves consideration of a complex
set of discourses including the question of math-
ematical proof and how proof is achieved within
mathematical communities. We see a similar
need to replicate such human processes of trust
in trusting computer systems. We have argued
that the making of standards to be applied within
software quality assurance procedures shows
ways in which mechanisms of trust are inscribed
in software standards. Our case study, an action
research project in a military aircraft company,
demonstrates the difficulties which occur when
quality assurance procedures involving code
walkthroughs—procedures with built-in human
trust mechanisms—are incommensurable with
a system which relies on auto-code. The climate
of defence research and spending was a major
influence, both on our case study and the wider
development of standards. There is a continued
tension between needing to trust and trying to
control: trusting the software and controlling its
production. The story which we tell here is one
of continuing human ingenuity in finding ways
of trusting computer software.

Chapter 7.17
Global Information Ethics: The Importance of Being Environmentally Earnest

Luciano Floridi
Universita degli Studi di Bari, Italy, & Oxford University, UK

ABSTRACT

The article argues that Information Ethics (IE) can provide a successful approach for coping with the challenges posed by our increasingly globalized reality. After a brief review of some of the most fundamental transformations brought about by the phenomenon of globalization, the article distinguishes between two ways of understanding Global Information Ethics, as an ethics of global communication or as a global-information ethics. It is then argued that cross-cultural, successful interactions among micro and macro agents call for a high level of successful communication, that the latter requires a shared ontology friendly towards the implementation of moral actions, and that this is provided by IE. There follows a brief account of IE and of the ontic trust, the hypothetical pact between all agents and patients presupposed by IE.

INTRODUCTION:
FROM GLOBALIZATION TO INFORMATION ETHICS

Globalization is a phenomenon too complex even to sketch in this brief introduction. So I hope that I shall be forgiven if I am rather casual about many features that would deserve full attention in another context. Here, I wish to highlight just six key transformations characterising the processes of globalization. I shall label them contraction, expansion, porosity, hybridization, synchronization, and correlation. They provide the essential background for making sense of the thesis developed in the rest of the article, which is that Information Ethics (IE) can provide a successful approach for coping with the challenges posed by our increasingly globalized reality.
Global Information Ethics

Contraction

The world has gone through alternating stages of globalization, growing and shrinking, for as long as humanity can remember. Here is a reminder:

In some respects the world economy was more integrated in the late 19th century than it is today. ... Capital markets, too, were well integrated. Only in the past few years, indeed, have international capital flows, relative to the size of the world economy, recovered to the levels of the few decades before the first world war. (The Economist, 1997)

The truth is that, after each “globalization backlash” (think of the end of the Roman or British Empires), the world never really went back to its previous state. Rather, by moving two steps forward and one step back, sometime towards the end of the last century the process of globalization reached a point of no return. Today, revolutions or the collapse of empires can never shrink the world again, short of the complete unravelling of human life as we know it. Globalization is here to stay.

Globalization has become irreversible mainly thanks to radical changes in worldwide transport and communications (Brandt & Henning, 2002). Atoms and bytes have been moving increasingly rapidly, frequently, cheaply, reliably, and widely for the past 50 years or so. This dramatic acceleration has shortened the time required for any interactions: economic exchanges, financial transactions, social relations, information flows, movements of people, and so forth (Hodel, Holderegger & Lüthi, 1998). And this acceleration has meant a more condensed life and a contracted physical space. Ours is a smaller world, in which one may multitask fast enough to give and have the impression of leading parallel lives. We may regain a nineteenth-century sense of distance (space) and duration (time) only if one day we travel to Mars.

Expansion

Human space in the twenty-first century has not merely shrunk, though. ICTs have also created a new digital environment, which is constantly expanding and becoming progressively more diverse. Again, the origins of this global, transnational common space are old. They are to be found in the invention of recording and communication technologies that range from the alphabet to printing, from photography to television. But it is only in the last few decades that we have witnessed a vast and steady migration of human life to the other side of the screen. When you ask, “Where were you?,” it is now normal and common to receive the answer “Online”. More than 6 million people throughout the world play World of Warcraft, currently the leading subscription-based MMORPG (massively multiplayer online role-playing game, http://www.blizzard.com/press/060119.shtml). Globalization also means the emergence of this sort of single virtual space, sharable in principle by anyone, any time, anywhere.

Porosity

An important relation between our contracting physical space and our expanding, virtual environment is that of porosity. Imagine living as a flat figure on the surface of an endless cylinder. You could travel on the surface of the cylinder as a two-dimensional space, but not through it. So in order to reach any other point on the cylinder, the best you could do would be to follow the shortest path (geodesic) on the cylindrical surface. The empty space inside the cylinder would be inconceivable, as a third dimension would. Imagine now that the surface became porous and hence that a third dimension were added. The geodesics would be revolutionized, for you could travel through the vacuum encircled by the cylinder and reach the other side, thus significantly shortening your journeys. To use the rather apt vocabulary of surfing, you would be tubing: space would be curling
over you, forming a “tube”, with you inside the cylindrical space. From a 2D perspective, you would literally come in and out of space. This sort of porosity characterizes the relation now between physical and virtual space. It is difficult to say where one is when one is “tubing”, but we know that we can travel through cyberspace to interact with other physical places in a way that would have been inconceivable only a few decades ago. Telepresence (Floridi, 2005) in our porous environment is an ordinary experience and this is also what globalization means.

**Hybridization**

During the last decade or so, we have become accustomed to conceptualize our life online as a mixture between an evolutionary adaptation of analogue/carbon-based agents to a digital/silicon-based environment, and a form of postmodern, neocolonization of the latter by the former. This is probably a mistake. The threshold between analogue-carbon-offline-here and digital-silicon-online-there is fast becoming blurred, but this is as much to the advantage of the latter as it is of the former. Adapting Horace’s famous phrase2, “captive cyberspace is conquering its victor”. ICTs are as much re-ontologising (that is, modifying the essential nature of) our world as they are creating new realities. The digital is spilling over into the analogue and merging with it. This recent phenomenon is variously known as “ubiquitous computing”, “ambient intelligence”, or “the Internet of things” (ITU report, November 2005, http://www.itu.int/internetofthings), and it is, or will soon be, the next stage in the digital revolution. In the (fast approaching) future, objects will be *I*entities able to learn, advise, and communicate with each other. “RoboticCookware” is already available (http://www.vitacraft.com.nyud.net:8090/rfiq/home.html); MP3 players will soon be able to recommend new music to their users by learning from the tunes they (the users, we had better be clear) enjoyed (http://www.semanticaudio.com/). Your next fridge (http://www.lginternetfamily.co.uk/homenetwork.asp) will inherit from the previous one your tastes and wishes, just as your new laptop can import your favourite settings from the old one; and it will interact with your new way of cooking and with the supermarket Web site, just as your laptop can talk to a printer or to another computer. We have all known this in theory for some time; the difference is that it is now actually happening in our kitchen.

Globalization also means the emergence of this common, fully interactive, and responsive environment of wireless, pervasive, distributed, *a2a* (anything to anything) information processes, that works *a4a* (anywhere for any time), in real time. We are probably the last generation to experience a clear difference between onlife and online.

**Synchronization**

In a world in which information and material flows are becoming so tightly integrated and enmeshed, it is not surprising to see global patterns emerging not only from well-orchestrated operations (consider the tedious experience of any launch of a major blockbuster, with interviews in magazines, discussions on TV programs, advertisements of merchandise, and by-products throughout the world, special food products in supermarkets and fast-food, etc.), but also inadvertently, as the result of the accidental synchronization of otherwise chaotic trends.

All of a sudden, the world reads the same novel, or wears the same kind of trousers, or listens to the same music, or eats the same sort of food, or is concerned about the same problems, or cherishes the same news, or is convinced that it has the same disease. Some of this need not be the effect of any plan by some Big Brother, a secret agency, a powerful multinational or any other *deus ex machina* that is scheming behind the curtains. After all, worldwide attention span is very limited
and flimsy, and it is very hard to compete for it. The truth is that at least some global trends may merely arise from the constructive interference of waves of information that accidentally come into phase, and hence reinforce each other to the point of becoming global, through the casual and entirely contingent interaction of chaotic forces. It may happen with the stock markets or the fashion industry or dietary trends. The recurrent emergence of temporarily synchronized patterns of human behaviour, both transculturally and transnationally, is a clear sign of globalization, but not necessarily of masterminded organization. There is no intelligent plan, evil intention, autonomy, or purposeful organization in the billion snow flakes that become an avalanche. Social group behaviour is acquiring a global meaning. The distributed power that generates Wikipedia is the other side of the dark, mindless stupidity of millions of slaves of fashions and trends.

**Correlation**

Imagine a safety net, like the one used in a circus. If it is sufficiently tight and robust, the heavier the object that falls into it, the larger the area of the net that will be stretched, sending waves of vibration throughout the net. Globalization also refers to the emergence of a comparable net of correlations among agents all over the world, which is becoming so tight and sensitive that the time lag in the transmission of the effects of an event “dropping” on it is fast shortening, to the point that sometimes there is almost no distinction between what counts as local or remote. Global often means not everywhere but actually delocalized, and in a delocalized environment social friction is inevitable, as there is no more room for agents that allows for absorption of the effects of their decisions and actions. If anyone moves, the global boat rocks.

**Globalising Ethics**

If we consider now the profound transformations just sketched, it would be rather surprising if they did not have serious implications for our moral lives (see Ess, 2002; Weckert, 2001). In a reality that is more and more physically contracted, virtually expanded, porous, hybridized, synchronized, and correlated, the very nature of moral interactions, and hence of their ethical analysis, is significantly altered. Innovative forms of agenthood are becoming possible; new values are developing and old ones are being reshaped; cultural and moral assumptions are ever more likely to come into contact when not into conflict; the very concepts of what constitutes our “natural” environment and our enhanced features as a biological species are changing; and unprecedented ethical challenges have arisen (a reference to the notorious problem of privacy is de rigueur here), just to mention some macroscopic transformations in which globalization factors, as sketched above, play an important role.

What sort of ethical reflection can help us to cope successfully with a world that is undergoing such dramatic changes? Local approaches are as satisfactory as burying one’s head in home values and traditions. The ethical discourse appears to be in need of an upgrade to cope with a globalized world. Each ethical theory is called upon to justify its worldwide and cross-cultural suitability. This seems even more so if the theory in question seeks to address explicitly the new moral issues that arise from the digital revolution, as it is the case with IE.

I shall say more about IE in the next two sections. The specific question that I wish to address is whether, in a world that is fast becoming more and more globalized, information ethics can provide a successful approach for dealing with its new challenges. I shall argue in favour of a positive answer. But to make my case, let me first clarify what global information ethics may mean.
Global-Communication Ethics vs. Global-Information Ethics

There are at least two ways of understanding Global Information Ethics: as an ethics of global communication (Smith, 2002) or as a global-information ethics (Bynum & Rogerson, 1996). Since I shall concentrate only on the latter, let me briefly comment on the former first.

Global-information ethics, understood as an ethics of worldwide communication, may be seen as a commendable effort to foster all those informational conditions that facilitate participation, dialogue, negotiation, and consensus-building practices among people, across cultures and through generations. It is an approach concerned with new and old problems, caused or exacerbated by global communications or affecting the flow of information. Global-communication ethics is therefore a continuation of policy by other means, and it does not have to be reduced to a mere gesture towards the importance of mutual respect and understanding (meeting people and talking to each other can hardly do any harm and often helps). It is, however, faced by the serious problem of providing its own justification. What sort of ethical principles of communication and information are to be privileged and why? Is there any macroethics (e.g., some form of consequentialism or deontologism or contractualism) that can rationally buttress a global-communication ethics? And is not any attempt at providing such a macroethics just another instance of “globalization” of some values and principles to the disadvantage of others? Without decent theorization, the risk is that we will reduce goodness to goodiness and transform the ethical discourse into some generic, well-meant sermon. At the same time, a robust foundation for a global-communication ethics may easily incur the problem of failing to respect and appreciate a plurality of diverse positions. The dilemma often seems to be left untouched, even when it is not overlooked. The good news is that it may be possible to overcome it by grounding a global-communication ethics on a global-information ethics.

Global-Information Ethics and the Problem of the Lion

If we look at the roots of the problem, it seems that:

1. In an increasingly globalized world, successful interactions among micro and macro agents belonging to different cultures call for a high level of successful communication; but
2. Successful, cross-cultural communications among agents require, in their turn, not only the classic three “e”s—embodiment, embeddedness and hence experience (a sense of “us-here-now”)—but also a shared ontology (more on this presently); and yet
3. Imposing a uniform ontology on all agents only seems to aggravate the problem, globalization becoming synonymous with ontological imperialism.

By “ontology” I do not mean to refer here to any metaphysical theory of being, of what there is or there is not, of why there is what there is, or of the ultimate nature of reality in itself. All this would require a form of epistemological realism (some confidence in some privileged access to the essential nature of things) that I do not hold, and that, fortunately, is not necessary to make my case. Rather, I am using “ontology” to cover the outcome of a variety of processes that allow an agent to appropriate (be successfully embedded in), semanticize (give meaning to and make sense of), and conceptualize (order, understand, and explain) the agent’s environment. In simplified terms, one’s ontology is one’s world; that is, the world as it appears to, is experienced and interacted with, by the agent in question.
Agents can talk to each others only if they can partake to some degree in a shared ontology anchored to a common reality to which they can all refer.4

Imagine two solipsistic minds, α and β, disembodied, unembedded, and devoid of any experience. Suppose them living in two entirely different universes. Even if α and β could telepathically exchange their data, they could still not communicate with each other, for there would be absolutely nothing that would allow the receiver to interpret the sender. In fact, it would not even be clear whether any message was being exchanged at all.

The impossibility of communication between α and β is what Wittgenstein (2001) had in mind, I take it, when he wrote that “if a lion could talk, we could not understand him.” The statement is obviously false (because we share with lions a similar form of embeddedness and embodiment, and hence experiences like hunger or pain) if one fails to realize that the lion is only a placeholder to indicate an agent utterly and radically different from us, like our α and β. The lion is a Martian, someone you simply cannot talk to because it is “from another ontology”.5

From this perspective, the famous phrase hic sunt leones (here there are lions) acquires a new meaning. The phrase occurred on Roman maps to indicate unknown and unexplored regions beyond the southern African borders of the empire.6 In a Wittgensteinian sense, the Romans were mapping the threshold beyond which no further communication was possible at all. They were drawing the limits of their ontology. What was beyond the border, the locus inhabited by the lions, was nothing, a nonplace. Globalization has often meant that what is not inglobate simply is not, that is, fails to exist.

We can now formulate the difficulty confronting a global-information ethics as the problem of the lion: cross-cultural communication, which is the necessary condition for any further moral interaction, is possible only if the interlocutors partake in a common ontology. When Crusoe and Friday meet, after 25 years of Crusoe’s solitude, they can begin to communicate with each other only because they share the most basic ontology of life and death, food and shelter, fear and safety. Agents may be strangers to each other (“stranger” being an indexical qualification7). They do not have to speak the same language, empathize, or sympathize. But they do need to share at least some basic appropriation, semanticization, and conceptualization of their common environment, as a minimal condition for the possibility of any further moral interaction.

Can information ethics provide a solution to the problem of the lion? The short answer is yes; the long one is more complicated and requires a brief diversion, since it is now necessary to be more explicit about what I mean by information ethics.

Global Information-Ethics and Its Advantages

Information ethics8 is an ontocentric, patient-oriented, ecological macroethics. An intuitive way to unpack this definition is by comparing IE to other environmental approaches.

Biocentric ethics usually grounds its analysis of the moral standing of bio-entities and eco-systems on the intrinsic worthiness of life and the intrinsically negative value of suffering. It seeks to develop a patient-oriented ethics in which the “patient” may be not only a human being, but also any form of life. Indeed, land ethics extends the concept of patient to any component of the environment, thus coming close to the approach defended by information ethics. Any form of life is deemed to enjoy some essential proprieties or moral interests that deserve and demand to be respected, at least minimally if not absolutely, that is, in a possibly overridable sense, when contrasted to other interests. So biocentric ethics argues that the nature and well-being of the patient of any action constitute (at least partly) its moral standing and that the latter makes important claims on the interacting agent, claims that in principle ought to contribute to guiding the agent’s ethical decisions and constraining the agent’s moral
behaviour. The “receiver” of the action is placed at the core of the ethical discourse, as a centre of moral concern, while the “transmitter” of any moral action is moved to its periphery.

Now substitute “existence” for “life” and it should become clear what IE amounts to. IE is an ecological ethics that replaces biocentrism with ontocentrism. It suggests that there is something even more elemental than life, namely being—that is, the existence and flourishing of all entities and their global environment—and something more fundamental than suffering, namely entropy. The latter is most emphatically not the physicists’ concept of thermodynamic entropy. Entropy here refers to any kind of destruction or corruption of entities understood as informational objects (not as semantic information, take note), that is, any form of impoverishment of being, including nothingness, to phrase it more metaphysically.9

We are now ready to appreciate some of the main advantages offered by information ethics when it comes to the new challenges posed by globalization.

1. Embracing the New Informational Ontology

Not only do we live in a world that is moving towards a common informational ontology, we also experience our environment and talk and make sense of our experiences in increasingly informational ways. Information is the medium. This calls for an ethics, like IE, that, by prioritising an informational ontology, may provide a valuable approach to decoding current moral phenomena and orienting our choices.

2. Sharing a Minimal, Horizontal, Lite Ontology

There is a risk, by adopting an ontocentric perspective, as IE suggests, that one may be merely exchanging one form of “centrism” (American, Athenian, Bio, European, Greek, Male, Western, you-name-it) with just another, perhaps inadvertently, thus failing to acknowledge the ultimate complexity, diversity, and fragility of the multicultural, ethical landscape with which one is interacting. We saw how the problem of the lion may become a dilemma. This justified concern, however, does not apply here because IE advocates a minimal informational ontology, which is not only timely, as we have just seen, but also tolerant of, and interfaceable with, other local ontologies. Thick cultures with robust, vertical ontologies—that is, deeply-seated, often irreconcilable, fundamental conceptions about human nature, the value and meaning of life, the nature of the universe and our place in it, society and its fair organization, religious beliefs, and so forth—can more easily interact with each other if they can share a lite, horizontal ontology as little committed to any particular Weltanschaung as possible. The identification of an absolute, ultimate, monistic ontology, capable of making all other ontologies merge, is just a myth, and a violent one at that. Yet the alternative cannot be some form of relativism. This is no longer sustainable in a globalized world in which choices, actions, and events are delocalized. There simply is not enough room for “minding one’s own business” in a network in which the behaviour of each node may affect the behaviour of all nodes. The approach to be pursued seems rather to be along the lines of what IE proposes: respect for and tolerance towards diversity and pluralism and identification of a minimal common ontology, which does not try to be platform independent (i.e., absolute), but cross-platform (i.e., portable).

As in Queneau’s Exercises in Style, we need to be able to appreciate both the ninety-nine variations of the same story10 and the fact that it is after all the same story that is being recounted again and again. This plurality of narratives need not turn
into a Babel of fragmented voices. It may well be a source of pluralism that enriches one’s ontology. More eyes simply see better and appreciate more angles, and a thousand languages can express semantic nuances that no global Esperanto may ever hope to grasp.

3. Informational Environmentalism

The ontocentrism supported by IE means that at least some of the weight of the ethical interpretations may be carried by (outsourced to) the informational ontology shared by the agents, not only by the different cultural or intellectual traditions (vertical ontologies) to which they may belong. Two further advantages are that all agents, whether human, artificial, social or hybrid, may be able to share the same minimal ontology and conceptual vocabulary; and then that any agent may take into account ecological concerns that are not limited to the biosphere.

4. Identifying the Sources and Targets of Moral Interactions

One of the serious obstacles in sharing an ontology is often how the sources and targets of moral interactions (including communication) are identified. The concept of person or human individual, and the corresponding features that are considered essential to his or her definition, might be central in some ontologies, marginal in others, and different in most. IE may help foster communication and fruitful interactions among different, thick, vertical ontologies by approaching the problem with conceptual tools that are less precommitted. For when IE speaks of agents and patients, these are neutral elements in the ethical analysis that different cultures or macro-ethics may be able to appropriate, enrich, and make more complex, depending on their conceptual requirements and orientations. It is like having an ontology of agency that is open source, and that anyone can adapt to its own proprietary Weltanshaung.

The Cost of a Global-Information Ethics: Postulating the Ontic Trust

It would be silly to conclude at this point that a global-information ethics may provide an answer to any challenge posed by the various phenomena of globalization. This would be impossible. Of course, there will be many issues and difficulties that will require substantial extensions and adaptations of IE, of its methodology and of its principles. All I have tried to do is to convince the reader that such a great effort to apply IE as a global ethics would be fruitful and hence worth making.

It would be equally wrong to assume that the adoption of IE as a fruitful approach to global challenges may come at no conceptual cost. Every ethical approach requires some concession on the part of those who decide to share it and IE is no exception.

The cost imposed by IE is summarizable in terms of the postulation of what I shall define as the ontic trust binding agents and patients. A straightforward way of clarifying the concept of ontic trust is by drawing an analogy with the concept of “social contract”.

Various forms of contractualism (in ethics) and contractarianism (in political philosophy) argue that moral obligation, the duty of political obedience, or the justice of social institutions, have their roots in, and gain their support from a so-called “social contract”. This may be a real, implicit, or merely hypothetical agreement between the parties constituting a society (e.g., the people and the sovereign, the members of a community, or the individual and the state). The parties accept to agree to the terms of the contract and thus obtain some rights in exchange for some freedoms that, allegedly, they would enjoy in a hypothetical state of nature. The rights and responsibilities of the parties subscribing to the agreement are the terms of the social contract, whereas the society, state, group, an so forth, are the entity created for the purpose of enforcing the
agreement. Both rights and freedoms are not fixed and may vary, depending on the interpretation of the social contract.

Interpretations of the theory of the social contract tend to be highly (and often unknowingly) anthropocentric (the focus is only on human rational agents) and stress the coercive nature of the agreement. These two aspects are not characteristic of the concept of ontic trust, but the basic idea of a fundamental agreement between parties as a foundation of moral interactions is sensible. In the case of the ontic trust, it is transformed into a primeval, entirely hypothetical \textit{pact}, logically pre-dating the social contract, which all agents cannot but sign when they come into existence, and that is constantly renewed in successive generations.\textsuperscript{11}

The sort of pact in question can be understood more precisely in terms of an actual trust. Generally speaking, a trust in the English legal system is an entity in which someone (the trustee) holds and manages the former assets of a person (the trustor, or donor) for the benefit of certain persons or entities (the beneficiaries). Strictly speaking, nobody owns the assets. Since the trustor has donated them, the trustee has only legal ownership and the beneficiary has only equitable ownership. Now, the logical form of this sort of agreement can be used to model the ontic trust, in the following way:

- The assets or “corpus” is represented by the world, including all existing agents and patients;
- The donors are all past and current \textit{generations} of agents;
- the trustees are all current \textit{individual} agents;
- The beneficiaries are all current and future \textit{individual} agents and patients.

By coming into being, an agent is made possible thanks to the existence of other entities. It \textit{is} therefore bound to all that already is both \textit{unwillingly} and \textit{inescapably}. It \textit{should} be so also \textit{caringly}. Unwillingly, because no agent wills itself into existence, though every agent can, in theory, will itself out of it. Inescapably, because the ontic bond may be broken by an agent only at the cost of ceasing to exist as an agent. Moral life does not begin with an act of freedom but it may end with one. \textit{Caringly} because participation in reality by any entity, including an agent—that is, the fact that any entity is an expression of what exists—provides a right to existence and an invitation (not a duty) to respect and take care of other entities. The pact then involves no coercion, but a mutual relation of appreciation, gratitude, and care, which is fostered by the recognition of the dependence of all entities on each other. A simple example may help to clarify further the meaning of the ontic trust.

Existence begins with a gift, even if possibly an unwanted one. A foetus will be initially only a beneficiary of the world. Once it is born and has become a full moral agent, it will be, as an individual, both a beneficiary and a trustee of the world. It will be in charge of taking care of the world, and, insofar as it is a member of the generation of living agents, it will also be a donor of the world. Once dead, it will leave the world to other agents after it and thus becomes a member of the generation of donors. In short, the life of an agent becomes a journey from being only a beneficiary to being only a donor, passing through the stage of being a responsible trustee of the world. We begin our career of moral agents as strangers to the world; we should end it as friends of the world.

The obligations and responsibilities imposed by the ontic trust will vary depending on circumstances but, fundamentally, the expectation is that actions will be taken or avoided in view of the welfare of the whole world.

The ontic trust is what is postulated by the approach supported by IE. According to IE, the ethical discourse concerns any entity, understood informationally, that is, not only all persons, their cultivation, well-being, and social interac-
tions, not only animals, plants, and their proper natural life, but also anything that exists, from buildings and other artefacts to rivers and sand. Indeed, according to IE, nothing is too humble to deserve no respect at all. In this way, IE brings to ultimate completion the process of enlargement of the concept of what may count as a centre of a (no matter how minimal) moral claim, which now includes every instance of being understood informationally, no matter whether physically implemented or not. IE holds that every entity, as an expression of being, has a dignity, constituted by its mode of existence and essence (the collection of all the elementary proprieties that constitute it for what it is), which deserve to be respected (at least in a minimal and overridable sense) and hence place moral claims on the interacting agent and ought to contribute to guiding and constraining the agent’s ethical decisions and behaviour. The ontic trust (and the corresponding ontological equality principle among entities) means that any form of reality (any instance of information/being), simply by the fact of being what it is, enjoys a minimal, initial, overridable, equal right to exist and develop in a way which is appropriate to its nature.¹²

The acceptance of the ontic trust requires a disinterested judgement of the moral situation from an objective perspective, that is, a perspective which is as non-anthropocentric as possible. Moral behaviour is less likely without this epistemic virtue. The ontic trust is respected whenever actions are impartial, universal and “caring” towards the world.

CONCLUSION

One of the objections that is sometimes made against IE is that of being too abstract or theoretical to be of much use when human agents are confronted by very concrete and applied challenges (Siponen, 2004). Unfortunately, this is an obvious misunderstanding. Imagine someone who, being presented with the declaration of human rights, were to complain that it is too general and inapplicable to solve the ethical problems the person is facing in a specific situation, say in dealing with a particular case of cyberstalking in the company that employs the person. This would be rather out of place. The suspicion is that some impatience with conceptual explorations may betray a lack of understanding of how profound the revolution we are undergoing is, and hence how radical the rethinking of our ethical approaches and principles may need to be in order to cope with it. IE is certainly not the declaration of human rights, but it seeks to obtain a level of generality purporting to provide a foundation for more applied and case-oriented analyses. So the question is not whether IE is too abstract—good foundations for the structure one may wish to see being built inevitably lie well below the surface—but whether it will succeed in providing the robust framework within which practical issues of moral concern may be more easily identified, clarified, and solved. I agree that it is in its actual applications that IE, as a global ethics for our information society, will or will not qualify as a useful approach; yet the need to build on the foundation provided by IE is an opportunity, not an objection.

ENDNOTES

1 For a very synthetic but well-balanced and informed overview, I would recommend Held and McGrew (2001). In their terminology, I am a subscriber to the transformationalist approach, according to which “globalization does not simply denote a shift in the extensity or scale of social relations and activity. Much more significantly, argue the transformationists, it also involves the spatial re-organization and re-articulation of economic, political, military and cultural power” (see Held et al., 1999).

2 *Graecia capta ferum victorem cepit*- Epistles.

3 How an ontology is achieved and what sort of philosophical analysis is required to make sense of its formation is not a relevant matter in this context, but the interested reader may wish to see Floridi and Sanders (in press).

4 More technically, this means that two agents can communicate only if they share at least some possible level of abstraction. On the method of abstraction see Floridi and Sanders (2004) and Floridi and Sanders (in press).

5 If it took endless time and efforts to decipher the hieroglyphics, imagine what sense an extraterrestrial being could make of a message in a bottle like the plaque carried by the Pioneer spacecraft (http://spaceprojects.arc.nasa.gov/Space_Projects/pioneer/PN10&11.html)
Unfortunately, we do not have African maps drawn from the “lions’ perspective”. The Da Ming Hun Yi Tu, or Amalgamated Map of the Great Ming Empire, the oldest map of Africa known so far, dates back “only” to 1389.

Indexical expressions, such as “here”, “yesterday”, or “I”, acquire their meaning or reference depending on who utters them and in which circumstances. Thus, “stranger” is indexical (people are strangers to each others), whereas the original meaning of “barbarian” is not, if we believe its Greek etymology to be “to babble confusedly”, that is, someone who is unable to speak Greek properly.

The IEG, a research group in Oxford, has developed a general interpretation of Information Ethics in a series of papers. Here I provide a summary based on Floridi [in press]. The interested reader is invited to check the Web site of the group at http://web.comlab.ox.ac.uk/oucl/research/areas/ieg/.

Destruction is to be understood as the complete annihilation of the object in question, which ceases to exist; compare this to the process of “erasing” an entity irrevocably. Corruption is to be understood as a form of pollution or depletion of some of the properties of the object, which ceases to exist as that object and begins to exist as a different object minus the properties that have been corrupted or eliminated. This may be compared to a process degrading the integrity of the object in question.

On a crowded bus, a narrator observes a young man with a long neck in a strange hat yell at another man whom he claims is deliberately jostling him whenever anyone gets on or off the bus. The young man then sits down in a vacant seat. Two hours later the same narrator sees that same young man with another friend, who is suggesting that the young man have another button put on his overcoat.

There are important and profound ways of understanding this Ur-pact religiously, especially but not only in the Judeo-Christian tradition, where the parties involved are God and Israel or humanity, and their old or new covenant (διαθήκη) makes it easier to include environmental concerns and values otherwise overlooked from the strongly anthropocentric perspective prima facie endorsed by contemporary contractualism. However, it is not my intention to endorse or even draw on such sources. I am mentioning the point here in order to shed some light both on the origins of contractualism and on a possible way of understanding the onto-centric approach advocated by IE.

In the history of philosophy, a similar view can be found advocated by Stoic and Neoplatonic philosophers, and by Spinoza.
Chapter 7.18

Emotional Digitalization as Technology of the Postmodern: A Reflexive Examination from the View of the Industry

Claus Hohmann
Bergische Universitaet Wuppertal, Germany

ABSTRACT

This article introduces emotional digitalization as a phenomenon of future information systems. It argues that emotional digitalization is a progress that will lessen the gap between technology and humanity, as well as between computer and man. The author develops and verifies his assumption besides theoretical references arising from his experiences with the information technology within the BrandLand Autostadt.

INTRODUCTION

“The inmost force/which binds the world, and guides its course” is no longer only a philosophical thought or religious voice, as in Goethe’s “Faust,” verse 382-383. But they are also not just bits and bytes, cable and monitors. The connection of these elemental substructures of modern civilization first shows where the path must go. The functional elements of our daily life must subordinate themselves to our principles of thought and aesthetics. And they must also appeal to the people in an aesthetic, as well as communicative and sense. The modern, as a synonym for freedom and democracy, could thereby obtain a new dimension — to become an ethical entity. The technology of the third millennium must also define the new standards.

As the postmodern breaks down the barriers between art and pleasure, it breaks through the wall between technology and emotion. The aesthetic sensation from looking at, for example, a corporate homepage, accessible to all, suggests a fundamental change in the meaning which will be attributed to the presentation of technology today, when in direct comparison with the functional-rationalistic views of modern, purely informational Web sites. The Autostadt, Volkswagen’s new communication platform for marketing and
Emotional Digitalization as Technology of the Postmodern

culture, is on several levels a culmination of different developments, which operate under the term “postmodern” and therefore contribute to theoretical discussion.

This radical change of the basic conditions of our life has put us on a path which will be indicated by a catchy, yet imprecise phrase: “postmodernity.” The rationalization of the modern is being counteracted by the pluralization of our culture and humanization of technology, which was demanded, but not achieved, by the modern (Giddens, 1995). With Anthony Giddens, whose critique is applied here, we regard “posthistory“ as “a succession of immanent changes,” in order to face the prevalent conceptual dilemma (Giddens, 1995). One focuses the view to information technologies and sees that the humanization has an effect, particularly on aesthetics. And here alongside the desired effects lies a formidable danger: does IT go in the same ambivalent direction as the classic technologies, and will it give the manipulators of this world a leg up?

THE WORLD TODAY AND TOMORROW

The core problems of the industrial society (saturated markets, over-indebtedness, mass unemployment, etc.) demanded drastic mental reorientation and have at the same time uncovered innovation potentials. Spirituality and mental dimensions begin to replace the abstraction — the dream becomes a legend. The new technologies of the third millennium must also surrender to these new demands. With help from the most current technologies, we learn to tell stories. Contrary to the findings of Lyotard from the end of the great narrations of history1, one could also speak about a fragmentation, which transfers this narration from people to technology, especially the digital technologies. With a new neologism, one speaks of the necessity of a “homuter society,” which is in a position to propitiate the people with (information) technologies (Haefner, 1984). Haefner uses this term freely in order to verbalize his skepticism of the possibilities of future developments, which was obtained during the Cold War. However, we could also read it with a conscious hope.

Thus, a great possibility of the future lies in the development of technologies, stimulating creativity and inspiring thoughts. For example, the aesthetic layout of an intranet and the constantly used user interfaces eases the employee’s accessing of the media, prevents fatigue from using information and inspires emotions in the exposure to IT in everyday work. The effect is to state a higher degree of identification to the corporation, a more emotional, eventually better relationship to the employer and, ultimately and ideally considered, an increased labor efficiency accompanied by increased happiness. In this manner, IT of the postmodern can manage the reconciliation of the contradictions between technology and art, which are unimaginably present in the modern.

The IT of the present has the function of supporting the thoughts and actions of the individual and not to automate their work in order to eventually replace them. Comparably, the focus should be put on the installation of technologies that will save time. IT must be used to support work processes in order to optimize the concrete procedures and reduce the time requirements. Networked, Web-based systems with access points for all employees could be a first step. Important here are the user interfaces, which are adjusted to the work processes, aesthetically configured, self-explanatory, intuitive and can be understood spontaneously, thereby helping save time and increase room for further assignments.

The same exposed meaning, which electrification and mechanization had for the modern, could be digitization and computerization in the postmodern. The unreality, which challenges our terminology and understanding in increased
Emotional Digitalization as Technology of the Postmodern

measure, seems to be a display of something new in relation to the more palpable technological advances of the modern. We see, in this transition of information technology, a movement for a new understanding of our time, which can be labelled as “postmodern,” which is in this sense, in the shadows of abstract, fragmentary, and simultaneously emotional media. Thereby, no clearly differentiated epochs or outlined theories should be suggested — it should continue to deal with a change in our perception and “Lebenswelt.” In doing so, we understand postmodern as the “conscious of a socio-historical transition” and not as a “meta-historical category” of each epoch.

One of the basic requirements of this transition is the change from a technology that replaces the people to a technology that supports the people because they “understand” it. Thereby, it is imperative to restore various elements of IT, from management decisions and business processes down to connections with trade and commerce, to an original understanding of “experience.” The anchor of the complicated, indiscernible world in tangible lives can show in this manner how postmodernity can be made visible. The metaphor can be helpful to establish the meaning behind the experience.

POSTMODERNITY AND IT

The implementation and deployment of aesthetics in the technological area is a characteristic of the realization that IT is anchored fast in our world and no longer accepted as a modern achievement of an exceptional position outside our consciously experienced everyday life. This insight allows changed societal requirements to be inferred, but what about the above meaning is postmodern? Important is our understanding after the liberation from a conditioned past in a (self-) conscious act. As the technologies of modernity stand out due to their distinctiveness and are clearly contrasted with the people and their emotional world in which they coldly, precisely, and rationalistically fulfill their duties, the IT of postmodernity goes down a different path.

With the integration of aesthetics and emotion, the digitization completes the circle and appears as a new quality. This is only successful because IT has already begun to reflexively examine and question itself and its success, and not in the least can be measured as a clearly calculated result of other factors. A basic requirement, therefore, is the development of technology that supports activities with which people are discontent as a result of the holistic pursuit of new goals, with the focus on the people. IT must be there for the people, not the other way around, and it must be aware of this. It must be noticeable, but not necessarily visible.

When the technologies in our new world function imperceptibly and no longer distort the view of the contents from the surface, new space for aesthetics and emotion is created. Technological progress can and must give the people more time, space and capacity for creativity and to unleash their imagination to make the fundamental, structural change perceptible and understandable. In sociological terms, postmodernity seems to accompany the departure from middle-class feudalism. Information technology, which has been more or less privatized by the personal computer (PC), can also lead to further democratization and contribute to free communication, but it can also lead to chaos by making corporations unmanageable.

Thus, in the end the various technology images of “two cultures,” which are “Lebenswelt”- and system-orientated, according to Charles Percy Snow, should be brought into unison. But in order to accomplish this, technology will be considered as a social phenomenon, with the help of metaphor and symbolization. The symbols must orient themselves on the life-world, in that they become a part of the life-world. Just as modernity, with
its dichotomies and ambivalences, can be said to be a failure in dialect, it is conceivable that the discussion in the postmodern, founded in the definition of difference, will reveal endeavors leading to the harmony between the various positions. Contrary to Lyotard’s assertion, unanswerable contradictions, which lie in the open availability of information, could strengthen the democratizing tendencies of information technologies.

**WITH THE EYES OF INDUSTRY**

With the beginning of the new millennium, the world changes its vision. The blind trust of technology has a conscious practice of giving way to its possibilities. For example, Volkswagen’s new corporate platform culture and marketing—the Autostadt allows this change, which is currently being experienced by industry and society, to be precisely identified. With this example, we want to discuss the topic of postmodernity from the view of information technology, in order to stimulate further thoughts from the industry. Progress is nowadays something completely different, as it questions itself. Reflexivity and self-criticism take the place of the unconscious self-awareness of modern advances. Technology along with the information technology of modernity has undertaken a rapid development, which leaves the people and their imagination helplessly behind. In the physical sense, it is completely impossible to grasp IT, and an attempt at understanding it requires shifting the focus from a purely technical, modern-rational meaning to the interpersonal: addressing emotions via aesthetics, design and a process-logical functioning.

In practical industrial terms, the example of a “gated community,” such as the Autostadt, is used here to illustrate this transformation and discuss postmodernity in the digital light of information technology, in order to stimulate further ideas. The Volkswagen Group’s Autostadt presents itself as a holistic concept, which includes all details in a complex structure: “There are no details in the execution”. The mass tourism and amusement parks shape the leisure time culture of modernity, but the Autostadt vastly transcends this. It integrates, specifically with the involvement of IT, the science of the world of industry with the goal of getting through to the people.

The privatization of technology has extended continually since the 1980s the influence and impact of IT to all areas of life, but especially to the areas of personal computers and music and television technologies, and also to all other levels of everyday life. With the Autostadt, the attempt is made to take on these societal changes and harmoniously unite them. In the Autostadt, the ubiquity of IT starts with the central purpose of the corporation, namely the delivery of new cars from the Volkswagen Group to its customers. The delivery process is completely supported by digitization. From the ordering to the handing over of the new Volkswagen to the customer, IT technologies are deployed to support the process. Already in the sales dialog, the employee, by making use of online applications, is enabled to have a virtually intimate discussion, having a positive impact.

Also presentations, such as the LupoShow (a dramatic laser show demonstrating the internal functions of an automobile via cross-section model), the SunFuelLab (a plant computer, which generates personally assigned biofuels) or the NavigationsSpiel (a virtual Labyrinth), are entirely digitally controlled. However, even internal support processes such as the lighting controls in the buildings and at events, the watering of the on-site parks and the digital menus in the restaurants are based on IT technologies and displayed systematically. In all of these areas, IT supports the employees, as it is deployed in order to assist them in effectively accomplishing their work and saving time.

Naturally, this all comes with limits: the Autostadt has not realized certain global interactivity, and their video arts suggest only a portion of the
"Iconic Turn" of these years \(^{11}\), but even with the example of the Autostadt, it’s clear that the practical IT supports a form of the philosophy of imagery. The Autostadt is thereby also active in the area of bringing to life aesthetic contents in the framework of its marketing scene, and in this lies a threshold experience.

Entities such as the Autostadt must have come into existence, not as a storm of individual thoughts, but rather as a logical consequence of the mentioned societal changes. The Autostadt is then an answer to the liberation of the postmodern individual, unique to the VW Group, and thereby not a blueprint that can be taken as a model for others. In doing so, what can the technology accomplish?

The industry serves here as an aesthetic-philosophical realization, and in the case of the Autostadt, the first deliberate BrandLand. The societal developments have encouraged, if not called for, the opening of more subtle theme parks. Others have just been, or are yet to be, opened: Daimler-Chrysler, the BMW-World and Dr. Oetker, just to name a few from the nearby surroundings. With the help of IT, the economy of aesthetics and art can be greatly improved.

The interfaces of the IT, acting as the window to foreign worlds, allow a new “cultural relocation” in the sense of “immobile mobility”\(^{12}\), which places the people back in the focus. This liberation of the realm of reality expands, in a virtual manner, the consciously experienced world of the individuals, which would be impossible without IT. The people learn, experience, fulfill desires (and generate new desires) and expand their horizons via purposefully installed, yet unconsciously experienced, IT. The IT gives the phenomenology of perception\(^{13}\) a new, different touch. Multiperspective observation possibilities allow a concrete regard to objects and forms of interactivity. In this way, IT allows us to consider something from all sides, without forcing us to change our, or its, location.

The Autostadt is also a symbol for a trend. Corporations today present themselves differently. But what exactly is the Autostadt?

THE AUTOSTADT PROJECT

At a crucial interface, residing between the company and society, and with the old factory in the background in order to illustrate the coexistence of industry and BrandLand, the Autostadt is presented as a landscaped park with integrated, individually configured brand pavilions, where nature and technology are connected in an aesthetic manner so that the relevance of the corporate values are consciously absorbed by the people via the polyvalently applied presentations. The fundamental concept does not view art as a decorative end in itself, but rather as “a link between designed environments and the visitor experiencing them”\(^{14}\).

The borders between art and presentation are blurred in this regard. Culture, understood as a variable system of seeking truth and orientation relating to a variety of artistic forms of expression, education, and living, is finally the added value, which allows the Autostadt to obtain visitors. Thereby, it shows itself as an innovative cultural platform in a new understanding of the marketing of experiences and events\(^{15}\).

In this context, great significance is given to the development of innovative technologies, as the visible, evident use of digitization would inevitably undermine the functioning of the entire concept of the Autostadt based upon art and aesthetics. The organizational level of the Autostadt has therefore been deliberately made invisible and moved to underground tunnel systems and cable ducts. This form of understatement certainly gives the nearly ambitious technology a poetic touch. And just one step further are the Web-based information
Emotional Digitalization as Technology of the Postmodern

The glass auto-towers with their transparent aesthetics give the sublimity back to the technology and astonish the observer, yet their architecture, infused with aesthetics, prevents fright from their size, which large technologies commonly provoke. And in the park, the straight line, as the enemy of everything living, is already conceptually forbidden. Intuition and emotionality operate in the place of regularization and rationalization. The Autostadt triggers as the identification location of a momentum, that which is required of good advertisements (Jung & von Matt, 2003). In doing so, it takes in the danger of a novel logo-centric aberrance, as the brand, for which the logo is emblematic, outshines the product (Klein, 2001). What happens here is the becoming of a metaphor. The BrandLand, with its architecture, becomes a metaphor for the contents, the values of a corporate group, and simultaneously for the manner in which the underlying IT will be deployed in the postmodern.

The implementation of these requirements in the framework of the superior philosophy of a customer-oriented, personal technology seems to be a success. With examples such as the CCC (Customer Care Center) and the IAS (Integrated Autostadt System), the changed awareness with regard to the integration of technology in the personal and organizational relationships allows itself to be realized. It becomes clear that the path to a new, more emotional technology is possible and necessary. The Autostadt takes the first important steps on this long path. Beginning with the installation of networking and dataflow, which are not visible anywhere on the grounds of the park, to the artistic arrangement of the exhibits, which utilize the technical possibilities of imagery, sound and movement without seeming intrusive, and even with the Internet presence, which gives preference to aesthetics over self-presentation, technology gains acceptance and meaning in the service to ideas and content.

THE DIGITAL HEART: INVISIBLE NETWORKS

Embedded in a concept of future-oriented service is where the heart of the Autostadt beats. The “digital heart” is thereby probably only a paradox. Technology no longer presents itself, but rather it puts itself in the service of the people and subordinates to them. Digital technology, originally considered to be cold and sober, should become communicative and people-oriented, only to appear on the surface when necessary. This new “warmth” of the digital world can be transferred from the visitor to the relationship to the Volkswagen Group, and serves as a branding strategy based upon emotions. This is related to the paradigm shift in which technology is expected, regardless of its importance, to adapt to the people and act in the background like a good butler or referee.

The beautifully maintained park should have a convincing effect on the guests, positively touching the senses. Together with the architecture, it subliminally conveys an important message of the corporation; perfection. Thereby, it should convey a constant ability to renew itself. This breaking-out of the limits of style has the goal of higher quality and better service: the guest should feel well taken care of, safe and understood. But in order to ensure that this “emotional work” produces the “right” emotions, the IT systems are trusted with the responsible task of ensuring that the customer is served flawlessly. As the computer, with its algorithmic, binary-coded thinking, simplifies the concept of rationality, IT in the postmodern society can once again combine information with emotion and come across with a humanized approach (Glaser, 1994). “The chip-revolution,” says Glaser, “with its algorithmic, binary-coded thinking, made the concept of rationality radically one-sided”
Emotional Digitalization as Technology of the Postmodern

—with the danger of dehumanization, but yet the postmodern society still combines information and emotion (Glaser, 1994).

With the example of the Autostadt, it is recognizable that steps for a realization of the postmodern are just passable in the area of IT. Whereas the postmodern is concerned comparatively little with reality, the people-conscious deployment of IT shows that the path to a new, more emotional technology is possible and necessary. Endeavours such as the Autostadt take the first steps on this long path. To a far greater extent than in previous decades, today one’s wishes, demands and requirements constitute the parameters of successful process engineering.

The human aspect, particularly in such a service-oriented environment, assumes absolute priority. Thus, the Autostadt is not to be understood as a demonstration of technology; but rather as putting itself in the service of, and subsequently subordinating itself to, the people and the demonstration. In other words, without IT much of the Autostadt would not have been realizable, and thereby cannot be dismissed, but still presents itself in a gentle understatement. Due to this fact, it is explainable why the CTO (Chief Technology Officer) of the Autostadt is not an IT-specialist, but rather pursues psychodynamic and organizations-logical aspects in the exposure of IT in the Autostadt and thus sees his emphases in this area.

**IT AND POSTMODERNITY IN THE AUTOSTADT**

The Autostadt is, as the communication platform of the Volkswagen Group, the actual location of direct dialog between the producer and the consumer, the meeting point for the VW Group and its brands. The values of Volkswagen and the delivery of its automobiles will be “staged” here. The “stylistic device” of the Autostadt is infused with emotions and the urbanistic overall concept is based on the paradigm “structure and event.” Every square meter is staged, and nature and technology meet in a dialog, which is significantly supported by IT.

The IT in the Autostadt constantly produces new, surprising, emotion-awakening effects. For this reason, it is correct to assume that the actual core process of the Autostadt is the “process of generating feelings,” which should then be subsequently visualized. Based on its philosophy, the Autostadt pioneers new and surprising trails in the world of IT. A paradigm shift takes place, which can rightly be referred to as “emotional digitization.”

The concurrence of park, buildings, exhibits, staff and events results in a unity of the main components of emotional stimulants at the Autostadt. The conveyance of perfection is an attribute for which most individuals strive. In this sense, the charisma of the park positively influences the senses and subliminally conveys an important message of the corporate group. The buildings are also in accordance, as they portray a measure of perfection. They are constructed as entirely modern and stylistic. The visitor discovers methods of construction which are seldom, if ever, to be seen in normal surroundings. Beside the perfection, a new effect develops: the progress, orientation to new pathways, and the ability to continually reinvent itself.

With images, metaphors and sequences, the corresponding philosophies of the brands will be conveyed in the individual pavilions, giving further impulses to the above characteristics. In addition, in the events, the impossible will often be made possible with style. Further stylistic devices are also present in the perfection and progress. The Autostadt would like to inform the customer of new trends, acting as the trendsetter for the corresponding impulses.

For example, the POIs (Points of Information) are central components of the information landscape, but in the Autostadt, the POIs are elements of the Lebenswelt. The highly complex network
Emotional Digitalization as Technology of the Postmodern

computer with its front-end software allows itself to be intuitively understood and operated. The guests are not only using systems, but they are experiencing technology. The POIs approach the visitor and they adapt to the user’s size and position. Direct contact with the touchscreen can be seen as a metaphor for human interaction with the invisible network of information technology. As “emotional engineering,” this connection can be understood as a link between the complexities of IT, human gestures and aesthetics. The physically present technologies undergo an emotional exchange with the intellectual techniques to allow the visitor interactive comprehension.

We strive for understatement — that is how we see post-modern IT, which is what makes it possible to “produce” emotions in this context in the first place. Digital technology must be communicative and people-oriented. The complex system structure clearly shows the workload involved in making IT “invisible.” How is it possible to control something that is nearly invisible? Or to state it more clearly, how is the Autostadt itself capable of identifying possible malfunctions at the earliest point in time? Solutions have been found for this. With the bidirectionally media control system “Creston,” the presentations and the technology are systematically monitored. Thus the technology becomes self-referential.

All employees of the Autostadt have access, via PC workstations or central lounges for the Web-based intranet, to all information, e-mail and the Internet. The technology would better be described as “experienced” rather than “used.” This proves that the possibilities of digitization can be used and exploited to prepare the visitor for what they will experience. The invisible, unobtrusive digital elements can help make sure people will not be forgotten, even in a technological environment. Even the demand of philosophy for avant-garde art “within scientific-technical modernization rationality” can only be fulfilled where technology creates space (and scope) for art and aesthetics.

THE FUTURE OF IT

Has postmodernity found its end in the attempt to unify its differences? Have we at least reached a new level of the postmodern, with our humanization-oriented technology? And we continue to ask: where will information technology go from here? We no longer pull levers, we push a virtual button on a touchscreen and in the real world a reaction follows; a lamp goes on, a door closes or a lawn sprinkler starts watering. The same fascinating moments offered by technology in its early mechanical stages are now being provided by virtual technology. Is modernity simply repeating itself on a higher, more abstract level, or is this the beginning of something new?

In the interactive worlds of virtual media, something like a metaphor crystallizes itself out of reality. Due to IT, we experience and learn things that would normally be far out of reach. And what comes along are the new medias demand and encourage a strengthened inclusion of aesthetics in our daily life, and as each is more unobtrusive, its effect becomes stronger. Thus, the success of IT lies in its inclusion in our daily life, which must take place without obstruction and recognition.

The Internet presence of the Autostadt connects a demand of aesthetics to the POIs. The design quality, in which both Web-based systems will communicate informative content and interactive elements, has already been awarded prizes from, among others, New York and Cannes. In an intranet, which is (regarding its public sister) conceptionally and aesthetically behind in nothing, the employees can inform themselves about all-important concerns of the corporation. Standards will also be set here, almost unnoticeable to the public.

The formative characteristic of this aesthetic demand is not the eye-catching distinctive feature, but rather the opposite: the enjoyable appearance, the pleasing control of the view and the (visual) self-explanatory function and order, which lie
behind the contents. These aesthetics in the simulation of contents is effectively “unmodern” in a cultural sense, as a principal departure from rationalization. The people experience IT, they use it subconsciously. IT, as a medium, will be internalized and no longer understood and perceived as a “machine,” a tool, or means to an end. IT will become a medium for emotions and information. The visualized aesthetics of virtual worlds serve in the same way as the aesthetic architecture in the Autostadt.

One could also see the Autostadt as a metaphor, but it was not planned this way. It is a frame of reference for the characteristics and symbols of the postmodern world (not only for the area of IT). Everything – the automobile, as well as the art – will be presented in a different, atypical context. The character systems interlock virtually, and what results is a BrandLand as a liminal space, an area of the threshold, a location of change and the intervention – the barely apprehensible space between the world, which causes a threshold experience of the senses. A location, where we can foretell the future, without being able to see it.

What remains? The IT has taken a significant step: it has become a production factor; it has retreated to the background of business processes, because an IT-networked implementation is the prerequisite for “the social dimension of processes.” The workforce can no longer continue to work autistically. Interdisciplinary qualities such as commercial knowledge and organization talent are vital, at least in strategically decisive positions. The supporting IT does not serve as only the acceleration of postmodern phenomena such as globality and mobility, but it also serves – in a far more readily available manner – as the bridge between the aestheticizing and emotionalizing of our everyday world!

But it will not stop here. It is conceivable that IT in future mechanical engineering will not exist as a purpose in its own right, but will produce tools (systems) for the generation of products, to transfer knowledge. This forces everyday aspects back in the place of revolution, and finally integrates IT permanently into our postmodern world. In spite of all the risks of abuse and autonomy that accompany IT, the possibilities are there.

The Paleolithic Stone Age Effect?

Gender Differences Performing Specific Computer-Generated Spatial Tasks

Geoffrey S. Hubona

Gregory W. Shirah
National Aeronautics and Space Administration, USA

ABSTRACT

Most computer applications feature visual user interfaces that assume that all users have equivalent propensities to perceive, interpret, and understand the multidimensional spatial properties and relationships of the objects presented. However, the hunter-gatherer theory (Silverman & Eals, 1992) suggests that there are modern-day differences between the genders in spatial and cognitive abilities that stem from differentiated prehistoric sex roles. If true, there may be discrepancies in how males and females differentially utilize particular spatial visual cues and interface features. We report three experiments in which participants engage in visual spatial tasks using 2D and 3D virtual worlds: (1) matching object shapes; (2) positioning objects; and (3) resizing objects. Female subjects under-perform male subjects in the matching and positioning experiments, but they outperform male subjects in the resizing experiment. Moreover, male subjects make more use of motion cues. Implications for the design of gender-effective user interfaces and virtual environments are considered.

INTRODUCTION

A perennial trend in the evolution of computer technology relates to the ever-increasing power of hardware and the resulting burgeoning possibilities to develop more complex software. These trends have enabled the proliferation of more specialized and powerful computer applications that support users in a wide variety of personal...
and professional tasks. Associated with these trends are multiple challenges: (1) to make the presentation of geometrically increasing amounts of data ever more concise; and (2) to condense, convey, and present larger and larger volumes of useful information using smaller and smaller spaces. To meet these challenges, new and creative approaches to the design of visual user interfaces have emerged, many that present complex, multidimensional data sets and relationships into condensed visual forms and spaces.

Unfortunately, an implicit assumption in the design of commonplace visual user interfaces is that preponderant portions of the existing user population have similar abilities to cognitively perceive, process, interpret, and ultimately understand the intended visual and spatial properties of the objects presented. Yet, it is known that certain measures of spatial cognition are correlated with performance in user interface tasks (Cockburn, 2004). As an example of how individual perceptual differences can affect user interface design, professional Web designers are aware of color blindness patterns in the general population that affect the ability to correctly perceive color-encoded information. As a result, professional designers of high-traffic Internet Web sites avoid these color blindness traps in order to enhance the universal usability of the sites.

Clearly, the assumption of equivalent user capabilities runs the risk of impairing the usability of visual interfaces that ignore broad, existing population anomalies in spatial cognitive and task performance abilities. Through the process of evolutionary natural selection, the hunter-gatherer theory (Silverman & Eals, 1992) ties modern-day, gender-based differences in certain cognitive, spatial abilities back to sharply differentiated sex roles from prehistoric times. Also, it is recognized in behavioral research communities that there are innate differences between the male and female genders related to cognitive spatial abilities (Kimura, 2000; Linn & Petersen, 1985; Voyer, Voyer, & Bryden, 1995). These gender differences may directly impact the ability to perceive, interpret, and cognitively process spatial properties and spatial relationships of multiple visual objects presented on a computer screen. Thus, there may be fundamental differences between the genders with respect to the ability to use certain visual user interface features, particularly when these features relate to the perception of depth and to the spatial relationships of objects and scenes presented at varying levels of intended depth.

In this article, we review theory and empirical studies relating to (1) gender and human computer interaction and (2) gender differences in innate spatial cognitive and task performance abilities. We then describe three experiments that examine gender-based performance differences in object matching, positioning, and size estimation tasks using two-dimensional (2D) and three-dimensional (3D) virtual worlds. The observed gender performance differences are discussed with respect to applicable theory and with respect to the design of gender-neutral user interfaces and virtual environments.

THEORY AND BACKGROUND

Gender and Human-Computer Interaction

Researchers long have acknowledged the relevance of gender as impacting human computer interaction. Gender has been noted as a broad issue affecting computer skills and computer design issues (Balka, 1996). Gender has been recognized as an important consideration for the design of user interfaces (Leventhal, Teasley, & Stone, 1994) and display techniques (Shneiderman, 1990) and as an issue relevant to achieving universal usability among diverse users of Web-based computer services (Shneiderman, 2000). Gender has been related to the process of decision making, to preferences for investment models, and consequently, as an important consideration.
in the design of financial (Palma-dos-Reis & Zahn, 1999) and organizational decision support systems (Powell & Johnson, 1995) for men and women. It has been shown that there are different perceptions and preferences between men and women with respect to the use and satisfaction with different features of electronic commerce Web sites (Simon, 2001).

Numerous researchers have noted differences between the genders while interacting with computers. For example, it has been shown that boys and girls think differently about computers (Hall & Cooper, 1991; Wilder, Mackie, & Cooper, 1985), and that boys and girls have different motivations for using computers (Inkpen et al., 1994; Upitis & Koch, 1996). Moreover, gender-specific preferences for computer interface features and usage styles also have been documented (Lockheed, 1985). Hinckley, Pausch, Proffitt, and Kassell (1998) reported that females were faster than males performing a two-handed, 3D neurosurgical visualization (manipulation) task, and it has been suggested that females outperform males at certain dexterity tasks (Halpern, 1986; Hinckley, Pausch, Proffitt, Patten, & Kassell, 1997).

However, some studies have found no gender differences while interacting with computers. For example, Inkpen (2001) found no boy-girl differences in children’s interaction styles with point-and-click as compared to drag-and-drop interfaces. In addition, Riemann (1996) found no significant gender impact on the number of reported exploratory learning discoveries using new systems.

One area of HCI that has examined closely the gender performance differences is with respect to the exploration, use, and navigation of virtual reality (VR) and virtual environment (VE) applications. Investigating gestural input techniques for multimodal and virtual environment applications, Wexelblat (1995) reported that gender was not a reliable predictor of gesture frequency for subjects describing movie scenes. Basdogan, Ho, Srinivasan, and Slater (2000) found that female subjects engaged in haptic communication in shared virtual environments (SVEs) reported higher levels of sense of togetherness in performing a collaborative task with an unseen partner than did male subjects. Kauppinen, Kivimaki, Era, and Robinson (1998) argued that gender differences in interacting with others in Collaborative Virtual Environments (CVEs) can be traced to broader, societal-driven, gender-specific, identity distinctions that are also witnessed in natural, non-computer-mediated interactions.

Waller, Hunt, and Knapp (1998) suggested that the transfer of spatial knowledge in virtual environment training is responsible for males outperforming females in computer-generated environments. Similarly, other studies have reported men outperforming women (Astur, Ortiz, & Sutherland, 1998) and making use of different cues than women (Sandstrom, Kaufman, & Huettel, 1998) in navigating virtual worlds. Tan, Robertson, and Czerwinski (2001) reported that men completed 3D virtual environment navigation tasks more quickly than women while using smaller, 15-inch displays, but that this male performance advantage disappeared when using larger, 39-inch displays. Subsequently, Czerwinski, Tan, and Robertson (2002) extended this work with two navigation studies. The first study replicated their findings that a wider field of view combined with a large display reduces gender performance biases. Their second study demonstrated that wider fields of view assist females’ performances in navigating virtual worlds that are densely populated with objects.

**Gender Differences in Spatial Abilities**

Innate gender differences in mental spatial abilities generally are identified as the basis for gender disparities in performing spatial tasks (Kimura, 2000; Linn & Petersen, 1985; Voyer et al., 1995). Certain meta-analytic studies (Linn & Petersen, 1985; Voyer et al., 1995) do indicate a male ad-
The Paleolithic Stone Age Effect?

Vantage on particular cognitive spatial tests, but individual studies’ results are inconsistent in this regard. Further, the different studies often use varying test instruments to measure spatial abilities. Linn and Petersen (1985) categorized the various instruments reported in the literature into three distinct groups: those that measure (1) spatial perception, (2) mental rotation, and (3) spatial visualization. Spatial perception is described as the ability to determine spatial relations despite distracting information. Mental rotation refers to the ability to rotate quickly and accurately two- or three-dimensional figures in imagination. Spatial visualization is the ability to manipulate complex spatial information when several stages are needed to produce the correct solution. These meta-analyses (Linn & Petersen, 1985; Voyer et al., 1995) conclude that men score higher than women on spatial perception and mental rotation cognitive tests, but that neither gender has higher scores on spatial visualization cognitive tests.

The hunter-gatherer theory of the origin of sex-specific spatial attributes (Silverman & Eals, 1992) is one prominent theory that offers an evolutionary perspective on gender differences in modern-day spatial abilities. This theory suggests that men and women have different present-day cognitive skill predispositions that relate to handling differentiated sex role aspects from prehistoric times. Prehistoric females, or gatherers, who could effectively forage for food, and who were successful at keeping track of relationships, activities, objects, locations, and landmarks near their habitats, were superior at acquiring resources for bearing and raising offspring. On the other hand, prehistoric males, or hunters, who could travel better in unfamiliar territory, estimate distance, and navigate with a bird’s-eye view orientation, were, as a consequence, more successful at hunting, competing with other males, finding mates, and, thus, fathering offspring.

The hunter-gatherer theory suggests that these male-female cognitive predispositions persist today through the process of natural evolutionary selection. As evidence supporting this theory, it has been shown that contemporary females outperform men on spatial tasks related to foraging-related activities, such as remembering the location of objects (e.g., landmarks) in their environment (Dabbs, Chang, Strong, & Milun, 1998). Moreover, it has been demonstrated that women outperform men at keeping track of objects and in finding objects that are lost (Eals & Silverman, 1994; Silverman & Eals, 1992). In addition, studies have shown that women remember the locations of previously viewed items better than men (McBurney, Gaulin, Devineni, & Adams, 1997), and that women outperform men remembering the locations of specific objects (James & Kimura, 1997). In contrast, men typically outperform women at spatial tasks manipulating objects in space (Collins & Kimura, 1997; Goldstein, Haldane, & Mitchell, 1990; Kimura, 1983; Kolb & Whishaw, 1990; Linn & Petersen, 1985; Lohman, 1986; Maccoby & Jacklin, 1974). Other studies have demonstrated that men have more adept mental rotation spatial abilities than women (Dabbs et al., 1998; Silverman, Choi, Mackewn, Fisher, Moro, & Olshansky, 2000), purportedly as an evolutionary artifact of the ability to pursue an animal through unfamiliar terrain and then expeditiously find their way home.

**METHOD**

**Hypotheses and Experimental Tasks**

We report three experiments performing spatial tasks using 2D and 3D virtual worlds: object matching, object-positioning, and object resizing. The object-matching experiment was designed largely to tap mental rotation abilities (Linn & Petersen, 1985). The object-positioning and resizing experiments were designed to tap spatial visualization abilities (Linn & Petersen, 1985). Commensurate with the spatial abilities literature, we expect men to outperform women.
in the object-matching task, but there should be no male-female performance differences in the object-positioning/resizing tasks. Consequently, we propose the following two hypotheses:

H1: Male subjects will outperform female subjects matching objects using a mental rotation paradigm.

H2: Male and female subjects will exhibit equivalent performances positioning and resizing objects.

**Object-Matching Experiment.** The object-matching experiment was based on the mental rotation paradigm first developed by Shepard and Metzler (1971). Viewing successive pairs of object images presented from different angles, the task was to judge as accurately and as quickly as possible whether the two images represented identical or different objects. For example, Figure 1 shows a typical object-matching image pair. As quickly as the subject could judge whether the split-screen image pair represented the same or different objects, she or he clicked a corresponding *same* or *different* button on the interface, causing the next image pair trial to be presented. Exactly one-half of the 208 randomly presented image pairs represented identical objects, and the other half showed non-identical objects in the pair.

One-half of all trials were viewed by the men and women subjects in stereo, using 3D Crystal-Eyes™ glasses. The remaining trials were viewed in 2D (monoscopically). The left object image in each trial was always stationary, while the right image was always capable of motion and, specifically, two kinds of motion: (1) in one-half of the trials, subjects could control the motion of the right object image by rotating it in any direction for 360 degrees around the center; and (2) in the remaining trials, the right object always rotated automatically in a fixed and random direction about the center point, rotating at a constant speed of approximately 18 degrees per second. The measured performance variables included *error rate*, the percentage of incorrect matching responses, and *response time*, measured in milliseconds.

Seventeen males and 14 female subjects volunteered to participate in the object-matching experiment. All subjects were employees or contractors of the Goddard Space Flight Center in Greenbelt, Maryland. Subjects with corrected vision wore their eyeglasses underneath the stereoscopic
viewing glasses. All subjects had professional occupations and included engineers, computer programmers, and computer scientists. The mean age of the subjects was 34.97 years with 4.48 mean years of education beyond high school, 17.03 mean years of computer experience, and 12.65 mean years of professional work experience.

Object-Positioning Experiment. The object-positioning task consisted of subjects viewing computer-generated virtual worlds containing three identically sized spherical objects suspended in 3D space (see Figures 2 and 3). As quickly and accurately as possible, subjects were asked to reposition a target object in order to complete a straight line vector configuration defined by three spheres positioned at equal distances from each other. For example, Figure 2 shows a typical initial scene presented at the beginning of a positioning trial. Subjects would fly the object to be repositioned within the virtual world using a (six-degrees-of-freedom) spaceball input device. When satisfied that they had correctly positioned the misplaced object, they pressed a button on the spaceball that recorded their performance data in an output file and caused the next world to appear immediately. Figure 3 shows the correct (solution) placement of the spheres for the initial trial scene presented as Figure 2. Note that correctly performing the positioning task required subjects to locate the displaced object in three dimensions: x (left and right); y (up and down); and z (toward and away from the viewer). One hundred and forty-four unique worlds were presented to each subject in random order.

Thirty volunteer subjects, 14 female and 16 male, participated. All had professional occupations as computer programmers, analysts, and scientists at the Goddard Space Flight Center. The subjects’ mean age was 35.03 years, with 5.53 mean years of education beyond high school, 17.07 mean years of computer experience, and 13.12 mean years of professional work experience.

One-half of all positioning trials was viewed stereoscopically using 3D CrystalEyes™ glasses, while the remaining trials were viewed in 2D (monoscopically) without wearing the glasses. Because subjects wore the glasses to view scenes in 3D, the stereo and mono trials were presented in cohesive blocks of 72 scenes each. The starting order for presenting the stereo and mono blocks was alternated between subjects.

The measured performance variables included distance error magnitude, response time, and rotational distance magnitude. Distance error magnitude was defined as the Euclidean summation of the three directional errors in the x, y, and z dimensions, or $((e_x^2 + e_y^2 + e_z^2) ^ {1/2})$. Thus, this metric measured the exact absolute distance of the repositioned target object from its correct location in three-dimensional space. Response time again was measured in milliseconds. Also, subjects were able to voluntarily rotate the world left or right a total of 45 degrees from the center in either direction, using the left and right arrow keys on the keyboard. The total number of degrees in which the world was rotated in both the left and right directions was captured as a performance rotational distance metric. In addition to positioning distance accuracy and response latency, we were particularly interested in observing mean variances in rotational distance as a function of gender. We introduced the ability for the subjects to rotate the worlds for two predominant reasons: (1) to extract another dependent variable performance measure in addition to standard accuracy and response time measures; and (2) to provide an additional motion-related cue and to see if the male and female subjects would use this cue differentially.

Object-Resizing Experiment. The object-resizing task consisted of subjects viewing virtual worlds containing two differently sized spherical objects suspended in 3D space and displaced at different depths from the viewer (see Figures 4 and 5). Unlike the positioning task, the resizing objects were fixed in position. The task was to adjust the size of a target object in order to correspond with the apparent size of a referent object. Figures 4
The Paleolithic Stone Age Effect?

Figure 2. Initial positioning scene trial

Figure 3. Completed positioning scene trial
Figure 4. Initial resizing scene trial

Figure 5. Completed resizing scene trial
and 5 show a typical set of starting and correctly resized ending virtual worlds. One hundred forty-four unique worlds again were displayed in random order to each subject within alternating blocks, consisting of 72 2D (monoscopic) or 3D (stereoscopic) scenes. Each subject viewed the same 144 worlds (although in a random order); thus, the average target and referent ball sizes across all scenes were equivalent and, therefore, the same for all males and females.

The same 30 subjects from the object-positioning experiment participated in the object-resizing experiment. The measured performance variables included radius error percentage in addition to response time and rotational distance magnitude. Specifically, radius error percentage was defined as the absolute value of the difference between the correct (e.g., referent sphere) radius length and the final resized (e.g., target sphere) radius length divided by the radius length of the referent sphere, or 

\[
\frac{\left| (\text{Correct}_RL - \text{Final}_RL) \right|}{\text{Correct}_RL}
\]

An accuracy measure relative to the size of the referent object was used, because the referent objects randomly varied in size from large to very small. The response time and rotational distance performance metrics were identical to those used in the positioning experiment.

**Assessing Gender Differences in Cognitive Spatial Abilities**

Gender-based differences in subjects’ mental (cognitive) spatial abilities were assessed using the factor-referenced cognitive tests (Ekstrom, French, Harman, & Dermen, 1976) developed by the Office of Naval Research (ONR) and licensed for research use through the Educational Testing Service (ETS). In all three experiments, subjects were administered the cube comparisons and paper-folding cognitive tests. The ETS cube comparisons test assesses mental rotation cognitive ability. In this timed test, subjects were presented with image pairs of wooden cubes, or blocks. Each cube had a different letter, number, or symbol on each of the six faces (i.e., top, bottom, four sides) of the cube. However, in each pair of cubes presented, only three (of the six) sides of the cube were visible. The task was to determine whether the pair represented identical (e.g., the same) or different cubes.

Unlike cube comparisons, which assess mental rotation ability, the ETS paper-folding test assesses spatial visualization ability. In the timed paper-folding test, subjects had to imagine correctly the folding and unfolding of pieces of paper with holes punched through them. According to ETS, cube comparisons require only the mental rotation of the cube configurations, whereas paper folding requires both rotation and visualization, defined as performing serial operations on the configuration. Since both cube comparisons and object-matching task performances are based on the mental rotation process, as described by Shepard and Metzler (1971), cube comparison ability should correspond with object-matching task performances. Similarly, paper-folding skill should correspond to task performances in the object-positioning and resizing experiments, since all are based on spatial visualization ability.

**Results**

**Cognitive Abilities Test Scores.** Tables 1 and 2 reflect the mean scores of the male and female subjects by experiment on the cube comparisons and paper-folding cognitive abilities tests. According to Dr. Ruth Ekstrom (by personal correspondence), the appropriate approach to assess these test results is to consider separately for each test the total number of items answered correctly, the number answered incorrectly, and the number omitted, or unanswered. As indicated in Table 1 (and after checking for equal variances in the male-female scores populations), t-test comparisons of male-female scores on each test indicated that for the object-matching subjects, female subjects answered incorrectly significantly more cube comparison items than males. How-
ever, there were no male-female differences in the number of cube comparison items answered correctly or in the number omitted. Moreover, for the paper-folding test, there were no significant male-female differences in the number of items answered correctly, answered incorrectly, or omitted. By answering significantly fewer cube comparison items incorrectly, there is at least some evidence that the male subjects in the object-matching experiment had an advantage over the females in innate mental rotation cognitive ability. However, the paper-folding test scores indicate no significant male-female differences in innate spatial visualization cognitive abilities.

As indicated in Table 2, t-test comparisons of male-female cube comparison test scores for subjects in the object-positioning and resizing experiments indicate that male subjects answered (1) significantly more items correctly than females and (2) significantly fewer items incorrectly than females. However, there were no significant male-female differences in the number of items omitted in the cube comparisons test. Moreover, there were no significant male-female differences in the number of paper-folding test items answered correctly, answered incorrectly, or omitted. Thus, in the object-positioning and resizing experiments, there again is evidence that males

compared to females had superior innate mental rotation cognitive abilities. However, similar to the cognitive test data for subjects in the object-matching experiment, there again is no evidence of significant male-female differences in innate spatial visualization cognitive abilities.

Object-Matching Experiment Results. The object-matching data were fitted to a repeated measures multivariate analysis of variance model (MANOVA). There were significant differences in both error rate \((p < 0.0001)\) and response time \((p < 0.0001)\) as a function of gender. Males were

* The minimum significant performance differences (at \(p < 0.05\)) between the genders for the object-matching task are (1) mean error rate: 1.51%; (2) mean response time: 0.43 seconds.

Figure 7. Object-matching error rate by gender by type of motion

Figure 8. Object-matching response time by gender by viewing mode
more accurate at judging whether the objects were identical or different (see Figures 6 and 7). The overall mean male error rate was 9.39%, whereas the overall mean female error rate was 13.05%. Furthermore, the male subjects were faster at making these object comparisons (see Figures 8 and 9). Males exhibited an overall mean response time of 12.53 seconds, whereas females responded in an overall mean time of 13.58 seconds.

To further investigate the gender-based impact of the viewing and motion conditions on object-matching performances, the sample then was split by gender and tested for the effects of viewing mode and type of motion on the object-matching error rates and response times for each gender. The data are presented in tabular form in Table 3. Figures 6, 7, 8, and 9 present these data using line graphs that indicate the minimum significant differences (at $p < 0.05$) between the genders for object-matching error rate and response time (noted in Table 3).

Both male and female subjects were more accurate and faster at matching objects when viewing the object pairs in stereo (see Figures 6 and 8). When the males controlled the motion of the right-hand object image, also called the comparison object (recall that the left image was always stationary), they were more accurate than when they did not control this motion (see Figure 7). For females, there was no significant difference in object-matching accuracy whether they controlled the motion of the comparison object or not (see Figure 7). However, both males and females took longer to judge whether the objects were identical or different when they were controlling this motion (see Figure 9).

**Object-Positioning Experiment Results.** The positioning data were also fitted to a MANOVA model. There were significant differences in distance error magnitude ($p < 0.0001$) and in rotational distance magnitude ($p < 0.0001$) as a function of gender. The male subjects were more

accurate in the positioning task (see Figure 10). The overall mean male distance error was 0.573 units, whereas the overall mean female distance error was 0.851 units. Furthermore, the male subjects rotated the positioning scenes to a greater extent than did the females (see Figure 12). The overall mean male rotational distance was 171.99 degrees, whereas the overall mean female rotational...

![Object Positioning Rotational Distance by Viewing Mode](image2)
distance was 150.78 degrees. The difference in positioning response time as a function of gender was not significant \( (p = 0.97) \). Both males and females exhibited a mean positioning response time of 20.1 seconds (see Figure 11).

To further investigate the gender-based impact of the viewing conditions on object-positioning performances, the sample again was split by gender and tested for the effects of mono and stereo viewing on positioning accuracies, response times, and rotational distances for each gender. The data are presented in tabular format in Table 4. Figures 10, 11, and 12 present these data using line graphs that indicate the minimum significant differences \( (at \ p < 0.05) \) between the genders for object-positioning radius error, response time, and rotational distance (noted in Table 4). Both males and females were more accurate and faster at positioning objects in stereo (see Figures 10 and 11). Stereo viewing particularly improved the positioning response time for males more than for females (see Figure 11). Furthermore, both males and females used less rotational distance positioning objects when viewing the objects in stereo, although males exhibited more of this effect than did the females (see Figure 12).

**Object Resizing Experiment Results.** In the resizing task, there were significant differences in radius error percentages \( (p < 0.027) \) and rotational distance magnitudes \( (p < 0.006) \) as a function of gender. The male subjects were less accurate resizing the objects than were the females (see Figure 13). The overall mean male radius error percentage was 15.14\%, whereas the overall mean female radius error percentage was 14.05\%. However, the male subjects rotated the resizing scenes to a greater extent than did the females (see Figure 15). The overall mean male rotational distance was 112.68 degrees, whereas the overall mean female rotational distance was 105.43 degrees. Furthermore, males and females were equally fast at performing the resizing task (see Figure 14). The difference in resizing response time as a function of gender was not significant \( (p = 0.37) \). The mean male response time was 10.68 seconds, and the mean female response time was 10.98 seconds.

The resizing data sample also were split by gender and tested for the effects of mono and stereo viewing on resizing accuracies, response times, and rotational distances for each gender. The data are presented in tabular format in Table 5. Figures 13, 14, and 15 present these data using line graphs that indicate the minimum significant differences \( (at \ p < 0.05) \) between the genders for object resizing radius error, response time, and rotational distance.

rotational distance (noted in Table 5). Viewing the worlds in stereo compared to mono had no significant effect on the mean resizing accuracy for either gender (see Figure 13), although it did reduce mean response times for both genders (see Figure 14). Similar to the results from the positioning task, both males and females rotated the scenes less while resizing objects viewed in stereo compared to mono viewing, although the males reduced this stereo-viewed rotational distance more than the females (see Figure 15).

SUMMARY OF FINDINGS

Table 6 summarizes relative task performance differences by gender with each experiment. The spatial abilities literature indicates a robust male performance advantage in mental rotation tasks but no clear advantage for either gender in spatial visualization tasks. Indeed, the ETS factor-referenced cognitive tests administered to our subjects generally corroborate the existing literature. The male subjects answered significantly fewer cube comparisons (mental rotation) test items incorrectly than the females, but there were no differences in male-female paper folding (spatial visualization) test scores.

We hypothesized a male performance advantage in the (mental rotation) object-matching experiment (H1) but no advantage for either gender in the (spatial visualization) object-positioning and resizing experiments (H2). Consistent with the prediction of hypothesis H1, males did exhibit more accurate and faster performances than females in the object-matching experiment. As this task was based on a mental rotation paradigm (Shepard & Metzler, 1971) and coupled with

Figure 15. Object resizing rotational distance by gender by viewing mode

---

Object Resizing Rotational Distance by Viewing Mode

![Graph showing object resizing rotational distance by viewing mode for males and females.](image-url)
spatial literature meta-analyses indicating male advantages in mental rotation tasks and cognitive tests, it is not surprising that the male subjects outperformed the female subjects in the accuracy and speed of matching objects. Moreover, controlling the motion of the right-hand comparison object image significantly improved (i.e., reduced) male object-matching error rates but had no effect on female error rates. Since controlling the motion facilitated the mental rotation task in general, and since males typically outperform females at mental rotation tasks (Dabbs et al., 1998; Silverman et al., 2000), this could explain why males made more effective use of this motion cue.

However, contrary to the prediction of hypothesis H2, in the object-positioning and resizing (spatial visualization) experiments, the relative gender performances were mixed; males were more accurate at positioning objects, whereas females were more accurate at resizing objects. Moreover, the male subjects made more use of the rotational distance feature in both the positioning and resizing tasks. Note that the rotational distance feature, by nature, is a type of motion cue. That is, by rotating the virtual world left or right, the viewer is able to adjust the locations and displacements of the objects in relation to the other objects and in relation to the viewer. The males evidently found this rotating feature to be more useful than females in attempting to position and resize objects in the virtual worlds.

To understand why males were more accurate at positioning objects and why females were more accurate at resizing objects, it is worthwhile to scrutinize the elements of each task. In this regard, object motion was a critical attribute for successfully positioning objects but not for resizing objects. Accurately positioning the target object in a straight line segment required flying the object around the visual space. This essential motion attribute may have contributed to a male performance advantage at positioning objects and is consistent with previous findings that men typically outperform women in tasks manipulating objects in space (Collins & Kimura, 1997; Goldstein et al., 1990; Kimura, 1983; Kolb & Whishaw, 1990; Linn & Petersen, 1985; Lohman, 1986; Maccoby & Jacklin, 1974).

However, the females were more accurate than the males at resizing the target object to match the apparent size of the referent object. The females evidently had a better sense of the relative comparative size of the two objects that were displaced in distance but otherwise fixed in position. It has been demonstrated that females, compared to men, rely more on landmarks for way finding (McGuiness & Sparks, 1983; Miller & Santoni, 1986) and refer to landmarks when

* There was no formal rotational distance dependent variable performance measure in the object-matching experiment. However, when males controlled the motion of the comparison object, they were more accurate (unlike the females) in their object-matching performances.
giving directions (Miller & Santoni, 1986). The literature also indicates that females outperform males in remembering the location of objects that are fixed in space (Dabbs et al., 1998; McBurney et al., 1997). Accurately resizing the target object required the cognitive calibration of the relative apparent sizes of two objects that were displaced in distance from the viewer but otherwise fixed in position. We speculate that the female resizing accuracy advantage could be related to a female propensity to recognize better the locations of landmark objects that are fixed in position (Eals & Silverman, 1994; Silverman & Eals, 1992).

CONCLUSION AND DISCUSSION

In general, the results of these experiments indicate the following:

1. Males outperform females at matching abstract, visual objects using mental rotation in computer-generated virtual worlds.
2. Males make more use of certain motion-related cues in performing visual tasks in computer-generated virtual worlds.
3. Males are more accurate at moving and positioning objects in computer-generated virtual worlds.
4. Females are more accurate at estimating the relative sizes of objects displaced in depth but fixed in position in computer-generated virtual worlds.

How do these findings suggest approaches to developing gender-neutral visual interfaces? The ideal goal in this regard is to move toward the design of user interfaces that will improve usability for both genders and, particularly, to mitigate the postulated female handicap with mental rotation and motion cues. Simply adding a third dimension to an otherwise 2D display does not guarantee improved task performances (Cockburn & McKenzie, 2002). One suggestion is to add meaningful landmarks and to decrease user reliance on mental rotation ability. For example, visual interfaces that allow the stationary user to look right or look left (or up, down, backward, etc.) for familiar landmarks may prove to be an effective, gender-neutral alternative to the use of typical motion cues such as flying around virtual spaces. Our research suggests that the reliance on motion cues, in particular, to extract information can be especially problematic and can lead to a male performance advantage.

An evolving area of visual computing technology to which these findings are relevant is computer-generated virtual environments (VEs). The spatial structure of a VE and the objects that are visible sometimes are used to represent information. According to Vinson (1999), “a VE could contain objects whose spatial properties (e.g., shape, position, size) represent data values on different dimensions. Here, it is necessary for the navigator to quickly develop accurate representations of those spatial properties in order to understand the relationships in the data” (p. 279). These spatial properties (i.e., shape, position, and size) correspond with the three spatial task manipulations analyzed in our studies. To the extent that there are gender biases when cognitively processing and understanding these spatial properties, then these biases likely would extend to understanding the corresponding data relationships in VEs.

Although the tasks analyzed in our studies are not navigation tasks per se, the findings, nevertheless, have implications for the design of navigable VEs, since recognizing object shape and estimating the size and distance of objects are intrinsic activities of successful VE navigation (Vinson, 1999). Navigation is a process of tracking one’s position in an environment in order to arrive at a desired destination. Doing so requires knowledge about positional, velocity, and acceleration attributes, which are derived from location, depth, and motion cues (Cutmore et al., 2000). Location information comes from landmarks and other
fixed, distant features in the environment. The ability to recognize object shapes and to estimate their relative distances (or positions) is necessary in order to acquire basic location information that is a foundation of successful navigation. Moreover, correctly estimating the relative size of a landmark directly relates to understanding its distance and also promotes successful navigation.

Previous studies have indicated male performance advantages when navigating virtual worlds (Astur et al., 1998; Sandstrom et al., 1998; Waller et al., 1998). However, other researchers have noted that the apparent male navigation superiority is mitigated when the virtual worlds are presented to users with wider fields of view and larger display screens (Czerwinski et al., 2002; Tan et al., 2001). Indeed, both genders benefit under these conditions. Tan, Gergle, Scupelli, and Pausch (2003) reported that using larger displays improved both male and female performances in a static, 2D, mental rotation task, but there was no corresponding performance benefit in a reading comprehension task. Subsequently, Tan, Gergle, Scupelli, and Pausch (2004) also demonstrated that users are more effective when performing 3D virtual navigation tasks on larger displays. They noted that when navigating, users continually update their mental sense of position and orientation within the environment (termed spatial updating) using two basic strategies: (1) piloting, or using external landmarks to position themselves within the environment; and (2) path integration, or sensing self-velocity and acceleration to determine their position relative to some starting point. There is evidence that women rely more heavily on the piloting strategy (Czerwinski et al., 2002; Golledge, 1999).

Cockburn (2004) suggested that human spatial capabilities could be leveraged while interacting with computer-generated 3D scenes if the scenes were presented in ways “that better reflect the way we perceive our natural environment” (p. 25). We submit that user interface technology will best support all users to effectively navigate virtual worlds when those worlds are presented to user groups in ways that most closely mirror how users typically and best navigate in natural environments. Flying around over terrain that is visually presented on a limited 2D display screen is not a natural approach for ordinary human navigation. Extending the wider field of view and wider display arguments of Czerwinski et al. (2002), we suggest that the total immersion of users navigating a pedestrian and, apparently, terrestrial virtual world can better support individual human navigation in those worlds. Spatial navigation is improved with an increased sense of presence, or being in the virtual environment, which is a direct outcome of immersion (Tan et al., 2003). For women, these worlds perhaps would be designed best using highly visible and easily recognizable landmarks that are stationary in position and visible within a 360° field of view. That is, women users should be able to look around the virtual landscapes in all directions. Furthermore, the mode of navigating, or movement, should be along the surface of the virtual landscape, especially with alignment and orientation to and from those salient landmarks. For men, cues that further suggest Euclidean distance and direction also should be helpful. Virtual worlds that support both genders’ existing propensities to navigate would be most effective for the majority of users.

**Limitations**

The results of this study should not be interpreted as suggesting that either gender is superior in terms of spatial abilities. Rather, the study suggests (and the reported findings confirm) that there are differences in relative male and female performances on particular spatial processing tasks. Some of these differences are explored in this study. Many others are well-documented in the gender-specific mental abilities literature. In point of fact, both males and females have performance advantages in particular cognitive tasks.
The domain of this study is limited. It focuses on the gender-effective use of abstract visualizations and visual tasks that may relate to particular attributes of visual user interfaces. For example, visual user interface domains that involve the mental rotation of objects or the user-controlled motion, orientation, or resizing of objects, particularly in scenes representing three-dimensional space, are germane. However, domains relating to typical two-dimensional point-and-click activities or to the user interpretation of textual information are not addressed in this study.

In terms of methodology, a limitation of this study is that there was a separate set of subjects in the mental rotation experiment compared to the positioning and resizing experiments. As a result, there was a combination of within- and between-subject comparisons pertinent to the findings and related discussions. However, because these experiments were conducted over a period of time, the attrition of some subjects was unavoidable.

Further, in generalizing these findings, we note that these subjects likely have heightened spatial abilities relative to the general population. They were all working professionals in a premier scientific governmental organization, many holding advanced degrees. Therefore, whether these findings generalize to the population at large is debatable. However, one could argue that any performance effects fostered by the spatial cues would be more pronounced within this group than within the general population. That is to say, if there were no observable effects with these select subjects, then there likely would be no effect within the general population.

Finally, we mention one additional limitation. Egocentric motion tasks, for example, physically walking through a 3D environment, and finding one’s way along a route and/or to and from landmarks have additional perceptual dimensions than do the tasks in our study. However, some elements of egocentric way-finding are embedded in our tasks, such as recognizing the relative shapes, orientations, distances, and sizes of objects in the visual field. Additionally, we did incorporate aspects of egocentric motion skills by enabling the rotation of objects and the rotation of the scenes left and right. However, these tasks do not capture completely all of the perceptual cues and sensory elements inherent in egocentric motion tasks.

**Considerations for Future Research**

There are large segments of the general population that are characterized by differing opportunities, propensities, and abilities to access and make effective use of computer technologies. For example, the very young, the elderly, and the handicapped all have particular impediments to using computer technologies that most people take for granted. As computer applications become increasingly prevalent in everyday life, it is a worthwhile goal to try to mitigate intrinsic barriers and to equalize access and opportunities in order to make effective use of computer technologies.

In terms of gender differences in using visual interfaces, this research is an attempt to identify and highlight broad categories of disparities in male-female abilities to interpret and to manipulate visual abstractions. The intent is to work toward the development of gender-neutral guidelines for effective visual user interfaces and virtual environments. Future research should explore the relative efficacies of different approaches of augmenting computer-generated visualizations so as to promote equal understanding and effective interfaces for different user groups. To this end, investigating approaches that do not rely strictly on abstract visualizations to convey information is warranted. Although it has been demonstrated that visual abstractions effectively can condense and convey large volumes of tabular, multi-dimensional (2D and 3D) data, the combination of visual with, in some cases, textual as well as multi-modal approaches likely will lead to more
effective user interfaces across a larger number of user groups. Furthermore, investigating the design of virtual worlds that most closely mimic how men and women navigate real worlds likely would benefit the largest share of all users.

Chapter 7.20

Optimality-Theoretic Lexical Mapping Theory: A Case Study of Locative Inversion

One-Soon Her
National Chengchi University, Taiwan

ABSTRACT

Locative inversion verbs seem to share the same argument structure and grammatical function assignment (i.e., <th-OBJ loc-SUBJ>) cross-linguistically. This article discusses the nature of argument-function linking in LFG and demonstrates how the Lexical Mapping Theory (LMT) rendered in Optimality-Theoretic (OT) terms, where argument-function linking is governed by universal violable constraints that consistently favor the unmarked function, accounts for locative inversion straightforwardly. Within this OT-LMT, locative inversion is due to a universal morphosyntactic constraint, and language variation in locative inversion is due to the difference in its relative ranking. This account also offers a potential explanation for the markedness of the locative inversion construction.

INTRODUCTION

The locative inversion construction, as shown in Figure 1, cross-linguistically has similar characteristics in discourse information packaging, which allows the more familiar information to precede the less familiar information (Ackerman & Moore, 2001b; Birner, 1994; Cheng, 1983; Tan, 1991). Between the canonical construction in Figure 1a and the inverted form of 1b, along with the switch of focus from the locative to the theme, is the change in syntactic function assignment. An example from Chinese is given in the figure. The theme role in Figure 1a is assigned the subject function and locative an oblique function; the canonical linking is, thus, <th-SUBJ loc-OBL>. In the inverted Figure 1b, however, the locative is the subject, while the theme now occupies the object position (Her, 1990; Huang, 1993; Huang & Her, 1998; Tan, 1991).
This \textit{<th-OBJ loc-SUBJ>} argument-function “mismatch” was first identified and convincingly argued for in locative inversion verbs in Chichewa (Bresnan, 1994; Bresnan & Kanerva, 1989) and in English (Bresnan, 1989; Tan, 1991). Examples in Figure 2 are from Bresnan and Kanerva (1989).

The subjecthood of the inverted locative phrase \textit{tai-shang} “stage-top” in Figure 1b is evidenced by the fact that it is a bare NP and occupies the usual position for subjects. This is further confirmed by the usual raising test. As shown in Figure 3, \textit{tai-shang} “stage-top” is, indeed, the raised subject, while the “demoted” theme in the post-verbal position, also a bare NP, must be recognized as the object (see Figure 3).

Chinese data thus further confirm Bresnan’s (1994) observation that cross-linguistically, locative inversion verbs share an identical argument
structure <th loc> and the function assignment of the canonical <th-SUBJ loc-OBL> in Figure 1a and the inverted <th-OBJ loc-SUBJ> in Figure 1b. This article aims mainly to account for the syntactic assignment of the argument roles in locative inversion verbs.

In any syntactic theory that aims at characterizing UG, it would be a considerable compromise to simply leave the syntactic assignment of argument roles to lexical idiosyncrasies (Pesetsky, 1995). This article focuses on how the syntactic assignment of argument roles is accounted for universally in the syntactic theory of Lexical Functional Grammar (LFG). This article is organized as follows. The first section discusses how argument-function linking is accounted for by the lexical mapping theory (LMT) in LFG. We will also demonstrate how certain versions of this theory do not account for the locative inversion data from Chinese and English straightforwardly. Furthermore, we will demonstrate how the theory can be improved upon for more consistency and computational efficiency. In the second section we propose a revised LMT formulated as declarative constraints in Optimality-Theoretic (OT) terms. The locative inversion data from Chinese is then accounted for in the third section. The fourth section consists of a discussion on the implications of this study, and the fifth section concludes the article.

The goal of the article is, thus, two-fold: (1) to come up with a universal lexical mapping theory based on violable declarative constraints in OT terms; and (2) to account for Mandarin locative inversion within this comprehensive OT-LMT.

**LEXICAL MAPPING THEORY**

LFG mainly posits three distinct, parallel planes of grammatical description: the argument structure, the functional structure, and the constituent structure (Bresnan, 2001; Dalrymple, 2001; Falk, 2001). The argument structure, or a-structure, consists of the predicate’s thematic and non-thematic argument roles, while the constituent structure, or c-structure, represents the configurational structure, which is the surface structure and allows no syntactic derivation. The functional structure, or f-structure, is the locus of grammatical information, such as grammatical functions (e.g., SUBJ and OBJ), case, person, number, gender, and so forth. The linking of these structures, each with a distinct formal nature, is constrained by correspondence principles. The lexical mapping theory (LMT) is the UG component that constrains the linking between a-structure roles and f-structure functions. The f-structure thus can be viewed as the interface level that links the a-structure and the c-structure. An argument role thus is linked to a grammatical function in the f-structure, which, in turn, is linked to a certain c-structure configuration. The lexical mapping theory (LMT) is the subtheory within LFG, which constrains the syntactic assignment of a-structure roles.

The pioneering work by Levin (1987) started the exploration of more principled accounts to replace the earlier stipulated function-changing rules in LFG. The first comprehensive formulation of LMT was proposed in Bresnan and Kanerva (1989). Since then, even though the essential underpinning assumptions have remained largely stable, the issue of argument-function linking, especially its precise formulation, has yet to be resolved (Butt & King, 2000). A number of different versions of the theory have been proposed (Ackerman, 1992; Ackerman & Moore, 2001a; Alsina, 1996; Bresnan, 1989, 2001; Butt, Dalrymple & Frank, 1997; Her, 1998; Huang, 1993; Zaenen, 1987), among others. A review of these existing versions is clearly outside the scope of this article1. Instead, we will outline mainly the version that seems to be the most widely circulated, found in Chapter 14 of Bresnan (2001), which, in turn, is based largely upon Bresnan and Zaenen (1990)2.
The Theory of A-Structure

Conceptually, LMT consists of two components: the theory of a-structure and the mapping constraints. LFG assumes a universal hierarchy among a-structure roles in terms of their relative prominence in the event denoted by the predicate. This scale descends from the most prominent agent role to the least prominent locative role (Bresnan & Kanerva, 1989, 1992) (see Figure 4).

The most prominent role in an a-structure is called the “logical subject” and is designated \( \Theta \) (pronounced “theta-hat”). In Figure 5, the two-place predicate break requires two argument roles in a-structure, agent (also \( \Theta \)) and theme; the three-place predicate put requires agent (again \( \Theta \)), goal, and theme. Roles in a-structure, by convention, descend in prominence according to the thematic hierarchy.

Grammatical functions (GFs) that can be linked to argument roles are called argument functions. In Figure 6, LFG distinguishes argument functions (shown in bold) from non-argument functions (in italics).

It is important to note that in structure-oriented theories, such as Transformational Grammar (TG) and all its later incarnations, notions such as subject and object are secondary and are derived from structural configurations. In contrast, in relation-oriented theories, such as Relational Grammar (RG) and LFG, these are primary notions in syntax. However, in LFG, argument functions

\end{array}
\]

\([\sigma] = (\text{an})\text{restricted} \quad [\sigma'] = (\text{an})\text{objective}\)
are further decomposed by two binary features: $[r]$ (whether the function is restricted to having an argument role) and $[o]$ (whether the function is objective) (see Figure 7).

In this system, each argument function is composed of exactly two features and natural classes can be identified, as shown in Figure 8. Furthermore, assuming the minus feature to be the unmarked value, a markedness hierarchy also can be obtained.

Similar to the intrinsic classification of argument roles in Bresnan and Kanerva (1989), Bresnan (2001) assumes that the underlying lexical semantics partially determine the syntactic assignment of different event participants. The universal classification shown in Figure 9 is proposed to capture these predetermined choices of grammatical function assignment.

Cross-language variation in the syntactic assignment of a-structure roles is thus subject to the above universal constraints. The agent role, for example, as a non-patientlike role, is classified $[{-o}]$ by Figure 9c and is thus not associated with OBJ canonically. Patient and theme roles, with the $[{-r}]$ classification, are associated canonically with either SUBJ or OBJ. Under the assumptions in Figure 9, each role in the a-structure is assigned one and only one feature for syntactic function assignment, as morpholexical processes are not allowed to add syntactic features. Language-specific morpholexical operations are allowed, however, to alter the “lexical stock” of an a-structure by adding, suppressing, or binding thematic roles (Bresnan, 2001). Passivization, for example, suppresses $\theta$, the most prominent role, from syntactic assignment (see Figure 10).

In summary, the theory of a-structure renders the argument roles a given predicator requires into an a-structure representation, where roles are listed in a descending order in prominence, and each role is assigned exactly one feature specification for function assignment. The second

---

**Figure 8. Markedness hierarchy of argument functions**

**Figure 10. Passivization**
component in LMT (i.e., the universal set of mapping constraints) then determines exactly which GF each role is assigned to.

**Mapping Principles**

Argument-function linking is subject to certain universal constraints; otherwise, each argument role is freely mapped onto any and all GFs with compatible features. Bresnan (2001) proposes the principles shown in Figure 11.

Two more well-formedness conditions (WFs) are needed in addition to the mapping principles in order to further constrain the non-deterministic argument-function linking: the function-argument biuniqueness constraint and the subject condition:

- Function-Argument Biuniqueness. Each a-structure role must be associated with a unique function, and conversely.
- The Subject Condition. Every predicator must have a subject.

The function-argument biuniqueness constraint ensures a strict one-to-one mapping relation between roles and functions. Computationally, it forces a deterministic assignment to an “unattached” GF between the two GFs with which a role is compatible. The subject condition serves the obvious purpose to ensure that one role in a-structure must be mapped to SUBJ. This condition also forces a deterministic choice when a role’s syntactic assignment is compatible with SUBJ and some other function and when all other

---

b. Other roles are mapped onto the lowest compatible function in the Markedness Hierarchy.

---

**Figure 12.**
roles in the a-structure, if any, are incompatible with SUBJ.

We demonstrate how three different types of verbs receive correct argument-function linking in the LMT just described. An unaccusative verb is given in Figure 12, while an unergative verb is illustrated in Figure 13. A typical transitive verb is given in Figure 14.

**Improvement to the Conventional LMT**

There are several areas at the theoretical level upon which the conventional LMT may be improved. First, the uniform underspecification of each role with exactly one syntactic feature can be relaxed to allow the formalism to be more expressive, yet without compromising its formal power. This classification scheme also may be too rigid in that it does not allow the possibility of agentive objects, which have been observed in several languages (Bresnan, 2001; Dalrymple, 2001). A desirable improvement to the theory is to allow such linking possibilities and, at the same time, be able to express the marked nature of such a linking as agent-OBJ.

As for the mapping principles, two disjunctions are observed. The first one is in the mapping
principles of subject roles: a disjunction exists between $\Theta_{[\alpha]}$ and $\theta_{[\theta]}$, each a stipulation for linking to SUBJ. In a more general theory of UG, it would be desirable not to include such function-specific linking conditions. Notice also the specification that $\Theta_{[\alpha]}$ be the initial role in the a-structure. This principle thus must refer explicitly to the ordering in the a-structure. The second disjunction is found between subject roles and non-subject roles. For the former, a qualified role is mapped to SUBJ (i.e., the most prominent GF). However, on the contrary, non-subject roles must be linked to the least prominent compatible GF. A consistent principle for all roles would make a simpler and more general theory.

Finally, note that the Subject Condition in LFG states explicitly that every clause must have a subject. Similar constraints are also necessary in other syntactic frameworks; for example, the same is accomplished by the Extended Projection Principle (EPP) in Transformational Grammar and the Final-1 Law in Relational Grammar. However, as it often has been noted, such an inflexible stipulation may not be empirically accurate. As cited in Ackerman and Moore (2001a), clauses may truly be without a subject (Babby, 1989; McCloskey, 2001). Bresnan (2001) thus hinted that this condition should perhaps be stipulated as a parameter. Again, ideally, a UG theory should be able to account for such subjectless clauses and their marked nature at the same time.

Assuming that the conventional LMT takes the same position advocated first in Alsina and Mchombo (1993) and does not allow morphologi-
Optimality-Theoretic Lexical Mapping Theory

Optimality-Theoretic Lexical Mapping Theory

As shown in Figure 16, the argument-function linking of <th-OBJ loc-SUBJ> in the locative inversion construction cannot be obtained, even though the canonical linking of <th-SUBJ loc-OBL> is accounted for in Figure 16. Therefore, it would make sense empirically to allow morphological processes in the theory to alter syntactic assignments by adding features, as proposed in Zaenen (1987), Ackerman (1992), Markantonatou (1995), and Her (1998, 2003). The default locative classification employed by Bresnan and Kanerva (1989) and Bresnan (1989), which assigns loc_[r] when th is focused, likewise can be viewed as such a feature-adding morphological operation. In the fourth section, we also will discuss the advantages of feature-adding morphological operations from the standpoint of expressivity and formal power.

In the second section, we will propose an LMT in OT terms, thus an OT-LMT, that attempts to incorporate the desirable improvements suggested here.

**AN OPTIMALITY-THEORETIC LMT**

Optimality Theory has exerted great influence over the field of phonology; however, its application in syntactic theory is still in its infancy. Recently, there have been some explorations within the OT-LFG framework (aka Optimal Syntax [Bresnan, 2000]). From the OT point of view, OT-LFG can be seen as OT with a universal LFG as GEN. From the point of view of LFG, a constraint-based grammatical framework, generalizations are interpreted in OT terms with (violable) constraints ranked in relation to one another (Sells, 2001). A number of studies have been carried out within this general framework (Mikkelsen, 2003; Sells, 2001). There also have been efforts to render argument-function linking in OT terms (Butt et al., 1997; Lødrup, 1999).

**An OT-LFG Overview**

Bresnan (2000) depicts the basic structure of OT-LFG, or Optimal Syntax, where LFG’s correspondence theory of parallel structures serves as a model for GEN. The standard OT-LFG assumes

![Figure 17.](image)
input to be “a (possibly underspecified) feature structure representing some given morphosyntactic content independent of its form of expressions” (Bresnan, 2000). An example is given in Figure 17, which assumes I saw her as its optimal form of expression. Note that in the input structure, \(<x, y>\) is the a-structure of see and GF\(_1\) and GF\(_2\) are unspecified grammatical functions that argument roles with which \(x\) and \(y\) are associated.

The candidate set comprises pairs of f-structure and corresponding c-structure (and perhaps other corresponding planes of information) generated by the LFG grammar (Bresnan, 2000; Kuhn, 2001). For ease of presentation, I am simplifying the matter by taking the input to be an a-structure \(<x, y>\), and a set of \(<x\)-GF\(_1, y\)-GF\(_2>\) pairs as candidates in OT-LMT, which is a module within OT-LFG that constrains argument-function linking specifically. The candidates are evaluated by a universal set of lexical mapping constraints. The output is taken to be the most harmonic, or optimal, candidate pair; namely, the one with the least (serious) violations (Kuhn, 2001).

### A Comprehensive OT-LMT

The OT-LMT proposed here modifies and expands the LMT component in Bresnan (2001) and is based specifically on the particular formulation of LMT in Her (1997), Huang and Her (1998), and Her (2003), where syntactic feature assignments are simplified, and the multiple mapping principles and well-formedness conditions in the conventional LMT are all unified into a single consistent mapping principle. Here, I will take this further and reinterpret the entire simplified LMT as a set of Optimality-Theoretic constraints and thus offer a comprehensive OT-LMT.

Crucial to the theory are two prominence scales discussed earlier: a universal thematic hierarchy and a markedness hierarchy of grammatical functions (GFs) (see Figures 18 and 19).

Mapping constraints are classified into three categories: well-formedness constraints on argument roles, well-formedness constraints on argument functions, and constraints on linking. Note that we are ignoring athematic arguments in this article. “R” is thus a thematic role in a-structure, and “F” is a corresponding grammatical function. We first examine the well-formedness constraints on the representation of argument roles (see Figure 20).

UniqRol ensures the uniqueness of each and every role in the a-structure and thus rules out a-structures like \(<ag ag th>\) and \(<th loc loc>\). DescendRol further formalizes the a-structure representation, where argument roles descend in prominence. For example, given the locative verb sit and its two roles, theme and locative, in a-structure, \(<th loc>\) is the only well-formed representation; \(<loc th>\) is ill-formed. Two corresponding constraints are proposed for argument functions (see Figure 21).

UniqFun ensures the uniqueness of each and every function in the a-to-f mapping; thus, both of the following are ill-formed: \(<\theta_a\)-SUBJ \(\theta_b\)-SUBJ>, and \(<\theta_a\)-OBJ \(\theta_b\)-OBJ>. DescendFun penalizes a candidate with a violation of the descending order in prominence. For example, because SUBJ outranks OBJ, \(<\theta_a\)-SUBJ \(\theta_b\)-OBJ> has 0 violation and is favored over the inverted \(<\theta_a\)-OBJ \(\theta_b\)-SUBJ>, which incurs one violation. Thus, given \(n\) GFs in a candidate form, there are at most \(n - 1\) violations as there are \(n - 1\) consecutive pairs (Kuhn, 2001). Inversion is still possible, given that all OT constraints are violable in order to satisfy higher-ranked constraints, including language-specific morphosyntactic operations. (We will discuss the possibility of a language-specific component in the next section.)

Next, we move on to the general constraints on the linking between roles and functions.

The two constraints in Figure 22, LinkRol and LinkFun, ensure that each expressed role is linked to a GF and that each GF is linked to a role. A role that is not linked to an argument function causes incompleteness, while an argument function that is not linked to an argument role in a-structure...
causes incoherence. Notice that there is no need to specify a constraint just to ensure that a role is linked to a GF with compatible features. This is accomplished automatically by the universal constraints on the morphosyntactic properties of argument roles shown in Figure 23. LinkPtTh reflects the unaccusative hypothesis that cross-linguistically the primary patient/theme

- c. **LinkUnobj**\( (R, F) \): Given \( \langle \ldots, F \rangle \), \( F \) is \( [\gamma] \)
- d. **LinkUnres**\( (R, F) \): Given \( \langle \ldots, F \rangle \), \( F \) is \( [\gamma] \)
Optimality-Theoretic Lexical Mapping Theory

is encoded as an unrestricted \([-r]\) GF (i.e., SUBJ or OBJ) (Bresnan & Kanerva, 1989; Bresnan & Zaenen, 1990; Zaenen, 1993). LinkRolRes captures the generalization that a non-patient/theme internal argument prefers the syntactic assignment of a thematically restricted function. Finally, LinkUnobj and LinkUnres consistently favor the assignment of a role to the most unmarked function, SUBJ, \([-r-o]\). Each function may have zero to two violations. These two constraints together are more general and insightful than the previous Subject Condition, which simply stipulates that every clause should have a subject.

Note that LinkRolRes does not apply to agent, the external argument. Being the highest-ranked role, it is linked to SUBJ due to LinkUnobj and LinkUnres. This thus accounts for the fact that, for the majority of the world’s languages, agent cannot be realized as an object. However, given the violable nature of these constraints and their variable ranking, the possibility of agent-OBJ does exist as a marked morphosyntactic option. This reflects the insight of Falk (1989) cited in Lødrup (2000) that in Norwegian, “what has been called external theta roles are in fact structurally unspecified theta roles” (p. 173).

-I will follow the standard view in OT and assume that these constraints are universal, but their ranking may be language-specific. For Chinese, I propose the ranking shown in Figure 24.

**An Illustration of OT-LMT**

We will now look at the lexical mapping of three different verbs in their canonical active construction as examples: “melt<th>,” “laugh<ag>,” and “sell<ag th>.” To save time and space, the (many) candidates that violate any of the five highest-ranked well-formedness constraints will be excluded and we only will be concerned with the lower five. Following standard OT notation, in Figure 25, a violation is marked with “*”; a “fatal” violation causing a candidate to lose in evaluation is highlighted with “!” . The shaded area covers the constraints that are no longer relevant in the evaluation of a particular candidate, and finally, the \(\nabla\) sign indicates the optimal selection.

The candidate \(C1, <th-SUBJ>\), with no violation, is clearly the optimal selection, where SUBJ is an unrestricted \([-r]\) function allowed by LinkPtTh, and also the unmarked \([-r-o]\) function preferred by LinkUnobj and LinkUnres.

Next, we turn to the a-structure of an unergative verb “laugh<ag>” (see Figure 26). Here, the only relevant constraints are LinkUnobj and LinkUnres, which again select SUBJ, the unmarked function.

Again, the candidate with no violation (\(CI\)) is the optimal selection.

The final example, *sell*, is a transitive verb with an agent role and a theme role. Again, Figure 27

Optimality-Theoretic Lexical Mapping Theory

excludes candidates that violate any of the five highest-ranked constraints.

Among the candidates, \( C1, <\text{ag-SUBJ th-OBJ}> \), is the optimal selection, even though it does violate one of the two lowest-ranked constraints (i.e., LinkUnobj) due to the linking of theme to OBJ, a function with the marked feature \([+\sigma]\). All other candidates, however, violate at least one higher-ranked constraint. Note that a candidate a-structure where both roles are linked to the unmarked function, thus \(<\text{ag-SUBJ th-SUBJ}>\), violates the highest ranked UniqFun and, therefore, is not included in the figure.

AN OT-LMT ACCOUNT OF LOCATIVE INVERSION IN CHINESE

We first apply the OT-LMT to the canonical a-structure of the locative verb. The theory correctly predicts the following optimal argument-function linking: \(<\text{th-SUBJ loc-OBL}_u>\), shown in Figure 28.

With \( C2, <\text{th-SUBJ loc-OBL}_u> \), as the optimal selection, this constraint ranking obviously does not account for locative inversion, which is represented by candidate \( C4, <\text{th-OBJ loc-SUBJ}> \). An additional constraint is needed.

The constraint shown in Figure 29 draws on the insight found in the default rule for focused theme posited by Bresnan and Kanerva (1989) and also faithfully reflects Bresnan’s (1994) observation on the universals of locative inversion verbs. Given the fact that the complement of the predicador usually carries the discourse function of marking the less familiar information and that the subject is the default grammatical function for topic or more familiar information, the locative inversion operation forces the locative to map onto SUBJ such that the focused theme can surface

</table>
as a complement of the locative verb. With this constraint in place, we now have an important decision to make; that is, whether to posit LinLocInv as a language-specific constraint. Recall that locative inversion is found in many languages and locative inversion verbs share an identical a-structure and function assignment. However, locative inversion certainly does not occur in all languages. In non-configurational languages with extensive case-marking for grammatical relations (e.g., Korean and Japanese), locative inversion may not be found (Huang & Her, 1998). Figure 30 depicts a Japanese example.

Notice that even though the locative phrase indeed may invert positions with the subject and thus affect the focus in Figure 30b, its grammatical functions remain the same. In other words, locative inversion does not affect argument-function linking. Recall the standard OT view that constraints are universal and that only their ranking is subject to variation. Therefore, if we follow the standard OT view and posit LinkLocInv as a universal constraint, languages such as Japanese also must be accounted for, but only with a different ranking of the same constraints. This is the path we will explore. Figures 31 and 32 show the revised ranking we propose for Chinese. Notice that LinkLocInv outranks LinkRolRes and is outranked by LinkPtTh. Again, we continue to ignore the five highest-ranked well-formedness constraints.

We also need to point out that LinkLocInv is irrelevant in the selection of the canonical in Figure 28, because there, the theme is not focused. Now, to account for the data from languages like Japanese, where the focused theme does not result

in mismatches of the function assignment of argument roles, we posit the ranking in Figures 33 and 34. Notice here that LinkLocInv is outranked by all other constraints.

**DISCUSSION**

This section discusses three issues in further detail. The first issue relates to the nature and the
scope of the OT-LMT proposed in the article. The second issue concerns the potential advantages that the OT-LMT may have over the conventional LMT. Finally, we explore some of the directions for further research concerning the OT-LMT.

Morphosyntactic vs. Morpholexical Processes

Given the often idiosyncratic nature of language-specific lexical information, it is not yet clear how
the technical integration of the lexicon should be envisaged in OT syntax, in general (Kuhn, 2001). This article clearly does not address this larger issue. In order to have an insightful lexical mapping theory in OT syntax, we first must be explicit about its nature and scope. The OT-LMT envisioned here is part of a universal OT-LFG theory that constrains argument-function linking. In other words, it constrains the syntactic function assignment of argument roles required by a predicator. Thus, this OT-LMT, as it is currently formulated, has nothing to say about morpholexical processes that alter the “lexical stock” in a-structure (Bresnan, 2001; Bresnan & Kanerva, 1989). Therefore, it is purely morphosyntactic in nature and scope. Crucially, Ackerman (1992) differentiates and characterizes morpholexical and morphosyntactic operations as follows:

**Morpholexical (Operations),** affect the lexical semantics of predicates by altering the semantic properties associated with predicates...**Morphosyntactic (Operations),** assign features supplemental to those supplied by IC assignment\(^{10}\): these operations can affect the final GF assignments to arguments but cannot affect the lexical semantics. (p. 56)

Morpholexical operations thus are word-formation processes that produce predicates with an altered inventory of argument roles, or a-structures, which serve as input to OT-LMT. Morphosyntactic operations, however, are within the proper domain of LMT. Assuming that only morpholexical operations may be language-specific, the OT-LMT proposed thus universally governs how argument roles are mapped to GFs, with constraints that may vary from language to language only in terms of ranking. Thus, as Huang and Her (1998) have argued, given the nature of syntactic assignment of argument roles in the theory, it, in fact, makes the theory more coherent by allowing syntactic feature assignment in morphosyntactic operations. This is precisely how we treated locative inversion. Similar proposals that allow morphological processes to affect syntactic assignments by adding features are found as early as Zaenen (1987) and Her (1990) and later in Ackerman (1992), Markantonatou (1995), Her (2003), among others.

Allowing feature-adding morphosyntactic operations, in fact, also offers a computational advantage. Morpholexical operations constitute a much more powerful formal device computationally in that they are not subject to the general monotonicity condition that information only can be added but cannot be deleted or changed (Bresnan, 1990; Falk, 2001).\(^{11}\) Monotonic morphosyntactic operations with the feature-adding capacity enable a formalism that is more consistent and also more expressive, without any increase in its formal power. Empirically, such operations also have been adopted to account for syntactic variations in several languages; for example, Greek (Markantonatou, 1995), Chinese (Huang, 1995; Her, 1999), and English (Zaenen, 1987).

We will now illustrate this view of the OT-LMT with two more constructions from Chinese that are related to locative verbs. The first one is a passivized locative construction. Three-place transitive predicates like xie “write,” with the argument structure \(<ag th loc>\), do not allow inversion in spite of the locative role it requires. However, there may be locative inversion if the agent role is suppressed. This is observed in Chinese (Huang & Her, 1998) and other languages (Bresnan, 1989; Bresnan & Kanerva, 1989). The examples in Figures 35 and 36 are from Chinese and English.

Recall that passivization, repeated in Figure 36, suppresses the logical subject. In effect, it gives rise to an argument structure \(<ag th loc>\), precisely that of a locative inversion verb. Locative inversion, therefore, is allowed, as in Figure 35c. Passivization thus falls outside of the realm of LMT and is regarded as a language-specific operation. One indication of its language-dependence is in the indirect expression of the suppressed
Figure 35.

| ‘Amei sleeps *(on) the floor.’ |
agent role as an adjunct; for example, the English *by*-expression (Bresnan, 1994). Chinese, however, does not allow such indirect expressions.

The second construction we will examine is the transitivized locative verb. It has been noted that, in Chinese, a two-place locative verb with an argument structure <th loc> in fact allows its locative phrase to be a PP or an NP. The locative phrase thus may be alternatively mapped onto OBL or OBJ (Huang & Her, 1998). This, however, is not allowed in English, as shown in Figures 37 and 38.

Huang and Her (1998) treat this function change as a morphosyntactic variation of the same argument structure; thus, <th-SUBJ loc-OBL> in Figure 37 and <th-SUBJ loc-OBJ> in Figure 38. However, further evidence indicates that this view may be incorrect and that locative transitivization involves a morpholexical change, instead. In other words, without the preposition *zai*, the argument structure is, in fact, no longer <th loc>. Note that the presence of the locative preposition *zai* requires a place noun as its complement in Figure 39. In Chinese, certain nouns are place nouns inherently, such as *xuexiao* “school,” *zheli* “here,” and *gongyuan* “park,” and thus can be the complement of preposition *zai* directly. Non-place nouns, however, must form a constituent with a locative affix such as –*shang* and –*xia*, or a locative noun such as *shangmian* and *xiangmian*; or there

**Figure 39.**

| b. Amei shui diiban. | Amei sleep floor  
| "Amei sleeps *(on) the floor." |

**Figure 41. Locative transitivization**
must be a place noun as the complement of locative preposition zai. Notice in Figure 40 that the object required by the transitivized verb zuo “sit” and shui “sleep” is free of this restriction.

Therefore, it is clear that the objects in Figure 40 do not denote the location where the theme that undergoes the movement ends up; rather, they are the entities that receive the action denoted by the verbs. To account for this construction, I propose a morpholexical operation (see Figure 41).

Two more syntactic tests, shown in Figures 42 and 43, confirm that this argument structure is now <ag th>: passivization and resultative compounding.

In the passive construction, the suppression of the agent results in the theme role’s “promotion” to SUBJ, as seen in Figure 42. In Figure 43, the single composite role, formed by the binding of the theme role of the action verb and the theme of the result state verb, maps to SUBJ (Her, 2004)13.

Based on the prevailing evidence, locative transitivization should be treated as a morpholexical operation that alters the lexical stock of an argument structure, and, as such, it is again outside of the realm of the OT-LMT proposed here.

According to the previous discussion, it is now possible to indicate exactly how the OT-LMT system is envisaged as the module in LFG that links the lexical semantic structure and the syntactic structure of a predicator (Bresnan & Kanerva, 1989; Bresnan & Zaenen, 1990). The particular conceptualization of the a-structure assumed here, as shown in Figure 44, is based on Bresnan (1996, 2001), which, in turn, follows Baker (1983).

The a-structure is a lexical syntactic representation with the minimally necessary information on the syntactic arguments of a predicator, such as the number of arguments, their thematic and syntactic types, and their hierarchical organi-

Optimality-Theoretic Lexical Mapping Theory

As shown in Figure 44, the a-structure “sink <ag pt>” states that the verb sink requires two arguments, one of the type agent and the other theme, and also that agent is thematically more prominent than theme. The a-structure thus contains information necessary for the final syntactic manifestation or more precisely, the mapping of agent and theme to SUBJ and OBJ, respectively.

Morpholexical operations interact specifically with lexical semantics and, as such, are outside the proper domain of the LMT, while morphosyntactic operations are part of the LMT, which constrain the syntactic assignment of a-structure roles. All OT-LMT constraints thus are conceived to be morphosyntactic and universal in nature, while morpholexical operations may be language-specific.

Potential Advantages of OT-LMT

The OT-LMT proposed here targets specifically at the universal constraints on argument-function linking. We leave the OT formulation of morpholexical operations to further research. In this section, we discuss some of the advantages that the OT-LMT may afford.

We start from the fact that all OT constraints are declarative. In the conventional LMT, the two subject conditions must apply sequentially, not simultaneously, to prevent $\theta[-r]$ from mapping to SUBJ, when $\theta[-o]$ is present. Likewise, only after the mapping of the subject role can other roles be mapped. In contrast, all constraints in OT-LMT apply declaratively and, thus, simultaneously. Furthermore, in the conventional LMT, all roles are uniformly assigned exactly one feature for func-
tion assignment, while the OT-LMT allows a more expressive system with only the patient/theme role pre-assigned to unrestricted functions. This OT-LMT thus allows the possibility of agent-OBJ as a marked morphosyntactic selection, which is ruled out in the conventional LMT.

Recall also that two disjunctions are observed in the conventional LMT: the disjunction between the two principles of subject role mapping and the disjunction between subject roles and non-subject roles. The OT-LMT, however, consistently favors the unmarked values for all roles. This characteristic ultimately may lead to the replacement of the stipulation in the Subject Condition while preserving its insight. Thus, in general, this revised LMT formulated in OT formalism offers a potentially more consistent and simpler computational system.

As noted earlier, the LinkLocInv constraint proposed in the OT-LMT account essentially reflects the insight of Bresnan and Kanerva’s (1989) locative default, which assigns \( \text{loc}_{-[r]} \) when \( \text{th} \) is focused. Thus, both accounts are descriptively equivalent in explicating locative inversion in the various languages observed, Chinese included. However, Bresnan and Kanerva’s (1989) account would need to state that languages like Japanese and Korean lack the mechanism of linking \( \text{loc} \) to \( [-r] \). The OT account, on the other hand, has the advantage of a more general solution in attributing the presence or absence of locative inversion in a language to the relative ranking of LinkLocInv, which, like all OT constraints, is universal.

Finally, we will indicate exactly how the OT-LMT better reflects the intuition that the locative inversion construction of \(<\text{th-OBJ loc-SUBJ}>\) is marked in comparison to the canonical locative construction of \(<\text{th-SUBJ loc-OBL}>\). In Figure 46, we examine the constraints that each of the two violates.

Notice that the canonical form constitutes only one violation of one of the two lowest-ranked constraints. The inverted form, on the other hand, violates two of the higher-ranked constraints, LinkRolRes and DescendFun, in addition to one of the two lowest-ranked constraints. Nonetheless, even with such violations, the inverted form still outranks all other candidates. It is, therefore, still the optimal choice, in spite of its markedness. The OT-LMT is, therefore, more expressive and flexible, accounts for a wider range of data, and reveals the (un)markedness of different linking relations. It is, in short, a simpler, more consistent, and more general theory.

**Directions of Further Research**

Considering its limited number of principles, LMT is a relatively small theory but with ambitious goals. In the previous sections, an OT version of the theory has been laid out and tested against cross-linguistic data of locative inversion as

generalized by Bresnan (1994). However, there are locative constructions closely related to locative inversion that have not been covered. For instance, locative inversion might bear some relation to sentences with an expletive subject and a locative argument (Bresnan, 1994). Figure 47 is an example from French.

The expletive subject is an athematic argument, and, as such, it must receive an intrinsic \([-r]\) classification by the very nature of thematic restrictedness \([r]\), (Bresnan, 2001). Given its initial position, it invariably links to \(\text{SUBJ}\)\(^7\). Similar to the locative inversion discussed earlier, this construction also indicates that the object function of the theme role renders it more focal than the oblique locative role. An athematic argument in the a-structure is indicated by an underscore outside of the angled brackets, while thematic arguments are within the angled brackets. Thus, the a-structure of Figure 47 is “\(\text{arrive} \_<\text{th}[\text{foc} \text{loc}]>\)” An expletive subject also may be associated with the linking of agentive objects. Figure 48 is an example from French.

Similar phenomena also are observed in Bantu languages (Demuth, 1990; Demuth & Mmusi, 1997; Harford, 1990; Machobane, 1995). All these issues are important and interesting but cannot be adequately addressed in the current article. Further research is needed on how the a-structure “\(\text{arrive} \_<\text{th}[\text{foc} \text{loc}]>\)” and “\(\text{work} \_<\text{ag}[\text{foc}]>\)” come about, whether they are morpholexically or morphosyntactically related to “\(\text{arrive} <\text{th loc}>\)” and “\(\text{work} _<\text{ag}[\text{foc}]>\),” respectively, and how best to incorporate such relations within the OT-LMT proposed here.

**Figure 49. Asymmetrical object parameter (AOP)**

\[
\begin{array}{c|c|c|c|c}
* & \_\_ & \_\_ & \_\_ & \_\_ \\
\_r & \_r & \_r & \_r & \_r \\
\end{array}
\]
Further development of this OT-LMT also will need to address the issue of secondary patient-like roles as a parameter of variation in double object constructions, known as the Asymmetrical Object Parameter (AOP) (Alsina & Mchombo, 1993; Bresnan, 2001). In a non-AOP language, all patient-like roles are linked to an unrestricted function, while AOP languages must link the secondary patient/theme to an object function. An additional constraint may be necessary, and constraint ranking then may reflect this variation. This asymmetrical object parameter is stated in Figure 49.

Finally, the OT-LMT developed here needs to be applied to a much wider range of data cross-linguistically; for example, complex predicates in various languages (Abaitua, 1988; Ackerman, 1992; Alsina, Bresnan & Sells, 1997; Her, to appear; Ishikawa, 1985), the valence-changing morphemes and inversion constructions in Georgian (Blevins, 2005; Harris, 1981; Holisky, 1981), among others. A solid analysis of some of these facts would be a significant test of the linking theory proposed here.

CONCLUSION

In this article, we set out to accomplish two goals. The more ambitious one is to come up with a simpler and more general lexical mapping theory in OT terms, or OT-LMT. The second one is to test this theory and account for locative inversion in Chinese, English, and Chichewa on the one hand and Japanese and Korean on the other. Following the standard view in Optimality Theory, the mapping constraints we proposed are all universal, and language variation in locative inversion is accounted for by different constraint rankings. The OT-LMT we proposed is the UG component that constrains the argument-function linking, or morphosyntactic processes. It thus does not govern language-specific morpholexical processes, such as passivization, locative transitivity, and resultative compounding. Locative inversion, on the other hand, involves only morphosyntactic operations and, therefore, is accounted for within the OT-LMT.

In summary, the OT-LMT we proposed not only covers a wider range of empirical data, but it also affords a simpler, more consistent, and more general theory.

ACKNOWLEDGMENTS

I am genuinely grateful to the three anonymous reviewers for their insightful comments and exceedingly generous suggestions, and also to Adams Bodomo for his encouragement. I also thank Nissa Hui-shan Lin for discussions on OT. However, I am solely responsible for the content of the article. Research reported in this article has been funded partly by NSC grants 92-2411-H-004-024 and 93-2411-H-004-006. Part of the research for the article was done while I visited the School of Information Technology, Bond University in 2003 and 2004. I thank the dean, Professor Ron Davison, for his kind and continuous support.

ENDNOTES

1 See Bresnan (2001, chapter 14) for a brief exposition of other formulations.

2 Falk (2001) also presents a concise introduction to LMT and a more precisely defined theory of argument roles. Dalrymple (2001) offers more examples in her introduction to the theory.

3 The concept of thematic hierarchy is well-established (Grimshaw, 1990; Li 1995). The hierarchy in “The Subject Condition” also might be derived from the proto-role properties proposed by Dowty (1991) (Ackerman & Moore, 2001b; Bresnan, 2001).

4 Note that following Zaenen and Engdahl (1994), the two propositional argument functions COMP and XCOMP are treated as instances of OBL.

5 Note that Θ refers to the most prominent role in the a-structure. The fact that it is also the left-most role within the angled brackets is inconsequential. Θ is usually also the initial role, unless there is an initial athematic argument.

6 Alsina (1996) also argues that the function-argument bi-uniqueness condition, which is fully integrated in the OT-LMT proposed later, is too strong.

7 A constraint for athematic roles must restrict such roles to [-r]. Alternatively, a constraint may be proposed to outrank LinkFun in Figure 22b and thus allow a GF in a-structure to be unmatched.

8 An additional constraint is needed for the secondary patient/theme, which restricts the secondary pt/th to [+o]. Again, we will ignore this issue in this article.

9 DescendFun and DescendRol effect a parallel alignment between the thematic hierarchy and the markedness hierarchy. This parallel alignment is similar to a harmonic alignment, but with an important difference. In a harmonic alignment, according to Prince and Smolensky (2004), the correspondence between a more prominent element on one scale and a less prominent element on the other is worse than the correspondence between two elements that are equal in prominence (Aissen, 1999; Asudeh, 2001; Lee, 2001; Sharma, 2001). Thus, it is better for agent, the most prominent role, to link to SUBJ, the most prominent function, and likewise for locative, the least prominent role, to link to OBJ. However, in our scheme here, due to LinkUnobj and LinkUnres, a more prominent GF is favored, regardless of the prominence of the role.

10 IC refers to the intrinsic classification of argument roles. See Figure 7.
Therefore, as I have proposed elsewhere (Her, 2003), morpholexical operations likewise can add features and, thus, alter syntactic assignments of argument roles, besides changing the lexical semantics of a predicator.

See Her (1989) and Ting (1998), among others, for compelling arguments against viewing the *bei*-NP phrase as a PP *by*-phrase. In fact, the same concept of suppression in passives is used here, as well. See Her (2004) for details of mapping the composite role, formed by two roles, to a single GF.

Note that I am only referring to computational efficiency in formulation and formalism, not in practical terms of an actual computational implementation. See Kuhn (2003) for extensive discussions on the computational aspects of OT. However, there is little practical evidence for the computational efficiency of a large-scale OT implementation of a grammar, as there seems to be no such practical systems yet. For the computational efficiency of LFG in general, see Maxwell and Kaplan (1996, 1993, 1991); for LFG in practice, refer to Kaplan, et al. (2004). I thank the anonymous reviewer who made this point and provided the references.

I thank another anonymous reviewer for pointing this out to me.

I thank the anonymous reviewer who suggested this direction of further research and provided this French example and its discourse analysis.

Refer to Bresnan (2001, section 14.1) for a more in-depth discussion on athematic arguments in raising constructions.
Section VIII
Emerging Trends

This section highlights research potential within the field of human-computer interaction while exploring uncharted areas of study for the advancement of the discipline. Chapters within this section highlight the socio-semantic web, podcasts, and the emergence of increasingly intelligent user interfaces. These contributions, which conclude this exhaustive, multi-volume set, provide emerging trends and suggestions for future research within this rapidly expanding discipline.
Chapter 8.1
Podcastia:
Imagining Communities of Pod-People

Jonathan Cohn
UCLA, USA

ABSTRACT

While podcasting has become a valuable advertising tool for many companies, it has also become a major way in which geographically spread out communities have been able to stay connected. Podcasts, like many other new Internet genres, are thought to be listened to mainly by an affluent audience who create podcast themselves. By looking at the various institutional and production issues and audiences of the podcast medium, this chapter will show how this genre works to create and sustain mass communities of “prosumers” and mobile audiences. Also, this chapter will historically contextualize the podcast by showing ways in which it is not simply a reiteration of earlier technologies, but also a distinct new medium with a unique, prosumer-friendly mode of transmission and reception.

INTRODUCTION

The sudden rise of podcasting on the “new media” scene has stunned, perplexed, and pleasantly surprised a vast majority of techno-savvy producers and consumers. According to the The New Oxford American Dictionary, which named “podcast” the word of the year in 2005 (“Wordsmiths hail,” 2005), this term refers to “a digital recording of a radio broadcast or similar program, made available on the Internet for downloading to a personal audio player” (“podcast n,” 2005). This is a simplified definition that does not take into account that almost any type of media can be podcasted, including audio, video, or even text. While “radio broadcasts” make up a large proportion of popular podcasts, they are by no means the only possible origins of a recording. While much of the reporting and advertising of podcasting has centered around commercial podcasts like recorded radio programs or newspaper articles, most are still made by amateurs who design them with the podcast as the intended platform. It has been most compared to amateur mediums like the communal ham radio, the subversive pirate radio, and the editorial and journalistic blog, which podcasts are usually formally attached to.

What separates a podcast from Internet radio, another genre of streaming media, which podcasts
Podcastia are often conflated with, is that a podcast is not live, and it is stored on the user’s computer or mp3 player. A podcaster records a show using any of a number of audio programs that can range from simple and free to professional and expensive. They then often use a sound-editing program, like the free Audacity or GarageBand, to edit and clean up their recording. These programs offer extensive Help Menus and excellent podcasting tutorials. The final steps involve getting your sound file online before they put it on their Web site attached to an RSS, or Really Simple Syndication feed. This is a file format that allows for media to be easily syndicated throughout the Web. There are many Web sites that will both turn your file into an RSS feed and upload the file to the Web for you. For example, professors are now beginning to record their lectures and put them on campus Web sites attached to an RSS feed. The RSS feed tells students when new recordings are available and allows them to download them automatically. For instance, Google search for “LectureCast” brings up many Web sites, like the popular www.podcastdirectory, which offer many free podcasts of UNLV lectures.

There are many different ways to create a podcast and finding the way that works best for you is largely based on your knowledge of sound editing and Internet technologies, as well as the type of computer and software you are using. Due to this large range of methods that can be used to achieve your goals, I will not be going into very much detail on the techniques of podcast creation, but luckily there are many great online tutorials that I advise everyone to explore. My favorite is www.how-to-podcast-tutorial.com. This site goes into a great deal of detail on both how to create and improve podcasts, as well as how to promote and think about your content. The Podcasting Tools Web site (http://www.podcasting-tools.com/how-to-podcast.htm) is another site that is particularly good at explaining how to record and edit audio. Most new audio recording software should also include a help section on podcasting as well. Also, a simple Internet search will bring up many more helpful sites and as this technology is still changing and growing, this is the best way to get up-to-date information on podcasting technology.

For podcast consumers, the process starts with them either scouring the Internet, or a podcast directory for LectureCast. There are many searchable directories online, but the most well known is the one attached to the iTunes Music Store (iTMS), which is part of Apple’s iTunes music software. After the professor’s podcast has been found, the user must subscribe, or download a link, to LectureCast into a “podcatching” program, like iPodder, or iTunes. This program will keep track of the LectureCast RSS link and download the individual lectures as soon as the professor attaches them to it. Consumers can then listen to them on their computers, or move them to an mp3 player so that they can listen to them on the go.

This mode of reception, which is not dependent on time or space, as most radio and television broadcasts are, has become particularly popular with those living in urban, subway-ridden environments, where radio transmissions are unreliable at best, and also those who have moved away from these cities, or have simply moved around often in general. They are also, like many other new Internet genres, thought to be listened to mainly by those who also produce them. By looking at the various institutional and production issues and audiences of the podcast medium, this chapter will show how this genre works to create and sustain mass communities of mobile audiences and “prosumers,” or consumers who also occasionally produce media. This term has long been used by electronics and camera equipment companies, who consider this market segment to be quite profitable.
BACKGROUND

The term, “podcasting,” was coined in The Guardian in February of 2004 (Hammersley, 2004), but it was not until an article in the March 2005 issue of Wired called, “Adam Curry Wants to Make You an iPod Rock Star,” that it moved from a very obscure and tech-centered genre, to a popular emerging genre. Curry, the former MTV VJ along with Dave Winer, the original author of RSS code, have both been major innovators and proponents of podcasting technologies since their inception. Curry is also credited with having produced one of the very first podcast, The Daily Source Code, which was a place “where developers and users party together” (2005). Even at its inception, podcasting was envisioned as a genre that could discard the distinctions between producers and consumers, as both groups were always part of the same creative community.

In the Wired article, Curry evangelizes this new genre, which he hopes will allow for amateurs to compete with commercial radio. He proceeds to make a podcast with his interviewer in the front seat of his car, while extolling the virtues of what he called “unregulated, low-cost, on-demand radio.” This forum has created, according to the interviewer, Annalee Newitz, products that are “obsessively internecine and gloriously, honestly unprofessional.” She also notes that everybody in the podosphere seems to know everybody else...On his show, Curry coos over a daily Bible podcast that features kids reading bits of the new Testament, while husband-and-wife podcast team Dawn and Drew speculate about whether Whole Wheat Radio is really recorded in a shack...When was the last time you heard your favorite morning show team crack an in-joke that referred to what a movie reviewer said two days ago on another station? (Newitz, 2005).

While in the television industry, until very recently, networks compete for viewers during timeslots, during this early period of podcasting, there was no competition, as the audience could listen to all of the podcasts that it wanted to in consecutive order. It also helped that there was no money involved, as this was a communal hobby for most people who “never would have had the time for Internet broadcasting if it hadn’t been as easy as “clicking a button and talking’” (Newitz, 2005). Newitz reports that many of the first podcasters took advantage of the easy, quick, and FCC-less production process by simply screaming expletives for long periods of time, playing indie songs they liked, lazily chatting on the couch, and giving sex advice. These interesting, if usually unsuccessful experimentations with the form only encouraged more listeners to become producers themselves as their seems to be no downside in expressing one’s amateurish self, or at least one’s guttural utterances of offensiveness, as loud as possible in this medium.

MAIN FOCUS

In 2005, podcasting became more popular and many of the products began to become more polished. One such podcast was Cinecast, a movie review show that featured two friends, Adam Kempenaar and Sam Hallgren, in Chicago. At the time of this book’s publication, this podcast is now called Filmspotting and can be subscribed to through the iTMS. Kempenaar saw the article in Wired and read the instructions in the article on how to cast. He saw how easy it was to do and called his friend Hallgren to ask, “Do you want to be a radio star?” (“Interview,” 2005). They heard all of the amateur-type shows and thought that although “that’s kind of the beauty of podcasting...We thought we could do something that seemed like a real radio show” (2005).
This has made them very popular with both the original podcasters community, and with those who were just discovering the technology. Curry even mentioned them in the first two episodes of his Podfinder podcast, “an audio directory” in which Curry points out “the latest and greatest in podcasting” (Curry, 2005). This is a very influential podcast among certain pod audiences and producers, and it is generally an honor to be included in it.

Cinecast was also featured on the front page by the iTMS when it started including podcasts on June 29, 2005. This resulted in a jump from hundreds to many thousands of listeners. This exposure, “along with a plug from podcast guru Adam Curry, sent their show skittering up to the iTunes list of the top 100 podcasts, peaking No. 13” (Green, 2005). Within a month, “Cinecast jumped from 250 to 50,000 subscribers” (Friess, 2005a). This large and sudden growth illustrates the importance of trusted gatekeepers, like Curry and iTunes, in emerging genres, as they tend to direct information traffic to what they consider worth at least checking out. By “gatekeeping,” I am referring to the way these entities process and filter information even as they relay it from the producer to the consumer. As gatekeepers, they decide which podcasts are heard and what information is important.

Curry fulfills his role as gatekeeper through both his Podfinder cast, and his larger network of podcasters, called Podshow network. Many networks, or communities of podcasters have formed in an effort to bolster their ranks, legitimate the format, and hopefully gain sponsorship (“PodShow,” 2006). This business model is based around the idea that by forming larger networks, advertisers will be able to feel more comfortable advertising through them. So far, placing commercials at the beginning or halfway through an episode has been one of the more popular podcasting business models for more established podcasters.

In Wired in September 2005, Tim Bourquin, the producer of Endurance Radio, a sports themed podcast, which was successful at gaining sponsorship from Gatorade and Fleet Feet Sports said that one of the biggest challenges was that “most potential sponsors don’t even know what a podcast is” (Friess, 2005a). By forming these larger communities, many podcasters have been able to gain a visibility and marketability that they probably could not have gotten on their own. This business model is similar to ad-based television, which is organized into networks, which sell a commodity, or the audience, to advertisers. However, it should be pointed out that the money podcasters are earning for their work is miniscule and virtually all independent podcasters have day jobs.

While Cinecast has Peerflix (a Netflix-like company) as their title sponsor, and other secondary sponsors (like HBO, USA Network and Honda) through Podtrac, their “network,” they aren’t actually making very much money: “we’ve been making enough off sponsorship and listener donations to cover our costs and pay a little bit out to ourselves…We’ve saved enough to start thinking about advertising, upgrading equipment, etc…But full-time job? No, we’re not really close to that at all” (A. Kempenaar, personal communication, June 6, 2006). It is certainly possible that as the podcast audience grows, the revenue stream will as well, but for now, most podcasters do it simply because they enjoy it and hope, or “expect profits to come later” (Friess, 2005b).

The addition of podcasts on iTMS, the most pervasive gatekeeper of all digital media, has also had a profound effect on the podcasting community. Most importantly, by legitimizing the technology and making it readily available to anyone who listens to, or watches media on their computer, iTunes made it extremely appealing to many television networks and film conglomerates. Now, only a handful of the iTunes top 100 podcasts are independently made, and those that are usually have an “explicit,” or “X,” rating
next to them. Many of the corporate podcasts are repurposed material from Comedy Central, Cartoon Network, ESPN, NPR, and various news channels and programs. Fox has podcasts for many of their shows, including Family Guy and The Simpsons, which are literally just the reading of a plot summary of the last week’s episode. Film studios also regularly now make podcasts to advertise their movies.

There is also now a large number of fan podcasts, devoted to discussing the worlds of Harry Potter, Lost and other popular programs. The quality of these fan podcasts ranges and many of these appear to be paid for by media conglomerates, but it is not always clear, as they don’t have commercials and they do not usually advertise their affiliations. Instead, the show itself acts as a commercial even as it acts as a site of a fan-based community in the same way sci-fi conventions do.

By looking at the iTMS top100 list, one might come to the conclusion that independent podcasts have been decimated by the onslaught of corporate media, but this is highly misleading and the situation is not so dire. There is a fear that “once a podcast drops off the top 100 list, it’s almost impossible for a casual visitor to find it...it will be harder for a new indie podcaster to get an audience” (Chin, 2005). It is true that when iTMS podcasting started, “47 of its most popular podcasts were produced by what some call “independents,” and by July 18, 2005, that number had dropped to 31 and continued to fall (Barnako, 2005), the actual audiences of most independent podcasts has risen considerably.

In one blog entry on the subject of whether iTunes was hurting indie podcasts, many people posted replies saying that even though their rankings might have gone down, their subscribers have greatly increased” (“Comments,” 2005-2006). Others also wrote in saying that their “subscriber…base has gone up 12x since our listing on iTunes. So being an independent “niche” podcast with no hope of breaking the top 100, we are thankful for iTunes” (2005-2006). While the very top podcasts are controlled by major companies, it is clear that there is a rather long, and large tail behind it filled with the independents, which can skew the total podcast listenership to the indies (Honan, 2005). iTMS also donates commercial banner space to some of the independent podcasters that they think should be noticed, like Cinecast, in the hopes of leveling the playing field a bit (A. Kempenaar, personal communication, May 12, 2006).

Users can also go to alternative, independent podcaster network and directory sites instead of iTunes to find more obscure titles that iTMS might not be carrying or promoting. There are many sites that are easily searchable by looking on Google, or by typing in addresses like www.podcast.com, which is one of many alternative sources for podcast feeds. Original, independent and amateur (if sometimes absolutely bizarre) podcasts still exist but they are just a bit more difficult to find than those made by Viacom and News Corporation.

The biggest dilemmas for some independent podcasters on iTMS come not when they fall off of the top 100 list, but when they suddenly find themselves on it. The day after podcasting went live on the iTMS, Cinecast, and many other casters suddenly discovered that the number of people accessing their podcast RSS feeds had exponentially increased, which meant they had to upgrade their server plan to one that allowed for more bandwidth. This can be expensive, as while a small, 100 Gigabyte server package can cost $25 a month, a 1,200 Gigabyte package, which was what was necessary for some to handle the increased traffic, is $300 a month, a much more expensive proposition for a group that mostly thinks of podcasting as a hobby that they do not expect to be compensated for (Friess, 2005a). Luckily, those that do make it onto this list usually pick up sponsors pretty quickly, which usually pay for at least the amount that it costs to get the podcast on the air.
However, this process of getting a sponsor can be extremely difficult for those who have only recently found their audience. Companies like to know the size and demographics of audiences before they commit to advertising and this information can be extremely difficult to figure out in this medium. iTMS doesn’t share these kinds of statistics with anyone and they also do not share how they rank podcasts on their top 100 and top 25 lists. This has irked many, as at times these two lists, which should be identical, have had unexplained discrepancies (Friess, 2005b). Theoretically, these issues should not be a problem when figuring out exactly how many subscribers a podcast has, as iTMS really only provides links to other Web sites and RSS feeds, and those other Web sites can normally keep a tally of how many people are using them.

This system breaks down, unfortunately, right as most independent podcasters need it to work best. If iTMS features a small podcast on one of their pages in the hopes of helping it find an audience, as they did with Cinecast, Apple will sometimes cache the podcast on their own server in order to make sure the added traffic doesn’t overwhelm, or crash the originating server. This is necessary, as iTMS “counted more than 1 million podcast subscriptions through iTunes in the first two days alone,” an impressive number considering that before this launch very few people even knew what a podcast was (Friess, 2005a). Unfortunately for the podcasters, this also means they have no way of knowing how many people are actually subscribing to their podcast through this program and cannot give accurate information to prospective advertisers.

Luckily, many businesses have sprung up in order to help podcasters with gathering information for advertisers. One such company is Podtrac, “The podcaster-advertiser connection” (www.podtrac.com, 2006). This entity provides surveys to podcasters, who put them on their Web sites, along with Third Party Measurements and Media Kits. For a cut, Podtrac will also help podcasters get advertising from companies like HBO, USA Network and Honda. Podtrac paid for a survey study in December 2005, that showed that only 32% of their correspondents were familiar with the term “podcasting,” 32% of those familiar (10-12% of the whole) had ever listened to one, and 41% of that group (4-5% of the whole) had listened to one in the last week (“Men are listening,” 2005). The study also found that 78% of those who had ever listened to podcasts were male, but women were just as likely to have listened in the past week. Podtrac expects this gender difference to disappear after a while and compares it to the early days of the Internet: In 1994, 95% of Internet users were male, but now that number is closer to 48%. They also point out that the PodTrac surveys for individual podcasts has shown that the demographics vary greatly from show to show, and therefore podcasts can act as a good outlet for advertisers to target specific audiences (2005).

While these numbers are small compared to most other mass medias, this ability to target specific audiences has convinced many that this could be a lucrative investment. Other surveys, from companies like Jupiter Research have come out with statistics saying that the average consumer of podcasts is “male, earns big bucks and...is a youngster” (Vaas, 2005). The Cinecast audience, according to their PodTrac survey of almost 700 people, is very similar, made up mainly of 18-34 year old white, college educated, single men (A. Kempenaar, personal communication, June 6, 2006). This has historically been a highly sought-after demographic and explains why many companies, like Chrysler, were “excited about supporting this new technology...in general, we’re finding that advertisers are looking for new and different ways to reach people” (Friess, 2005b).

Specifically, the group that can be targeted easily by podcasts in a way that is much more difficult for other types of media is the mobile audience. The mobile audience has been linked to all electronic modes of communication, from the radio to the television. In his essay, “The Technol-
ology and the Society,” Raymond Williams explores the “operative relationship between a new kind of expanded, mobile, and complex society and the development of a modern communications technology” (Williams, 2000). He explains that the television and radio complex “is characterized by two apparently paradoxical yet deeply connected tendencies of modern urban industrial living: on the one hand mobility, on the other hand the more apparently self-sufficient family home … a form of mobile privatization” (Williams, 2000). Williams uses the mobile audience as a useful way of thinking about how, in the 1950s, instantaneous media forms could unite and inform large populations. As it became easier to move around the country via freeways and live on the outskirts of cities in suburbs, television became a way in which these secluded and private homes could still be part of the imagined national community.

This same principle underlies the ways podcasting works to create and maintain spread out communities that are both national and global in size. Just as people turn on television sets to reestablish communication, or at least gather information about the national community, which they have separated themselves from through their mobile, privatized existence, iPod users listen to podcasts to reconnect to the outside world. The term “iPod” implies that by putting on your microphones, you are enclosing yourself inside of it, and removing yourself from whatever dirty bums have chosen to sit next to you on the subway. The ads for the iPod and iTunes both support this reading, as some of them show a woman walking down the street with earphones on, as her reflection dances to the music. Others show outlines of people with cool hair dancing in place as they listen to their iPods, as if the body’s movements were removed from the body itself. As a mobile medium, the iPod, and podcasts allow for you to virtually move wherever you might want to go, while your body stays in one place, “on the subway or waiting in line at the post office,” two of the more widely prescribed ways of listening.

Oddly enough, the place many mobile audiences seem to want to virtually go is home. WBEZ, the NPR affiliate in Chicago released many of their radio programs as podcasts in the hopes of exposing “listeners potentially around the world to the variety of the city.” They did get an international audience and e-mails from places like Australia and Iraq, but “a lot of them are displaced Chicagoans” (Coomey, 2006). This points to the popular use of podcasts to keep track of what is happening in their hometowns. There are many podcasts devoted to local news and many others that highlight various sports teams and regions. If one was a big West Virginia Mountaineers fan but had left the area, they could easily go on iTunes and find a podcast of local sports news. One can even listen to a podcast that will tell you the weather in Charleston, West Virginia and many other cities throughout America.

The ease of use and inexpensive nature of podcasting has also made it an easy way for families to stay up to date with each other over large distances. When Apple announced that they were going to make it easier to photocast (i.e., send collections of photos like one would send audio or video tracks using RSS feeds, to view on iPods or on your computer), they framed it as being an easy way for grandparents to send people in their family pictures they were taking. While it might seem just as straightforward to read an e-mail or look at a blog about your hometown or family, one does not always have the time to sit down at a computer and read through an entire blog or long e-mail. If one does not have the time for reading an e-mail, one also usually does not have the time to watch television and the podcast is an easy solution.

Even if one is traveling long distance in a car, by subway to work, or is running on a treadmill, the podcast allows one to stay firmly connected to local, national, and global news. Radio and other live broadcast technologies are not feasible in these scenarios as you either can’t get a clear signal or are moving so much that the signal can’t
stay strong. These are the kinds of activities that one is supposed to partake in while listening to podcasts, as emphasized by the glut of iPod to car adapters, clothing designed to hide iPods on “dangerous” subways, and arm bands to keep iPods firmly in place as you jostle about in time and space.

Conversely, the price of this ability to stay in place as you move around is that the technology could be said to dislodge you from your particular location in time and space and put you in the realm of the virtual. By necessity, podcasts are always taped in advance and it usually takes iTMS and other sites at least a day to make an episode available. Among other things, this means that if you are listening to an ESPN podcast, you are most likely hearing the announcers speculate about a game that has already taken place. Spatially, even if you are on a bus in Los Angeles, listening to a podcast about people starving in Sudan, you might no longer be aware of your surroundings and miss your stop.

In “The Poetics of Augmented Space,” Lev Manovich questions this image that people plugged into earphones, on the Internet, or running around in a virtual reality simulation are actually divorced from their physical bodies and positions in space. He points to the fact that the image of “a person checking her e-mail or making phone calls using her personal digital assistant/ cell phone combo while at the airport, on the street, in a car, or in any other actually existing space” has superseded the earlier image of a person with a plug in their head, wandering around cyberspace as their body lies limp and cold (2003).

Instead of removing you from space, augmented Reality “helps the user to do the work in a physical space by augmenting this space with additional information” (Manovich, 2003). If one thinks about the iPod as a way of augmenting, instead of obscuring space, the event of riding a bus while listening to a podcast about the poor in Sudan may become conjoined and the audio may affect what and how you see the people around you. It is also possible that by listening to your grandmother tell you in a podcast how her day was, the subway ride might become a little less “dangerous,” and a bit more like home.

These spatial and temporal connections and dislocations that can be made by listening to a podcast in one place that was made in another, are also created and sustained within the shows themselves. For example, while Cinecast started out as made up of a few sections, including recent film and DVD reviews, along with a weekly top 5 list (i.e., top 5 horror films, westerns, break up movies, etc.) quickly their episodes got longer and longer as they started to read listener’s e-mails and play their voicemail. While they started out ranging from 20-30 minutes long, they usually span 50-60 minutes and usually almost half of the podcast is dedicated to replying to e-mails. These e-mails range from asking how the host could have left one of their favorite movies off of their top 5 list, to correcting them for saying someone won an Oscar when they most certainly did not. All of the e-mails are treated as if they come from places of knowledge and usually the answer to why they left a movie out is because they haven’t actually seen it.

Every few weeks they also do short movie marathons, where they will watch a few films from a genre or director that they do not know enough about, and then talk about their reactions during the podcasts. The films they watch are always decided by listener’s e-mails and online responses, as are the choices of recent films to go see. Thus, while you listen to this podcast, you are constantly reminded that you are not the only one and that many others across the planet share your same interests and are just as knowledgeable as you, or the hosts of the podcast itself.

When referencing the e-mails, the hosts always say both the first name of the person and their physical location, which only makes this communal activity of bashing cinema and nostalgizing old films more explicit. Kempenaar said that while reading e-mails has not directly helped get them
sponsors, it has encouraged more people to start and continue to listen to the program. This is an old radio and television trick that helps to both create a larger, more active audience and also the image of said audience.

Anecdotally, Kempenaar said he was talking to someone at a company that puts content on phones and had obviously seen a lot of podcasts. He “provided 4 e-mails from a cross-section of listeners and they were so persuasive that he started listening to the show and is now a regular listener” (A. Kempenaar, personal communication, May 12, 2006). Cinecast, and many other podcasts, also have frappr maps. These are maps from http://www.frappr.com, that a podcaster, or anyone, can make a link to on their page. Then, anyone who wants to can go to that link, click on where on the map they are living, and see where all of the other listeners are from.

It is impossible to tell how many people are actually interested in this feature, but there are many “push-pins” on the page for Cinecast, spread out across the globe, though most of the people are located in urban areas along major bodies of water (as are, in general, most cineastes...and people). Kempenaar wrote that their acts of “promoting feedback is more to engage [their] audience and make them part of the discussion...the key is interesting feedback, not necessarily where it’s coming from. But it has been great to get e-mails from Germany, Sweden, France, Japan and so on...” (A. Kempenaar, personal communication, June 4, 2006). These techniques have helped make podcasts like Cinecast a large community of equals that stretches globally, in which everyone can learn from each other.

Unfortunately, this spread out audience also makes it more difficult to find and retain sponsors for these relatively small podcasts. Small and local businesses are usually the ones most likely to advertise on community-based programming, but since podcasting communities are usually spread so thin, there is no way for these types of establish-

ments to prosper from working in this medium. Cinecast’s first sponsor was ChicagoMixer.com, a dating service for the Chicago area. After seeing “very little increased traffic for its money,” the sponsor left and the show was later picked up by Peerflix, a service that is not very location specific, though they probably won’t make any money from the 20% of their listeners that are from “59 other countries” (Friess, 2005b).

**FUTURE TRENDS**

The virtues of podcasting and the communities that they can create are not simply good for amateurs, but also for radio, television, and film. While these other forms of media slowly appear to be infiltrating podcasts, some radio stations are beginning to incorporate podcasts into their programming. CurrentTV regularly features material that used to be or could become a podcast. The format of that channel is basically the same as a podcast network, but on a much larger scale.

In radio, the CBC recently said that the shows they have made into podcasts have helped reach to a new demographic and that they hope “podcasting will become a two-way street: ‘We hope to get content from average people who will effectively become citizen producers’” (Newitz, 2005). KYOU radio in San Francisco is now programmed almost completely out of podcasting programs. The hosts of Cinecast now have a monthly radio show on WBEZ in Chicago, and Adam Curry, the guru of podcastia, can be heard regularly on Sirius Satellite Radio. As amateur podcasts migrate into these more mature, or at least older, forms of media, podcasting will become a more prevalent way of experiencing world news, arts and culture. In the process, TV and radio are even now beginning to take a few lessons and are trying to go more global in their scope, and personal in their reach.
CONCLUSION

Podcasting has become one of the most popular ways for both amateur and commercial broadcasters to transmit their own programs. While the process of putting a podcast online is simple compared to getting a program on television or radio, it is notoriously difficult to sustain an audience for more than a short period of time. It is also difficult to make any money through this medium, as few will pay to listen to podcasts and advertisers still see the form as an uncertain platform with a small audience.

However, it has tremendous potential for use in classrooms and other educational settings. The largest dilemma for podcasters is the difficulty of making the public aware that their programs exist. This is not a problem for professors, who can simply announce to their classes how to find their programs. Professors can record their classes for students to listen to at home and augment their studying, conferences can record their panels for those who can’t attend, and libraries and other facilities can use them to announce new programs, archives, and upcoming events. This is a great way to advertise and increase the audience for local events as well as make these events known to a larger group of international listeners.

REFERENCES

Men are listening to podcasts but women are getting hooked, too. (2005, December 27). PodTrac Press Center. Retrieved February 8, 2008, from

**Key Terms**

**Autocasting:** The use of software to automatically create audio podcasts out of text on a blog or other Web site.

**Blog:** A shortening of Web Log. It is a diary, or log-like Web site. New entries are displayed at the top of the Web site and older ones get pushed down. Podcasts are often formally attached to blogs.

**Digital Audio Player:** Also commonly known as an MP3 player. These are often small handheld devices, which minimally contain memory storage, a battery, and audio output. Most, if not all, are able to play compressed MP3 music files, though MP3 is just one of many types of digitally encoded audio files. The most popular of these are iPods. While iPods have lent their name to “podcasts,” any type of digital audio player can play podcasts. Many cars and home entertainment systems now also play digital audio files.

**Gatekeeping:** The process of filtering and editing information for a consumer. This is done through the editing of information within a piece of media, or through the decision of which media will be advertised and made more easily available to the public.

**Internet Radio:** Audio that is streamed and listened to via the Internet. Unlike Podcasting, Internet radio is not saved to a user’s computer and can therefore not be listened to on an mp3 player or away from the computer itself.

**MP3:** Also known as MPEG-1 Audio Layer 3. This is a popular compressed digital audio format. Most podcasts are compressed as MP3s. While the sound quality of MP3s is not as good as an uncompressed audio file, most people find it to be adequate for their needs.

**Podcast:** A digital recording of audio, video, text or other media that is distributed by subscription over the Internet.

**Podcatcher:** Software on a user’s computer that manages podcasts. One can search for and download podcasts using a podcatcher. This program will then continually check online to see if any new files have been added to a subscribed podcast. If they have, then the Podcatcher will download them. The most common Podcatcher software is Apple’s iTunes Music Store.

**Prosumer:** Usually thought of as an amateur producer, or someone who normally consumes media, but occasionally also produces it. This
Podcastia

segment of the population has paradoxically been thought of as a lucrative market segment that in many ways has a great amount of independence from the mainstream economy.

RSS: Stands for Really Simple Syndication. This is a simple piece of XML code that allows online media to be easily and frequently updated and added to. A Podcast is a type of RSS feed.

Chapter 8.2
Maximizing Web Accessibility Through User–Centered Interface Design

Soonhwa Seok
The University of Kansas, USA

ABSTRACT

Digital inclusion and Web accessibility are integral parts of modern culture and, as such, have implications for social accountability. The World Wide Web Consortium (W3C) has suggested standards and guidelines regarding the inclusion of people with special needs, with an emphasis on higher accessibility and adaptability as the main goal of Web design. The user interface is the place where users can interact with the information by using their minds. Users with special needs can acquire information by using a human centered user interface. This article highlights the need to investigate the relationship between cognition and user interface.

INTRODUCTION AND BACKGROUND

A highly developed digital society needs to be integrated in order to function to meet each individual’s differentiated needs. Inclusion is reflected in the modern special education classroom. This practice of teaching and learning mirrors the changes in society because the classroom is the place where a collaborative, collective and real-time community is built consisting of teachers, educational executives, administrators, researchers, and parents. The terms inclusion, zero reject, and universal design, characterize a fully inclusive classroom. Zero reject means “students cannot be excluded from educational services based on their disability, severity of disability, contagious conditions, or costs of services” (Wood, 2006, p.9). The term inclusion is used to designate educational services and placement of students
with disabilities in the general education classroom, facilitated by classroom-provided supports, adaptation, modification, and accommodation for each individual student (Hunt & Marshall, 2006; Wood, 2006). Finally, universal design for learning refers to a curriculum or educational approach using assistive or educational technology to individualize teaching and learning (Turnbull, Turnbull, & Wehmeyer, 2005). In the inclusive classroom, the learning characteristics of the student with the disability are analyzed, and all characteristics are integrated into a teaching unit that best meets the student’s needs.

DIGITAL INCLUSION AND WEB ACCESSIBILITY

Digital inclusion and Web accessibility are leading the change of the digital Web culture. This movement brings about zero reject and differentiated inclusion on the Web by using universally designed content with built-in flexibility. Digital inclusion involves “social inclusion, the ever-developing information and communication technologies,” and Web design for “equal accessibility and opportunity” for all the individuals, especially for the individuals with disabilities; Web accessibility is therefore, “social inclusion” (Bradbrook & Fisher, 2004, p. 2; World Wide Web Consortium [W3C], 2005, ¶ 5).

The ultimate goal of Web access is to improve productivity and the quality of communication. Productivity is improved as individual’s social function improves as a result of his or her efforts in a social unit. The term Web accessibility means that individuals with disabilities are able to function on the Web, including engaging in cognitive and physical activities, such as navigating, comprehending, analyzing, synthesizing, manipulating, producing and evaluating information. They can also communicate with others on the Web for their own purposes, and contribute to the Web culture. In short, Web accessibility results in productive and universal access to information and other individuals (Bowie, Adler, Civille, & Gill, 1996; W3C, 2005).

Web accessibility brings about social accountability for individuals who would otherwise be placed outside the Internet culture because of their physical, sensory, or cognitive limitations, as well as different cultural and linguistic backgrounds. The term disability is often not defined in a Web context, although it is broadly used in Section 508 of the American law, W3C, and other legal documents. This is because some individuals with special needs regard themselves as not having a disability and being very independent, although they may have functional limitations or barriers imposed by society and the environment (Hunt & Marshall, 2006; Thatcher, 2006; W3C, 2005). Multiple social attempts have been made to facilitate and build Web accessibility, including guidelines, standards, and Website evaluation efforts established by the Americans with Disabilities Act, Section 508, the W3C, the Center for Applied Special Technology (CAST), the British Broadcasting Corporation (BBC), IBM, and Microsoft (Thatcher, 2006).

GUIDELINES FOR WEB ACCESSIBILITY

The ADA is a piece of civil rights legislation that protects people with disabilities from discrimination in four major areas: (a) private-sector employment, (b) public services, (c) public accommodations, and (d) telecommunications. When passed in 1990, the ADA sought to reduce obstacles to “equal access to employment, state and local government programs, transportation, public buildings, and communication technology” (Wisdom, White, Goldsmith, Bielavitz, Davis, & Drum, 2006, p. 20). While the ADA attempts to include the Internet and other services, the law itself is not explicitly clear on the Internet access.
Although the accessibility of a Web site is ultimately the responsibility of the designer of the site, federal legislation sets the standard for accessibility. Section 508 was implemented to ensure that government Web sites are accessible; however, the law now extends to include all schools that receive federal and state funds (Carter, 2004). Meant to create high-quality information that is accessible to all viewers, key components of Section 508 state that there should be “a text equivalent for every nontext element; all information conveyed through color must also be conveyed without color; and frames should be titled with text that identifies the frame and facilitates navigation” (Jaeger, 2006, p. 170). By passing laws such as Section 508, the federal government has made it clear that Web accessibility is an important issue and must be provided in the field of education. Table 1 lists the URLs of organizations that have established Web accessibility guidelines.

W3C guidelines developed by Chisholm, Jacobs, and Vanderheiden (2000) identify the following ways to ensure Web content accessibility:

1. Provide equivalent alternatives to auditory and visual content.
2. Don’t rely on color alone.
3. Use markup and style sheets and do so properly.
5. Create tables that transform gracefully.
7. Ensure user control of time-sensitive content changes.
8. Ensure direct accessibility of embedded user interfaces.
10. Use interim solutions.
11. Use W3C technologies and guidelines.
12. Provide context and orientation information.
13. Provide clear navigation mechanisms.
14. Ensure that documents are clear and simple. (Chisholm, Jacobs, & Vanderheiden, 2000, ¶ 6).

Furthermore, Section 508-1194.22 provides Web accessibility guidelines related to 16 usability items (Section 508, 2006, § 1194.22):

1. A text equivalent for every nontext element shall be provided (e.g., via “alt,” “longdesc,” or in element content).
2. Equivalent alternatives for any multimedia presentation shall be synchronized with the presentation.
3. Web pages shall be designed so that all information conveyed with color is also

available without color, for example from context or markup.

4. Documents shall be organized so they are readable without requiring an associated style sheet.

5. Redundant text links shall be provided for each active region of a server-side image map.

6. Client-side image maps shall be provided instead of server-side image maps except where the regions cannot be defined with an available geometric shape.

7. Row and column headers shall be identified for data tables.

8. Markup shall be used to associate data cells and header cells for data tables that have two or more logical levels of row or column headers.

9. Frames shall be titled with text that facilitates frame identification and navigation.

10. Pages shall be designed to avoid causing the screen to flicker with a frequency greater than 2 Hz and lower than 55 Hz.

11. A text-only page, with equivalent information or functionality, shall be provided to make a Web site comply with the provisions of this part, when compliance cannot be accomplished in any other way. The content of the text-only page shall be updated whenever the primary page changes.

12. When pages utilize scripting languages to display content, or to create interface elements, the information provided by the script shall be identified with functional text that can be read by assistive technology.

13. When a Web page requires that an applet, plug-in or other application be present on the client system to interpret page content, the page must provide a link to a plug-in or applet that complies with §1194.21(a) through (l).

14. When electronic forms are designed to be completed on-line, the form shall allow people using assistive technology to access the information, field elements, and functionality required for completion and submission of the form, including all directions and cues.

15. A method shall be provided that permits users to skip repetitive navigation links.

16. When a timed response is required, the user shall be alerted and given sufficient time to indicate more time is required (¶ 7).

Section 508 (2006, § 1194.24) also mandates specific modes of video and multimedia presentation. Three items were developed related to multimedia accessibility:

1. All training and informational video and multimedia productions which support the agency’s mission, regardless of format, that contain speech or other audio information necessary for the comprehension of the content, shall be open or closed captioned.

2. All training and informational video and multimedia productions which support the agency’s mission, regardless of format, that contain visual information necessary for the comprehension of the content, shall be audio described.

3. Display or presentation of alternate text presentation or audio descriptions shall be user-selectable unless permanent.

The Web-accessibility standards in W3C and Section 508 are designed to increase the usability, accessibility, and adaptability of the Web information system for people with sensory, cognitive, cultural, linguistic, and any other physical impairments, by means of the user-computer interaction, or user interface. The standards address the built-in, flexible technology or its application on the Web. Section 508 and W3C cover the following areas:

- Usability of software applications and operating systems
Maximizing Web Accessibility Through User-Centered Interface Design

- Accessibility of Web-based Internet information and application
- Application of built-in telecommunication product
- Flexibility of built-in video or multimedia product
- Assistive technology of self contained, closed products, desktop and portable computers.

The universal goal of a democratic society is to improve the quality of all citizens’ lives. Thus, Web accessibility should benefit all individuals, with or without disabilities. The Internet, especially for individuals with a disability, can provide information to improve the quality of all citizens’ lives.

DOMAINS OF INSTRUCTIONAL OBJECTIVES

Bloom, Engelhart, Frust, Hill, & Krathwohl (1956) defined the three domains of instructional objectives as cognitive, affective, and psychomotor domains. The three domains have been employed in instructional design, Web design, software design, and program design (Belanger, & Jordan, 2000; Bloom et al., 1956). Hodell (2000) added a fourth domain, the interpersonal domain. These domains respectively deal with (a) the process of the mind, (b) motor skills or physical movement, (c) individuals’ attitudes and feelings, and (d) interactivity between individuals (Belanger & Jordan, 2000; Bloom et al. 1956; Hodell, 2000).

All four domains should be considered when a Web environment is built, including three layers of the Web environment: (a) content, (b) user interface, and (c) infrastructure. These mirror the construct of Web design, the Website’s purpose, its usability, and the designer’s philosophy and plan.

Harris (1999) argued that each layer creates synergy between the layers, as well as between users and the layers. The content layer provides the user with knowledge, information, simulation, and other resources. The user interface layer called human computer interface or human-computer interaction allows the users to interact with the content (information), the computer itself, and other users. Finally, the infrastructure layer, which includes the inner, hardware, mechanical system and technology of the machine, supports the interface, content, the user, as well as interactions between all of them.

COGNITION AND THE USER INTERFACE

Web accessibility is a construct that reflects digital inclusion, focusing on individuals with special needs and facilitating human-centered interaction and functionality. The user interface is a computer, Web or technology system that enables users to see, hear, and interact with the content, the computer, or other users. Thus, the user interface is a collective representation of cognitive, psychomotor, affective, and interpersonal processes that can be used to enhance the usability of the system. All users, including those with disabilities, need effective ways to access and acquire knowledge. An effective interface allows individuals to use their minds without heavy physical or mental efforts, which especially benefits individuals with various special needs. This highlights the need to investigate the relationship between cognition and user interface. The next section will discuss cognitive processing models.

COGNITIVE PROCESSING MODELS

The cognitive processing models developed by cognitive constructivists emphasize the most effective strategies for building knowledge (Jonassen, Davidson, Collins, Campbell, & Hagg, 1995; Miller & Miller, 1999; Wilson, Teslow, &
Osman-Jouchoux, 1995). Thus, the cognitive processing model considers knowledge as reality and an obtainable objective outside of the individual. Therefore, the individual and knowledge are independent of each other, at a distance, in their own structure. Further, within this model, knowledge is objectively measurable so that the individual can “acquire, replicate, and retain an accurate representation” (Jonassen et al., 1995; Miller & Miller, 1999, ¶ 18; Wilson et al., 1995). The model provides directions for acquiring information.

Cognitive constructivists employ three types of memory to acquire correct information: sensory, short-term, and long-term. Sensory memory is used to emphasize the concentration of the mind for a short time, while information is processed. Strategies in this area include psychophysical variation (e.g., change in color, size, pitch) and discrepant activities (e.g., choice of words, images)” (Miller & Miller, 1999, ¶ 21-23). When the strategies of iconic short term memory are implemented in designing Website for individuals with disabilities, items can be divided into (a) four to five chunks (Cattell, 1886), and (b) visual or audible partial content or cue representations, instead of whole reports (Averbach & Sperling, 1961). These strategies are generally employed in teaching practices for all students. Finally, strategies employing models of long-term memory include (a) activation of prior knowledge, (b) presenting information within a meaningful context, and (c) hierarchical sequencing and organization that elaborates and connects new with existing knowledge (Miller & Miller, 1999, ¶ 21-23).

Appropriate strategies for acquiring information should be applied to authentic, functional experiences that have a purpose in the context of the individual’s life. Strategies should also encourage the individual to pay attention to the information, so the experience can be transferred to sensory store, short-term memory, and long-term memory with little cognitive load. Figure 1 illustrates the information processing system and types of memory (Ally, 2004, p. 9).

The construct of Web accessibility can more precisely and diversely form this structure (Figure 1) than any other application because the Web construct is adaptable and flexible. The needs of the individual user and the function of the individualized Website determine the structure of the display, degree of user control of navigation, and level of interactivity. The essential goal of this cognitive constructivist paradigm for Web accessibility is easy and accurate transmission and reception of functional information. Digital inclusion generates synergy by applying the cognitive processing models to the individual’s needs, and builds an authentic digital functional community, which is the nature of the Web environment.

THE HUMAN-COMPUTER INTERFACE

The human-computer interface (HCI) is a crucial element in producing meaningful and determining factors of usability (Kim & Moon, 1998; Nielsen & Norman, 2000; Roy, Dewit, & Aubert, 2001). Specifically, the user interface is a computer system (Ciavarelli, 2003) that connects the contents or infrastructure and Web users. Thus, users can operate, control, and manage the contents and infrastructure through the medium and user interface (Ciavarelli, 2003; Harris, 1999; Laurillard, 1993). Further, the user interface “provides feedback to the user, such as acknowledging inputs, advising the user of processing wait periods, and providing navigational assistance, error alerts, and corresponding recovery methods” (Ciavarelli, 2003, p. 14).

The goal of the interface is to produce higher usability that will increase users’ effectiveness and efficiency in using the computer and navigating its contents or texts. It also enhances users’ satisfaction and perception of the interaction with the computer (Ciavarelli, 2003; Harris, 1999; Nielsen, 1993; Roy et al.). Higher usability is reflected by the following characteristics: (a) requiring minimum efforts to operate, (b) visually agreeable and enjoyable to use, and (c) pursuing few errors and quick recovery from them (Howe, 2005). Therefore, usability is a “cognitive, social,” communicational process with an integrated computer technology system (Adler & Winograd, 1992; Berg, 2000, p. 353; Maddix, 1990).

HCI refers to “the design, evaluation, and implementation of interactive computing systems for human use” (Berg, 2000, p. 350; Card, Moran, & Newell, 1983; Ciavarelli, 2003; Head, 1999). Therefore, HCI is the set of knowledge about interaction between the computer systems, users, and productive working environment (Berg, 2000; Carey, 1991; Ciavarelli; Reisner, 1987). Tasks related to theories support interface design, including (a) the perceptual approach (Gibson, 1986); (b) constructivism (Ciavarelli; Duffy & Jonassen, 1992); and (c) the activity theory or information processing approach.

THE GOMS MODEL

Based on the cognitive information processing model, Card, Moran, and Newell (1983) developed a cognitive model of human computer interaction, GOMS. As discussed earlier, the cognitive information processing model has three different memory stages; (a) sensory store, (b) short-term memory, and (c) long-term memory. The sensory store and working memory stages are related to perceptual and motor processing, whereas short-term memory and long-term memory are related to cognitive processing (Card et al., 1983). According to Card et al. (1983), the GOMS model consists of four components that demonstrate how to process tasks between users and a computer system: (a) goals to be achieved in the process, (b) operators performing the sequencing methods and interacting with the system, (c) methods representing the sequences of the tasks performed by the operators, and (d) selection rules choosing the best strategies and solutions for the best methods to obtain the goals. The GOMS model seeks to “predict the time required to complete the task. In addition, the model can be used to identify and predict the effects of errors on task performance. Error recovery is assumed to involve the same four components as correct actions” (Card, Moran & Newell, 2005. ¶ 2).

ERROR AND COGNITION

Error types mirror the working load of short-term memory. Error occurs when the short-term memory has a heavy workload. There seem to be millions of errors in everyday life. Some research
shows that errors have several visible patterns, which can be prevented or reduced by the human centered interface design. James Reason and Donald Norman are two of the most notable psychologists with expertise in error models as illustrated in their books, Human Error and The Design of Everyday Things, respectively. In addition, they deal with the effective use of the human mind and the design of objects that we encounter everyday.

Reason (1990) used Rasmussen’s (1986) classification of human performance to generate his generic error modeling system (GEMS), which is the classic error model associating human errors with the actions or action planning of the working memory. The GEMS model involves three types of action control: skill, rule, and knowledge-based levels. Reason argued that slips and lapse are errors that result from skills, whereas mistakes result from knowledge.

Reason (1990) linked error types to the cognitive steps, planning, storage, and execution, those for which short-term memory is mostly in charge. According to Reason (1990) human error can be categorized into three observable, measurable behaviors: skill, rule, and knowledge:

At the skill-based level, human performance is governed by stored patterns of preprogrammed instructions represented as analogue structures in a time-space domain. Errors at this level are related to the intrinsic variability of force, space or time coordination. (p.43)

Reason asserted that at the rule-based level, “errors are typically associated with the misclassification of situations leading to the application of the wrong rule or with the incorrect recall of procedures” (p. 43). At the knowledge-based level, errors “arise from resource limitations (‘bounded rationality’) and incomplete or incorrect knowledge” (p. 43). As expertise increases, “the primary focus of control moves from the knowledge-based towards the skill-based levels; but all three levels can co-exist at any one time” (p. 43).

Reason (1990) claimed that the knowledge that is meaningful in a specific context or is not correct, is the main cause of errors. Thus, he argued that most errors are related to the knowledge level, whereas the two skill-level errors are slips and lapses. Based on Reason’s error frame, slips are errors caused by over-attention or inattention after an action is completed while intention is forming and the execution or storage of action sequence is failed.

According to Norman, slips are “the performance of an action that was not what was intended” (2002, p. 1). Thus, Norman argued that slips appear as results of the similar, triggering actions or thoughts with inattention. Norman’s natural observation resulted in six categories of slips: “capture errors, description errors, date-driven errors, associative activation errors, loss-of-activation errors, and mode errors” (p. 107). He employed an activation-trigger schema system to explain schemata (2002). Rumelhart defined schemata as “data structures for representing generic concepts stored in memory” (Rumelhart & Ortony, 1977, p. 101); “schemata have variables with constraints and that these variables (or slots) have a limited distribution of possible default values” (Reason, 1990, p. 35; Rumelhart & Ortony, 1977). In Norman’s an activation-trigger schema system, errors mostly appear when schema is appropriately chosen and activated but triggered and operated over the longer time frame as a response to activators. This activation-trigger schema system is schematic control model using the working short-term memory; it handles familiar knowledge with speed without heavy workloads (Reason, 1996).

The activation framework has both specific and general activators. The specific activator uses a mental model which is composed of explanations of intended actions and plans (Norman, 2002; Reason, 1996). A less detailed explanation for the planned action is necessary if a collection of intended actions is to be effectively carried
Maximizing Web Accessibility Through User-Centered Interface Design

at short intervals. General activators support the work of the mind by providing contextual and affective background information, regardless of intentions.

Human-centered interface design analyzes and synthesizes an individual’s needs, cultural practice, cognitive ability, and preferences against the measurable goal of functioning in a certain context, using cognitive, psychomotor, and affective constructs (Badre, 2002). Applied to human center design, the systems increase usability, visibility, and functionality: “They save lives” (Norman, 2002, p. iv) by reducing errors of every day life. The outcome of the human-centered design is “ease of use, ease of learning, memorability, lack of errors, and satisfaction” (Barde, 2002, p.5; Gould & Lewis, 1985; Nielsen, 1993).

When the design that enhances human-computer interaction is considered in the context of Web accessibility, analysis and synthesis of the individual’s special needs and the work of the mind, “human perception, memory, and attention,” is important so as to ensure the minimal use of their efforts and interaction with technology (Norman, 2002, p. iv). The interdependence and interaction between people, information, and technology exists with a special function and purpose (where there is communication). Thus, analyzing and defining the user’s characteristics is the first step to building a Website for individuals with special needs. Their interactions with technology, content, information and other individuals are to be synthesized in the user interface.

Understanding users, their needs, mastery level of technology and their physical and cognitive ability is a prerequisite for designing the human computer interface and evaluating Web accessibility. The goal is to determine the most appropriate interaction modes and reduce the rate of error by providing physical, semantic, cultural and logical constraints (Badre, 2002; Norman, 2002).

Ecology (Web accessibility) should be adapted to meet the needs of individuals in the different categories of disability and the different degrees within a category (severe to mild). Barde (2002) described individual factors that influence Web design. Individual differences may be “grouped into four categories: knowledge, experience, and skill; personality factors; physical and demographic attributes; and user levels” (p. 70). Individuals may differ in “level and type of education as well as in their knowledge, experience, and skill levels” (p. 70). Barde elaborated:

These factors describe the cognitive abilities and styles of projected users as well as their knowledge and experience of the projected Website’s domain. Not all factors are necessarily applicable in every Web design situation, but there will be situations in which they all have direct implications for designing the constituents of the interactive environment (p. 70).

HUMAN-CENTERED DESIGN

Design is communication. Human-centered design yields synergy between the content information, the user, the designer, and infrastructure, and enhances communication effectiveness. Norman (2002) suggested that human-centered design consists of three elements:

1. Conceptual models which make invisible functions visible by using feedback, as the effect of an interaction, and explanations of its use.
2. Constraints which are a proactive measure to limit the choices of interaction and reduce human errors. Physical, semantic, and cultural constraints are three types of constraints.
3. Affordance is the “perception and actual properties of the thing. It suggests how the device can be possibly operated (p. 9).
The three elements make up a psychology of communicative design. Communication enhances visibility and usability by using the communication medium and human-computer interaction. Usability is defined as “the degree to which users can perform a set of required tasks” (Brinck, Gergle, & Wood, 2002, p. 2). The usability of Web accessibility is measured by the degree of efficiency of the individualized Web design and communication with the technology: functionality given the individual’s needs; efficiency of operating time, ease in remembering and learning operations as determined by the individual’s physical, cognitive ability and the degree of disability; proactive error-tolerant system; and built-in flexibility of the infrastructure design for the digital inclusion (Brinck, Gergle, & Wood, 2002; Norman, 2002).

**DISABILITY CATEGORIES**

Most special education textbooks divide disabilities into 12 categories, in accordance with the Individuals with Disabilities Education Act (see Table 2). The potential population of the Web accessibility users reaches over six million, age 6 to 21. Table 2 also illustrates the number of potential Web users in each disability category (Turnbull, 2004).

Section 508 and the W3C do not clearly define Web accessibility users in terms of the individual’s age or the degree of disability, only recommending that the Web be made “accessible to people with disabilities” (W3C, ¶ 1). The W3C indicates how the Web may be employed by users with different types of disabilities and “how people with disabilities use the Web.” The W3C

developed series of scenarios of Web usability by individuals with disabilities: (a) an individual taking online courses with hearing impairment, (b) an accountant with visual impairment, (c) a student with a specific learning disability, and (d) a student with a cognitive disability transitioning from high school. In each case, the assistive technology and the human-computer interface reduced the work-load of short-term memory to enhance the usability of the given Website. The technologies and human-computer interactions are as follows:

1. Keyboard equivalents for mouse-driven commands;
2. Captioned audio portions of multimedia files
3. Appropriate markup of tables, alternative text, abbreviations, and acronyms; synchronization of visual, speech, and Braille display
4. Use of supplemental graphics; freezing animated graphics; multiple search options
5. Magnification; stopping scrolling text; avoiding pop-up windows
6. Clear and simple language; consistent design
7. Consistent navigation options
8. Multiple search options (W3C, ¶ 2)

CONCLUSION AND RECOMMENDATIONS

Web accessibility, especially human-centered, is an ideology because it involves an effort to change the traditional Web culture into digital inclusion, whereby the Web design meets an individual’s special needs considering the user’s social, cultural, physical, and cognitive characteristics. Access to the Web translates into access to knowledge and information that enable people to work in a digital society, and therefore, be digitally included. Access to information in turn, translates into access to society and the world. The Web must be accessible to all individuals, regardless of any physical or intellectual disabilities one may have. In order to ensure Web accessibility, guidelines such as the W3C standards and federal legislation such as Section 508 of the Rehabilitation Act have been developed.

It is important to research and design a human-computer interface that will enhance the usability and effectiveness of communication between the users, and between users and technology. Based on the error and cognitive processing models presented here, cognitive, psychomotor, and affective domains should be considered when the user interface is developed. As illustrated, the activities of action planning and storage take place at the knowledge and skill level in the cognitive domain. Execution occurs based on judgment, experience or preference. Execution is related to the affective domain. One of the most effective ways to reduce error is to present conceptual models/frameworks (Nielsen, 1993; Jonassen, Strobel, & Gottdenker, 2005), which enable Web users to construct knowledge of how to navigate, determine what can be done, and the sequence of work, with little cognitive demand. Thus, conceptual models help Web users explain and interpret (a) how to access information and technology, (b) how to adapt the context of the interface, and (c) how to communicate with the computer, itself. Jonassen et al. (1995) argued that users can build cognitive strategies to reason, engage, support, and assess information using the qualitative and quantitative model.

Web accessibility must be differentiated and individualized to meet the individual’s special needs. Developing effective interfaces for individuals with disabilities involves (a) identifying the user’s purpose of digital activity, b) identifying the information and placing it sequentially and, (c) if possible, applying Bloom’s five learning objective levels: knowledge, comprehension, analysis, synthesis and evaluation. This classification scheme will improve communication
between the information and technology. The relationship between processing and acquiring information is better-linked, and the information is more efficiently retrieved. The levels will provide insight into information processing and individuals with disabilities may interact with the technology simply and easily. In addition, strategies using short-term memory have been adapted from memory strategies for exceptional children and youth, such as (a) chunking information by dividing it into multiple pages, (b) repeating patterned rules to navigate a site, (c) representing meaningful, functional information, and (d) categorizing of information (Hunt & Marshall, p.128). Sound or visual effects, such as feedback or cues at certain intervals, will enhance attention by making hard-to-view items visible.

In a digital age, technology is always present—any where, any time. Winner (1980) argued that technology structures the mode of communication, work and consumption in a society. Technology is a pattern of modern culture; it is not just technological device (Borgmann, 1984). Intertwined with cultural, societal and economic factors, the Web is a subculture of modern technology. It is a structure by which we communicate and connect with the external world. In today’s digital information society, information is knowledge and can be used as a tool with which people can work (Bowen, Bereiter, & Scardamalia, 1992). The Web is a major source for acquiring information and connecting with the world, especially for the people with physical and intellectual limitations; all without the limitations of time and space. Therefore, all individuals need access to the Web, thus allowing them more opportunities to access and process information independently (Gilbert & Driscoll, 2002).

To meet the needs of our modern technological culture, the number of Web sites continues to increase. With this increase, concerns regarding the quality of Web sites and Web accessibility arise. A major concern is the need for evaluation strategies of Web site effectiveness, and usability, and a system of moral principles or ethics. Other concerns involve (a) the importance of knowing what factors of Web designs maximize Web accessibility, (b) how best to structure content and information for Web delivery and accessibility, and (c) how to evaluate accessibility in a manner that is valid and reliable, while also providing evidence on how to improve the quality of Web information. Given the growth in Web accessibility and the varied circumstances under which it is offered, evaluation instruments and processes are needed to ensure societal, cultural, educational, technical, and economic equity of high-quality Web accessibility.

Maximizing Web Accessibility Through User-Centered Interface Design

KEY TERMS

Americans with Disabilities Act (ADA): A civil rights legislation that protects people with disabilities from discrimination against them in four major areas: 1) private-sector employment, 2) public services, 3) public accommodations, and 4) telecommunications.

Cognitive Processing Models: Models developed by cognitive constructivists emphasizing effective strategies for building knowledge.

Domains of Instructional Objectives: Cognitive, psychomotor, affective and interpersonal domains addressing (a) the process of the mind, (b) motor skills or physical movement, (c) individuals’ attitudes and feelings, and (d) interactivity between individuals.

GOMS Model: A cognitive model of human computer interaction consisting of four components: (a) Goals to be achieved in the process, (b) Operators performing the sequencing methods and interacting with the system, (c) Methods representing the sequences of the tasks performed by the operators, and (d) Selection rules choosing the best strategies and solutions for the best methods to obtain the goals.

Human-Centered Interface Design: A system used to analyze and synthesize an individual’s needs, cultural practice, cognitive ability, and preference with the measurable goal and function in a certain context, using cognitive, psychomotor, and affective constructs.

Section 508: A law implemented to ensure that government Web sites are accessible. The law now extends to include all schools that are provided with federal and state funds.

Web Accessibility: Equal accessibility and opportunity to the Web for all the individuals, especially for individuals with disabilities.

Chapter 8.3
Voice-Enabled User Interfaces for Mobile Devices

ABSTRACT

The use of a voice interface, along with textual, graphical, video, tactile, and audio interfaces, can improve the experience of the user of a mobile device. Many applications can benefit from voice input and output on a mobile device, including applications that provide travel directions, weather information, restaurant and hotel reservations, appointments and reminders, voice mail, and e-mail. We have developed a prototype system for a mobile device that supports client-side, voice-enabled applications. In fact, the prototype supports multimodal interactions but, here, we focus on voice interaction. The prototype includes six voice-enabled applications and a program manager that manages the applications. In this chapter we describe the prototype, including design issues that we faced, and evaluation methods that we employed in developing a voice-enabled user interface for a mobile device.

INTRODUCTION

Mobile devices, such as cell phones and personal digital assistants (PDAs), are inherently small, and lack an intuitive and natural user interface. The small keyboards and displays of mobile devices make it difficult for the user to use even the simplest of applications. Pen input is available on PDAs, but is difficult to use on handheld devices. Voice input and output for mobile devices with small screens and keyboards, and for hands- and eyes-free operation, can make the user’s interaction with a mobile device more user friendly. Voice input and output can also facilitate the use of Web Services (Booth, Hass, McCabe, Newcomer, Champion, Ferris, & Orchard, 2004) from a mobile device, making it possible to access the Web anytime and anywhere, whether at work, at home, or on the move. Global positioning system (GPS) technology (U.S. Census Bureau, 2006)
Voice-Enabled User Interfaces for Mobile Devices

can provide location information automatically for location-aware services.

Many everyday applications can benefit from voice-enabled user interfaces for a mobile device. Voice input and voice output for a mobile device are particularly useful for:

- Booking theater and sports tickets, making restaurant and hotel reservations, and carrying out banking and other financial transactions
- Accessing airline arrival and departure information, weather and traffic conditions, maps and directions for theaters, restaurants, gas stations, banks, and hotels, and the latest news and sports scores
- Maintaining personal calendars; contact lists with names, addresses, and telephone numbers; to-do lists; and shopping lists
- Communicating with other people via voice mail, e-mail, short message service (SMS), and multimedia message service (MMS).

It is important to provide several modes of interaction, so that the user can use the most appropriate mode, depending on the application and the situation. The prototype system that we have developed supports client-side, voice-enabled applications on a mobile device. Even though the applications support multimodal input, allowing keyboard and pen input, we focus, in this chapter, on voice input and on multimodal output in the form of voice, text, and graphics. The prototype includes a program manager that manages the application programs, and six voice-enabled applications, namely, contacts, location, weather, shopping, stocks, and appointments and reminders.

BACKGROUND

A multimodal interface for a mobile device integrates textual, graphical, video, tactile, speech, and/or other audio interfaces in the mobile device (Hjelm, 2000; Oviatt & Cohen, 2000). With multiple ways for a user to interact with the applications, interactions with the device become more natural and the user experience is improved. Voice is becoming an increasingly important mode of interaction, because it allows eyes- and hands-free operation. It is essential for simplifying and expanding the use of handheld mobile devices. Voice has the ability to enable mobile communication, mobile collaboration, and mobile commerce (Sarker & Wells, 2003), and is becoming an important means of managing mobile devices (Grasso, Ebert, & Finin, 1998; Kondratova, 2005).

The increasing popularity of, and technological advancements in, mobile phones and PDAs, primarily mobile phones, is leading to the development of applications to fulfill expanding user needs. The short message service (SMS) is available on most mobile phones today, and some mobile phones provide support for the multimedia messaging service (MMS) to exchange photos and videos (Le Bodic, 2002). The mobile phone manufacturers are no longer focused on making a mobile phone but, rather, on producing a mobile device that combines phone capabilities with the power of a handheld PC. They recognize that the numeric keypad and the small screen, common to mobile phones of the past, do not carry over well to handheld PCs (Holtzblatt, 2005).

With the emergence of Web Services technology (Booth et al., 2004), the Web now provides services, rather than only data as it did in the past. Of the various Web Services available to mobile users today, the map application seems to be the most popular, with online map services available from Google (2006) and Yahoo! (2006b). Much progress has been made in creating the multimodal Web, which allows not only keyboard and mouse navigation but also voice input and output (Frost, 2005).

GPS technology (U.S. Census Bureau, 2006) already exists on many mobile devices, and can be used to provide location-aware services (Rao
Voice-Enabled User Interfaces for Mobile Devices

& Minakakis, 2003), without requiring the user to input geographical coordinates, again contributing to user friendliness.

Speech recognition technology (Rabiner & Juang, 1993) has been developed over many years, and is now very good. Other researchers (Kondratova, 2004; Srinivasan & Brown, 2002) have discussed the usability and effectiveness of a combination of speech and mobility. Currently, handheld voice-enabled applications use short commands that are translated into functional or navigational operations. As observed in Deng and Huang (2004), speech recognition technology must be robust and accurate, and close to human ability, to make its widespread use a reality. Noisy environments present a particular challenge for the use of speech recognition technology on mobile devices and, therefore, multimodal interactions are essential. For example, the MiPad system (Deng, Wang, Acero, Hon, Droppo, Boulis, et al., 2002; Huang, Acero, Chelba, Deng, Droppo, Duchene, Goodman, et al., 2001) uses a strategy where the user first taps a “tap & talk” button on the device and then talks to the device.

Distributed speech recognition (Deng, et al., 2002), in which the speech recognition happens at a remote server exploits the power of the server to achieve fast and accurate speech recognition. However, studies (Zhang, He, Chow, Yang, & Su, 2000) have shown that low-bandwidth connections to the server result in significant degradation of speech recognition quality. In contrast, local speech recognition (Deligne, Dharianpragada, Gopinath, Maison, Olsen, & Printz, 2002; Varga, Aalburg, Andressy, Astrov, Bauer, Beaugeant, Geissler, & Hoge, 2002) utilizes speech recognition technology on the mobile device, and eliminates the need for high-speed communication. Local speech recognition limits the kinds of client handsets that are powerful enough to perform complicated speech processing and, thus, that can be used; however, the computing power of mobile handsets is increasing.

THE PROTOTYPE

The prototype that we have developed allows mobile applications to interact with the user without the need for manual interaction on the part of the human. Speech recognition and speech synthesis software are located on the mobile device, and make the interaction with the human more user friendly. The prototype that we have developed processes natural language sentences and provides useful services while interacting with the user in an intuitive and natural manner. A user need not form a request in a particular rigid format in order for the applications to understand what the user means.

For our prototype, we have developed six application programs and a Program Manager. These applications are Contacts, Location, Weather, Shopping, Stocks, and Appointments and Reminders applications. The Program Manager evaluates sentence fragments from the user's request, determines which application should process the request, and forwards the request to the appropriate application.

The prototype is designed to interact with a human, using voice as the primary means of input (keyboard, stylus, and mouse are also available but are less convenient to use) and with voice, text, and graphics as the means of output. The speech recognizer handles the user's voice input, and both the speech synthesizer and the display are used for output. Characteristics of certain applications render a pure voice solution infeasible. For example, it is impossible to convey the detailed contents of a map through voice output. However, voice output is ideal when it is inconvenient or impossible for the user to maintain visual contact with the display of the mobile device, and it is possible to convey information to the user in that mode. Voice output is also appropriate when the device requests confirmation from the user.

Thus, an appropriate choice of speech recognition and speech synthesis technology is vital to
Voice-Enabled User Interfaces for Mobile Devices

the success of our prototype. Our choices were constrained by:

- The processing and memory capabilities of typical mobile devices
- The need for adaptability to different users and to noisy environments

The use of speech recognition and speech synthesis technology on a mobile device is different from its use in call centers, because a mobile device is associated with a single user and can learn to understand that particular user.

The Underlying Speech Technology

The prototype uses SRI’s DynaSpeak speech recognition software (SRI, 2006) and AT&T’s Natural Voices speech synthesis software (AT&T, 2006). It currently runs on a handheld computer, the OQO device (OQO, 2006). We chose this device, rather than a cell phone, because it provides a better software development environment than a cell phone.

Speech Recognition

The DynaSpeak speech recognition engine (SRI, 2006) is a small-footprint, high-accuracy, speaker-independent speech recognition engine. It is based on a statistical language model that is suitable for natural language dialog applications. It includes speaker adaptation to increase recognition accuracy for individuals with different accents or tone pitches. It can be configured so that it performs speech recognition specific to a particular individual. DynaSpeak is ideal for handheld mobile devices, because of its small footprint (less than 2 MB of memory) and its low computing requirements (66 MHz Intel x86 or 200 MHz Strong Arm processor).

DynaSpeak supports multiple languages, adapts to different accents, and does not require training prior to use. It incorporates a Hidden Markov Model (HMM) (Rabiner & Juang, 1993). In an HMM, a spoken expression is detected as a sequence of phonemes with a probability associated with each phoneme. A probability is also associated with each pair of phonemes, that is, the probability that the first phoneme of the pair is followed by the second phoneme in natural speech. As a sequence of phonemes is processed, the probability of each successive phoneme is combined with the transition probabilities provided by the HMM. If the probability of a path through the HMM is substantially greater than that of any other path, the speech recognizer recognizes the spoken expression with a high level of confidence. When the response is below an acceptable confidence threshold, the software seeks confirmation from the user or asks the user questions.

The HMM is augmented with grammars for the particular applications that are required for understanding natural language sentences (Knight, Gorrell, Rayner, Milward, Koeling, & Lewin, 2001). When the user says a new word, the word can be added to the vocabulary dynamically. The HMM is also extended by adapting the vocabulary of the speech recognizer to the current and recent past context of interactions of the user with the applications.

Accuracy of the speech recognition system can be increased by training it for the voice of the particular user. There are two kinds of training, explicit and implicit. Explicit training requires the user to read a lengthy script to the device, a process that is likely to be unpopular with users. Implicit training allows the device to learn to understand better its particular user during normal use. Implicit training can be provided in two modes, confirmation mode and standard mode.

In confirmation mode, the system responds to a user’s sentence, and the user confirms or corrects the response. If the user corrects the sentence, the learning algorithm tries to match a rejected, lower probability, interpretation of the original sentence with the user’s corrected intent. If a match is found, the learning algorithm adjusts
the HMM transition probabilities to increase the probability of selecting the user’s intent. Initially, a new user of the system will probably prefer confirmation mode.

In standard mode, the system does not confirm sentences for which there is one interpretation that has a much higher probability than any other interpretation. If no interpretation has a high probability, or if several interpretations have similar probabilities, the speech recognition system responds as in confirmation mode. More experienced users of the system are likely to use standard mode.

The success of implicit training strategies depends quite heavily on starting with a speech recognizer that is well matched to the individual speaker. It is possible, from relatively few sentences, to classify a speaker and then to download, to the mobile device, an appropriate initial recognizer for subsequent implicit training.

DynaSpeak can be used with either a finite-state grammar or a free-form grammar. We used the finite-state grammar because it offers greater control over parsed sentences. The tendency for DynaSpeak to accept or reject spoken sentences is heavily influenced by the complexity of the grammar. The complexity of the grammar is quantified by the number of paths by which an accepting state can be reached. The greater the complexity of the grammar, the higher its tendency to accept an invalid spoken request. Conversely, the lower the complexity of the grammar, the higher its tendency to reject a valid spoken request. To minimize the complexity of the grammar and to improve speech recognition accuracy, each application has its own relatively simple grammar. The program manager determines which applications are involved in a sentence and then reparses the sentence using the appropriate grammars.

Speech Synthesis

Natural Voices (AT&T, 2006) is a speech synthesis engine that provides a simple and efficient way of producing natural (rather than electronic) sounding device-to-human voice interactions. It can accurately and naturally pronounce words and speak in sentences that are clear and easy to understand, without the feeling that it is a computer that is speaking.

Natural Voices supports many languages, male and female voices, and the VoiceXML, SAPI, and JSAPI interface standards. Using Natural Voices, we created text-to-speech software for our prototype that runs in the background and accepts messages in VoiceXML format. Each message contains the name of the voice engine (i.e., “Mike” for a male voice and “Crystal” for a female voice) and the corresponding text to speak.

Managed Applications

For the prototype we developed six multimodal applications (contacts, location, weather, shopping, stocks, appointments, and reminders) that use speech as the main form of input. The stocks, maps, and weather applications exploit existing Web Services on the Internet. Communication with those Web Services uses a local WiFi 802.11 wireless network. The program manager controls the operation of the applications. The graphical user interface for the program manager with the six applications is shown in Figure 1. We now present an explanation of the functionality of each application and its role in the overall system.

Contacts

The contacts application stores personal information regarding friends and acquaintances in a database, including their addresses and phone numbers. The contacts application is a mobile extension of a physical contact list or address book that is controlled by voice input. It retrieves data from Microsoft Office Outlook® to populate the database when in docking mode. After using the mobile device and possibly entering new contact information, the user can synchronize informa-
tion on the mobile device with that on a desktop or server computer. The contacts application is configured to interact with other applications that require information about names, addresses, phone numbers, and so forth. The contacts grammar is the least complex of the application grammars that we developed. The contacts vocabulary grows linearly as contacts are added to the user’s contact list.

Location

The Location application allows the user to search for restaurants, movie theaters, banks, and so forth, in a given area, using the Yahoo! LocalSearch Web Service (2006b). For example, if the user says to the mobile device “Search for a Mexican restaurant in 95131,” the location application on the mobile device sends a Web Service request to Yahoo! LocalSearch, gets back the results, and presents up to 10 results to the user in list form. The user can then view additional information about a single location by indicating the location’s number in the presented list. For example, the user can choose to view additional information about “Chacho’s Mexican Restaurant” by speaking, “Get more information about number one.” On processing this request, the location application presents the user with detailed information about the restaurant including its phone number, address, and a detailed street map showing its location. Figure 2 shows a screen shot of the graphical user interface for the location application.

The location application is loosely coupled with the contacts application to provide responses related to individuals listed in the user’s contact list. For example, the request, “Search for a movie theater around Susan’s house” uses the contacts grammar to determine the location of Susan’s house and replaces the phrase “Susan’s house” with the specific address so that the actual search request looks something like this: “Search for a movie theater around 232 Kings Way, Goleta, CA, 93117.” The location application then searches for a movie theater in the vicinity of that address.

The location application is also loosely coupled with a GPS module that is contacted when the user has a question related to the user’s current location. For example, if the user says “Look for a pizza place around here,” the word “here” is recognized by the application and replaced with the GPS coordinates of the user’s current location.
The location application then sends a Web Service request to Yahoo! LocalSearch, which returns a map of the user's current location, indicating where the user is, along with the 10 nearest pizza places. The Yahoo! LocalSearch Web Service is ideal to use with GPS because of its ability to locate positions on the map on the basis of longitude and latitude. With GPS, the user is no longer limited to requests involving a particular city or zip code. The user now has the ability to create requests that are truly location-aware.

Compared to the grammars of the other applications, the location grammar is one of the most complex. For information like maps and lists, it is desirable to use a graphical or textual display, as well as speech output, in a multimodal user interface. Thus, the most appropriate kind of output can be chosen, depending on the kind of information, the capabilities of the mobile device, and the context in which the user finds himself or herself.

Weather

The weather application supplies weather forecasts obtained from the Web Service provided by the National Weather Service (NOAA, 2006). It allows the user to query for weekly, daily, and 3-day weather information in major U.S. cities using voice input. It allows the user either to select a city or to use the user's current location, as the location for which the weather forecast is to be retrieved from the National Weather Service. The weather application knows the geographical coordinates of dozens of cities in the continental United States. It references those coordinates when the user requests a weather forecast from the National Weather Service for one of those cities.

A user can say “Tell me the weather forecast in San Jose,” which then uses “today” as the starting time of the forecast, and produces the graphical user interface for the weather application shown in Figure 3.

Because the weather application operates on a mobile device, it is necessary to be able to determine the user’s location dynamically. If the user asks “What’s the weather like here two days from now?” the weather application consults the GPS module to obtain the geographical coordinates of the user, contacts the Web Service, and responds with the high and low predicted temperatures and an indication that there is a change to cloudy in
Thus, the user does not need to provide his/her current location or to obtain the weather forecast for that location.

Our prototype takes into account the many ways in which a person can convey, semantically, equivalent requests in English. For example, a user can ask for the weather in many ways including “What is the weather in Boston like?” or “Tell me what the forecast is like in Boston.” These two requests are semantically equivalent because they both contain the same essential parameter, namely the Boston location.

Shopping

The shopping application provides the user with a service capable of reducing the time that the user spends on grocery shopping and the associated stress. The shopping application maintains shopping lists, recipes, and floor plans of supermarkets. The multimodal interface includes speech, text, and graphics, which makes the shopping application easy to use. Figure 4 shows a screen shot of the graphical user interface for the shopping application.

The shopping application allows a user to update his/her shopping list and to forward it to another user. When a user issues a command, like “Remind John to go grocery shopping,” the contacts application is used to find John’s phone number or e-mail address in the user’s contact list. A dialog box then appears asking the user if he/she wants to send, to John, not only a reminder to go shopping but also the shopping list. If so, the shopping list, consisting of the product ids and the quantities of the items needed, is formatted in XML, and appended to the message containing the reminder. The message is then sent to John’s shopping application.

The shopping application also displays graphically the floor plan of the supermarket and the location of items in the store, as shown in Figure 4. This feature provides assistance to the user without the need for the user to contact an employee of the supermarket. The shopping application also allows the user to retrieve recipes while shopping.
possibly on impulse, for an item that is on sale. A newly chosen recipe is cross-referenced with the current shopping list, so that needed items can be added automatically. The shopping application has the largest grammar of the applications that we developed, with a vocabulary that depends on the items that the user has purchased recently.

**Stocks**

The stocks application allows the user to manage his/her stock portfolio using voice input and output. The objective of the stocks application is to monitor stock fluctuations, rather than to trade stocks. The stocks application exploits the Yahoo! Finance Web service (2006a) to store and update stock information in a database. It stores the most recent stock information in the database so that it can reply to the user’s requests when connectivity to the Yahoo! Finance Web Service is limited. Although such stored data can be somewhat stale, it allows the user to obtain information whenever the user requests it. The vocabulary of the stocks application grows to match the user’s portfolio each time the user adds a new stock.

**Appointments and Reminders**

The appointments and reminders application manages the user’s calendar and allows the user to send reminders to other people. It supports time-based requests of various forms, for example, “Remind me to go to the dentist on Monday,” “Remind me to see the dentist on August 15th,” and “Remind me to see the dentist a week from today.” It displays an easily readable schedule, so that the user can recall what is planned for the day. The appointments and reminders application interacts with other applications, such as the shopping application. For example, the request “Remind John to go shopping on Monday” sends a reminder to John, along with the current shopping list, if the user wishes to forward that information. It also supports reminders to the user that are location-aware using GPS, for example, if the user is in the vicinity of a supermarket. The appointments and reminders...
application is an extension of a calendar service. It links to Microsoft Office Outlook®, and updates scheduled appointments and reminders when in the vicinity of the user’s desktop.

**Program Manager**

The program manager evaluates sentence fragments from a user’s request, identifies keywords that determine which application or applications should process the request, reparses the sentence using the grammars for those applications, and forwards the parsed request to the appropriate application. If more than one user is involved, the program manager on one user’s mobile device sends messages to the program manager on another user’s mobile device, which then handles the request.

The program manager leverages DynaSpeak and a weighted keyword recognition algorithm to break down recognized sentences into application-specific fragments. Those fragments are then processed by the appropriate applications, and are subsequently merged to form the final sentence meaning. This process allows the program manager to handle requests that involve more than one application, for example, “Search for a gas station around Paul Green’s house.” The parsing of this sentence, using the location grammar, requests a search centered on a location that the location grammar cannot itself provide. The program manager must recognize a keyword from the contacts grammar, parse the sentence using that grammar, and query the contacts application for the address of Paul Green’s house. The response to the query is then sent to the location application to obtain the location of the gas station nearest his house.

**Graphical User Interface**

The graphical user interface (GUI) of the program manager, shown in Figure 1, displays the current running application programs and allows the user to select an application by using voice or keyboard input. The GUI provides buttons that appear gray when an application has not been started and blue after startup. If the user makes a spoken request
that requires an application to display a result, the display for that application is topmost and remains topmost until the user issues another request or a timeout occurs. Whenever the GUI is displayed, the user must provide a keyword in a spoken request to wake up the program manager, or click on one of the application-specific buttons on the display.

**EVALUATION**

Several experiments were performed to collect qualitative and quantitative data to evaluate the prototype system. Although it is difficult to determine a clear boundary between the user interface and the speech recognizer, it is important to evaluate the user interface and the speech recognizer separately, so that the qualitative and quantitative data gathered from the experiments are not mixed, leading to inconclusive results.

Thus, the experiments were designed as a classical “Don't mind the man behind the curtain” study. In this type of study, the user interacts with a system that is identical to the actual system except that the experiment is being controlled by someone other than the user. The man behind the curtain controls what is spoken as responses to the user’s requests and changes the current screen to an appropriate graphical response. This method was used, so that the responses to the qualitative questions would not be biased by the accuracy of the speech recognizer.

To evaluate the system quantitatively, the program manager was instrumented with time segment metrics and data were collected for several performance metrics, including:

- Total time a participant took to complete all tasks
- Overhead of the DynaSpeak speech recognizer during live and batch recognition
- Runtime overhead of the program manager without DynaSpeak
- Spoken length of a request vs. processing time

The results are shown in Figure 6. The time segment metrics represent the runtime complexity of the code associated with the speech recognition.

*Figure 6. Processing overhead per task*
and processing. The amount of time taken by each segment adds to the delay associated with the user’s request. If any of the time segments has a large duration, the user might become irritated. By measuring each segment separately, the bottleneck in the system can be determined.

The speech processing time increases with the size of the grammar. However, by means of a multiphase procedure that uses keywords organized and weighted by application relevance, the grammar size and the speech processing time can be improved. After live recognition, the system provides a keyword-associated request, which it processes for application weights and then reprocesses using an application-specific grammar, possibly more than once with different grammars. This procedure increases both the speed and the accuracy of the speech recognition, by decreasing the size of the grammar size in the initial phase.

An alternative approach (Kondratova, 2004) is to force the user to make repeated requests, possibly from a menu, with responses by which the device asks for the next step or for more information, so that the device arrives at a better understanding of the user’s request. Such an approach introduces navigational complexity for the user. Reducing the speech processing time by creating a complex navigational structure is not the best way to improve usability of the system.

The speech recognizer works better for some speakers than for other speakers. The accuracy of the results can be improved by tuning the speech recognition parameters and enabling learning capabilities. However, the developers of DynaSpeak advise against modification of the speech recognition parameters and use of learning until a relatively high success rate is achieved. For appropriately selected users, quite good speech recognition and understanding can be achieved without using learning capabilities. However, speech recognition accuracy can only improve if voice profiling is combined with learning.

Ambient noise and microphone quality also affect speech recognition accuracy. The internal microphone in the OQO device is of rather poor quality. To ameliorate this problem, a Jabra© Bluetooth headset, was used to provide noise cancellation and reduce the distance between the microphone and the user’s mouth. In addition, when the confidence score from DynaSpeak falls below an acceptable threshold, the program manager seeks confirmation from the user or asks for clarification. These mechanisms greatly improve the accuracy of the speech recognizer.

The accuracy of speech recognition is degraded when the grammar contains words that are phonetically similar. During preliminary experiments for the shopping application, we had problems recognizing differences between similar sounding requests like “Add lamb to my shopping list” and “Add ham to my shopping list.” These problems arise particularly when users are non-native English speakers or when they have accents. Creating more specific requests can reduce the phonetic similarity, for example, by saying “Add a lamb shank to my shopping list” and “Add a ham hock to my shopping list.” However, modifying requests in such a way is undesirable because the requests are then less intuitive and natural.

The location, weather, and stocks applications all use Web Services and require communication over the Internet and, thus, have longer application runtimes than the other Web Services. The location application is written in Java, which runs more slowly than C#. Both the weather application and the stocks application cache data associated with previous requests to take advantage of timing locality. Location requests are different because the caching of maps can involve a large usage of the memory, and users are not inclined to perform the same search twice. Memory is a precious commodity on a handheld device and needs to be conserved; thus, the location application is coded so that it does not cache maps resulting from previous queries.
To evaluate the qualitative aspects of the system, we performed a user study with participants from diverse backgrounds of education, ethnicity, and sex. The user study was completed with 10 individuals performing 10 tasks resulting in 100 request results. The participants were given a questionnaire that assessed their general impressions about the prototype, with the results shown in Table 1.

After analyzing the averaged responses of the participants, we found several trends. The participants’ scores are not strongly correlated with speech recognition accuracy. Participant G gave the system a high score, but was one of the two participants who encountered the most speech recognition problems. Participant B gave the system a low score despite good speech recognition.

The participants agreed that speaking to a mobile handheld device as if it were a human is not comfortable. It is difficult to get used to interacting with a computer that can understand tasks that would be commonplace for humans. The participants were relatively pleased with the GUI interface design and felt the system is relatively easy to use. However, the ease-of-use metric needs to be taken lightly. Ease of use can be assessed more concretely by measuring the number of times a user must repeat a command.

The scores for response appropriateness and relevance are high, indicating that the spoken responses of the applications were well crafted. The scores related to recommending the service to friends and daily life helpfulness are relatively high, from which one might infer that the participants would purchase a device providing the speech-enabled applications. However, this conclusion is not necessarily justified. The participants were not enthusiastic about having to pay for such a device or for such services. However, most participants in the study were quite pleased with the prototype system and found the user interface helpful and easy to use.

grammed to work together, as in our prototype. However, future systems will need to support tens or hundreds of applications, many of which will be designed and programmed independently. Integration of those applications and their grammars will be a challenge.

Currently, speech-enabled applications typically use short commands from the human that are translated into navigational or functional operations. More appropriate is speech recognition technology that supports a more natural, conversational style similar to what humans use to communicate with each other (McTear, 2002).

A mobile device that listens to its owner continuously can provide additional services, such as populating the user’s calendar. For example, when a user agrees to an appointment during a conversation with another person, the mobile device might recognize and automatically record the appointment, possibly confirming the appointment later with its user. Similarly, the mobile device might note that the user habitually goes to lunch with the gang at noon on Mondays, or that the user leaves work promptly at 5pm on Fridays. With existing calendar systems, the user often does not record appointments and other commitments, because it is too much bother using the human interfaces of those systems, greatly reducing the value of the calendar.

A useful capability of speech recognition systems for mobile devices is being able to recognize intonation and emotional overtones. “The bus leaves at 6” is, overtly, a simple declaration, but appropriate intonation might convert that declaration into a question or an expression of disapproval. Existing speech recognition systems do not yet recognize and exploit intonation. Similarly, the ability to recognize emotional overtones of impatience, uncertainty, surprise, pleasure, anger, and so forth, is a valuable capability that existing speech recognition systems do not yet provide.

Speech recognition requires a relatively powerful processor. Typical cell phones contain a powerful digital signal processor (DSP) chip and a much less powerful control processor. The control processor operates continuously to maintain communication with the cellular base stations. The DSP processor uses a lot of power and imposes a significant drain on the battery and, thus, analyzes and encodes speech only during calls. The DSP processor is capable of the processing required for speech recognition, although it might need more memory.

For mobile devices, battery life is a problem, particularly when speech recognition or application software requires a powerful processor. The limit of 2 hours of talk time for a cell phone is caused at least as much by the power drain of the DSP processor as by the power needed for wireless transmission. The DSP processor might be needed for speech processing for more than 2 hours per day. There are several possible solutions to this problem, namely, larger batteries, alcohol fuel cells, and DSP processors with higher speeds, reduced power consumption, and better power management.

Background noise remains a problem for speech recognition systems for mobile devices, particularly in noisy environments. The quality of the microphone, and the use of a headset to decrease the distance between the microphone and the speaker’s mouth, can improve speech recognition accuracy.

**CONCLUSION**

The use of voice input and output, in addition to text and graphics and other kinds of audio, video, and tactile interfaces, provides substantial benefits for the users of mobile devices. Such multimodal interfaces allow individuals to access information, applications, and services from their mobile devices more easily. A user no longer has to put up with the annoyances of a 3-inch keyboard, nested menus, or handwriting recognition, nor
does the user need to have a tethered desktop or server computer in order to access information, applications, and services. Providing multiple ways in which the users can interact with the applications on mobile devices brings a new level of convenience to the users of those devices.

Voice-Enabled User Interfaces for Mobile Devices

**KEY TERMS**

**Global Positioning System (GPS):** A system that is used to obtain geographical coordinates, which includes a GPS satellite and a GPS receiver.

**Hidden Markov Model (HMM):** A technique, based on a finite state machine that associates probabilities with phonemes, and pairs of phonemes, that is used in speech recognition systems, to determine the likelihood of an expression spoken by a user of that system.

**Location Aware:** An application that is based on a particular physical location, as given by geographical coordinates, physical address, zip code, and so forth, that determines the output of the application.

**Mobile Device:** For the purposes of this chapter, a handheld device, such as a cell phone or personal digital assistant (PDA), that has an embedded computer and that the user can carry around.

**Multimodal Interface:** The integration of textual, graphical, video, tactile, speech, and other audio interfaces through the use of mouse, stylus, fingers, keyboard, display, camera, microphone, and/or GPS.

**Speech Recognition:** The process of interpreting human speech for transcription or as a method of interacting with a computer or a mobile device, using a source of speech input, such as a microphone.

**Speech Synthesis:** The artificial production of human speech. Speech synthesis technology is also called text-to-speech technology in reference to its ability to convert text into speech.
**Web Service:** A software application identified by a Uniform Resource Indicator (URI) that is defined, described, and discovered using the eXtensible Markup Language (XML) and that supports direct interactions with other software applications using XML-based messages via an Internet protocol.

ABSTRACT

This chapter presents a method for the evaluation of user interfaces for mobile applications. The method is based upon an approach that combines user opinion, standard conformity assessment, and user performance measurement. It focuses on the evaluation settings and techniques employed in the evaluation process, while offering a comparison between the laboratory evaluation and field evaluation approaches. The method’s presentation and the evaluation comparison will be supported by a discussion of the results obtained from the method’s application to a case study involving a Personal Digital Assistant (PDA). This chapter argues that the experience gained from evaluating conventional user interfaces can be applied to the world of mobile technology.

INTRODUCTION

As proposals for new techniques and methods emerge for the evaluation of mobile device usability, it becomes more difficult for practitioners to choose among them. To be able to evaluate the efficacy of these techniques and methods, as well as to reproduce their steps, they have to be described in a level of detail not often found in the literature. Claims are often made without solid statistical results and are usually based on superficial descriptions. This makes it difficult, if not impossible, to compare alternative choices. Given the features of these new devices (such as mobility, restrictive resources for information input and output, and dynamic contexts of use), HCI specialists may question the efficacy of the methods, techniques, and settings already known.
Multilayered Approach to Evaluate Mobile User Interfaces

to them from previous experiences. Thus, the major question that is addressed is whether it is possible to adapt the methods, techniques, and settings from previous evaluation experiences to this new class of devices, given their distinctive features.

The most frequent question raised in the vast majority of studies presented in the literature is whether to adopt a field approach or a laboratory approach. However, little is discussed in terms of which techniques are best suited for the specific evaluation target and its context of use. While this polemic subject may represent to the HCI specialist an important concern, it is equally important to consider the efficacy of the method, which accompanies this choice of approach (efficacy meaning the quality of the answers to the questions formulated as the basis of the evaluation). This is because the efforts employed in the evaluation may not pay off if a method is not well chosen or well employed.

This chapter presents a method for evaluating mobile devices based upon a set of techniques already known to the HCI specialist community. Each technique evaluates the problem from different perspectives: the user perspective (expressed as views on the product obtained through a questionnaire), the specialist’s perspective (expressed when analyzing the user performance during the usability evaluation), and the usability community perspective (expressed in the form of standards conformity assessment). Each of these perspectives identifies evaluation problems and, when overlaid, they lead to a more reliable and complete product appraisal.

The remainder of this chapter is structured as follows. The second section gives a brief overview of the evaluation approaches currently in use for mobile devices, according to the literature review. The third section outlines the multi-layered approach. The fourth section illustrates the application of the multi-layered approach by means of a case study involving a Personal Digital Assistant (PDA). The fifth section discusses the results of the case study and their implications for the questions posed in this chapter. Finally, the sixth section concludes with the discussion of future trends in evaluation methods and how to apply the existing experience to the evaluation of this new class of products.

USER INTERFACE EVALUATION FOR MOBILE DEVICES

In the context of user-centered design processes, a significant portion of usability work involves the coordinated acquisition of valid and reliable data by a team of professionals. These specialists have varied backgrounds and skills and employ a number of evaluation methods. The expected result is an improved system design. This is achieved by the successful identification of a system’s usability problems that might impact the interaction quality for a range of users.

Usability data consists of any information that can be used to measure or identify factors affecting the usability of a system being evaluated (Hilbert & Redmiles, 2000). These data are crucial for designing successful systems intended for human use. Such data are gathered by usability evaluation methods and techniques that can assign values to usability dimensions (Rosson & Carroll, 2002) and/or indicate usability deficiencies in a system (Hartson, Andre, & Williges, 2003). According to the International Organization for Standardization (ISO, 1998), usability dimensions are commonly taken to include user efficiency, effectiveness, and subjective satisfaction with a system in performing a specified task in a specified context.

Usability data are gathered via either analytic or empirical methods (Nielsen, 1993; Mayhew, 1999; Rosson & Carroll, 2002). Analytic methods, in which a system is evaluated based on its interface design attributes, are usually conducted by HCI specialists and do not involve human participants performing tasks. This means that these
Multilayered Approach to Evaluate Mobile User Interfaces

methods often rely on the specialists’ judgment. Empirical methods, in which the system is evaluated based on observed performance in actual use, involve data collection of human usage.

Other classifications include direct methods (recording actual usage) and indirect methods (recording accounts of usage) (Holzinger, 2005). There are also formative and summative methods (Wixon & Wilson, 1997). The direct methods are used to generate new ideas and gather data during the development of a system in order to guide iterative design (Hix & Hartson, 1993). The indirect methods are used to evaluate existing systems and gather data to evaluate a completed system in use (Scriven, 1967). Discovery methods (also called qualitative methods) are used to discover how users work, behave, and think, and what problems they have. Decision methods (also called quantitative methods) are used in selecting a design among several alternatives or in picking elements of interface designs (Wixon & Wilson, 1997).

In essence, usability data have been classed in a number of other models and frameworks, often focusing on (1) the approach employed for gathering the data (including the resources expended and the degree of formality) (Danielson, 2006); (2) the context of use (including lighting, noise level, network connectivity, communication costs, communication bandwidth, and the social situation) (ISO, 1998; ISO, 1999; Jones & Marsden, 2006); (3) the nature and fidelity of the artifact being evaluated (EATMP, 2000); and (iv) the goal of the acquisition process (Kan, 2002).

It is a fact that usability evaluation for stationary computer systems has grown in the last two decades. In spite of debates still taking place within the HCI area, they are often based on a tacit understanding of basic concepts. One example of this understanding is in relation to the distinction between field and laboratory evaluation approaches and their importance to the area. Classical extensive guidelines were written that describe how usability evaluation in controlled environments should be conducted (e.g., Dumas & Reddish, 1999; Mayhew, 1999; Nielsen, 1993). Additionally, experimental evaluations of the relative strengths and weaknesses of different techniques are available that can be applied in a usability evaluation (e.g., Molich et al., 1998).

In the last decade, methodologies and approaches in HCI have been challenged by the increasing focus on systems for wearable, handheld, and mobile computing devices. One such move beyond office, home, and other stationary-use settings has pointed to the need for new approaches in designing and evaluating these systems (Kjeldskov, 2003). While the primarily task-centered evaluation approaches may be applicable to the desktop computing paradigm (often structured with relatively predictable tasks), they may not be directly applicable to the often-unpredictable continuous interaction possibilities and relatively unstable mobile settings. Additionally, it is not easy for evaluation methods to integrate completely or even adequately in real world or simulated settings contexts during the evaluation process. Authors argue that mobile computing demands not only real users but also a real or simulated context with device interaction tasks. It also demands real tasks or realistic task simulations.

There are a number of studies that discuss the question of whether the evaluation should be carried out in a laboratory or field context (e.g., Goodman et al., 2004; Kjeldskov & Stage, 2004; Kjeldskov et al., 2005; Po et al., 2004). All of these papers have a common theme, in that they apply a multi-method approach to performance measurement and discuss solutions for efficient data analysis. Nonetheless, it is important to note that the approach to usability evaluation depends on the relevance of the results presented as well as on the quality of the data analysis process. In general, the reports only present the results of the data analysis, omitting the details of the analysis process itself. While the data gathering method is critical for data quality, a more rigorous analysis
on user comments and problem reports could help specialists better assess their choices.

There is a lot of current human-computer interaction research on alternatives for data collection methods and techniques. However, adequate data analysis and validation are only presented in few cases (e.g., Nielsen, 1994; Dumas & Redish, 1999; Po et al., 2004). In general, this aspect of the HCI research is poorly described in the literature, there being only vague conclusions and little guidance for attempts at successfully replicating the findings in other evaluation contexts. Many methods and techniques have been employed in the analysis of empirical data gathered during usability evaluations. Examples are for field testing analysis, video data analysis (Sanderson & Fisher, 1994), expert analysis (Molich et al., 1998), and head-mounted video and cued recall (Omodei et al., 2002). Its time-consuming character and its poor applicability for industrial purposes can explain the absence of an in-depth usage data analysis when under resource constraints (Bailie & Schatz, 2005). Nonetheless, it is strongly recommended for research purposes as a means to support new findings. For the same reason, it is equally important to provide sufficient detail to allow for replication and a substantiated choice of methods with similar levels of description.

THE MULTILAYERED EVALUATION APPROACH

The method described here was originally proposed for evaluating desktop interfaces. It was then adapted to evaluate the usability of mobile devices. It is based upon a multi-layered approach that combines standard conformity assessment, user performance measurement, and user satisfaction measurement. Each one of these evaluation techniques detects problems from a specific point of view. The multilayered approach is based on the premise that the combination of techniques (triangulation) will produce complementary and more robust results.

Standard Conformity Assessment

According to the International Organization for Standardization (ISO), conformity assessment means checking whether products, services, materials, processes, systems, and personnel measure up to the requirements of standards (ISO, 2006).

In its original version, this evaluation method adopts the standard ISO 9241 (Ergonomic Requirements for Office Work with Visual Display Terminals).

In the PDA case study it was found that only some parts of this standard can be applied to this mobile device: Parts 11 (ISO 9241-11, 1998), 14 (ISO 9241-14, 1997), 16 (ISO 9241-16, 1999), and 17 (ISO 9241-17, 1998). There are also some other standards that apply to this kind of device such as the ISO/IEC 14754 (Pen-based Interfaces—Common gestures for text editing with pen-based systems) (ISO/IEC 14754, 1999) and others that, although applicable to mobile devices, do not apply in this specific case. Examples are the ISO/IEC 18021 (User interfaces for mobile tools for management of database communications in a client-server model), since it is for devices capable of performing data interchange with servers (ISO/IEC 18021, 2002); and ITU-T E.161 (Arrangement of digits, letters, and symbols on telephones and other devices that can be used for gaining access to a telephone network, also known as ANSI T1.703-1995/1999, and ISO/IEC 9995-8:1994) (ITU, 2001).

User Satisfaction Measurement

User satisfaction has received considerable attention from researchers since the 1980s as an important surrogate measure of information systems success (Aladwani & Palvia, 2002; Goodhue &
Thompson, 1995; Bailey & Pearson, 1983). While most user satisfaction measuring instruments were not Web-based at the time of development, others have been successfully validated in a Web-based environment (e.g., De Oliveira et al., 2005).

The user satisfaction diagnosis provides an insight into the level of user satisfaction with the product, highlighting the importance of the problems found and their impact on the product acceptance.

**User Performance Measurement**

The user performance measurement aims in general to provide data on the effectiveness and efficiency of a user’s interaction with a product. It enables comparisons with similar products, or with previous versions of the same product along its development. Additionally, it can highlight areas where a product can be enhanced to improve usability. When used with the other methods, the evaluator can build a complete picture of the usability of a system.

The most significant user interface problems can be found by conducting experiments (usability tests) with representative users to observe how quickly, easily, and safely they can operate a product. The major change introduced in the original method concerns the introduction of field tests as a complement to the original laboratory tests.

**The Experiment: Comparing Field and Laboratory Use of a PDA**

The main objective of this study is to investigate the need for adapting the original evaluation method to the context of mobile devices, based on the analysis of the influence of the context (field versus laboratory and mobility versus stationary interaction) on the evaluation of mobile devices and applications.

The mobile device chosen as the target for this study was a PDA, the *Nokia 770 Internet Tablet* and some of its native applications. Tests were performed in a controlled environment (the usability laboratory) and also in the field. Twenty-four users took part in the experiment, divided into two groups of twelve.

**Experiment Design**

The study was designed to investigate the influence of the context (field and laboratory) and associated aspects such as mobility, settings, and so forth, and the user experience on the evaluation results. The independent variables are those that are not influenced by the context, by the test facilitator, or by external factors such as noise and lighting. An experiment plan was drawn from the study’s objectives. The independent variables were chosen as follows:

- **Task context** comprises factors that may affect the users’ behavior and their performance during the experiment (usability test). These factors may be internal or external to the user. The external factors originate in the field environment, examples being noise level and light intensity. The internal factors, on the other hand, are stress or other health conditions that may affect the user’s mental and physical abilities.
- **User mobility** refers to the conditions under which the task is being performed. An example is if the user is required to work while being mobile, that is, moving between places or wandering while working.
- **User experience level** refers to the user’s knowledge regarding mobile devices in particular and desktop computers systems in general.

The dependent variables are all dependant on the user’s experience level:
Multilayered Approach to Evaluate Mobile User Interfaces

- **Task time** represents the time taken by a device’s user to perform a task.
- **Number of incorrect choices** measures how many times the user has made incorrect choices while selecting options in the interface through a menu dialogue.
- **Number of incorrect actions** measures how many times the same error (excluding the number of incorrect choices) was committed by the user while performing a task.
- **Number of accesses to the online help** and **number of accesses to the printed help** measure how many times the user accessed the online and printed help while performing a task.
- **Perceived usefulness** represents the user’s opinion about the usefulness of the mobile application for the prescribed task.
- **Perceived ease of use** represents the user’s subjective satisfaction when using the mobile device.

Table 1 summarizes the experiment plan, which states the independent and dependent variables to be observed during the experiment and used as indicators to answer the research questions.

**Test Environment**

A software tool was used in the field environment to remotely capture the device’s screen through a wireless connection to the lab. The user inputs (through keypad and stylus) were registered by a micro-camera coupled to the device and also remotely connected to the laboratory through a wireless connection. The interaction was regis-

Multilayered Approach to Evaluate Mobile User Interfaces

tered in the controlled environment using two
video cameras installed in the laboratory. One
was focused on the users’ facial expressions and
the other registered the device screen. As in the
field environment, software was used to remotely
capture the device’s screen. Since the field setting
required a wireless network, the field experiment
was performed in the area surrounding the univer-
sity’s computer department. In both cases, the test
facilitator was a human interface specialist who
remained within reach in case the user required
any explanation on the test procedure.

Participants

Users participating in the PDA experiment were
selected on the basis of having previous experi-
ence with mobile devices (such as mobile phones),
computers, and the Internet. They were also re-
quired to have some familiarity with the English
language, since this is the language adopted in
the device’s user interface and in its documenta-
tion. The user sample was then classed according
to the users’ experience level into the categories
shown in Table 2.

The recruited users were divided into two
groups of 12 to participate in the field and labora-
tory tests. Based on user experience level, both
groups were then subdivided into three subgroups
of four beginners, four intermediates and four
experts.

Materials

Laboratory Test Materials

• **Hardware**: The Nokia 770 Internet Tablet;
  PC based Workstation (2); Video cameras
  (3); Microphones (2).

• **Software**: VNC (Virtual Network Com-
  putting) software to capture the screens
during the interaction with the device; the
WebQuest tool with the questionnaires pre-
test (to gather the user profile) and post-test
(to collect and process the user satisfaction
level).

• **Miscellaneous**: The Nokia 770 Internet
  Tablet Manual; chronometer (1); CDs for
  video backup; participant registration form;
test conditions acceptance forms on which
  the users declared their acceptance of the
  experiment conditions; task script that con-
sists of a written task description to guide
  the user during the session (versions for the
  user and for the evaluator); Form for event
  log.

Field Test Materials

• **Hardware**: The Nokia 770 Internet Tablet;
  PC-based Portable (laptop) Workstation (1);
  wireless video micro-camera (1); apparatus

to support the video micro-camera (1); television set (1); VCR equipment (1).

- **Software:** VNC (Virtual Network Computing) software to capture the screens during the interaction with the device; WebQuest tool with the questionnaires pre-test (to gather the user profile) and post-test (to collect and process the user satisfaction level).

- **Miscellaneous:** Chronometer (1); CDs and VHS tapes for video backup; participant registration form; test conditions acceptance forms on which the users declared to accept the experiment conditions; task script that consists of a written task description to guide the user during the session (versions for the user and for the evaluator); form for event log.

**Camera Apparatus**

The apparatus shown in Figure 1 was built to couple a video micro-camera to the mobile device. This allowed the recording of user interaction through a remote link with the laboratory computer.

**The WebQuest Tool**

A Web tool named *WebQuest* supports the method application (De Oliveira et al., 2005). This tool was developed to support the specialist during data collection, to provide automatic score computation, to perform statistical analysis, and to generate graphical results. *WebQuest* also enables the specialist to reach a more diverse and geographically widespread sample of users through the Internet. One of its features is a flexible questionnaire structure, which enables specific context adaptation and, by means of an estimation model, ensures a higher degree of confidence on the indicators of user satisfaction. Currently *WebQuest* supports two questionnaires: (i) a pre-test questionnaire, the *USer* (*User Sketcher*), conceived to raise the profile of the system users; and (ii) a post-test questionnaire, the *USE* (*User Satisfaction Enquirer*), conceived to raise the user degree of satisfaction with the system. The pre-test questionnaire incorporates a model to estimate the user’s subjective satisfaction and can be answered directly on the Web. The questions are related to the users’ physical characteristics, knowledge, and skills. Both questions and answers are configurable.

As for the *USE* (*User Satisfaction Enquirer*), it allows gathering quantifiable variables on the user acceptance of the device. Three of its aspects are of special interest. Firstly, it incorporates a model to estimate user subjective satisfaction. Secondly, the questionnaires can be answered directly on the Web. Thirdly, the items are partially or totally configurable. The adoption of an estimation model by *USE* allowed us to establish a subjective satisfaction coefficient directly from the inspection of the respondents’ samples. The *WebQuest* tool allows the specialist to easily edit the questionnaire’s items. These items are orga-
nized into groups: (1) fixed, which are applicable to various evaluation contexts and thus are not allowed to be altered; (2) semi configurable, which allow for changes in the answer options; and (3) configurable, which can be fully configured (both the question and respective options of answers). USE supports the specialist from the data collection through to automatic score computation, performing statistical analysis, and generating graphics with the results.

**Experiment Procedure**

The techniques employed in the experiment procedure were the observation and subsequent video analysis for accumulating quantitative data (such as time spent and error rate). An automated video capturing tool recorded the interactions of the subjects during the field tests to ensure a non-intrusive observation method. During task execution, the users were asked for their consent before being filmed. The conditions of test-subject participation included a written commitment not to disclose any product information. The users were also asked to give consent so that their images and/or sound recordings made during the experiment could be used for research purposes or in a multimedia product evaluation report. On the other hand, the users were given assurances from the evaluation team that no personal information or individual performance results would be disclosed.

The first step in following the method consisted in defining the evaluation scope for the product as well as a scenario for the test. Table 3 illustrates the sequence of tasks performed during the experiment.

The decision was based on a heuristic evaluation performed by the evaluation team. This initial step also supports the definition of a general profile for the user sample and a classification into categories. Following, the method the evaluation objectives were defined. These became the basis for choosing the product evaluation scenario (product context of use and laboratory settings) and the corresponding tasks to be performed by the users during the experiment. Having planned the evaluation, a pilot test was conducted to verify the adequacy of the proposed experiment procedural, materials, and environment. Through this fine tuning procedure it was found, in the PDA case study, that the time to perform the tasks had been underestimated. This resulted in re-dimensioning the test scenario to six tasks, with a review of the tasks themselves to fit the established session time of sixty minutes to prevent user tiredness.

All subjects were submitted to the same procedure prescribed in the experiment protocol. The study was conducted first in a laboratory setting and then in the field environment. During the field tests the participants were taken outdoors, and the tasks were conducted in an environment that was as close to real-use conditions as possible.

The experiment conducted in the usability laboratory had the audio and video of each session recorded. In the field experiment, only the video of the sessions was recorded, supplemented by comments written by the specialist. As described in the experiment protocol, each session consisted of the following steps: (1) introducing

the user to the test environment by explaining the test purpose, the procedure to be followed and the ethics involved in terms of the conditions of participation; (2) applying the pre-test questionnaire; (3) performing the task script; (4) applying the post-test questionnaire; and (5) performing a non-structured interview.

At the time of the experiment, the Nokia 770 Internet Tablet device was not yet widely known in the Brazilian market. The users who claimed to have had no previous contact with it were given a quick introduction. This introduction consisted of an instructional material given to the recruited users and also a quick explanation about the device’s input and output modes and its main resources.

Results

The results obtained from the experiment in which the multi-layered method was applied support the original assumption that, in spite of the distinctive features of this class of devices, it is possible to adapt from the evaluation experience with conventional devices. This conclusion is supported by the evidence that the evaluation context did not significantly influence the user performance or the opinion about the device’s usability, given through the analysis of the objective and subjective indicators associated with the experiment.

Standard Conformity Assessment Results

The results of the conformity assessment to the standards ISO 9241 Parts 14 and 16 and ISO 14754 are illustrated in Table 4. According to ISO, conformity assessment results can be summarized by computing an adherence rate (AR). This is the percentage of the applicable recommendations (Ar) that were successfully adhered to (Sar).

In spite of the device’s characteristics that limit the number of applicable recommendations, these results corroborate the idea that the standards inspection is still applicable in the evaluation process. The efficacy of this technique can be considerably improved if it is based upon standards conceived specifically for mobile devices, which could evidence more usability problems.

User Satisfaction Measurement Results

For the PDA case study context, both questions and answers of the USE questionnaire were configured. The questionnaire was applied soon after the usability test and answered using the mobile

Sar—Successfully adhered recommendations
Ar—Applicable recommendations
AR—Adherence Rate

\[ AR = \frac{Sar}{Ar} \times 100\% \]
device itself. As mentioned before, its purpose was to collect information on the user’s degree of satisfaction with the device and on aspects such as interface navigation, documentation, and overall impressions.

The USE was composed of three sections. The first section is relative to “the product Use and Navigation.” It is composed of 17 items and focuses on aspects such as menu items, navigation between functions, understandability of the messages, ease of use of the basic functionalities, and of the device’s input and output mechanisms. The second section consists of six questions related to the online and off-line (printed manuals) documentation. The last section (“You and the product”) consists of 15 items and aims to get the user’s impressions and product acceptance level. The first 23 items use a 5-point semantic scale (1: very easy; 2: easy; 3: not easy nor difficult; 4: difficult; and 5: very difficult). The last 15 items use another 5-point semantic scale (1: completely agree; 2: agree; 3: do not agree nor disagree; 4: disagree; and 5: completely disagree). The users were asked to answer the questions and to assign an importance level to each one of them, on a scale from 0 to 10.

For the post-test questionnaire, USE adopts the model proposed by Bailey and Pearson (Bailey & Pearson, 1983) for measuring the overall user’s sense of satisfaction. The following adaptations to the dimensions were considered: (1) the association of only one (1) semantic differential scale to the items, instead of the four (4) semantic differential scales, as proposed in the original model; (2) the adoption of a 5-point Likert scale, delimited by the ends -2 and 2 (instead of the 7-point scales delimited by the ends -3 and 3 as originally proposed); and (3) the incorporation of a 11-point importance scale (0 corresponding to non applicable), varying from 0.0 to 1.0 in intervals of 0.1 (instead of the original 7-point scales, which varied from 0.1 to 1.0 in intervals of 0.15).

The user’s subjective satisfaction indicators for the PDA case study were 0.330 for the laboratory experiment and 0.237 for the field experiment. The normalized value ranges of the user satisfaction concerning a product are 0.67 to 1.00 (Extremely Satisfied), 0.33 to 0.66 (Very satisfied), 0.01 to 0.32 (Fairly satisfied), 0.00 (Neither satisfied nor unsatisfied), 0.01 to 0.32 (Fairly dissatisfied), 0.33 to 0.66 (Very dissatisfied), and 0.67 to 1.00 (Extremely dissatisfied). This is in accordance with the Bailey and Pearson model (Bailey & Pearson, 1983). The results obtained correspond respectively to Very satisfied and Fairly satisfied.

**Performance Measurement Results**

**The User Sample Profile**

The user sample profile was drawn with the support of the questionnaire USer. It was composed of 13 male and 11 female users, of which eight were undergraduate students, 12 post-graduate students, two graduate level, and two post-graduate level. The ages varied between 18 and 29 years. They were mainly right handed and mostly used some sort of reading aid (either glasses or contact lenses). All of them had at least one year of previous experience of computer systems and were currently using computers on a daily basis.

**User Performance Data Analysis**

After having analyzed the data gathered during the experiment on the user performance and having analyzed the list of problems found with this technique, it was possible to evaluate their impact and class them as: minor (50%), medium (50%), major (0%), consistency (35.7%), recurrent (64.3%), and general (0%).

The data analysis consisted of a statistical processing and had two main purposes: (1) to investigate the influence of the context on the results of the evaluation method (through the comparison of the results obtained from both environments); and (2) to investigate the influence of the user experience with the mobile device on
the test results within each context. For the latter purpose, the three categories illustrated in Table 2 were used.

The statistic analysis performed consisted of: (1) building a report with univariance statistics; (2) generating the covariance matrices for the objective and subjective indicators that were previously defined; (3) applying the one-way F ANOVA test (Tabachnick & Fidell, 2006) to the data obtained from the previous step in order to investigate possible differences; and (4) applying the Tukey-Kramer process (Tabachnick & Fidell, 2006) to the one-way F ANOVA results aiming to investigate if the found differences were statistically significant to support inferences from the selected sample. The result of this technique was the identification of 13 problems, of which 92.3% were found in the laboratory and 61.5% in the field as: Laboratory (38.5%); Field (7.7%); and Laboratory & Field (53.8%).

Overlaying Results

Since the multi-layered evaluation is based upon a triangulation of results, Table 5 summarizes the usability problem categories identified by the three techniques.

The numbers correspond to the identification of each problem from a list of problems found through each technique. As can be seen from Table 5, some of the usability problem categories were more related to the performance measurement (e.g., hardware aspects, help mechanisms, processing capacity) whereas others (e.g., menu navigation, presentation of menu options) were identified by the conformity assessment. It was possible to identify 66.7% of the problems found by other methods when combining the results from the post-test questionnaire with the user comments made during the experiment and the informal interview at the end of the experiment. This confirms the importance of combining techniques to obtain a more complete result when performing usability evaluation. It must be pointed out that 29.62% of the problems based on the user opinion about the product were in disagreement with the results of the other two evaluation dimensions (specialist and the community points of view). This discrepancy can originate from the users’ perception of product quality and the perception of their own skills to perform the task, accepting full responsibility over the difficulties that might arise during the interaction. When overlaying the problems in Table 5, in the category Menu navigation, the same problem was found by the techniques Standards Inspection and Performance Measurement.

DISCUSSION

From this study’s data analysis it became evident that certain problem categories are better found by specific techniques, as shown in Table 5. For instance, problems associated to the device’s physical characteristics are better found by means of conformity assessment, whereas the user performance located problems associated to the device’s applications.

The analysis of the pre-test and post-test questionnaires and the informal interviews showed that domain knowledge and computer literacy have significant influence on user performance with mobile devices. This was true both under laboratory conditions and in the field, in relation to the incidence of errors. The univariate analyses of variance of the performance variables: Time, Errors, and Accesses to help, are presented in Table 6.

From this table, it can be seen that the user experience level had a more significant effect on the number of errors in the field experiment than in laboratory experiment.

The studies in the literature fit basically into two categories: (1) user mobility, which means moving while using the device (inside of a laboratory or outdoors) and (2) user attention division. However, this study considers both aspects as...

part of the task context. In this experiment, the field test subjects were free to choose between moving or remaining still as they performed the task with the mobile device. During the informal interview the users stated that in a real context they would not perform the experiment tasks on the move, since they demanded too much attention. The specialist encouraged users to wander around the environment, although they could choose to enter a room in the building, sit down, or even lay the device on a table (which they did in most cases, under the argument that this setting was more comfortable). The movement registered was limited to situations in which the user waited for some device processing. (e.g., Web page downloads). There was a clear interference of the environment on the user attention during the field tests while moving.

The device’s physical characteristics affected the user performance and the data gathering during the experiment. Outdoors, in ambient light, the device’s legibility was reduced and aggravated by the reflections on the screen. According to the user’s opinion stated during the informal interview, the camera apparatus did not interfere with the task execution, but the majority decided to lay the device down during task execution.

As for the entry of text information, the users showed a preference for the virtual keyboard instead of hand written character recognition. Based on their comments, as well as on the informal interview, it was concluded that writing long messages is very cumbersome both using the virtual keyboard and using the handwriting recognition application. Confirming previous findings, the experiment demonstrated that applications that require a lot of interaction and user attention are inappropriate for performing while walking due to attention division. This conclusion reinforces that, for the device targeted in this study, in spite of its mobility, the evaluation settings did not need to differ substantially from the one employed in the evaluation of stationary devices since the users tend not to wander while performing tasks that demand their attention or consisted of text input.

Until recently, studies have been published which deal with new paradigms and evaluation techniques for mobile devices. Few of the proposed new techniques are really innovative if compared to the ones traditionally employed. On the other hand, the main argument for proposing new techniques concerns the user and device mobility and the influence of this mobility on user performance. In contrast, this study evaluated the effect of mobility not only from the user performance perspective but also from user opinion point of view and the user level of satisfaction. From the application of the multi-layered approach, the data gathered and analyzed support the initial assumption that minor adaptations in the traditional evaluation techniques and respective settings are adequate to accommodate the evaluation of the category of mobile devices targeted by this study.

The conclusions corroborate with the views of the authors and that of Po (Po, 2003) that the laboratory and field evaluations do not diverge but are complimentary. As shown in this study, they both add to the evaluation process, producing data that is significant to the process and reinforcing the relevance of a multi-layered approach for the usability evaluation of mobile devices.

FUTURE TRENDS

Mobile devices impose challenges to the usability evaluation that are unique in respect to the observation strategies and the conception of test scenarios. With the continuous technological advances, a wider variety of new devices is being released into the market, challenging users with the complexity of the interaction. In this scenario, the importance of the product usability is undisputable as is also the correct choice of evaluation methods, techniques, and tools.

One emerging trend in the mobile devices evaluation field is the possibility of gathering data
in an unobtrusive way, using tools for remote, and automatic data capture that are transparent to the user. Developing those tools is a challenging activity given the inherent restrictions presented by the mobile devices (such as their limited processing power and limited storage capacity). But, in spite of the current limitations, it was shown in this study that the tools are becoming available to provide a great contribution to the evaluation setup and that these tools would benefit from further development.

Multilayered Approach to Evaluate Mobile User Interfaces

laboratory and field testing. *Human-Computer Interaction, 9*, 251–317.

**KEY TERMS**

**Conformity Assessment:** A collective term used for a number of techniques used to determine if a product, system, or process (including design) meets a defined specification.

**Device Mobility during a Usability Evaluation:** The ability to interact with the user and continue to perform its functions while being transported.

**Efficacy of an Evaluation Method or Technique:** Translated into the number of problems found, gravity of those problems versus the time, and cost of performing the experiments.

**Likert Scale:** An attitude scale in which respondents indicate their degree of agreement/disagreement with a given proposition concerning some object, aspect, person, or situation.

**Multi-Layered Evaluation Approach:** A product or prototype usability evaluation method that combines techniques for data gathering and analysis based on multiple perspectives (the user’s, the specialist’s, and the usability community). The results are overlaid in order to find discrepancies and offer more robust results.

**User Mobility during the Usability Evaluation:** The ability to move while performing a task with a product.

**User Performance Measurement:** The process of gathering actual data from users as they work with a system and its documentation. Usually, the user is given a set of tasks to complete and the evaluator measures the relevant parameters such as the percentage of tasks or subtasks successfully completed, time required to perform each task or subtask, frequency and type of errors, duration of pauses, indications of user frustration, and the ways in which the user seeks assistance.

**User Satisfaction Measurement:** The process of obtaining qualitative and quantitative information which indicates the extent to which user expectations concerning some object, process, product, or situation are being met. Such information can be obtained in a variety of ways, both formally and informally.

**Virtual Network Computing (VNC):** A desktop sharing system that uses the RFB (Remote Frame Buffer) protocol to remotely control another computer. It transmits the keyboard presses and mouse clicks from one computer to another over a network, relaying the screen updates back in the other direction.

Chapter 8.5

Digital Imaging Trek: A Practical Model for Managing the Demand of the Digitally Enabled Traveller

Stephen C. Andrade
Johnson & Wales University, USA

Hilary Mason
Johnson & Wales University, USA

ABSTRACT

This chapter introduces the concept and activities of the digitally enabled tourist and the impact such as tourist has on the travel and tourism industry. It summarizes the existing and emerging technical environments that encourage the use of hand held digital recording devices and personal Internet communications. Additionally, it looks at ways tourists publish and exhibit digital visual and written artifacts of their travel experience. The chapter introduces general types of digital communication infrastructure to be considered by the industry to create an experience to support this type of tourism. The authors hope that further understanding of the digitally enabled tourist will inform travel professionals to better facilitate commerce and practice in the industry.

INTRODUCTION

Technology has had a great influence on the tourism and travel industry. In recent years digital communication platforms and technologies have evolved and become accessible to a wide mainstream audience of tourists and travelers. Organizations engaging in travel and tourism commerce need to understand this wave of innovative behavior among their customers. From cell phones to high speed wireless Internet connection to the variety of creative ways customers have applied digital technologies—the travel and tourism industry is being widely affected by these emerging trends in information and communications technologies (ICT). Is the digitally enabled traveler the wave of the future? How will companies and services shift business models to optimize the experience of people with digital
devices? Are there commercial opportunities embedded in these? What does a traveler need to know to keep current with changing technologies? It is critical that services providers and travelers alike stay informed, because one thing is certain, technological innovation and change will be a constant companion for the travel and tourism industry.

This chapter provides insight into technology trends that will be helpful to the practitioner, student, educator and the tourist-travelers themselves. Being prepared to meet the new demands of customers will provide rewarding experiences for parties on all sides of the tourism equation.

BACKGROUND

Since the wide spread use of the telephone in the 1920s, information and communications technologies (ICT) have had a great influence on the industry of tourism. In the 1990s, the wide spread use of powerful desktop computers, enterprise wide systems, and the World Wide Web (WWW) continued to transform the way business was conducted in all facets of the travel and tourism. While ICTs have had a dramatic impact on the mechanics of tourism business practices, the virtual explosion of new inexpensive digital communication technologies is transforming the experience of tourism from the traveler’s point of view.

The new generation of hand held mobile technologies, the expansion of wireless (WiFi) networks and the surge in digitally hosted social interchange services present new opportunities for engaging all sectors of the tourism industry. This new generation of technologies also presents new challenges to the industry to structure services with the digital service users in mind.

New services that provide online collaborative and social interaction through the World Wide Web now shape and influence vast communities of millions of online customers. Traveler-centered mobile technologies are increasingly used for many activities embedded in the tourist and traveler experience. This chapter will explore the model of the digital imaging trek and the digitally enabled traveler as a way to structure experiences to satisfy the demand of the technically savvy traveler in a world of advancing mobile technologies and online services. It also will provide basic technical background about the devices and infrastructure that drives these technological innovations.

Understanding the use of advanced hand held devices from the traveler’s point of view is becoming more critical to tourism industry providers. Both new and veteran professionals in the tourism industry need to think about how these technologies influence the customers’ choices, activities and ultimately their economic decisions about tourism. Customers have eagerly adopted the cheap and easy to use digital technologies. Tourism professionals need to understand the role mobile digital technologies play in the expanding global tourism field. For customers, mobile digital technologies are helping to shape the experience of tourism from initial research of a destination, through the reservation process to the final visual record of the experience.

Mobile digital technologies include a wide array of products that are inexpensive and easy to use. When mobile digital technologies are used to shape a tourist’s experience they become powerful digital communication tools reaching out to an infinite audience of like-minded users on the World Wide Web. New products in cellular telephony, visual still imaging, motion and sound recording, wireless digital connections to the World Wide Web and the services on the World Wide Web, all converge to offer a digital environment unlike any before it. The combinations of these technologies are dynamic, unique and ever expanding. These digital technologies are in a constant state of enhancement—services become faster, devices become more powerful and feature-rich, and prices come down. This
Moore’s Law is the observation made in 1965 by Gordon Moore, co-founder of Intel. In it he states that the number of transistors per square inch on integrated circuits had doubled every year since the integrated circuit was invented. Moore predicted that this trend would continue for the foreseeable future. In subsequent years, the pace slowed down a bit, but data density has doubled approximately every 18 months, and this is the current definition of Moore’s Law, which Moore himself has blessed. Most experts, including Moore himself, expect Moore’s Law to hold for at least another two decades. (http://www.webopedia.com)

Consider what it means to double the capacity of digital technologies every 12-18 months. Few if any physical systems or resources in the world of tourism have this capacity and potential. Moore’s Law not only means faster and better technology, it also enables dynamic changes in the way people use technology. In fact, it is difficult to predict exactly how consumers will respond to innovative devices and new digital gadgets. Tourism professionals need to understand this dynamic process and prepare for the digitally enabled traveler.

Who is the Digitally Enabled Traveler?

The digitally enabled traveler is a new breed of traveler equipped with devices, connectivity, skill
and motivation to create and access real-time, online, rich media knowledge bases of travel and tourism experience.

The digitally enabled traveler is motivated by the same principles as the conventional tourist. People involved in tourism are visiting locations for leisure, recreation, sight seeing, vacation and other activities. The global travel industry hosts not only tourists, but professional travelers on professional missions as well. People travel for business, cultural, scientific, educational, governmental and other kinds of activities in the world of global tourism. Most forecasts for travel of all types indicate a steady rise of 4% a year over the next decade. Even a causal observation in any busy transportation hub, such as an airport or train station will reveal how critical mobile technologies and wireless connections are to both the recreational and professional traveler alike.

People who travel with digital devices are highly motivated to stay connected to business and social networks. Minimally, most travelers today require basic voice and Internet connectivity service to maintain contact with families and tourism providers. Travelers want to stay in touch with the sources of lodging, travel bookings, reservations and other critical contacts during their trip. Some travelers thrive on constant digital connection to not only monitor progress in plans, but also stay in touch with their virtual communities.

Beyond the basic business function and family contact, travelers are using a wide array of digital devices to capture, record, edit, and exhibit the experience of tourism and travel. The days of a single film camera used in a casual manner to take pictures of highlights are over. As the tourism industry embraces near-endless global locations for travel destinations, travelers are highly motivated to capture and share their experience with digital recording and connection devices. Why? In spite of all the technical gadgetry, it is still human nature to want to discover and share a new experience. This mode of communication has been going on for generations, only now, it is played out on a global digital stage.

Digital still and video cameras along with powerful laptops and hand held devices have opened new territory for the digitally enabled traveler. These new digital technologies also offer new service-business opportunities for the tourism industry.

Today’s digitally enabled traveler is highly motivated to stay in-touch with a virtual community of people through services on the Internet. With millions of people subscribing to World Wide Web sites that host virtual communities the trend of communicating in digital interactive space has been set. Social networking through digital services is widely accepted as common practice. This segment of the technology service industry is rapidly growing as the each successive generation matures into an economic demographic that can afford the expense of travel and tourism. Millions of people are now involved in what is called “social networking.” As counter intuitive as it may seem, the way to establish human bonds is through digital technologies. Numerous Web sites have been established as sources for self-published digital image galleries, digital video galleries, audio files, user profiles, and blogs.

Social Networking: The Latest Trend

Social networking systems are an emerging technology that is beginning to have a significant influence on how people communicate. Social networking systems are Web sites that offer a collaborative or shared virtual experience, generally around a particular theme or human interest. Visitors to the site can connect with each other through shared attributes, such as interests, activities, or geographic location.

Some social networking sites, such as Facebook (http://www.facebook.com), are designed simply to facilitate the process of making social connections. Other sites, such as Delicious
An essential quality of a social networking site is that it must allow users to share information via a network of nodes (users) and connections (users with similarities). Users also can easily identify other users with similar interests.

Most social network sites utilize the community to develop an ontology via tagging. Tagging is a simple method of allowing users to attach key words to a piece of data. Users searching for those keywords can then locate a wide variety of matching media. This works on the assumption that humans will generally choose similar terms to describe similar items. Most of the time, the assumptions works well, and people network with other people's experiences.

Tags are often represented in a “tag cloud” (see Figure 2). Larger text indicates a more popular tag. Other visualizations include history, topics, and information origin. This visual model of popularity makes these sites friendly to even the most non-technical visitors.

Social networking sites are beginning to have a large impact in business. Consider the common professional activity of attending industry-specific conferences. Attendees meet for seminars, meals, and networking. Several attendees may take photos of this event. They can upload their photos to a photo networking site such as Flickr (http://www.flickr.com), and tag them with the name of the conference. Anyone searching for the conference would be able to find a complete photographic record of the event.

Social networking has even made an impact in tourism. “Where Are You Now?” (http://www.wayn.com) is a site that connects travelers, for logging trips and comparing destinations, finding travel buddies, and making friends with like-minded people. WAYN even helps with off-line networking by allowing users to send SMS (short text messages) to each other's cell phones.

Social networking presents an innovative solution to the problem of information overload. By organizing information collaboratively, useful content filters toward the people who would most like it, while useless content is dropped altogether. Finally, it is a core technology with implications that will touch all disciplines in the years to come.

A blog, or “Web log” for short, is a collection of posts around a theme or topic collected on a Web site. At the time of this writing, blog search firm Technorati (http://www.technorati.

---

**Figure 2. Sample tag cloud**

![Sample tag cloud](image)
Digital Imaging Trek

Digital Imaging Trek (http://www.digitalimagingtrek.com/) was tracking 25.4 million blogs with 1.9 billion links.

A blog is a collection of time-stamped journal entries on any possible topic. Blogs cover every subject from politics to education to technology to one particular person’s social life. Some blogs are only of interest to a few people while others have thousands of readers daily.

The Pew Internet Survey estimates that about 11%, or 50 million people, read blogs. (http://www.pewInternet.org/PPF/r/113/report_display.asp). Eighty percent of people contacted by the Business Blog Consulting Web site, a site focused on the growing use of blogs in business, believe that blogs are not a fad. Traditional media outlets (such as the BBC) have begun to add blogs to their media offerings.

The digitally enabled traveler is motivated to share experience in an immediate, visual and highly subjective manner. For a digitally enabled traveler, the personal reaction to a destination like a museum, a historic site, or a travel adventure is typically recorded as a highly personalized written blog. The digitally enabled traveler will supplement the blog with a gallery of digital images. The gallery will then be linked to a short video, compressed for Web hosting, of the activity at the site. With a reasonably fast wireless Internet connection or access to a local Internet café, this material can be posted within minutes of the experience, or in some cases, in near real time. Digitally enabled travelers with the proper digital gear and Internet connection can produce a personalized digital stream of video, images and words. Often defined as “rich” media, the mix of all these files—sound, still, motion, text—are a critical and creative connection to a virtual world for the digitally enabled traveler. For the

Application base still developing | • Typically less functional than laptop
• Consumers are urged to match intended use to tablet functionality

Digitally enabled traveler, contact with the social network on the Web is critical. This technical and artistic practice is easy to achieve and among the members of the digital generation, a routine and necessary activity.

Table 1 offers a way to understand the devices, practices, skills, and motivations of a digitally enabled traveler.

Professionals in travel and tourism should understand that the focus of these technologies is the individual consumer, not necessarily the business enterprise.

**Digital Imaging Trek: A Model for the Tourism Industry**

The digitally enabled traveler is equipped with an endless array of digital products designed to capture and record the tourism experience. Through these devices travelers are highly motivated to stay connected to virtual communities online. Patrons of tourism will use their technology skills to create visual and rich media collateral—high quality digital media artifacts. There are countless Web-based outlets to connect the traveler’s experience and collateral to an eager virtual community and social interaction network. As digitally enabled tourism becomes an expectation among patrons and customers, tourism professionals need to understand and shape usage models.

The model of the digital imaging trek proposes information and technical architectures to capture travel experience, create a virtual record of tourism, and meet the demands of the digitally enabled traveler.

From early times of travel, the notion of a “trek” has long been regarded as a journey of self-exploration for the traveler. Many tourists
and travelers today are seeking a heightened experience as part of their tourism through digital communication technologies. Putting practice into models, especially the practice of the digital imaging trek, is a way to understand the processes and practices of the digitally enabled traveler (See Figure 3). Using all the digital tools available, a digital trekker will produce files from a wide range of sources and self-publish material in two methods; saved as CD-based files (or some other permanent memory such as DVD or portable USB Flash Memory) or published on the World Wide Web.

A typical day on digital imaging trek starts with a destination selection. Digitally enabled travelers will turn to the Internet to locate and decide upon a location. Whether it is a museum, a regional historic location or a cultural performance, the digitally enabled traveler will seek all types of information from Web site based services to make plans. When made available on a Web based system, transportation schedules, phone numbers, hours of operations, special information about exhibits, costs, and other related information about the region, are always instantly available to the traveler. Web based systems allow the digitally enabled traveler to acquire information regardless of time and in a preferred language.

In digital imaging trek model, the traveler is focused on acquisition of digital still and video

Figure 3. The general digital imaging trek model embraces technology communication devices and self publishing
Digital Imaging Trek

images that record the daily experience of the trip. In any environment—built or natural—the visitor will always encounter new scenes that are novel, exciting, and educational and from the perspective of the traveler, representative of the tourism experience. With cheap recording memory in the form of Flash Memory, a digitally enabled traveler has near infinite storage space to capture images. Digitally enabled travelers also can edit on the fly. The advantage of digital imaging over traditional film imaging is in the use of storage and field editing. If an image is not worth keeping, it can be immediately erased. Images worth keeping are filed and stored until needed later.

As the day progresses on the digital imaging trek, travelers will want to spend time reviewing images, editing images, and corresponding to the social network with e-mail, uploads and blogs. Editing and organizing images are tasks that most travelers will conduct when time is available. Typically image editing is done on a portable laptop computer. Many people prefer to travel with laptop computers as they are light weight, highly functional, and a repository of software tools and information necessary to conduct digital imaging while traveling. (For the business traveler, a laptop is practically required gear for the trip.) Editing image files requires some time and concentration and will like occur during a break in activities. When editing still images with a popular image editing software such as Adobe Photoshop, travelers will crop, color-correct, merge and manipulate images.

Figure 4. Students and faculty from Johnson & Wales University on a digital imaging trek to Paris; wireless digital connection to the Internet is abundant in urban environments; checking e-mail and editing images in a street side café is now a common tourist experience
Similarly, digital video footage also will be edited. Travelers on a digital imaging trek will likely download and edit video footage with commonly available video editing software such as Adobe Premiere or Apple’s iMovie and Final Cut Pro. Still image editing software and video editing software is widely available. With basic skill and proficiency, digital travelers can achieve remarkably high quality results. For travelers on a digital imaging trek, it is the primary focus of experience and a rewarding achievement to acquire these images.

The ease of use of digital imaging equipment—still cameras, video cameras and laptops—promotes the phenomena of “hyper-imaging”—taking thousands of images to sort through later. Travelers who are serious about digital imaging are continuously shooting images throughout the day and night. The result of hyper-imaging is an overabundance of images and footage that must be sorted and organized. Powerful laptop computers with optimized internal and external storage are perfect for this task. Sorting and organizing images and footage is typically done to suit the desires of the traveler on a digital imaging trek. Images are categorized by group or class and notated with keywords for access at a later time. Various gallery and filing software makes the task of organizing relatively easy.

A Short Primer on Digital Photography

Unlike film cameras, which store images on film, digital cameras capture images via electric sensors and store those images on reusable solid-state memory.

The first digital cameras targeted toward consumers were released in the early 1990s. Since then the digital camera revolution has taken off, and there are hundreds of models available. Competition has remained fierce and manufacturers are producing digital cameras with limitless capacity. Just 15 years after the introduction of the first consumer digital cameras, current models are take pictures that are as high or higher quality than film cameras. Digital cameras take some getting used to, but tourists and travelers who taking digital imaging seriously will find numerous camera choices in the marketplace.

Digital cameras fall into three general categories: consumer, prosumer, and professional. Consumer cameras generally have a single, non-removable lens that mimics a standard 35mm film lens. However, manufacturers now produce consumer level models with nearly every feature of a traditional Single-Lens Reflex or SLR camera.

The term prosumer is a blend of “professional” and “consumer” and refers to consumers who demand more than the standard technology available while being unable to afford professional equipment. In the digital camera market, the prosumer devices are Single-Lens Reflex, or SLR, models, and are falling below the $1000

Figure 5. Digital cameras are popular among travelers and tourists; they are portable, easy to use, and affordable.
price point. Prosumers tend to be technologically savvy and more tolerant of quirks and bugs in new products.

Many professional photographers are moving entirely to digital photography, enticed by the low cost of shots, ease of printing, high resolutions, and ability to edit photos easily with software such as Adobe Photoshop. Professional cameras generally accept the same standard lenses as film cameras and store photos in RAW format, which allows for greater flexibility in editing. The RAW format can be thought of as a digital negative.

The editing and sorting activity is often a precursor activity to the act of e-mail, blogging and posting images on a Web site to interact with digitally connected social network. Travelers with a laptop and access to the Internet will use the online connection to communicate frequently and for sustained periods of time—sometimes hours at a time. If connectivity is available from a wireless service, the traveler with a laptop will connect, log in to services, and communicate on a frequent basis throughout the day. If the Internet connection is more concentrated, in an Internet café with computers for instance, the traveler will dedicate a portion of the day to connect and communicate online. It is not unusual to see Internet cafés through Europe and Asia, but the model is less attractive in the U.S. Internet connection services should allow the traveler to connect and spend as much time as necessary to conduct the typical activities as blogging, image

</table>
posting, e-mail, checking itinerary, and so on. As the day winds down on the digital imaging trek, the digitally enabled traveler has acquired a new database of images, published and shared select image-files, and communicated stories of their experience with their social network online through e-mail and blogs.

Taking pictures on a vacation is not new to the world of tourism, but digital equipment has changed the business and behavior equation. Given the proper technical infrastructure, images can be acquired and posted—essentially published—to a world-wide audience in a matter of minutes.

Digital photos are easy to share. Most photos are already stored on a computer or memory card, and it is a simple matter to upload them to the Internet, either through a private gallery (such as the digitaltrek.org site), or a social photography Web site such as Flickr (www.flickr.com).

Most thriving urban centers and developed destination resort complexes have a mature ICT infrastructure to support instant access to the Internet. Even smaller rural locations now boast access to the greater world of the Internet. The goal of a traveler on a digital imaging trek is to capture and publish images that reflect travel experience in new places and foreign cultures.

Tourism and Information Architecture

It is critical that both traveler and tourism enterprise alike prepare for the use of digital technologies through “architecture.” Travelers and organizations need to plan and think ahead of how to respond and conduct activities through the travel and tourism experience. While some things are left to chance or serendipity the deployment of digital infrastructure requires some thought. That plan is called “architecture.”

Architecture for information services is similar to that of architecture for buildings—it is the deliberate planning, modeling, and delivery of ICT services. Architecture requires adopting a model of approach and solution, both in systems architecture and information architecture. How does a highly connected, fast speed digital environment that serves the digitally enabled traveler sprout up? It is not a singular act by any tourism organization, but a system wide policy approach of local and national partners in business and governmental bodies. In most cases, experts from companies that provide ICT services will consult on the array of services available in the technology marketplace.

Much of the communications infrastructure that has developed in the past decade is a confluence of commercial profit-driven interest, digital user culture, and regional policy and laws. The combined effect of the built ICT environment serves residents and visitors alike. Localities with new digital infrastructure enjoy digital connection to a broader world. Travelers to areas that are served with high speed digital services also reach out and use the infrastructure for all their related travel communication activities. This ever growing presence of widely accessible digital communication services represents different challenges to different cultures. While most Western cultural sensibilities accept the openness of access to the World Wide Web, other cultures are more circumspect and reserved, wishing to control the vast onslaught of information pouring out of the Web.

Cost has always been considered the primary barrier for entry in the world of ICT. The receding cost barrier—as Moore’s Law predicts—has lowered the cost barrier, particularly with technology products and services. Tourist properties such as hotels and resorts now can achieve Internet access as easily as telephone access. In many instances, travel infrastructure such as airports, train stations, and the aircraft and trains themselves, provide Internet and advanced telephone access. Countries and regions are now adopting
ICT’s and installing a fiber-optic telecommunications system with widespread wireless digital access points, which has distinct advantages over older, legacy “wire based” telecommunications infrastructures—particularly for the traveler. In some ways, the new fiber and wireless based connectivity infrastructure offers advantages for the digitally enabled traveler.

Of course, this entire ICT infrastructure model represents enormous business opportunity for the properties in which they exist. Hotels, resorts, travel destinations, travel hubs, restaurants, coffee houses, business outlets can differentiate themselves from competitors by providing ICT for a fee to the traveler. Travelers in turn, view access to ICT as a cost associated with travel and plan to spend money to acquire it. It is common for travelers to purchase short term access to ICT services at these sites on terms ranging from a few hours to several days.

When collaboration on planning and development of digital infrastructure occurs, the stage is set to promote services to the digitally enabled traveler. A highly developed infrastructure and usage model promotes rapid creation and publishing of rich media collateral by the digitally enabled traveler. All parts of the technology infrastructure work in unison to support the activities of the traveler.

Figure 7. The architecture for wireless network and infrastructure model for digitally enabled traveler
Digital communication technologies of many platforms have become accessible to even the most inexperienced traveler. Mobile technologies of all types and sizes and wireless network signal have brought the Internet to the most distant of locations. This convergence of technical infrastructure and tourism presents opportunities and challenges to the tourism industry.

Yet even as the cyber-record of digital travel experience explodes, there are many issues the profession must consider. The more available common digital technologies become, the more travelers and tourism enterprises grapple with the complexity (and confusion) of choices including but not limited to privacy, intellectual property, systems integration, systems management, training, best practice, and so on.

**Digitally Enabled Travel: Knowledge Targets for the Novice**

As the digitally enabled traveler becomes more of an influence in the world of travel and tourism, young professionals seeking degree based education and career opportunities in the field need to be familiar with basic technology. Whether looking at a college level curriculum or training opportunities for adults wishing to gain new skills, look for some of the topics covered here.

College level curriculum in hospitality, travel, and tourism programs should include an introductory level course in this area of digital technology. The topics taught in such a course do not necessarily have to be technical but young professionals entering the business should know the basics and be prepared to research and understand technology. A sample of college level curriculum might include topics such as the following.

**Foundations in Technology**

Many professionals and educators mistakenly think that learners know all there is to know about basic computer operations, productivity software and Internet access, Web searching and surfing. While these topics are often part of many school systems, not everyone has mastered basic skill and techniques in all these areas. Interacting with computer interfaces and mastering the sophistication of some productivity tools such as word processing, spreadsheets, databases and browsers requires instruction, time and practice. Many colleges, universities, technical institutions and similar educational organizations offer courses in computer technology. The popular press is filled with instructional books complete with CD based video for those who are adept at self instruction. Many conferences, training seminars, and “Webinars” (seminars of text, sound, and motion hosted on the Web), offer similar instruction. Regardless of the model one uses to get trained, using digital technologies requires constant “tune ups” to one’s skill set. Find the type of education that works for you and take advantage of it.

**Basic Information and Systems Architecture**

Information and systems architecture introduces models to help solve problems in the field of technology. As with providing digital services for travels to use to communicate with social networks, technology applications start as a way to provide a solution to a problem.

While it is convenient to say technology will solve a problem or make some situation more efficient or less cumbersome, the idea has to be communicated in a visual model. Professionals in the world of information technology communicate regularly with visual models that reflect the structure or architecture of a system. Devices and the networks that connect them are shown so all can understand and agree on system solutions. Understanding basic architecture in work flow, information flow, and management, networking, service devices, client side devices, and so on will be very valuable for new professionals in the world of hospitality, travel, and tourism.
Digital Imaging Trek

Basic Web Design and Interface

Many professionals in the field of hospitality, travel, and tourism will likely be asked to participate in design teams to design and build Web sites that will host information for customers or be used internally as sources of information for the business enterprise. Conceptualizing and building a Web site is a skill that requires practice and experience although of software tools such as Microsoft FrontPage and Adobe (formerly Macromedia) Dreamweaver make it easy to try this activity. With a little training in software features of such applications, college level courses can quickly teach students the essentials in basic Web site design. This is both a technical and creative challenge, but most people quickly see the results of a little effort. For people just wishing to start with a simple Web site to host information about a trip or a destination, these tools are cheap, accessible, and relatively easy to learn.

Basic Digital Imaging and Image Manipulation

There are an abundance of off-the-shelf software tools in the marketplace that will introduce college student (or anyone with the motivation to learn) skills in digital imaging and image manipulation. While many people have digital cameras a course on digital photography will introduce a wide range of topics from composition to technical specifications. Understanding the wide range of options in today’s digital cameras can be helpful for young professionals who need to deal with a customer base that is armed with the latest camera gadgetry. Learning the process involved in capturing an image and uploading an image to a devices that can store the image in important. More knowledge in these areas will help improve customer empathy and ultimately customer satisfaction.

Editing images in software like Adobe Photoshop has a double benefit to a college curriculum. Students with added technical skills such as digital photo editing are in more demand. Many businesses need such skills to help with developing creative collateral to promote the commercial activity of the business. Understanding the creative process from image acquisition to image editing also will help the professional in dealing with agencies that provide that service. For instance, image editing is a time consuming activity, and in negotiating advertising contracts, such knowledge will be helpful.

Desktop Publishing

Desktop publishing is a content area that will provide a young professional with the knowledge of how to put assets such as text and images together in print collateral to serve the business. Even in the digital age, many businesses still have a great need for printed products to advertise, inform and attract potential customers. Tourism properties still have a great need for pamphlets, brochures and signage to keep customers informed about policies, regulations, events, calendars, and so on. A course in desktop publishing will give practitioners an opportunity to learn a skill that will help promote and organize business. In desktop publishing, students can learn how to conceive and construct various types of print pieces using software such as Microsoft Publishing or Adobe Indesign.

Editorial, Content Creation and Content Management

While learning technical tools is vital, helping young professionals identify and manage the message is critical to the success of travel and tourism businesses. Courses that emphasize the basics of how to construct the message in both text and visual design are important for a basic college curriculum.
Systems and Technology Primer for the Digitally Enabled Traveler

As digital communications platforms and technologies have become adopted by a wide mainstream audience two factors have been critical to widespread use—practicality and ubiquity. Along with the explosion of digital gadgets, contemporary travelers now have high expectations of availability of connectivity and complimentary technologies.

If the tourism industry is to appropriately harness and cater to this new and demanding audience, the industry must build a model of digitally enabled travel that supports both traditional goals of tourism and the new goals of digital media acquisition. Understanding the pieces of the technology puzzle can serve as a starting point.

Several recent world events have highlighted the role mobile technology plays on the world stage. The first images of the London tube bombing in 2005 came from the cell phone cameras of survivors. These images were published by the BBC and forwarded around the world within minutes of the attack. Similarly dramatic images, particularly digital video, were quickly spread after the 2005 tsunami disaster in the Indian Ocean. Whether it is a global or local scale, digital imaging devices are ever present and serve as eyes to the world. Building a world class digital environment brings with it many more challenges, not just in the technical realm, but in the human realm as well.

A Word on Privacy and Security in the Digital Age

Privacy, security of information, copyright, information ownership, censored, and uncensored material are all issues that become concerns of the industry when technology is introduced. It is a grey area because decorum and respect relies as much on personal behavior as it does on personal technology. Travelers with powerful digital recording tools must understand the local cultural norms, as well as the global broadcast power of the World Wide Web.

Privacy is an important and sensitive issue. Visitors to a Web site may be reluctant to share information—such as their e-mail address—because they fear that their personal information will be sold and they will be subjected to unsolicited advertisements. Spam, the endless barrage of meaningless e-mail advertising, has become an onerous burden to all citizens using online tools. It is best avoided by constricting the use of e-mail addresses.

Information that may be personal or sensitive, such as vacation photos or a travel journal, should be posted with care. In many cultures people do not wish to have their images posted for the world to see. Privacy for individuals is a sensitive matter. Even in public tourism venues, digital photographers are challenged when taking images and asked to refrain. Religious and private properties often post requests to refrain from photography and video recordings.

Institutional Web sites should consider developing a privacy policy, or a legal statement that reflects what the institution may and may not do with information provided by users. The World Wide Web Consortium (the standards body for the Web) has developed the Platform for Privacy Preferences (P3P) (http://www.w3.org/P3P/), a standardized language which provides Web site administrators with a simple and automated way to quickly generate a customized policy for their site. Individual digital travelers, eager to capture a unique image, must apply their own standards. The golden rule though is “do unto others” as you would have done to yourself. Consider the impact of each image that is posted.

Travelers must be aware of their physical safety and security at all times. Broadcasting information on the Web can add to this worry. For example, travelers, especially solo-travelers, are advised
against posting a personal and complete itinerary until their trip is complete. No only does it tell the world where you will be, but it also tells the world where you are not. Home safety as well as trip safety is the paramount concern.

With reasonable precautions, a Web site can increase safety. It allows a large number of people to check in on the well-being of travelers. While theft and other dangers cannot be eliminated, careful use of a Web site, instant messaging, and e-mail can reassure those back home. The personal technology of a digital enabled traveler is an attractive target for thieves. Common sense should guide the novice and experienced traveler in protecting personal possessions.

### Web Hosting: What Travel and Tourism Professionals Need to Know

All Internet applications such as a Web site or a search engine run on a server. The server is a computer workstation in a class of computing machines that is specially constructed to manage the constant demand of service to clients on the network. Servers require special software and in most cases, comparably advanced knowledge and skill to configure and maintain. While it is possible to run a server in-house, it involves purchasing a machine, installing and supporting an operating system and applications, and maintaining an “always-on” Internet connection. Managing a server

<td>Intermediate to advanced computer knowledge required to build and support. Entry level user knowledge to access and use.</td>
<td>Wireless internet connections can be found in built environments, particularly popular in urban settings with restaurants, parks, museums, hotels, and cafes.</td>
</tr>
<tr>
<td>Mass Storage</td>
<td>Any secure building location, typically attached to host devices such as advanced workstations or mainframes.</td>
<td>Intermediate computer knowledge required to configure, install and support.</td>
<td>A mass storage device, is a very large, commercial grade hard drive. It supports data and functions core to large businesses. While computer users may see the results of such devices in a routine web search, these devices work in the background of daily user activities.</td>
</tr>
<tr>
<td>Servers</td>
<td>At a hosting company; typically a technology company which provides a secure physical location, as well as technical knowledge to support services. Locations are typically built specifically to house the servers.</td>
<td>Advanced technical skills in web hosting and server based data services.</td>
<td>The server will host all of the content for a web site and code for web applications such as a gallery or blog. Often a class of computers known as workstations; function solely as servers. A hosting service provider will maintain and support all server hardware and software. Computer users access these devices through client computers to update websites, post images in galleries and blog.</td>
</tr>
</tbody>
</table>
Digital Imaging Trek

requires routine management as well as prompt response emergencies, 24 hours a day, 7 days a week. For most travel and tourism providers, becoming a technology company is a distraction from the core business. It is generally advisable that any business requiring a host on a server be outsourced to a Web host business provider.

A Web host is a company that provides space on their Web servers, use of their programs, and a certain amount of bandwidth use for a monthly cost. Often referred to as a “solutions provider” or a “Web hosting service” the hosting company will handle all computer hardware and software issues such as installations, configurations, back-ups, updates, and any unforeseen maintenance. Of course, solution providers contract these services for a fee, but competition works in this marketplace as it does in any other, and a shopper is wise to research and compare costs and services among a range of businesses.

There are many Web hosting companies and there are many attributes to consider when researching them. Choosing a hosting company is a long-term commitment. Transferring a site from one hosting service to another generally involves several days of unreliability and possible downtime. Carefully consider all of the factors outlined in Table 3 before making a decision.

All of these considerations are important indicators of a successful Web hosting experience. Remember, anyone can run a server, including a college student living in an apartment with a space for a computer on a network. Make sure that you are dealing with a professional company that has

Table 3. Qualities for evaluating a hosting company

<table>
<thead>
<tr>
<th>Factor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reputation</td>
<td>Every company must market itself on its reputation for service to customers. Ask for reference of other businesses that have used the services. Search for comments on the web about the company and its performance. Are there any instances of how the company performed in a crisis, such as a virus attack or power failure? Have you toured the facilities or conducted due diligence on the company?</td>
</tr>
<tr>
<td>Reliability</td>
<td>Does the company publish statistics on technical performance? What level of support and customer service contact is there? Will you be able to contact people in off hours? What kind of technology do they support? Is there a specific platform or hardware and software and do you recognize the vendor? Ask about back-up, power supply, physical security, data security, etc. Do they publish their reliability data? Conduct an internet search through popular search engines to find information about them.</td>
</tr>
<tr>
<td>Technology</td>
<td>Is the hardware and software platform up to date and current? Can you speak to vendors who supply the company with technology. Do they publish any related information about platforms?</td>
</tr>
<tr>
<td>People</td>
<td>Making a business agreement is as much about people as it is price structure. Have you met the principals of the company? Are you generally familiar with their organization and business structure? Do you have confidence in the people you have met? Is there generally superior business communication to your proposals?</td>
</tr>
</tbody>
</table>
a reputation for handling routine business as well as crises. Like the travel and tourism industry, professional protocol in handling technical matters as well as high grades on customer service are key to sound business practice in the technology marketplace.

As with every business, hosting is about people as much as technology. Find a company with knowledgeable employees who are happy to deal with their clients. You should find support personnel who are professional, courteous and eager to answer questions at your knowledge level, no matter how basic or advanced.

Every good host publishes their uptime (the amount of time the service has run without interruptions) and customer testimonials. Don’t necessarily trust the quotes on the company’s Web site; do an Internet search with any popular search engine (Yahoo, Google, etc.), and find out for yourself.

Once you have identified a few companies that you feel comfortable dealing with, consider the technical requirements of your project. The first decision is about the type of hosting that the project requires. The options are:

- **Dedicated hosting** means that you are leasing an entire computer, which gives you access to the entire hard drive and allows you to make certain configuration requests that are not possible on a shared machine. By leasing a server (rather than purchasing it and placing it in your office), you outsource the need for physical setup, administration and backup services. You also avoid the upfront cost of a powerful machine, and take advantage of your hosting company’s ability to quickly purchase and maintain the machine with professional qualified vendors.

- **Shared hosting**, sometimes called managed hosting, means that you are leasing part of a server, which you will share with other customers. This kind of plan generally involves very low monthly fees (as low as $10/month) and provides complete technical support. Unless you are hosting multiple blogs or Web sites, a shared hosting plan is probably sufficient.

Travel and tourism organizations could have a range of needs to contract an outside hosting provider. Setting up a Web page to inform customers of features and offerings of a property or package, or architecting more advanced online services for customers may be among the ideas you will have. The next step in this process of selecting a hosting provider is to explore what you want to do with your hosting provider. The type of service you offer will determine the software applications that the hosting provider will need to run on the server. Additionally, your requirements will guide the features that you’ll select for the server. Each software package will list the special requirements on their Web site, but some general guidelines are:

- **Static Web page**: Simple Web pages that hyperlink information that is relatively static. Information does not change too often. Static Web pages require little to no special software or technical support.

- **Downloadable images**: No special requirements, similar to static Web page

- **Image gallery with uploading**: Image galleries containing collections of image (often hundreds and thousands) require server-side programs. Server side programs mean that special software has been loaded and manipulated to provide an easy user interface and experience. A database will be required to track and maintain a medium to large size collection of gallery images.

- **Blogs**: Blogs, or written text entries also require special server-side software to accepted entries, organize them and display them, blog software, like image galleries is generally database-driven.
Several hosts offer blog-friendly plans that require minimal configuration and no technical skills. Lists of these can be found at http://wordpress.org/hosting/ and http://www.sixapart.com/movabletype/hosting.

Identify your minimum technical requirements. In general, look for the criteria listed in Table 4.

**More Technical Tools of the Digitally Enabled Traveler**

Digitally enabled travelers will quickly embrace new and experimental technologies. For them, it is a challenge to figure out ways to adopt a technology and make it work in the daily flow of travel.

For instance, instant messaging, or “IM,” is a technology for rapid-fire asynchronous messaging across a network. Instant messages can be thought of “instant e-mail,” and are generally used to communicate to a select social network, but often composed on the computer screen while doing something else. Digitally enabled travelers multitask on the computer—that is, they conduct more than one activity at the same time—with ease.

<table>
<thead>
<tr>
<th>Feature</th>
<th>What to Look For</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technical Support</td>
<td>At the very least, 24-hour email technical support. Also consider telephone support (generally, the company promises to address your problem and call you back within 24 hours).</td>
</tr>
<tr>
<td>Domain</td>
<td>Most hosting plans include one domain registration (for example, <a href="http://www.yournamehere.com">www.yournamehere.com</a>) for free. Make sure that the price for a second is reasonable (not more than $20/year).</td>
</tr>
<tr>
<td>Disk space allocation</td>
<td>Disk space, the space on the hard drive that is allocated to you, should be adequate for your application. Storing web pages or blogs requires a small amount of space, while storing photographs requires multiple gigabytes. Look for at least 10GB of space. Also, research in advance what it will cost to expand your allocated space. Understand the incremental hikes in cost for more disk space.</td>
</tr>
<tr>
<td>Server-side program access</td>
<td>The applications that you wish to run will guide your need for server-side program access. In general, look for PHP, which is a coding language that manages how customers see and interact with your services.</td>
</tr>
<tr>
<td>E-mail addresses</td>
<td>Your plan should offer the ability to create your own <a href="mailto:me@mydomain.com">me@mydomain.com</a> e-mail addresses. Web-based e-mail access is a nice feature for frequent travelers, and is offered at no additional cost by many hosts.</td>
</tr>
<tr>
<td>Bandwidth</td>
<td>Bandwidth refers to the total amount of data transfer between your server and visitors to your web site. More bandwidth is good. Understand that bandwidth to the end user is limited by their personal connection and rate of speed.</td>
</tr>
<tr>
<td>Statistics</td>
<td>It’s always helpful to know exactly how many visitors your site has. Hosting companies typically provide this information with some graphics and analysis.</td>
</tr>
<tr>
<td>Databases</td>
<td>If you wish to run a dynamic application such as a blog, you’ll need access to a database.</td>
</tr>
<tr>
<td>Operating System</td>
<td>Your operating system choice should be guided by your application requirements. Most hosting plans are based on either Linux (which tends to be cheaper), or Windows.</td>

</table>
IM was first popularized in the mid-1990s by ICQ, a product introduced by Mirabilis Ltd in 1996. Mirabilis Ltd was later acquired by America Online, which ran a competing product called “AOL Instant Messenger,” or AIM. By acquiring ICQ, AOL became the largest operator of instant messaging networks in the world.

Other competitors include Microsoft, which offers an instant messaging feature as part of the Microsoft Network (MSN), and Yahoo!, which offers the feature as part of their community-building options. All of these services are free to use, though some may display advertisements.

Unfortunately, all of these services are based on proprietary protocols and do not interoperate. Therefore, a digital traveler must choose the service that most of the people that they wish to communicate with use. If this is not practical, digital travelers can invest in a product such as Trillian, from Cerulean Studios (http://www.ceruleanstudios.com/), which is an IM program that supports all major networks.

Instant messaging is favored by digital travelers, because it allows instant communication with anyone on the network, no matter where their physically located. If a device (such as a computer or cellular telephone) has Internet access, it can connect to an IM network. This is an extremely low-cost method for travelers to communicate with their social network of friends, family, and colleagues around the world.

More recently, voice over Internet protocol (VoIP) has become an important buzzword in the latest digital tools becoming available to digital travelers. VoIP is a technology for transmitting traditional “telephone calls” over the Internet. Imagine using a laptop as a phone and conducting routine two-way audible conversations. Such calls are indistinguishable from normal Internet data and promise to make international conversational calls extremely cheap. Imagine no more phone calling cards and the end to frustrated travelers trying to decipher local and international calling codes.

While still in the early stages, VoIP is available to any digital traveler with a laptop, speakers, and a microphone. Services such as Google Talk or Skype (http://www.skype.com/) are up and running and can be used to converse with telephone quality audio for free. Skype also offers “Skype Out,” which permits computers to connect with telephone numbers anywhere in the world for extremely reasonable rates.

Needless to say, it is important for travel and tourism organizations to be familiar with trends such as VoIP for two reasons. The early adopters of such technology—the digitally enabled traveler—are the bell weather for change in the industry. It won’t take long for entrepreneurial technology providers to create a competitive business model for VoIP and shift the commerce to a new marketplace.

CONVERGENCE AND FUTURE TRENDS

Given the rapid evolution of digital communication tools, both hardware and software based, it is not hard to imagine that many of these products will continue to transform.

The technology industry is creating faster, lighter, devices that better integrate with each other. This trend of “convergence” is one to watch for. It wasn’t long ago that a cell phone was simply a way to have voice conversations with other parties. Today, other features have converged on the platform of a cell phone. Is a cell phone a camera, a video recorder, a video viewer, organizer and personal digital library? The answer is “yes”—it is all those things and more.

A digital camera is no longer a camera; it is an image processing workstation. Images can be acquired, edited, filed, and stored. Images are dynamic files that merge and morph into other applications and devices through infrared proximity connections.
The ubiquitous iPod from Apple computer started off not too long ago as a just another platform for listening to music. Today an entire lucrative industry revolves around providing rich media content for viewing on a tiny screen. Need an exercise multimedia instruction package for keeping fit during travel, it can be purchased and downloaded to your iPod.

CONCLUSION

Digital gear to enhance the travel and tourism industry is a constantly evolving marketplace. The future is part evolution and part revolution, from wildly popular devices to culturally challenging information flow. Regardless of the intricacy, allure or popularity of digital devices, the seasoned digitally enabled traveler will always find ways of incorporating new devices and new services to enhance experience and communicate to a social network in digital space. Travel and tourism providers must influence the role of the digital imaging trek by understanding the role they themselves play in this ever changing landscape. Who is the provider, the host, the arbitrator of this new world of digital travel? By seeing and understanding the big digital picture, tourism and travel providers will retain perspective and offer quality services to patrons worldwide.

Chapter 8.6
Intelligent User Interfaces for Mobile Computing

Michael J. O’Grady
University College Dublin, Ireland

Gregory M. P. O’Hare
University College Dublin, Ireland

ABSTRACT

In this chapter, the practical issue of realizing a necessary intelligence quotient for conceiving intelligent user interfaces (IUIs) on mobile devices is considered. Mobile computing scenarios differ radically from the normal fixed workstation environment that most people are familiar with. It is in this dynamicity and complexity that the key motivations for realizing IUIs on mobile devices may be found. Thus, the chapter initially motivates the need for the deployment of IUIs in mobile contexts by reflecting on the archetypical elements that comprise the average mobile user’s situation or context. A number of broad issues pertaining to the deployment of AI techniques on mobile devices are considered before a practical realisation of this objective through the intelligent agent paradigm is presented. It is the authors hope that a mature understanding of the mobile computing usage scenario, augmented with key insights into the practical deployment of AI in mobile scenarios, will aid software engineers and HCI professionals alike in the successful utilisation of intelligent techniques for a new generation of mobile services.

INTRODUCTION

Mobile computing is one of the dominant computing usage paradigms at present and encapsulates a number of contrasting visions of how best the paradigm should be realized. Ubiquitous computing (Weiser, 1991) envisages a world populated with artefacts augmented with embedded computational technologies, all linked by transparent high-speed networks, and accessible in a seamless anytime, anywhere basis. Wearable computing (Rhodes, Minar, & Weaver, 1999) advocates a
Intelligent User Interfaces for Mobile Computing

world where people carry the necessary computational artefacts about their actual person. Somewhere in between these two extremes lies the average mobile user, equipped with a PDA or mobile phone, and seeking to access both popular and highly specialized services as they go about their daily routine.

Though the growth of mobile computing usage has been phenomenal, and significant markets exists for providers of innovative services, there still exist a formidable number of obstacles that must be surpassed before software development processes for mobile services becomes as mature as current software development practices. It is often forgotten in the rush to exploit the potential of mobile computing that it is radically different from the classic desktop situation; and that this has serious implications for the design and engineering process. The dynamic nature of the mobile user, together with the variety and complexity of the environments in which they operate, provides unprecedented challenges for software engineers as the principles and methodologies that have been refined over years do not necessarily apply, at least in their totality, in mobile computing scenarios.

How to improve the mobile user’s experience remains an open question. One approach concerns the notion of an application autonomously adapting to the prevailing situation or context in which end-users find themselves. A second approach concerns the incorporation of intelligent techniques into the application. In principle, such techniques could be used for diverse purposes, however, intelligent user interfaces (IUIs) represent one practical example where such techniques could be usefully deployed. Thus the objective of this chapter is to consider how the necessary intelligence can be effectively realized such that software designers can realistically consider the deployment of IUIs in mobile applications and services.

BACKGROUND

Research in IUIs has been ongoing for quite some time, and was originally motivated by problems that were arising in standard software application usage. Examples of these problems include information overflow, real-time cognitive overload, and difficulties in aiding end-users to interact with complex systems (Höök, 2000). These problems were perceived as being a by-product of direct-manipulation style interfaces. Thus, the concept of the application or user interface adapting to circumstances as they arose was conceived and the terms “adaptive” or “intelligent” user interfaces are frequently encountered in the literature. How to effectively realize interfaces endowed with such attributes is a crucial question and a number of proposals have been put forward. For example, the use of machine learning techniques has been proposed (Langley, 1997) as has the deployment of mobile agents (Mitrovic, Royo, & Mena, 2005).

In general, incorporating adaptability and intelligence enables applications to make considerable changes for personalization and customization preferences as defined by the user and the content being adapted (O’Connor & Wade, 2006). Though significant benefits can accrue from such an approach, there is a subtle issue that needs to be considered. If an application is functioning according to explicit user defined preferences it is functioning in a manner that is as the user expects and understands. However, should the system autonomously or intelligently adapt its services based on some pertinent aspect of the observed behavior of the user, or indeed, based on some other cue, responsibility for the system behavior moves, albeit partially, from the user to the system. Thus, the potential for a confused user or unsatisfactory user experience increases.

A natural question that must now be addressed concerns the identification of criteria that an
application might use as a basis for adapting its behavior. Context-aware computing (Schmidt, Beigl & Gellersen, 1999) provides one intuitive answer to this question. The notion of context first arose in the early 1990s as a result of pioneering experiments in mobile computing systems. Though an agreed definition of context has still not materialized, it concerns the idea that an application should factor in various aspects of the prevailing situation when offering a service. What these aspects might be is highly dependent on the application domain in question. However, commonly held aspects of context include knowledge of the end-user, for example through a user model; knowledge of the surrounding environment, for example through a geographic information system (GIS) model; and knowledge of the mobile device, for example through a suitably populated database. Other useful aspects of an end-user’s context include an understanding of the nature of the task or activity currently being engaged in, knowledge of their spatial context, that is, location and orientation, and knowledge of the prevailing social situation. Such models can provide a sound basis for intelligently adapting system behavior. However, capturing the necessary aspects of the end-user’s context and interpreting it is frequently a computationally intensive process, and one that may prove intractable in a mobile computing context. Indeed, articulating the various aspects of context and the interrelationships between them may prove impossible, even during system design (Greenberg, 2001). Thus, a design decision may need to be made as to whether it is worth working with partial or incomplete models of a user’s context. And the benefit of using intelligent techniques to remedy deficiencies in context models needs to be considered in terms of computational resources required, necessary response time and the ultimate benefit to the end-user and service provider.

**SOME REFLECTIONS ON CONTEXT**

Mobile computing spans many application domains and within these, it is characterized by a heterogeneous landscape of application domains, individual users, mobile devices, environments and tasks (Figure 1). Thus, developing applica-

*Figure 1. An individual’s current activity is a notoriously difficult aspect of an individual’s context to ascertain with certainty*
tions and services that incorporate a contextual component is frequently an inherently complex and potentially time-consuming endeavor, and the benefits that accrue from such an approach should be capable of being measured in some tangible way. Mobile computing applications tend to be quite domain specific and are hence targeted at specific end-users with specialized tasks or objectives in mind. This is in contrast to the one-size-fits-all attitude to general purpose software development that one would encounter in the broad consumer PC arena. For the purposes of this discussion, it is useful to reflect further on the following aspects of the average mobile user’s context: end-user profile, devices characteristics, prevailing environment and social situation.

User Profile

Personalization and customization techniques assume the availability of sophisticated user models, and currently form an indispensable component of a number of well-known e-commerce related Web sites. Personalizing services for mobile computing users is an attractive proposition in many domains as it offers a promising mechanism for increasing the possibility that the end-users receive content that is of interest to them. Though this objective is likewise shared with owners of e-commerce sites, there are two issues that are of particular importance when considering the mobile user. Firstly, mobile interactions are almost invariably short and to the point. This obligates service providers to strive to filter, prioritize, and deliver content that is pertinent to the user’s immediate requirements. The second issue concerns the question of costs. Mobile users have to pay for services, which may be charged on a KB basis, thus giving mobile users a strong incentive to curtail their use of the service in question if dissatisfied.

A wide number of features and characteristics can be incorporated into user models. As a basic requirement, some information concerning the user’s personal profile, for example, age, sex, nationality and so on, is required. This basic model may then be augmented with additional sub-models that become increasingly domain-specific. In the case of standard e-commerce services, a record of the previous purchasing history may be maintained and used as a basis for recommending further products. Electronic tourist guides would require the availability of a cultural interest model, which as well as indicating cultural topics of interest to the user, would also provide some metric that facilitated the prioritization of their cultural interests.

Device Characteristics

Announcements of new devices are occurring with increasing frequency. Each generation successively increases the number of features offered, some of which would not be associated with traditional mobile computing devices, embedded cameras and MP3 players being cases in point. Though offering similar features and services, there are subtle differences between different generations, and indeed interim releases within the same generation, that make the life of a service provider and software professional exceedingly difficult and frequently irritating. From an interface perspective, screen size and support for various interaction modalities are two notable ways in which devices differ, and these have particular implications for the end-user experience. This problem is well documented in the literature and a number of proposals have been put forward to address this, the plasticity concept being a notable example (Thevenin & Coutaz, 1999). Other aspects in which mobile devices differ include processor, memory and operating system; all of which place practical limitations on what is computationally feasible on the device.
**Prevaling Environment**

The notion of environment is fundamental to mobile computing and it is the dynamic nature of prevailing environment in which the mobile user operates that most distinguishes mobile computing from the classic desktop usage paradigm. As an illustration, the case of the physical environment is now considered, though this in no way diminishes the importance of the prevailing electronic infrastructure. Scenarios in which mobile computing usage can occur are multiple and diverse. The same goes for physical environments. Such environments may be hostile in the sense that they do not lend themselves to easily accessing electronic infrastructure such as telecommunications networks. Other environments may experience extreme climatic conditions thus causing equipment to fail.

Developing a service that takes account of or adapts to the local physical environment is an attractive one. Two prerequisites are unavoidable, however. A model of the environment particular to the service domain in question must be available, and the location of the end-user must be attainable. In the former case, the service provider must construct this environmental model, possibly an expensive endeavor in terms of time and finance. In the latter case, an additional technological solution must be engaged—either one based on satellites, for example GPS, or one that harnesses the topology of the local wireless telecommunications networks. Each solution has its respective advantages and disadvantages, and a practical understanding of each is essential. However, by fulfilling these prerequisites, the service provider is in a position to offer services that take the end-users’ physical position into account. Indeed, this vision, often termed location-aware computing (Patterson, Muntz & Pancake, 2003), has grasped the imagination of service providers and end-users alike. In essence, it is a practical example of just one single element of an end-user’s context being interpreted and used as a basis for customizing services.

**Social Situation**

Developing a service that adapts to the end-user’s prevailing social context is fraught with difficulty, yet is one that many people would find useful. What exactly defines social context is somewhat open to interpretation but in this case, it is considered to refer to the situation in which end-users find themselves relevant to other people. This is an inherently dynamic construct and capturing the prevailing social situation introduces an additional level of complexity not encountered in the contextual elements described previously.

In limited situations, it is possible to infer the prevailing social situation. Assuming that the end-user maintains an electronic calendar, the detection of certain keywords may hint at the prevailing social situation. Examples of such keywords might include lecture, meeting, theatre and so on. Thus, an application might reasonably deduce that the end-user would not welcome interruptions, and, for example, proceed to route incoming calls to voicemail and not alert the end-user to the availability of new email. Outside of this, one has to envisage the deployment of a suite of technologies to infer social context. For example, it may be that a device, equipped with a voice recognition system, may be trained to recognize the end-user’s voice, and on recognizing it, infer that a social situation is prevailing. Even then, there may be a significant margin of error; and given the power limitations of the average mobile device, running a computationally intensive voice recognition system continuously may rapidly deplete battery resources.
ARTIFICIAL INTELLIGENCE IN MOBILE COMPUTING

Artificial intelligence (AI) has been the subject of much research, and even more speculation, for almost half a century by now. Though failing to radically alter the world in the way that was envisaged, nevertheless, AI techniques have been successfully harnessed in a quite a number of select domains and their incorporation into everyday applications and services continues unobtrusively yet unrelentingly. Not surprising, there is significant interest amongst the academic community in the potential of AI for addressing the myriad of complexity that is encountered in the mobile computing area. From the previous discussion, some sources of this complexity can be easily identified. Resource management, ambiguity resolution, for example, in determining contextual state and resolving user intention in multimodal interfaces, and adaptation, are just some examples. Historically, research in AI has focuses on various issues related to these very topics. Thus, a significant body of research already exists in some of the very areas that can be harnessed to maximum benefit in mobile computing scenarios. A detailed description of these issues may be found elsewhere (Krüger & Malaka, 2004).

One pioneering effort at harnessing the use of intelligent techniques on devices of limited computational capacity is the Ambient intelligence (AmI) (Vasilakos & Pedrycz, 2006) initiative. AmI builds on the broad mobile computing vision as propounded by the ubiquitous computing vision. It is of particular relevance to this discussion as it is essentially concerned with usability and HCI issues. It was conceived in response to the realization that as mobile and embedded artefacts proliferate, demands for user attention would likewise increase, resulting in environments becoming inhabitable, or more likely, people just disabling the technologies in question. In the AmI concept, IUIs are envisaged as playing a key role in mediating between the embedded artefacts and surrounding users. However, AmI does not formally ratify the use of any particular AI technique. Choice of technique is at the discretion of the software designer whose selection will be influenced by a number of factors including the broad nature of the domain in question, the requirements of the user, the capability of the available technology and the implications for system performance and usability.

Having motivated the need for AI technologies in mobile contexts, practical issues pertaining to their deployment can now be examined.

STRATEGIES FOR HARNESING AI TECHNIQUES IN MOBILE APPLICATIONS

It must be reiterated that AI techniques are computationally intensive. Thus, the practical issue of actually incorporating such techniques into mobile applications needs to be considered carefully. In particular, the implications for performance must be determined as this could easily have an adverse effect on usability. There are three broad approaches that can be adopted when incorporating AI into a mobile application and each is now considered.

Network-Based Approach

Practically all mobile devices are equipped with wireless modems allowing access to data services. In such circumstances, designers can adopt a kind of client/server architecture where the interface logic is hosted on the mobile devices and the core application logic deployed on a fixed server node. The advantage of such an approach is that the designer can adopt the most appropriate AI technologies for the application in question. However, the effect of network latency must be considered. If network latency is significant, the usability of the application will be adversely
affected. Likewise, data rates supported by the network in question must be considered. Indeed, this situation is aggravated when it is considered that a number of networks implement a channel sharing system where the effective data rate at a given time is directly proportional to the number of subscribers currently sharing the channel. It is therefore impossible to guarantee an adequate quality of service (QoS) making the prediction of system performance difficult. Often, the worst case scenario must be assumed. This has particular implications where the AI application on the fixed server node needs either a significant amount of raw data or a stream of data to process.

One key disadvantage of placing the AI component on a fixed server node concerns the issue of cost. There is a surcharge for each KB of data transferred across the wireless network, and although additional revenue is always welcome, the very fact that the subscriber is paying will affect their perception of the application in question and make them more demanding in their expectations.

A network-based AI approach is by far the most common and has been used in quite a number of applications. For example, neural networks have been used for profiling mobile users in conversational interfaces (Toney, Feinberg & Richmond, 2004). InCa (Kadous & Sammut, 2004) is a conversational agent that runs on a PDA but uses a fixed network infrastructure for speech recognition.

Distributed Approach

In this approach, the AI component of the service may be split between the mobile device and the fixed network node. The more computationally expensive elements of the service are hosted on the fixed network node while the less expensive elements may be deployed on the device. Performance is a key limitation of this approach as the computational capacity of the devices in question as well as the data-rates supported by the wireless network can all contribute to unsatisfactory performance. From a software engineering perspective, this approach is quite attractive as distributed AI (DAI) is a mature research discipline in its own right; and a practical implementation of DAI is the multi-agent system (MAS) paradigm.

One example of an application that uses a distributed approach is Gulliver’s Genie (O’Grady & O’Hare, 2004). This is a tourist information guide for mobile tourists, realized as a suite of intelligent agents encompassing PDAs, wireless networks and fixed network servers. Agents on the mobile device are responsible for manipulating the user interface while a suite of agents on the fixed server collaborate to identify and recommend multimedia content that is appropriate to the tourist’s context.

Embedded Approach

As devices grow in processing power, the possibility of embedding an AI based application on the actual physical device becomes ever more feasible. The key limitation is performance, which is a direct result of the available hardware. This effectively compromises the type of AI approach that can be usefully adopted. Overtime, it can be assumed that the capability and variety of AI techniques that can be deployed will increase as developments in mobile hardware continue and the demand for ever-more sophisticated applications increases. From an end-user viewpoint, a key advantage of the embedded approach concerns cost as the number of connections required is minimized.

One example of an application that uses the embedded approach is iDorm (Hagras et al., 2004), a prototype AmI environment. This environment actually demonstrates a variety of embedded agents including fixed motes, mobile robots and PDAs. These agents collaborate to learn and predict user behavior using fuzzy logic principles and, based on these models, the environment is adapted to the inhabitant’s needs.
Deployment Considerations

Technically, all three approaches are viable, but the circumstances in which they may be adopted vary. For specialized applications, the networked AI approach is preferable as it offers greater flexibility and maximum performance, albeit at a cost. For general applications, the embedded approach is preferable, primarily due to cost limitations, but the techniques that can be adopted are limited. The distributed approach is essentially a compromise, incorporating the respective advantages and disadvantages of both the networked and embedded approach to various degrees. Ultimately, the nature of the application domain and the target user base will be the major determinants in what approach is adopted. However, in the longer term, it is the embedded approach that has the most potential as it eliminates the negative cumulative effect of network vagrancies, as well as hidden costs. Thus, for the remainder of this chapter, we focus on the embedded approach and consider how this might be achieved.

So what AI techniques can be adopted, given the inherent limitations of mobile devices? Various techniques have been demonstrated in laboratory conditions but one paradigm has been demonstrated to be computationally tractable on mobile devices: intelligent agents. As well as forming the basis of mobile intelligent information's systems, a number of toolkits have been made available under open source licensing conditions thus allowing software engineers access to mature platforms at minimum cost. Before briefly considering some of these options, it is useful to reflect on the intelligent agent paradigm.

THE INTELLIGENT AGENT PARADIGM

Research in intelligent agents has been ongoing since the 1970s. Unfortunately, the term agent has been interpreted in a number of ways thereby leading to some confusion over what the term actually means. More precisely, the characteristics that an arbitrary piece of software should possess before applying the term agent to it are debatable. In essence, an agent may be regarded as a computational entity that can act on behalf of an end-user, another agent or some other software artefact. Agents possess a number of attributes that distinguish them from other software entities. These include amongst others:

- **Autonomy**: The ability to act independently and without direct intervention from another entity, either human or software-related
- **Proactivity**: The ability to opportunistically initiate activities that further the objectives of the agent
- **Reactivity**: The ability to respond to events perceived in the agent's environment;
- **Mobility**: The ability to migrate to different nodes of a network as the need to fulfill its objectives dictates; and
- **Social ability**: The ability to communicate with other agents using a shared language and ontology leading to shared or collaborative efforts to achieve individual and shared objectives.

To what extent an agent possesses or utilizes each of those attributes is at the discretion of the designer. For clarity purposes, it is useful to consider agents as existing on a scale. At the lower end are so-called reactive agents. Such agents act in a stimulus-response manner, and a typical usage scenario might involve the agent monitoring for user interaction and reacting to it. Such agents are generally classified as weak agents (Wooldridge & Jennings, 1995). At the other end of the scale are so-called strong agents. Such agents maintain a sophisticated model of their environment, a list of goals or objectives, and plans detailing how to achieve these objectives. Such agents support rational reasoning in a collaborative context and are usually realized...
as multi-agent systems (MAS). This strong notion of agenthood is synonymous with the view maintained by the AI community.

One popular interpretation of the strong notion of agency is that of the belief-desire-intention (BDI) paradigm (Rao & Geogeff, 1995). This is an intuitive and computationally tractable interpretation of the strong agency stance. To summarize: beliefs represent what the agent knows about its environment. Note that the term environment can have diverse meanings here and may not just relate to the physical environment. Desires represent the objectives of the agent, and implicitly the raison d’être for the application. However, at any moment in time, an agent may be only capable of fulfilling some of its desires, if even that. These desires are then formulated as intentions and the agent proceeds to fulfill these intentions. The cycle of updating its model of the environment, identifying desires that can be fulfilled, and realizing these intentions is then repeated for the duration of the agent’s lifecycle (Figure 2).

When should agents be considered for realizing a software solution? Opinion on this is varied. If the solution can be modeled as a series of dynamic interacting components, then agents may well offer a viable solution. However, many see agents as being particular useful in situations that are inherently complex and dynamic as their native capabilities equip them for handling the myriad of situations that may arise. Naturally, there are many situations that fulfill the criteria but, for the purposes of this discussion, it can be easily seen that the mobile computing domain offers significant opportunities for harvesting the characteristics of intelligent agents.

**Intelligent Agents for Mobile Computing**

As the capability of mobile devices grew, researchers in the intelligent agent community became aware of the feasibility of deploying agents on such devices, and perceived mobile computing as a potentially fertile area for the intelligent agent paradigm. A common approach was to extend the functionality of existing and well-documented MAS environments such that they could operate on mobile devices. It was not necessary to port the entire environment on to the device; it was just necessary to develop an optimized runtime engine for interpreting the agent logic. In this way, the MAS ethos is persevered and such an approach subscribes to the distributed AI approach alluded to previously. A further benefit was that existing agent-oriented software engineering

---

*Figure 2. Architecture of a BDI agent*
(AOSE) methodologies could be used. In the case of testing, various toolkits have been released by the telecommunications manufacturers that facilitate the testing of mobile applications. A prudent approach is of course to test the application at various stages during its development on actual physical devices, as this will give a more accurate indication of performance, the look and feel (L&F) of the application and so on. For a perspective on deploying agents on mobile devices, the interested reader should consult Carabelea and Boissier (2003).

While a number of environments may be found in the literature for running agents on mobile devices, the following toolkits form a useful basis for initial consideration:

1. **LEAP (Lightweight Extensible Agent Platform)** (Bergenti, Poggi, Burg, et al., 2001) is an extension of the well-documented JADE platform (Bellifemine, Caire, Poggi et al., 2003). It is FIPA (http://www.fipa.org/) compliant and capable of operating on both mobile and fixed devices.

2. **MicroFIPA-OS** (Laukkanen, Tarkoma & Leinonen, 2001) is a minimized footprint of the FIPA-OS agent toolkit (Tarkoma & Laukkanen, 2002). The original FIPA-OS was designed for PCs and incorporated a number of features that did not scale down to mobile devices. Hence, MicroFIPA-OS minimizes object creation, reduces computational overhead and optimizes the use of threads and other resource pools.

3. **AFME (Agent Factory Micro Edition)** (Muldoon, O’Hare, Collier & O’Grady, 2006) is derived from Agent Factory (Collier, O’Hare, Lowen, & Rooney, 2003), a framework for the fabrication and deployment of agents that broadly conform to the BDI agent model. It has been specifically designed for operation on cellular phones and such categories of devices.

4. **JACK** is, in contrast to the three previous frameworks, a commercial product from the Agent Oriented Software Group (http://www.agent-software.com). It comes with a sophisticated development environment, and like AFME, conforms to the BDI agent model.

A detailed description of each of these systems is beyond the scope of this discussion. However, the interested reader is referred to (O’Hare, O’Grady, Muldoon & Bradley, 2006) for a more advanced treatment of the toolkits and other associated issues.

**FUTURE TRENDS**

As mobile devices proliferate, and each generation surpasses its predecessor in terms of raw computational capacity and supported features, the potential for incorporating additional AI techniques will increase. In a similar vein, new niche and specialized markets for mobile services will appear. If a more holistic approach is taken towards mobile computing, it can be seen that developments in sensor technologies, fundamental to the ubiquitous and pervasive vision, will follow a similar trajectory. Indeed, the possibility of deploying intelligent agents on sensors is being actively investigated in widespread expectation that the next generation of sensors will incorporate processors of a similar capability to the current range of PDAs. Such a development is essential if the AmI vision to reach fruition.

As the possibility of incorporation of ever more sophisticated AI techniques increases, the potential for extending and refining the adaptability and IUI constructs for the support of mobile users increase. Indeed, adaptability may reach its fulfillment through the incorporation of autonomic computing precepts (Kephart & Chess, 2003). Self-configuring, self-healing, self-optimizing
and self-protecting are the key attributes of an autonomic system, and it can be seen that incorporation of AI techniques may make the realization of these characteristics more attainable.

Finally, the practical issues of engineering mobile AI solutions must be considered. Mobile computing poses significant challenges to the traditional software engineering process, and the broad issue of how best to design for mobile services still needs to be resolved. The situation is exacerbated when AI technologies are included. However, it may be envisaged that as experience and knowledge of the mobile computing domain deepens and matures, new methodologies and best practice principles will emerge.

CONCLUSION

Mobile computing scenarios are diverse and numerous, and give rise to numerous challenges that must be overcome if the end-user experience is to be a satisfactory one. IUIs offers one viable approach that software designers can adopt in their efforts to make their systems more usable in what is frequently a hostile environment. However, the pragmatic issue of realizing mobile applications that incorporate intelligent techniques is of critical importance and gives rise to significant technical and design obstacles.

In this chapter, the broad issue of realizing an intelligent solution was examined in some detail. At present, the intelligent agent paradigm offers an increasingly viable proposition for those designers who wish to include intelligent techniques in their designs. To illustrate the issues involved, the intelligent agent paradigm was discussed in some detail.

As mobile developments continue unabated, the demand for increasingly sophisticated applications and services will likewise increase. Meeting this demand will pose new challenges for software and HCI professionals. A prudent and selective adoption of intelligent techniques may well offer a practical approach to the effective realization of a new generation of mobile services.

Intelligent User Interfaces for Mobile Computing

**KEY TERMS**

**Ambient Intelligence**: (AmI) was conceived by the Information Society Technologies Advisory Group (ISTAG) as a means of facilitating intuitive interaction between people and ubiquitous computing environments. A key enabler of the AmI concept is the intelligent user interface.

**BDI Architecture**: The Belief-Desire-Intention (BDI) architecture is an example of a sophisticated reasoning model based on mental constructs that can be used by intelligent agents. It allows the modeling of agents' behaviors in an intuitive manner that complements the human intellect.

**Context**: Context-aware computing considers various pertinent aspects of the end-user's situation when delivering a service. These aspects, or contextual elements, are determined during invocation of the service and may include user profile, for example language, age, and so on. Spatial contextual elements, namely location and orientation, may also be considered.

**Intelligent Agent**: Agents are software entities that encapsulate a number of attributes including autonomy, mobility, sociability, reactivity and proactivity amongst others. Agents may be reactive, deliberative or hybrid. Implicit in the agent construct is the requirement for a sophisticated reasoning ability, a classic example being agents modeled on the BDI architecture.

**Intelligent User Interface**: Harnesses various techniques from artificial intelligence to adapt and configure the interface to an application such that the end-user's experience is more satisfactory.

**Mobile Computing**: A computer usage paradigm where end-users access applications and services in diverse scenarios, while mobile. Mobile telephony is a popular realization of this paradigm, but wearable computing and telematic applications could also be considered as realistic interpretations of mobile computing.

**Multi-Agent System**: A suite of intelligent agents, seeking to solve some problem beyond their individual capabilities, come together to form a multi-agent system (MAS). These agents collaborate to fulfill individual and shared objectives.

**Ubiquitous Computing**: Conceived in the early 1990s, ubiquitous computing envisages a world of embedded devices, where computing artefacts are embedded in the physical environment and accessed in a transparent manner.

Chapter 8.7
Intelligent User Interfaces for Ubiquitous Computing

Rainer Malaka
Bremen University, Bremen

ABSTRACT

Designing user interfaces for ubiquitous computing applications is a challenging task. In this chapter we discuss how to build intelligent interfaces. The foundations are usability criteria that are valid for all computer products. There are a number of established methods for the design process that can help to meet these goals. In particular participatory and iterative so-called human centered approaches are important for interfaces in ubiquitous computing. The question on how to make interfaces more intelligent is not trivial and there are multiple approaches to enhance either the intelligence of the system or that of the user. Novel interface approaches follow the idea of embodied interaction and put particular emphasis on the situated use of a system and the mental models humans develop in their real-world environment.

User interfaces for computational devices can be challenging for both their users and their designers. Even such simple things as VCRs or TV sets feature interfaces that many people find too difficult to understand. Reviews and tests of consumer electronic devices very often rank bad usability even higher than technical aspects and the originally intended main function of the devices or features. Moreover, for most modern appliances there is not much technical difference in their core functions. For instance TV sets differ less in quality of display and sound and more in the way the user interacts with the device. This already shows why user interface design is crucial for any successful product. However, we want to extend the question of user interface design in two directions: the user interface should become more intelligent and adaptive and we want more suitable interfaces for ubiquitous computing scenarios.

The first aspect seems to be clear at first sight: intelligent user interfaces are just what we want and nobody will neglect the need for smart, clever, and intelligent technology. But it becomes more difficult if we strip away the buzzwords and dig a bit deeper into the question of what an intelligent user interface actually should do and how
Intelligent User Interfaces for Ubiquitous Computing

it would differ from an ordinary interface. Would the standard interface then be a stupid one?

The second aspect introduces a new level of complexity: an interface is by definition a clear boundary between two entities. A user interface resides between human and machine; other interfaces mediate, for instance, between networks and computers. In ubiquitous computing we have the problem that there might not be a clear boundary any more. Computers are no longer visible and, in the end, they can disappear from the user’s conscious perception. We will, therefore, face the challenge of building an interface for something that is rather shapeless.

In the following, we will go into more detail through these questions and will introduce some general approaches for designing user interfaces. We will see that we can learn from good interface design for other—classical—devices, and that we can apply many of those user interface design principles for ubiquitous computing as well. A central aspect will be the design process that helps to find the right sequence of steps in building a good user interface. After discussing these general aspects of user interface design, we will focus on the specific needs for ubiquitous computing scenarios and finally on how to build intelligent user interfaces—or to be less euphemistic: to avoid stupid interfaces.

BUILDING GOOD USER INTERFACES

The design of a good user interface is an art, which has been ignored for a long time in the information and communication technology (ICT) business. Many software developers just implemented whatever they found useful for themselves and assumed it would also be beneficial for the respective users. However, most users are not software developers and their way of interacting with technology is very different. Sometimes, the result is technology that is highly functional and useful for a small group of people, namely the developers of the system, and highly inefficient, frustrating or even unusable for most other people. Some of the highlights of this dilemma can be found in the communication with the user when something goes wrong: An error message notifying the user: “an error occurred, code 127” might be of some use for the developer and help in his efforts in debugging the system, but a user will hardly be able to understand what went wrong.

Today usability plays a much bigger role and many systems (including computer systems) are now designed with more care for easy and safe usage. On the one hand this is due to legal constraints demanding accessibility, but also due to the fact that many systems do not differ so much in their technical details and vendors have to diversify their products solely in terms of their “look and feel.” We now have a wealth of methods, tools, and guidelines, which all help to develop a good user interface (Dix et al., 1998; Mayhew, 1999). However, there is not one single recipe whose application guarantees 100% success. The essence of usability engineering is to work iteratively in order to achieve the goal of better usability. Let us briefly go through these steps and summarize some of the most important issues of usability engineering. For more detailed information, a number of textbooks and research articles can be consulted (Dix et al., 1998; Nielsen, 1993; Shneiderman, 1997).

The first question of usability engineering is the question of what goals we actually want to achieve. The typical list of usability goals contains at least the following five (ISO 9241, 2006):

- **Safety and Security:** Good design should not harm users or other people affected by the use of a product. It should also help to avoid errors made by humans in using the system.
- **Effectiveness:** A good user interface supports a user in solving a task effectively,
that is, all aspects of a task can be actually handled.

- **Efficiency and Functionality:** A well-designed and usable system should allow for quick and timely work.

- **Joy and Fun:** How enjoyable is it to work (or play) with the system? Is it fun or is it a pain to interact with it?

- **Ease of Learning and Memorizing:** How fast can new users interact with the system and will they remember what they learned?

This list, of course, is not exhaustive and not all aspects can be fulfilled to the same (high) degree, which is to say that there are classic trade-offs. Some aspects, therefore, might even be in conflict with others and it is important to identify such conflicts and to decide which aspect to optimize and to what extent. For instance, when designing an interactive game, joy and fun might be more important and effectiveness is less important. In contrast, a system for firemen has to be more efficient and can be less fun. Another typical trade-off exists between the need for efficient work and for training. One solution can be to provide two modes: an expert mode and a novice mode.

As a general rule, all efforts and goals of usability should be measurable in quantitative or qualitative ways. And since most usability criteria depend on the actual use of a system, there is a need to involve users in the design process. Of course, many human factors have been studied and psychologists have theories about how people can perceive information and how they can—in principle—react. But, in order to actually find out if the goals are met, one must try things out with actual users. And the more unknown your application terrain is, the more involvement of users is required, which is of particular importance for ubiquitous computing because there is not yet a large set of experience, studies, and guidelines at hand.

The design process that involves users has been named *human-centered design* (ISO 13407, 1999). Its principle is to develop an application iteratively with evaluations in every cycle. Human-centered design also is regarded as the best approach when design goals are hard to formalize in technical terms.

There have been multiple approaches for system design processes that involve the users. Their roots are in the participatory design idea from Scandinavia that involves workers in the definition and design of their working environment (Olson & Blake, 1981). In contrast to the classical waterfall model in systems engineering (Royce, 1970) that segments the design process into a linear order of clearly separable steps, these models iterate and involve users and evaluations in each cycle. A number of models have been proposed replacing the waterfall scheme by cycles or stars, that is, the design process is open and decisions can be revised depending on user feedback during development (Gould et al., 1991; Hartson & Hix, 1989; Hix & Hartson, 1993). Since many usability goals are not well defined and cannot be formally defined beforehand, these models allow for a continuous evolution of the usability of the system (Figure 1).

The design steps in these models are the following:

- **Definition of the Context:** As a first step, designers should consider the context of their envisioned product. This includes defining the way the system will be used, if it will be used for life-critical or fun purposes, and in home or in office environments, as well as the market situation. The latter is important because it tells something about expectations of users and about who is going to buy the product. In general, not only the target users are involved in deciding about the success (i.e., sales) of a product. Decisions can be made by managers of the users and they can
influence third parties such as the customers or clients of the users.

- **Description of the Users**: Based on the context definition, each group of directly or indirectly affected users must be carefully analyzed. Their physical and cognitive abilities and their cultural and social background may affect the way they interact with the system. Special needs may play a role. Accessibility has become important for IT systems and is demanded by many legal constraints, in particular in working environments.

- **Task Analysis**: Multiple techniques help to derive a rather formal description of the task users want to solve from informal interviews and observations. Most importantly, designers should find out how users actually solve their task currently (not how they think they do it) and how they make use of tools at hand, how they communicate and how their context influences the course of activities.

- **Requirements/Specification**: This step would have been the first step of the classical software development process. For user-centered design, it is now based on a better understanding of the users, their context and their tasks. Moreover, the specifications can be changed in each iteration, when a better understanding of the system could be gained through evaluations.
Intelligent User Interfaces for Ubiquitous Computing

- **Conceptual Design/Formal Design:** The requirements and specifications are translated into system components.
- **Prototyping:** Instead of “doing it right the first time” we iteratively build prototypes of the system. A prototype can be a very simple design sketch or an almost complete and working system depending on the stage of iterations in the design process.
- **Evaluations:** Evaluations are essential for assessing the progress of the design process and for deriving a better understanding of the tasks, the requirements and thus a better specification and implementation of the system (prototype).
- **Implementation, Tests, Maintenance:** Whenever the iterations have got to a stage where the prototype sufficiently fulfills the design goals, the final prototype (product) can be implemented. Of course tests and maintenance are as important as in classical system engineering. Moreover, they can help to further improve the system and in particular user feedback after deployment can be used for defining new development cycles.

These design steps are the building blocks for good user interface design. They are very generic and they are valid for basically every interactive system. Iterative development, however, is inevitable for the design of human-computer interaction in ubiquitous computing as we enter a domain of interactive systems, where we cannot derive system requirements from interaction goals without user involvement. This is mainly due to the fact that interaction in ubiquitous computing aims at intuitively usable pervasive IT systems that assist users in their real-world endeavors. Without taking these aspects into account, these systems are subject to failure. Many ubiquitous computing prototypes are completely technology-driven. Their developers focus on smart new gadgets, networks and infrastructure but they do not focus their design efforts on their users. Just for the sake of plausibility, some usage scenarios and users are added to the design. Such systems will not leave the research labs and they will fail to find their market.

**EVALUATIONS, ALTERNATIVES, AND PROTOTYPES**

The importance of iterations in designing intelligent user interfaces for ubiquitous computing has now been emphasized. However, how should that bootstrapping actually happen? Where to start, how to proceed and when to stop? If we need a full-fledged prototype in each iteration along with an evaluation with a high number of users, the costs for developing a better ubiquitous computing application will rapidly explode. Fortunately, things can be done more efficiently and some techniques help to manage the process.

**Where to Start?**

In order to get a first impression of how to build a system that actually meets the usability goals, for example, being an understandable and enjoyable assistant for some user task, we do not need any system but can make up a fake system without bothering with how to build a real one. A number of methods can be used (Dix et al., 1998; Shneiderman, 1997):

**Design Sketches**

Instead of actually building something that looks like a real system, users or usability experts can evaluate early design ideas. First sketches on paper or on a blackboard can already give an impression of the designer’s ideas, and feedback can already help to avoid basic mistakes. Moreover, the discussion can facilitate the mutual understanding of the users’ world and the prospective system.
Wizard of Oz Experiments

If, however, the users should already get an impression of how the interaction with the system might look, a system can also be simulated. A human operator remote controls all functions of the environment and the test users are told they are already interacting with the system. This technique has been proven to be extremely fruitful for systems that need data on the interaction in advance. For instance for systems that are language controlled, Wizard of Oz experiments can be used to collect utterances and language patterns that help to build speech recognizers and grammars for the real system.

Mock-Ups

A mock-up is a model of the system that already exposes the “look and feel” but does not yet include real functionality of the intended system. Early mock-ups for graphical interfaces can, for instance, consist of a PowerPoint walkthrough through a system or some Web sites emulating a system.

Prototypes

In contrast to the mock-up, the prototypes include actual functionalities of the target system. They may iteratively evolve to the final system.

Since many applications for ubiquitous computing scenarios are embedded into real-world tasks and many of them are also affected by or affect other objects in the users’ surroundings, Wizard of Oz experiments are a cheap and very beneficial first step in system design. They can help to understand how people would interact in an environment that is enhanced by ubiquitous computing technology. Moreover, the designers get data that help to design interaction with the system. For most cases of more natural interaction such as speech or gesture, such data is necessary anyway because the recognizers need training data.

How to Proceed?

Evaluation is the core of the above-mentioned “star-model.” Depending on the maturity of the design, the budget and the nature of the system, a great variety of evaluation techniques can be used. Evaluation methods can be classified according to the following dimensions:

- **Qualitative vs. Quantitative Methods:** In qualitative methods, feedback in form of comments, impressions and subjective ratings is collected in interviews or questionnaires. Quantitative methods measure parameters such as error rates, task completion times or movements of users in order to estimate the quality and efficiency of an interface.

- **Studies in the Field or in the Lab:** Field studies are conducted under realistic conditions where the systems are actually used, for example, in the office or home of the users. They usually need more effort than studies in the lab under simulated conditions, but they yield more realistic results.

- **User Tests or Expert Evaluations:** User studies involve real test users. They are more expensive than expert evaluations where a few experts judge the system by their experience on user behavior and the application domain. There are many well-known techniques for both—such as cognitive walkthrough, discount evaluation, thinking aloud—and in some cases even combinations may be useful.

- **System State (Sketch, Mock-Up, Prototype, …):** As discussed above, in early evaluations, a system does not necessarily have to be fully functional but can rather be a sketch or a mock-up.
It is beyond the scope of this chapter to go into all details of evaluation techniques. We will focus rather on the most important aspects for ubiquitous computing interfaces.

Even though evaluation is crucial for the design of good interfaces, it should be noted that evaluation techniques do not solve all problems and can even be misleading. One of the main problems of evaluations is that they are always limited snapshot observations restricted in the time of usage and the complexity of the context. This is important to note, in particular, for ubiquitous computing systems interfaces. Take, for instance, the famous ubiquitous computing scenario of an intelligent refrigerator that keeps track of its contents and can alert a user when she is running out of milk. In an evaluation setting one could look at users while they are at home or while they are in a supermarket and one could measure how they react to notifications of the system. A questionnaire reveals if the users like the system and would like to buy it when it comes on to the market. In a realistic setting, a study would observe some 10 to 20 users each over a time span of one to two hours of interaction. All would be in the same representative supermarket and in some model kitchen. The results would be definitely interesting and the study would even go beyond many other evaluations of similar systems. However, it is too limited for multiple reasons:

- **No Long-Term Observation:** Since users would interact with such a ubiquitous computing system not only for a few hours but rather over months or years, the short interaction of a novice user does not reveal much about the user’s future interaction.

- **Limited Frame of Context:** In order to gain comparable results, all users are set to the same or a similar context. In everyday situations, however, contexts may differ a great deal and users show a much higher degree of variation in their behavior.

- **Additional Tasks, People, and Devices:** As with most ubiquitous computing applications, users may not be focused on just one task but may be doing many other things concurrently. They could have other devices with them or be interacting with their colleagues or family members.

These limitations of evaluation results make some of them questionable. However, by using a good and careful evaluation design, some aspects can be counterbalanced. Moreover, keeping the limitations in mind may help to focus on the right questions and avoid overstating the results. And finally: even when evaluations only shed limited light on the usability of a system, this is much better than working in complete darkness without evaluations.

As a rule of thumb, it should be noted that evaluations for ubiquitous computing interfaces should be made as realistic as possible. Thus field studies would be better than lab conditions. Moreover, the designers should have a clear understanding of what they want to achieve with their system in order to know what they want to prove using evaluations.

### When to Stop?

The development cycle should not be an endless loop. In general, the (re-)design-prototype-evaluation cycle can go on forever leading to a continuous increase of usability. In practice, either the number of cycles is fixed beforehand or certain measures define when the loop has to be stopped and the final design is achieved. Typically these measures would quantify the usability goals listed at the beginning of this chapter. Such a goal could be “95% of the test users rate the system as very convenient” or “the task completion rate within 30 minutes is 98%.” In some cases the stop-criterion is not bound to usability but to other measures.
such as “we are out of budget” or “the deadline is next week.”

**SPECIFIC CHALLENGES OF USER INTERFACES FOR UBQUITOUS COMPUTING**

So far we have learned about how to design a good user interface. The principles we discussed are rather generic and they apply—of course—for designing intelligent user interfaces for ubiquitous computing, but they are also valid for other user interfaces such as Web interfaces or interfaces of desktop applications. The general process of human-centered design could even be applied to non-IT products such as cars, coffee machines and other objects of our daily life. It is a matter of fact that we have got to such a generic process. On the one hand, good usability is a property that is generic and the design process is fairly similar in multiple domains. On the other hand, ubiquitous computing is about integrating things into the objects of our normal life. Thus usability has, owing to the very nature of ubiquitous computing, got something to do with the usability of everyday things.

Since the early days of ubiquitous computing, usability has been in its focus. Mark Weiser’s idea of ubiquitous computing encompasses “invisible” interfaces that are so naturally usable that they literally become invisible for the user’s conscious perception (Weiser 1999a, b). This notion goes back to the German philosophers Georg Gadamer and Martin Heidegger, who call such interaction with things that we use without conscious awareness things that are “ready-to-hand” or at our “horizon.” In this phenomenologist view, the meaning of the things is actually derived from our interaction with them. Such a view on interactive artifacts has become popular in ubiquitous computing and is closely related to the notion of embodiment (Dourish, 2001). This is a fundamental shift from the classical positivist approach in computer science, that is, modeling the real world in simplistic formal computer programs, to an embodied approach that takes the user in the real world into account. This is relevant for ubiquitous computing for multiple reasons. On the one hand, ubiquitous computing applications are to be used in complex real-world settings and their meaning (for the user) will, in fact, only evolve in the course of action. Additionally, if things should become natural extensions of our physical abilities, they must be designed such that they do not need conscious interference from their users.

Given this notion of being “invisible” we can see that this does not necessarily mean “not there,” but rather present without conscious interaction. The most basic examples for such physical objects are our body parts. We do not have to think consciously about what we do with our arms, but we just do the things we want. When we leave our house, we do not have to remember: “let’s take the arm with us, we might need it today.” It is there and ready for immediate use. When we throw a ball, we just throw it and we do not think and plan how to make our hand grasp the ball and our arm swing around in order to accelerate the ball. In this sense, our arm is invisible but also very present. Thus if we speak of ubiquitous computing interfaces that are “invisible” or computers that are “disappearing,” we actually speak of things that are present and “ready-to-hand.” However, the artifacts we interact with might not be consciously realized as computers.

A good example of such a “ubiquitous” technology is present in our homes already: electrical light. Whenever we enter a room that is dark, we just find a switch with our hands next to the door and the light goes on. Without thinking we turn on the light. We do not think of cables that conduct electrons. We do not have to consider how the light bulb works or how they generate electricity at the power plant.

We have a very simplistic model of how the thing works and it is internalized to such a de-
Intelligent User Interfaces for Ubiquitous Computing

gree that we do not have to think about it when we enter a room. These “mental models” of how things work play an important role in designing good user interfaces as well as in designing other everyday things (Norman, 1998). Donald Norman emphasizes that a good design is about providing good mappings (Figure 2):

- The design model must be mapped to the system image.
- Users must be able to map their understanding (mental model) to the system.
- The system must allow the user to map its image to the user’s model.

The question is now: how can a system image support the appropriate user’s mental model? The answer—with our notion of embodiment in mind—must bring the meaning of things into the things themselves and thus a user can derive the meaning of something from the interaction with it or from its mere appearance that may signal some properties indicating how to use it. Such properties have been named affordances (Norman, 1998). The idea of affordances is to bring knowledge into the world instead of having it in mind. Many highly usable things that surround us just let us know by their physical appearance how we can use them. A chair for instance does not need a label or instructions on how to sit on it. We just see and know it is a chair and we know what to do with it.

Similarly, affordances have been defined as virtual affordances for computer interfaces and many metaphors on our computer screens signal functionalities, for example, mouse pointers and scrollbars. With the advent of ubiquitous computing, the term affordance becomes again more literally a property attached to the physical properties of things. Many ubiquitous computing objects include tactile interfaces or smart objects with physical and not just virtual properties.

There are a number of consequences arising from this perspective of embodied interaction for ubiquitous computing:

Figure 2. Mappings of design model, mental model and system images (Norman, 1998)
• **Support Mental Models:** Humans use mental models to understand and to predict how things react to their actions. The system image should support such mental models and make it easy to understand it.

• **Respect Cognitive Economy:** Humans re-use their mental models. If there are well-established mental models for similar things, then they can be a good basis for an easy understanding of a new artifact.

• **Make Things Visible and Transparent:** In order to understand the state of an object it should be obvious what is going on. For instance, a container can indicate if it is loaded or not.

• **Design for Errors:** Mappings between the user's model and the system sometimes fail. Most “human errors” are, in fact, mapping errors. Therefore, systems must assist users in finding a solution for their task even if something has gone wrong. There are a number of techniques for doing so, for example, allowing undo-actions or sanity checks on user inputs.

• **Internal and External Consistency:** Things within an application should work consistently. For instance, pushing a red button always means, “stop.” External consistency refers to expectations users may have from usage of other applications. If we add some ubiquitous computing technology to a cup and turn it into a smart cup, a user will still expect the cup to work as a cup.

With these guidelines and the general design process considerations we are already well prepared for building very good interfaces for ubiquitous computing applications. However, there are a number of further practical considerations and human factors that play a role for ubiquitous computing user interfaces. Some of these issues are related to the very nature of these applications being “ubiquitous” and some are more related to technical problems in mobile and ubiquitous scenarios. We will briefly highlight some of these aspects. Due to the broad spectrum of possible applications, we cannot go into details of all possible factors.

### Human Factors for Ubiquitous Computing

In classical human-computer interaction, we have a well-defined setting. In ubiquitous computing, we do not know where the users are, what tasks they are doing currently, which other persons may be around. This makes it very hard to account for some human factors that can greatly influence the interaction. Depending on time, concurrent tasks, and so forth, the user’s cognitive load, stress level, patience, and mood may vary extremely. Thus an interface can, in one situation, be well suited and in another situation the user is either bored or overloaded.

Another problem lies in spatial and temporal constraints. In many ubiquitous computing applications, location and time play a crucial role. Users need the right information at the right time and place. In a system that helps a user to navigate her vehicle through a city, the information “turn right” only makes sense at a very well defined point in space and time. An information delay is not acceptable. Even though space and time are the most prominent context factors in systems today, other context factors may also play a big role (cf., the chapter “Context Models and Context Awareness”). An interface can adapt to such context factors and take into account what is going on. In particular, the user might not have the focus of attention on the system but rather might be busy doing something else. But not only user-driven activities can distract the user; other people and events are not the exception but the normal case in many ubiquitous computing scenarios. This has a huge effect on the interface and dialog design. While in desktop applications, the designer can
assume that the user is looking at the screen and a system message is (in most cases) likely to be read by the user, in ubiquitous computing we must reckon with many signals from the system being ignored by the user.

The interfaces can try to take the users’ tasks into account and thus adapt their strategy to reach the user’s attention. For example, when the user is driving a car, the system might interact in a different way than when the user is in a business meeting. However, when the system is literally ubiquitous, the number of tasks and situations the user might be in can be endless and it is not feasible to model each and every situation. The system interface might then instead be adaptable to a few distinct modes of interaction.

**Who is in Charge?**

As we mention adaptation and adaptivity, we get to a point where the system behaves differently in different situations. This can be a perfect thing and can significantly increase the ease of use. A mobile phone, for instance, that automatically adapts to the environment and stays silent in a business meeting, but rings in other situations is rather practical. However, the trade-off is a reduced predictability and, as discussed above, many usability goals can be in conflict with each other. The developers and (hopefully) the users have to decide which goal is more important. It is important to know about these conflicts and to decide explicitly how to deal with them.

Typically, usability goals in ubiquitous computing that come into conflict with others are:

- **Controllability:** Is it the system or the user who controls the situation?
- **Support of Mental Models:** How can a user still understand a very complex system?
- **Predictability:** Humans want to be able to predict the outcome of their actions. If a system is too adaptive and autonomous, users get lost.
- **Transparency:** If the system adapts to all sort of context factors, its state becomes less transparent.
- **Learn Ability:** A system that learns and behaves differently in new situations can be hard to understand.

The designers have to decide to what degree they want to achieve which level in each of these dimensions and how other aspects such as autonomy or adaptivity may affect them. In general, there are no rules or guidelines that can give clear directions. While in many other IT domains, such as Web systems, some established standards may set the stage and good guidelines exist, the designer of a ubiquitous computing system will have to derive his own solution on the basis of the goals he wants to achieve. The only way to prove that the solution actually fits these goals, are, in turn, evaluations. Therefore, a user-centered design approach is the only way to design ubiquitous computing systems that incorporate good user interfaces.

**INTELLIGENT AND DUMB INTERFACES FOR UBQUITOUS COMPUTING**

In the last part of this chapter we want to focus on intelligent user interfaces. The term “intelligent user interface” has been debated for a while and it is not so clear what it means and if at all intelligent interfaces are something beneficial. But even the term intelligence is not well defined and has been used (or misused) in multiple ways. Before going into technical details we should, thus, first discuss what the term means and then see some techniques that are used for realizing them. We will finish with a discussion on how much intelligence a good interface actually needs.
What is an Intelligent User Interface?

So far we have presented a number of techniques for building good interfaces. We also saw how the view of embodied interaction can be used as a paradigm for ubiquitous computing. In general, a technical solution can be called “intelligent” for two reasons: (1) there is some built-in intelligent computation that solves some otherwise unsolvable problem; (2) using the system, a user can solve an otherwise unsolvable problem, even though the system itself does not actually do anything intelligent. Suppose that calculating the logarithm of a number is a hard problem for a human, then a calculator is a good example for case (1) and an abacus would be an example for (2). The calculator solves the problem for the human and the abacus empowers the user to solve the problem on her own.

The classical approach of artificial intelligence (AI) is a rationalist one. According to this approach, a system should model the knowledge that human experts have and thus emulate human intelligence. In this sense, the “intelligence” moves from the user to the system (Figure 3a, 3b). This approach is valid for many cases, for example, if expert knowledge is rare and non-experts should also be able to work with a system. As discussed above, the embodied interaction view would rather try to make the interaction more intelligent (Figure 3c). This fits too many new trends in AI where embodied intelligence is viewed as a property that emerges from the interaction of an intelligent agent with the environment. In this view, even simple and lightweight agents can perform intelligent behavior without full reflective and conscious knowledge of the world. With respect to this definition, all of the above-mentioned material already describes how to build an intelligent interface. Because the processes for designing human-centered systems are just the right techniques for designing intelligent interac-

Figure 3. Multiple views on intelligent user interfaces
tive systems, we already defined to a great extent how to build intelligent user interfaces.

Instead of leaving all the intelligence to the system, the user or the interaction, we can also try to get the best of all worlds and combine these techniques into a cooperative system, where both the system and the user cooperate with their knowledge on solving some tasks supported by intelligent interaction techniques (Figure 3d).

As discussed above, we can make the system more intelligent by enhancing the system, the interaction or the user. Intelligent user interface techniques exist for all three aspects. We will briefly list the key methods. Some details on them can be found in other chapters of this volume.

Techniques for Enhancing the System’s Intelligence

A huge number of AI techniques can be used to put more knowledge and reasoning into the system. Besides state-of-the-art IT methods such as databases, expert systems, heuristic search and planning, a number of more recent developments have attracted a good deal of interest by researchers and practitioners in the field:

- **World Knowledge and Ontologies**: Semantic technologies and formal models of world knowledge have had a great renaissance in the last couple of years. In context of the Semantic Web efforts, ontologies have been established as a standard method for capturing complex relations of objects and events in the world. Ontologies (cf., the chapter "Ontologies for Scalable Services-Based Ubiquitous Computing") can be successfully used in user interfaces in order to give the system a better understanding of the domain of an interaction. In particular for natural language interaction, ontologies provide resources for better understanding and reasoning.

- **User Adaptation**: User models and techniques of user adaptation allow for individualized interaction (cf., the chapter "Adapting to the User"). A number of methods allow for autonomous and user-driven customization of systems and they are widely used for intelligent user interfaces. In particular for ubiquitous computing, user adapted systems play a big role since these systems often have to support a great variety of use cases where a single standardized interface is not appropriate.

- **Context Adaptation**: Context plays a crucial role for ubiquitous computing (cf., the chapter "Context Models and Context Awareness"). As discussed already, context-dependent user interfaces can greatly enhance the usability of these systems. However, context can also be challenging because it can depend on a huge number of parameters and it is hard to formalize the meaning of contexts and to learn the relations between them autonomously.

- **Service Federation**: Integrating a variety of services and providing a single interface can be a significant step towards intelligent user interfaces. If users do not have to interact with all sorts of services separately, but can use a single portal, they can work much more efficiently with less cognitive load. However, service integration can be a hard problem, in particular when multiple services have to be integrated semantically that had not originally been designed to be integrated. An intelligent ubiquitous travel assistant could, for instance, integrate maps, events, travel, sights and weather information from different providers and offer the user an integrated trip plan.

Of course, many other techniques are available. In principle all advanced semantic and AI-based methods with relation to user interaction can help
to make systems smarter and better understand what a user might need and want using ubiquitous information sources.

**Techniques for More Intelligent Interaction**

As discussed above, the most important aspect of intelligent interaction is to provide good and working mappings of the user’s models of the world and the system’s model. These mappings depend highly on the semiotics, that is, the meaning and perception of the signs and signals established between user and the system. These can be both actively communicated codes in form of a language but also passive features of the artifact that signal the user affordances. Both aspects can be supported through intelligent methods that aim at more natural interaction such that the interaction takes place based on the premise of human communication rather than machine languages.

- **Multimodal Interaction:** Multimodal techniques make use of the human ability to combine multiple input and output modalities for a semantically rich, robust and efficient communication. In many ubiquitous computing systems, language, gestures, graphics, and text are combined to multimodal systems (cf., the chapters “Multimodal and Federated Interaction” and ”Multimodal Software Engineering”). Multimodality is on the one hand more natural, and, on the other hand, it also allows for more flexible adaptation in different usage situations.

- **Cross-media Adaptation:** Ubiquitous computing systems often use a number of different media, devices and channels for communicating with the user. A user can, in one situation, carry a PDA with a tiny display and, in another situation, interact with a wall-sized display in public or even use no display but just earphones. Intelligent interaction can support media transcoding that presents content on different media adapted to the situation.

- **Direct Interaction:** Humans are very good at multimodal communication, but for many tasks we are even better using direct interaction. It is, for instance, much easier to drive a car using a steering wheel than to tell the car to which degree it should steer to the left or to the right. For many activities, direct interaction is superior to other forms of human-computer interaction.

- **Embodied Conversational Agents:** Since humans are used to communicating with humans (and not with machines), anthropomorphic interfaces presenting animated characters can in some circumstances be very useful. In particular in entertainment systems, so-called avatars have become quite popular. However, there is also some debate about these interfaces and some people dislike this form of interaction.

Again, the list of techniques could be much longer. Here we just highlight some of the most important trends in the field. More ideas have been proposed and there will be more to come.

**Techniques for Amplifying the User’s Intelligence**

In principle, we can try to build better interface techniques, but we will not be able to change the user’s intelligence—leaving aside e-learning and tutorial systems that might explicitly have teaching or training purposes. But even if we do not affect the user’s intelligence, we can still do a lot about her chances to make use of it. In the scientific community there has been a controversy about the goal of intelligent user interfaces over the last couple of years on where to put how much intelligence (Figure 3). And even though it might be counterintuitive, an intelligent interface can sometimes be the one that leaves the intelligence on the part of the user rather than putting it into
Intelligent User Interfaces for Ubiquitous Computing

In the debate about these approaches, the slogan “intelligence amplification (IA) instead of artificial intelligence (AI)” was coined. The idea is that a really intelligent interface leaves intelligent decisions to the user and does not take away all intelligent work from the user by modeling it in the system. The question is: how can the system support users in acting intelligently? The answers have been given already when we discussed usability goals: A system that is easy to learn, where users have control and understand what is going on, and where mental models are applicable is more likely to let people act intelligently. In contrast, a system that only leaves minor steps to the user, that does not provide information about its states and how it got there and for which the users do not have appropriate mental models will in the long run bore its users and decrease their creativity and enthusiasm.

It should be noted that both type of systems can be packed with AI and be extremely smart or very dumb things. It is more the kind of interaction design that facilitates human intelligence or not.

HOW MUCH INTELLIGENCE?

Intelligent user interfaces for ubiquitous computing will be a necessary thing in the future. However, there are multiple competing views and philosophies. In general, three things could be intelligent: the user, the system or the way in which they interact. Most researchers focus on enhancing the system’s intelligence and the assumption is that this will lead to a better usability. This is often the case but not always. A different approach is to say that users are the most intelligent agents and their intelligence should be enhanced rather than replaced by artificial intelligence (IA instead of AI). In practice, however, we should do all together in order to make the interaction as easy and efficient as possible. But each decision should be made carefully keeping in mind that the overall goal of an intelligent user interface still should be defined by the usability goals. And like with all good things “less is sometimes more” and some simple things often are more enjoyable and easier to understand than highly complex and automated devices.

CONCLUSION

This chapter introduced aspects of designing user interfaces for ubiquitous computing in general and intelligent interfaces in particular. The basics for building intelligent interfaces are techniques for building good interfaces. Consequently, we first presented an up-to-date introduction to methods of human-centered design. A central aspect of this technique is to iteratively design systems with repeated evaluations and user feedback. This approach is especially important for ubiquitous computing systems, since they lack clear guidelines and decades of experience; and thus iterations are crucial in order to approach the desired design goals.

Obviously, many of these basic techniques are also valid for many other systems. However, ubiquitous computing introduces some more specific issues, such as a high variety of contexts, the lack of single dedicated interface devices and—by its very nature—ubiquitous interaction at any time and location. Therefore, ubiquitous computing interfaces must place even more emphasis on good mappings to mental models and provide good affordances. The view of embodied interaction gives us a good theoretical idea of the way we should think of and model interaction in such systems.

With these prerequisites, designers can build very good interfaces and can take many usability aspects into consideration. However, so far the “intelligence” of the interfaces has not been discussed. We did that in the last part of the chapter and presented a modern and sometimes contro-
versial view on intelligent user interfaces. There are different paradigms that may contradict each other. The main question can be formulated as: “AI or IA—artificial intelligence or intelligent amplification?” We discussed these design philosophies and presented some ideas on how to combine the best of both worlds. We also presented a number of current trends in the field that can be found in modern ubiquitous computing systems.

FUTURE RESEARCH DIRECTIONS

As the field of ubiquitous computing matures, its user interface techniques will also undergo an evolutionary process and some best practices will be established, making things much easier. We currently see this happening for Web applications where developers can choose from established interaction techniques that are well known to the users and guarantee efficient interaction.

However, ubiquitous computing might never reach that point since the ambition to support users in every situation at every time and place, which is the final goal of it, requires such rich interfaces that have to cope with the complexity of the users’ entire life. This might be good news for researchers in the field because they will stay busy searching for better and more intelligent interfaces.

The main challenges for future research will lie in the problem of extensibility and scalability of intelligent user interfaces. How could a system that has been designed for a user A in situation S be extended to support thousands of users in a hundred different situations?

Vive la Différence:
The Cross-Culture Differences Within Us

ABSTRACT

In the ITC cross-cultural literature, we often talk about the differences among peoples and how their respective culture and history may affect their adoption and preference usage patterns of ITC. However, do we really need to look that far to find such cross-cultural differences? Considering language is one of the major defining attributes of culture, this article takes a sociolinguistic approach to argue that there is also a cross-cultural aspect to ITC adoption within the same culture. Sociolinguists have claimed for years that, to a large extent, the communication between men and women, even within the supposedly same culture, has such characteristics because men and women communicate with different underlying social objectives and so their communication patterns are very different. This article examines this sociolinguistic perspective in the context of online courses. A key finding is that although the stage is set to smother cultural and gender differences if participants wish to do so through ITC, gender based cultural patterns still emerge. These differences were actually strong enough to allow us to significantly identify the gender of the student, despite the gender neutral context of the course discussions. Implications for ITC, in general, in view of this Vive la Différence, are discussed.

INTRODUCTION

One of the major manifestations of culture is language and the way it affects communications: who we prefer to talk to and the sum of the underlying objectives of the communication.
Communication is not a mere exchange of words. It is a social process and, as such, it is imbued with a social meaning of inclusion, exclusion, and social hierarchy. These cultural aspects are a prime aspect of cross-cultural research, including in the context of ICT information technology and communications, adoption, and usage patterns. But one need not look that far to find cross-cultural differences. They are here among us all of the time—that, at least, is the basic premise of sociolinguistics.

Sociolinguistics deals, among other things, with the way culture affects and determines communication. Most important in the context of this study is that culture is not only a manifestation of language and national heritage. Culture is also a matter of gender. Men and women communicate differently, and do so with different underlying social objectives. This is part of our evolutionary past (Brizendine, 2006), which also affects online collaboration (Kock & Hantula, 2005). Gender is so much a part of communication that in many languages, there are distinct rules in the language about how men and women should conjure the sentences they speak and their expected speech patterns. It is much more than superimposed linguistic gender segregation though. It is, at least in the view of sociolinguists, a matter of a cultural difference between men and women.

In general terms, men, according to sociolinguistics, communicate more with the objective of creating and preserving their social status, while women communicate more with the objective of creating rapport and social inclusion. Not surprisingly, the result of this is that communication across genders is often an exercise in cultural miscommunication (Brizendine, 2006; Tannen, 1994; Tannen, 1995). Indeed, when men communicate with each other, it is often on a basis of exchanging information, or as Tannen calls it “report talk,” while women do so to exchange emotions, or as Tannen calls it “rapport talk” (Tannen, 1994). The consequence of this is often communication that are gender segregated (Hannah & Murachver, 1999; Yates, 2001). Looking at this distinction in the context of virtual communities and supporting it, Gefen and Ridings (2005) commented that when men joined virtual communities composed of mostly male members, they did so with the declared objective of sharing information, while when they joined mixed gender virtual communities, it was more for emotional support. In contrast, women who joined mixed virtual communities did so for information exchange, but when they looked for emotional support, they too joined mostly female ones. Indeed, even in what should be gender and emotion neutral settings, women perceive more social presence in e-mail (Gefen & Straub, 1997) and e-commerce websites (Gefen, 2003).

The objective of this study is to examine whether the expected gender-related cultural differences in oral communication, predicted by sociolinguists regarding oral communications, hold true also in the explicitly created gender-neutral ITC environment of online courses, where the nature of the controlled course conversations make social dominance and rapport rather irrelevant. If these gender communication patterns hold true also in this scenario, then how much more so that such cross-cultural differences should hold true in other ITC induced environments. This is a crucial question because if true, then cross-cultural research in ITC should look not only across the border, but also within.

The data support the basic Vive la Différence proposition of the study even in the stoic context of online course discussions. Male students did prefer to respond to other male students and female ones to females, and men did show a more domineering attitude in their postings. Cross-cultural studies in ITC should consider gender as another dimension of culture.

Theory

The tendency of society toward being masculine or feminine is a central aspect of the cultural di-
mensions of peoples (Hofstede, 1980; Hofstede, Neuijen, Ohayv, & Sanders, 1990). However, is gender also an aspect within a culture? According to sociolinguistics, it is (Yates, 2001). In fact, the popular press sometimes even takes it a step further claiming, perhaps jokingly, that this gender difference might even take on celestial proportions (Gray, 1992). If this is so, then gender-related social behavior should come through even in the stoically enforced context of online courses, thus demonstrating the need to include gender as an aspect of culture even within a given national and linguistic culture, as also biology implies (Brizendine, 2006).

One of the major manifestations of culture is in language and communication. Communication carries with it not only information, but often also a very strong social message—a social message which is interpreted and sometimes also misinterpreted, within the cultural context of the speaker and listeners. Even the very way words are pronounced carries a cultural burden with it, making people identify or not with the speaker, based on the national or local culture implied in the accent (Deaux, 1984; Deschamps, 1982). Speaking in the accepted dialect can in fact make all the difference between whether people agree or disagree with a speaker, based almost purely on the manifestation of the presumed culture of the speaker (Abrams & Hogg, 1987). This additionally crucial social level of communication is a function not only of national and local culture but, according to sociolinguists (Tannen, 1994; Yates, 2001) and hormones (Brizendine, 2006), also of gender. Men and women may communicate in what, on a superficial level, may seem as the same language, but the social message behind the words and this message is interpreted quite differently by the average man and the average woman. This is because men and women, on average, imbue and insert different social nuances into the message and do so even in languages, such as English, where there are no linguistically gender enforced styles. These gender related nuances can be so manifest as to result in the equivalent of cross-culture miscommunication (Tannen, 1994).

Picking up on this idea, Gefen and Straub (1997) showed that women, across cultures, sense more social presence in work-related e-mails and that increased sense of social presence affect their perceptions of the usefulness and ease of use of the ITC and ultimately its usage. Expanding on this theme, Venkatesh and Morris (2000) showed that women are more affected by social norms in their adoption of ITC.

A salient example of this underlying social message in communication brought by Tannen (1994) is asking for directions. On the face of it, asking for direction is no more than just asking a stranger a question in what may seem a neutral environment. It could be regarded as information exchange and no more. However, this is not the case. Asking for directions also carries a social meaning. That is why men will often drive around for hours rather than ask for directions, while women will think nothing of it and do so without hesitation when they think they are lost. The reason for this, sociolinguists say, is that in asking for directions, men are subconsciously implying at least to themselves (certainly women are often surprised to hear this) that the other guy knows more than they do. The person being asked for directions certainly may know more, after all that is why they are being asked for directions, but it is admitting this that bothers men and makes them drive around for hours. Admitting someone else knows more than I do, to men, carries with it a social inferiority message of the other guy is better than I am in something. Men, unless aware of the stupidity of this underlying message, are loath to admit this supposedly social inferior standing. The same communication with women, however, carries no such subconscious implication. If anything, to women this creates a chance to engage with others, rapport, which they more willingly do than men (Tannen, 1994).²

This example, adapted from Tannen (1994), highlights the cultural social difference in com-
munication between men and women. Beyond the meaning conveyed in the words themselves, men tend to communicate with the objective of exchanging information and in doing so establish their social pecking order. This is why men tend to try to control the conversation by talking more than others and employing various methods to silence or demote those who disagree with them. Generally, men, unless aware of the need to do otherwise, also tend to center the conversation more on themselves (Anderson & Leaper, 1998; Coates, 1986). Again, this is a manifestation of using conversation as a way of establishing the social pecking order. Tannen (1994) classes this communicational behavior report talk. In contrast, women tend more than men do to be inclusive in their conversational styles. This is because women are more centered on creating rapport, rather than self promotion (Holmes, 1992; Johnson, 1993; Kilbourne & Weeks, 1997; Lakoff, 1975; Mulac, Erlandson, Farrar, & Hallett, 1998; Tannen, 1994; Tannen, 1995). Tannen (1994) classes this communicational behavior rapport talk.

Supporting this report versus rapport distinction, previous research has claimed a greater tendency by men, at least in oral conversations, to try to dominate (Herring, 1993; Holmes, 1992) and control the discussion (Edelsky, 1993), to be more competitive (Kilbourne & Weeks, 1997) and more assertive by interrupting others (Anderson & Leaper, 1998; West & Zimmerman, 1983; Zimmerman & West, 1975), and generally be more forceful (Weatherall, 1998) and less complementary (Coates, 1986; Yates, 2001). These gender-based differences in the cultural message imbued into the conversation are evident across cultures (Costa, Terracciano, & McCrae, 2001; Hofstede, 1980) and seem to also carry over to listserves (Herring, 1996b; Stewart, Shields, & Sen, 2001) and to e-mail in general (Boneva, Kraut, & Frohlich, 2001; Parks & Floyd, 1995). A direct consequence of these gender-based differences and preferences is that men and women tend to congregate into same-gender conversations (Tannen, 1994). Men talk more to other men than to women; women talk more to other women than to men. Interestingly, this happens also online in virtual communities where people have a much broader choice of communities to join and where they can hide their gender and identities or even masquerade as anything they wish to be known as (Gefen & Ridings, 2005).

The ITC in charge of discussions in online courses provides a unique opportunity to examine these cross-gender differences because it is possible to create what are arguably gender-neutral settings. Also, if, in these induced gender-neutral ITC settings, cross-gender differences exist, then these differences are probably not a matter of setting alone, but are a matter of the ingrained nature or nurture considerations extensively discussed in the cross-culture literature (Hofstede, 1980; Hofstede, et al., 1990) and should thus be controlled in the context of cross-cultural ITC research.

Whether cross-gender differences, such as gender congregation, apply also in online courses is actually an open question because parallels cannot be drawn with the closest equivalent, virtual communities, where these do apply (Gefen & Ridings, 2005). Virtual communities are not regulated by a moderator and people are free to come and go as they wish, without being graded on it. Moreover, in typical online courses, students do not interact with other students except in controlled threaded discussion settings where the teacher posts a question and the class then discusses it. This discussion is usually graded. The discussion is asynchronous, so it is impossible to dominate air time or control the discussion and who talks when as in oral discussions. Inserting socially loaded comments and body language cues is also impossible. It is as close as possible to a gender neutral setting. Moreover, in contrast to virtual communities where people join for many reasons, including the stereotypical feminine rapport and the stereotypical masculine information exchange, the reason people join online class discussions is
usually a matter of being forced to by the grading policy—a matter antitypical of both masculine and feminine stereotypical and sociolinguistic behavior. While gender-based communication patterns do occur in the regular classroom (Tannen, 1991), and some evidence does exist that men use the online environment more to access information and women more to converse (Herking, 1996a; Yates, 2001), how these apply to a supposedly gender-neutral setting, such as an online class, remains an open question. Should these gender-related communication behaviors carry over to these neutral settings, then it could be argued that they are another aspects of culture-induced behaviors.

HYPOTHESES

Accordingly, applying the underlying proposition that gender differences are not induced by the settings alone but rather are a matter of culture, then even in the relatively gender neutral ITC setting of online course discussions, some typical gender communication patterns should be evident. While the basic cross-gender difference of rapport versus report might be somewhat mute in these settings, other aspects, such as gender congregation, should still be evident. The rapport versus report distinction should be rather mute because online class discussions are deliberately not conductive for the feminine rapport type communication and are explicitly managed to discourage the male dominating status building communication styles. Moreover, the technical settings in these ITC, such as the asynchronous nature of online course discussions, do not permit the students to control who speaks, when, what they say, and for how long—again making aspects of stereotypical male alleged domination conversation styles immaterial (Tannen, 1995; West & Zimmerman, 1983).

And yet, other aspects of typical gender behavior should come through if the proposition holds. Primary among these is gender congregation during discussions. Men’s preference to respond to other men more than to women and vice versa could still come through even in these settings because there is nothing in the technical aspects of the ITC or in the way these conversations can typically be managed to exclude this possibility. There are no technical ITC aspects or plausible conduct rules that can make a student address comments, or not be able to address comments, by any other specific given student. Practically speaking, this should translate to a gender preference with men preferring to refer to other men and women to other women.

- **H1**: The number of references to postings by students of the same gender is higher than the number of references to posting of students from the opposite gender.

Although we do not expect students to resort strongly to their alleged stereotypical report versus rapport conversational styles in these ITC in general, some weaker aspects of these styles should still come through in conversational aspects, which are not forced by the ITC or typical course conduct regulations. One aspect in which these aspects should come through is in the extent of support given to positions presented by other students. Conventional political correctness in online courses may not be overly encouraging of blunt disrespect and challenging others, but there is a nuance students can play in whether they choose to be explicitly supportive of the postings of others or not. Extrapolating from the literature about typical gender conversational styles, and hence assuming these styles are culture induced and should therefore carry over also to gender neutral ITC settings: men should be less supportive of the positions of other students. Generally, men are supposed to be more assertive, competitive, and dominating (Anderson & Leaper, 1998; Edelsky, 1993; Herring, 1993; Holmes, 1992; Kilbourne & Weeks, 1997; Weatherall, 1998; West & Zimmer-
man, 1983; Zimmerman & West, 1975), and less complementary (Coates, 1986; Yates, 2001) than women. All these mount up to ways of shoring up one’s own social standing, a motive strong among men but rather absent among women (Tannen, 1994). This behavior should especially come through strongly when male students refer to other male students because, extrapolating from sociolinguistics, they should be competing with each other. When male students refer to postings by female students the competition should be one way, only by the male student.

• **H2:** Men referring to postings by other men will be less supportive than women are.

With female students, on the other hand, inclusion should be a more dominant feature of the conversation, as it is in other settings (Tannen, 1994). A central strategy in creating inclusion is showing support and encouragement toward the other person. If this carries over to gender neutral ITC, then it could be expected that women will be more supportive of other women because of their tendency to be inclusive among other women.

• **H3:** Women referring to postings by other women will be more supportive than men are.

**Method and Data**

The data for this study were extracted from online course discussions in 14 online courses. There was an average of eight online course discussions in each online course. Every one of these online discussions was analyzed. For each student in each online course discussion, we recorded how many postings there were, how many related to a previous posting by other students in this discussion, how many of these references to previous posting were to postings by male students, how many of these were supportive, how many were to postings by female students and how many of these were supportive. A posting was counted as supportive if the student posting it explicitly stated agreement or support with a previous posting in this discussion. We then removed those records that related to students who did not refer to postings by other students in this specific online discussion. These records were removed from the analyses because evidently these students were not taking an active part in the specific conversation but only posting to fulfill the course requirements. This left us with 599 records, dealing with 83 students who each participated on average in 7.2 online course discussions. Among these 599 records, 381 were of men who took an active part in the online course conversation and referred to postings by other students in the specific conversation and 218 were by women. The data were classified by two raters. On the overlapping sample of 100 posting, which was classified by both raters, there was absolute agreement.

Supporting the stereotype of men trying to control the conversation (Edelsky, 1993), men did significantly (T=2.751, p=.006) post more (mean = 3.00, standard deviation= 2.096) than women (mean = 2.55, standard deviation= 1.542) and did significantly (T=3.959, p<.001) post longer messages (mean number of words = 346.30, standard deviation= 205.903) than women (mean = 286.99, standard deviation= 154.767).

**Data Analysis**

To examine hypotheses H1 through H3, we compared the means of men and women with a set of T tests. Men in a given online course discussion did not significantly (T=1.067, p=.286) refer more to others (mean=.69, standard deviation=1.255) than women did (mean=.58, standard deviation=1.032). However, men did significantly (T=2.525, p=.012) refer more to other men (mean=.45, standard deviation=.913) than women did (mean=.28, standard deviation=.605), although women did not significantly (T=.692, p=.489) refer more to other women (mean=.28, standard deviation=.620) than
men did (mean=.24, standard deviation=.602). These results give partial support to H1. Gender congregation does occur, but primarily among men.

Surprisingly however, men in a given online course discussion were significantly (T=2.082, p=.038) more supportive of other men (mean=.14, standard deviation=.445) than women were (mean=.07, standard deviation=.254). This contradicts the expected direction in H2. Also, men did not significantly (T=1.544, p=.123) refer in a supportive manner to other students in general (mean=.20, standard deviation=.540) more than women did (mean=.13, standard deviation=.414). In fact, women were not significantly (T=.148, p=.882) more supportive of even only other women (mean=.06, standard deviation=.264) than men were (mean=.06, standard deviation=.289). This does not support H3. The hypothesized differences in the supportive behavior of students in online course discussions were not supported. Apparently, the courses were sufficiently gender neutral to make this otherwise typical behavior mostly insignificant.

We then examined if the gender of the student could be identified in a linear regression by the characteristics of postings the student made in the online course discussion. If this is so, it would lend more support to the claim that gender and communication style, also in these gender neutral settings, are related. In the linear regression, the gender of the student making the posting was the dependent variable. The length of the posting in words, whether this posting was supportive, and whether it was addressed to a student of the same or opposite gender, were the independent variables. In all, the explained variance was low at .02. The only significant determinant of student gender was the length in words of the postings the student made in this online discussion (β=.149, p<.001). However, when only the more active students were examined, the results became more convincing. When the analysis was limited to only those students who posted at least 3 postings in the conversation, there were 268 such records, the degree of explained variance became .15. The significant determinants were the length in words (β=.175, p=.004), the number of postings referring to previous postings by women (β=-.173, p=.006), and the number of postings referring to previous postings by men (β=.123, p=.048). In other words, among more students who participated more actively in the online course conversation, students who referred more to previous postings by men and less to previous postings by women were mostly significantly more likely to be men.

Discussion

Language is a central pillar of culture and subcultures within the dominant culture. It is a central pillar even within what may otherwise be considered the same national or historical culture. It is enough to read the famous words of George Bernard Shaw in *Pygmalion*, “An Englishman has only to open his mouth, in order to have another Englishman despise him,” to realize how even dialects create a cross-cultural event. This is a conclusion supported by research (Abrams & Hogg, 1987). Along those lines of brilliant eloquence, this study presents another aspect of cross-cultural communication, the *Vive la Différence*, according to which gender too is a central cultural difference.

As sociolinguistics claim, men and women apply language, and communication in general, to such a differing social objectives that cross-gender communications can be sometimes best seen as nothing less than cross-cultural miscommunications among people with differing cultural backgrounds (Tannen, 1994). Examining a derivative of this sociolinguistic viewpoint, this study hypothesized that even in the gender neutral ITC environment of online course discussions with their asynchronous and topic focused orientation, cross-gender communication would show some aspects of a cross-cultural communication. These hypotheses were partially supported, but,
the pattern in the data was strong enough to significantly allow the correct identification of the gender of the student participating in the online course discussion.

That gender should come through significantly in this otherwise deliberately gender and culture independent ITC setting lends support to the claim that there is a need to include gender as another significant aspect of culture, even within the same national culture environment. One should pay special heed to this conclusion because, to some extent, there is a voluntary gender segregation occurring in these discussions. This is something quite amazing when one stops to think about it, because it is occurring despite the gender neutral environment, which supports neither the typical male report type communication nor the typical female rapport type communication.

Before discussing these implications in detail, a word should be said about the limitations of the study. The data in this study came from a convenience sample. This is okay because the objective of the study was to show support to the need to include gender as an aspect of culture. Generalization was not the objective. Generalization requires replication in other and more varied ITC settings, including, but not limited to, other online courses and ITC supported business interactions. To this, one should add that no two courses are the same. Having said this though, the data of this exploratory study do warrant further investigation. Some gender behavior patterns did come through and did allow a significant identification of student gender.

So what do the data tell us? Gender, as sociolinguists and eminent playwrights tell us, is also about culture. Cross-gender communications have cross-culture aspects to them. While it is still unknown whether these gender differences are ingrained or learned, they did come through even when the settings, such as the one of this study, should have made them mute. When considering how culture affects ITC adoption and usage patterns, and it does (Gefen & Straub, 1997; Rose & Straub, 1998; Straub, 1994), this aspect should be considered too. Although more research is needed, sociolinguistics is one possible theory base to support this inclusion. On a practical level, these conclusions imply some interesting tentative implications. If men and women communicate with different objectives and so understand messages differently, then awareness and practical steps to address these misunderstandings should be taken both in online conversations and in other instances of ITC.

Explaining the gender effect, by focusing on the culture of language, may also explain some previous research results. People are generally more accepting of answers given by a computer generated cartoon when the topic of the answer provided through this cartoon corresponds to its gender stereotypes: male cartoons about sports and female cartoons about fashion (Lee, 2003). If gender preference is so much part of our everyday behavior that people show a tendency to congregate by gender even in gender neutral discussions, then this carryover of oral discussion gender behavior might explain why this happens. The results also provide additional explanations why women sense more social presence in business e-mail than men do (Gefen & Straub, 1997). Again the carryover of the respective gender aspects of communication to an ITC environment, which is supposed to be gender neutral, might explain this.

Looking at the results in a broader manner, the results of the study, if generalized, tentatively suggest that just as culture should be a major aspect of ITC research, so should gender. ITC research, and especially human computer interaction research, is about many things, but one of its central topics of research is about how people use ITC to communicate with other people, be it through e-mail, e-commerce, or virtual communities. A key aspect in such communication, determining its meaning and success, is the use of language. Since language cannot be understood properly when analyzed devoid of its social underpinnings, these socially overlaid meanings should
be part of any research on how ITC is used and how it supports communication among people. Ignoring these central social components, how they contribute to the meaning and value of ITC based communication, and especially how misunderstandings may arise when communicating across genders as they are across cultures, is tantamount to ignoring a central tenet of the ITC interaction process itself.

Including gender into human computer interaction research, however, requires a solid theoretical base. This lack of a strong theory base may explain why gender has not come up often before as a central aspect of this research. It is not enough to say there is a significant T statistic. There must also be a theory base, which can explain why there is this significance and so tie it into other research and a broader understanding. There might be undeniable physiological reasons which affect gender differences in ITC behavior, as some research suggests (Cutmore, Hine, Maberly, Langford, & Hawgood, 2000), but there are also cultural reasons, such as those presented in this study. These cultural psychological reasons are central in determining behavior. Sociolinguistics could be one theory base on which such understanding could be achieved. Looking at things through this theory could make our understanding richer and broader, and, more importantly, avoid a joint misclassification of men and women into one group, which ignores the different social meanings men and women attach to communication.

Unfortunately, while culture is recognized as a key issue in ITC adoption and usage patterns, most such research has chosen to ignore this aspect of gender. This may be because of political correctness constraints, but it is taking the unnecessary risk of being scientifically wrong. Smothering this cultural aspect not only hides significant relationships and blotches construct validity, but it also skews our understanding of the world. We know men and women have different managerial styles (Beasley, 2005; Boon, 2003) and handle domination and conflicts differently (Chan, Monroe, Ng, & Tan, 2006). We all know men and women think and communicate differently, whether saying so is or is not politically correct. It is about time ITC research also paid homage to gender. Ignoring gender may be a mistake, if gender differences come through even in the controlled settings of this study, how much more so that they should be evident in less controlled settings.

ENDNOTES

1 These differences are also related to genetics and hormones (Brizendine, 2006).

2 By the way, this is no joke. I tried it out on many of my students and almost unanimously all the men admitted to having been in this situation and driven around for hours, while almost all the women said they would ask for direction immediately.

Chapter 8.9
Growing Up Wireless:
Being a Parent and Being a Child in the Age of Mobile Communication

Letizia Caronia
University of Bologna, Italy

ABSTRACT

This chapter illustrates the role of the mobile phone in the rise of new cultural models of parenting. According to a phenomenological theoretical approach to culture and everyday life, the author argues that the relationship between technologies, culture, and society should be conceived as a mutual construction. As cultural artefacts, mobile communication technologies both are domesticated by people into their cultural ways of living and create new ones. How are mobile phones domesticated by already existing cultural models of parenting? How does the introduction of the mobile phone affect family life and inter-generational relationships? How does mobile contact contribute in the construction of new cultural models of “being a parent” and “being a child”? Analysing new social phenomena such as “hyper-parenting” and the “dialogic use” of mobile phones, the author argues upon the role of mobile communication technologies in articulating the paradoxical nature of the contemporary cultural model of family education.

BEYOND THE USER-TECHNOLOGY DICHOTOMY: A PHENOMENOLOGICAL APPROACH TO EVERYDAY LIFE

“Some day we will build up a world telephone system making necessary to all peoples the use a common language, or common understanding of languages, which will join all the people of the earth into one brotherhood” (Dilts, 1941, p. 11, cited in de Sola Pool, 1977, p. 129)

Like an underground current, the same social discourse reappears each time a new technology enters the social world: the technology purportedly produces new unexpected behaviours and causes major changes in the way people live. Whether it is for the worse or for the better is not
Growing Up Wireless

important. What matters more is the underlying unidirectional causal-deterministic model that putatively accounts for the influence of technologies in people’s lives.

The deterministic approach to social phenomena and particularly to technological evolution has had a long and strong tradition that spans the 20th Century. Even if today no one would say “science discovers, industry applies, man conforms,” the deterministic model persists in both scientific and commonsense approaches. At least within commonsense reasoning and theories, information and communication technologies are supposed to determine not only people’s behaviours but also their attitudes, relationships, and even identities. Empowered technologies are perceived as overwhelming unskilled people as if they dominate their lives. Such a view of the role of technologies in people’s everyday life has the hallmarks of all commonsense theories. It is self-evident, taken for granted, and ready made. It shares commonsense’s advantages: it provides easy to grasp explanations for a number of social events and allows people to cope with more dramatic circumstances. Like most practical reasoning, the one concerning information and communication technologies is a shortcut. It reduces the complexity of the phenomenon making it simpler and apparently more manageable.

Often echoed by media discourse and sometimes reinforced by references to simplified expert discourse, commonsense reasoning and layman theories constitute a shared cultural system through which we make sense of technologies in our daily life.

Although the deterministic approach to social phenomena has nurtured commonsense theories more than any other approach, it is not the only one. A major philosophical approach has been supporting concurrent views on social phenomena and providing a different paradigm for understanding technologies in everyday life: the phenomenological approach to social life.

Since Edmund Husserl’s and Alfred Schutz’s philosophical investigations, scholars in both Europe and the United States have emphasized the role of individuals in constructing culture, social organization, and their relation to the material features of everyday life contexts. Against any form of social and cultural determinism, ethnomethodology has demonstrated that people create their social and cultural world through their everyday actions and interactions (Garfinkel, 1967). Everyday practices of ordinary people are the effective tools that make supposedly passive users behave as active subjects. Defying and subverting any determinism of both dominant culture and the systems of production, social actors invent and create, moment by moment, the meaning and functions of things that circulate in their social space (De Certeau, 1984). Far from obeying implicit logics inscribed in goods, consumers develop their own tactics and follow paths in often unforeseen and unpredictable ways. The uses and gratification approach to information and communication technologies (Katz, Blumer, & Gurevitch, 1974) is consistent with this antideterministic paradigm. Proponents of this stream have shed light on the role of users’ needs and goals in the adoption or rejection of a technology and its intended uses.

These approaches to social life and phenomena share a crucial theoretical assertion: the strength of human agency (Giddens, 1979, 1984) and subject intentionality in making the meaningful dimensions of the world people inhabit. Accordingly, everyday life is conceived as a never-ending cultural work through which social actors produce the meaning, structures, and social organization of the world they live in, as well as their own identities and those of the people they interact with. Everyday language and interaction are the primary tools of this culture construction. However, social structures as well as the material features of everyday life contexts are more than an inert background for culture construction.
Disregarding any radical subjectivistic drift, the phenomenological approach to culture and everyday life does not underestimate the constraints of the world of things nor does it claim for an omnipotent actor. Rather it conceives the process of culture creation as radically embedded in the cultural frames and the material resources available in the world people inhabit, which in turn makes this creation possible.

As renewed attention to the material aspects of social life indicates (Appadurai, 1986; De Certeau, 1984; Gras, Jorges, & Scardigli, 1992; Latour, 1992; Semprini, 1999), the artifactual dimension of daily life is a crucial component that affects and is affected by everyday interactions, social organizations, and cultural frames of reference. Things, whether technological or not, participate in such a process of creating cultural models of living: as cultural artefacts, they are domesticated by users into pre-existing patterns of meaning and create new social scenarios and identities.

As people establish meaningful interactions with objects and artefacts, they make them exist in their social world, making sense of and domesticating them according to their frames of relevance and “moral economy” (Silverstone, Hirsch, & Morley, 1992). Literature on the social uses of media and the cultural ways of coping with a technological environment has shown how these uses, like other social practices, may be considered semiotic actions in the strict sense of the term; that is, ways of communicating and tools for constructing meanings and social realities.

The available technologies, the material features of the objects which support them and the daily routines they create or are integrated in, are all tools for the everyday production of culture and identities. Through media-related practices, individuals construct themselves in specific ways and produce the forms of their social participation (Caronia, 2002). Simply put, through our uses of media, through the way we act out these uses, we define (at least locally) the communities to which we belong and our identities.

We define but we are also defined. If face-to-face interaction and talk may still be considered the basic forms of socialization (Boden & Molotoch, 1994), the ways in which media uses become topics of everyday conversation are powerful tools to construct their meanings and the identities of those who use them. People’s ways of using media, whatever real or imagined, enter everyday conversations as parts of the narratives through which people constantly construct who they are and who the people they talk about are (Ochs & Capps, 1996).

If human beings construct the meaning of things and make sense of them according to their goals, the reverse is also true. Things are not neutral nor are they “pure” material objects waiting to be defined. Even though they do not determine people’s life, things delineate the conditions of possibility for new behaviours and ways of life. Their features and engineering anticipate paths of action and project new possible identities for the users. By moving the image from the permanence of the analogical universe to the ephemeral digital world, the digital camera demands and proposes a radical nonrealistic ontology for photography. Even the social perception of the photographer’s work and identity has changed. The digital camera has definitively legitimized photography as a manipulation of reality through iconic representation. Whereas the assumption of the nonreferential nature of documentary images has always been taken for granted by epistemologists and philosophers, the digital camera has integrated this representation of photography in the layman’s culture. Allowing people to make, remake and unmake iconic representations of reality, the digital camera has produced a new everyday culture of photography.

Overcoming the “subject-object” duality, we need to rethink the relationship between humans and technologies in terms of reflexivity, that is, a mutual construction of meaning and reciprocal sense making.
This need is even more pronounced for information and communication technologies. Their progressive introduction into people’s everyday life, the multiplication of possible new courses of action, and ways of communicating and getting information, expand the range of tools through which individuals construct culture and identities.

Faced with this changing and growing technological environment (Livingstone & Bovill, 2001), it then becomes relevant to investigate how the work of everyday culture construction may be affected by the new forms of technologically mediated actions, and vice versa.

The process of mutual construction among technologies, culture, and society may be analyzed at the macro level of patterns of diffusion and uses, as well as at the micro level of ordinary everyday interactions. Drawing upon data from qualitative and ethnographic research on mobile communication devices in ordinary life, this author of this chapter discusses the role of these technologies in the construction of family relationships and inner culture. Particularly, the chapter focuses on the following aspects: the creation of a cultural model of “parenting” (hyper-parenting), the dialogic use of mobile phones in connecting the different socio-cultural universes to which children belong (i.e., family and peer), and the role of mobile communication technologies in articulating the paradoxical nature of the contemporary cultural model of family education.

CONTEMPORARY STUDIES ON MOBILE PHONE DIFFUSION AND APPROPRIATION

In recent years, considerable research has examined the adoption and diffusion of mobile phone technology. It seems quite evident that, even though important differences exist across different countries (Kats & Aakhus, 2002), adolescents are a major well-established target for the adoption of this technology (Colombo, & Scifo, 2005; Kasesniemi & Rautianen, 2002; Ling, 1999; Lobet-Maris, 2003).

It is not surprising, then, that research has focused on young people’s uses of the mobile phone, especially in European countries where the adoption rate among adolescents and young people had been quite high. Investigating adolescents’ uses of mobile phone, Ling and Yttery (2002) show how adolescents hypercoordinate their social life and construct social encounters moment-by-moment. Mobiles phones allow for “perpetual contact” (Katz & Aakhus, 2002), a form of social link that seems to fit perfectly with young people’s peer culture and developmental tasks. Rather than voice calls, young people have made the Short Message System (SMS) their typical use of mobile phone (Cosenza, 2002; Grinter & Eldridge, 2001; Grinter & Palen, 2002; Riviére, 2002) Along with the economic advantages, the diffusion of the SMS among teenagers may be explained by social and cultural factors (Taylor & Harper, 2003). The silent dimension of this distant communication is at the core of its domestication in young people’s underground life both in the family and in school (Caron & Caronia, 2007). Allowing for silent and hidden communication, the mobile phone perfectly integrates a typical teenagers’ cultural pattern: constructing their social world outside of their parents’ control and the official rules governing life in school. Young people have also interpreted the technical constraints of SMS according to their specific peer culture. The limit of the numbers of available characters has been transformed into a resource for constructing a new language and new language games. Competence in this language defines the boundaries of a community of users, creates group membership and cohesion, and distances users from adults’ culture (idem).

Studying teenagers’ discourses on mobile phone, some scholars have noted that this technology is a detonator of social thinking: it provokes reflective thinking on the ethics, politeness, and
Growing Up Wireless

aesthetic rules of everyday action and social life (Caronia & Caron, 2004). Reflecting upon social uses of the mobile phone, teenagers explore the identity-making processes involved in the presentation of oneself on a public scene. They interpret and make the uses of the mobile phone work as a social grammar through which people supposedly define themselves and those around them. In this sense, using a mobile phone in a teenage-appropriate way is not a matter of technical competence; it requires broader communicative skills that include cultural knowledge of when, where, why, and especially how to use this technology. Similarly, researchers have analyzed the normative aspect of mobile phone use among teenagers’ groups. In particular, they focus on the implicit cultural rules governing the sharing of the technology (Caron & Caronia, 2007; Weilenman & Larsson, 2001). According to teenagers’ cultural frames of reference, the ownership of a communication device is not an individual matter. Rather it is a radically social affair. Alliance and friendship, leadership and membership, require sharing individual property: mobile phones are loaned and borrowed among the members of the group and this performance entails a system of reciprocal obligations. This “gift exchange” (Mauss, 1954 {1924}) reinforces social links and ritually defines who belongs to the group.

These studies shed light on different aspects of what can be conceived as a single process: the domestication and integration of the mobile phone into youth-specific culture. The mobile phone seems to work as a developmental tool that meets the needs of the growing up process. Particularly, young people use it to attain a certain degree of autonomy with respect to family world, to mark their belonging to a community of peers, to create their specific social organization, and to develop the skills and share the knowledge needed to become competent members of their own community.

Less explored than the world of teens are the cultural and social micro-aspects involved in parents’ uses of the mobile phone in communication with their children. Research on this issue mostly describes mobile phones’ usefulness in mutual coordination of children and working parents and their perception of mobile phone as a security/safety/control device (Caronia & Caron, 2004; Ling & Yttri, 2002; Rakow & Navaro, 1993). These studies have investigated relevant dimensions of the process through which mobile phones affect and are affected by family culture. However, more detailed knowledge and a deeper understanding of the cultural and interpersonal aspects of such a process is required.

Our hypothesis is that this mobile communication device contributes to the creation of new cultural models of being a parent and being a child.

CULTURAL MODELS OF PARENTING: A THEORETICAL APPROACH

The cognitive approach to culture conceives cultural models as prototypical, language-based scripts of events, actions, and social actors. These shared definitions of situations supposedly work as frames of reference for inference-making and as guides for appropriate, mutually understandable, and accountable actions. Shared by individuals belonging to the same linguistic and cultural community, cultural models are models of reality as they define what counts as an occurrence of what type of event. They are also models for reality insofar as they are used as references to act in accordance with these shared definitions of social events. Cultural models thus constitute a background cultural knowledge providing resources to understand and to perform in culturally appropriate manners (D’Andrade, & Strauss, 1992; Holland & Quinn, 1987). Just as linguistic competence and grammatical knowledge make linguistic performance and language use possible, the shared set of cultural models of reality gener-
mates social actions. Conversely, people’s actions, discourses, and behaviours are seen as merely reflecting or expressing their mental representations of the social world.

The cognitive approaches to social knowledge and praxis give primacy to knowledge over praxis, to culture over everyday actions and discourses. This top-down theoretical perspective has been strongly criticized and programmatically reversed by radical bottom-up views. Building upon philosophy of language and speech act theory (Austin, 1962; Searle, 1969), ethnomethodology (Garfinkel, 1967; Heritage 1984), social constructionism (Gergen, 1985), conversation analysis (Atkinson & Heritage, 1984), and discursive psychology (Edwards, 1997; Potter & Wetherell, 1987), conceive cultural models that organize everyday life in intersubjectively shared ways, as constructed moment by moment by the ways people participate in social events. Actions and discourses do not merely reflect an existing culture stored as information in people’s minds. Rather, they are tools for constructing cultural definitions of reality. From a radical constructivist perspective, knowledge is thus a product of praxis.

In contrast, dialectical perspectives have emphasized the reductionism of both the knowledge oriented and action oriented approaches. Phenomenology (Giorgi, 1990), cultural psychology (Bruner, 1996), critical discursive psychology (Wetherell, Taylor, & Yeats, 2001), and contemporary linguistic anthropology (Duranti, 1997) propose a theoretical perspective that captures the reflexive relationship between culture and action. Individuals are historical beings belonging to an existing life-world. This background of taken-for-granted assumptions, beliefs, and traditions provides established, normalized ways of understanding the world and sets the limits and the opportunities for acting and thinking (Foucault, 1980). However, background cultural knowledge does not determine people’s actions and behaviours. Through their everyday actions and discourses, individuals become crucial agents of a creative process of culture making, remaking, and unmaking. In essence, “knowledge and praxis create each other” (Ochs, 1988, p. 15).

Praxis is also technologically mediated actions and communications. How does the use of mobile communication devices shape cultural models of “being a parent” and “being a child” and vice versa?

**HYPER-PARENTING: A TECHNOLOGICALLY MEDIATED ACHIEVEMENT**

As the mobile phone became a tool for parent-child communication, it has been shaped by a pre-established culture of parenting. Pagers and mobile phones have been interpreted by parents as means to exert control over and fulfill their responsibilities toward their children. They have thus been completely domesticated in the family’s moral economy and transformed into tools for family socialization. By analyzing parents’ and children discourses on their use of mobile phones, we can reconstruct the repertoire of official reasons family members invoke to make sense of the adoption of this technology. Some patterns of meaning are recurrent, namely being in touch and responding to emergencies.

In the following example, Guy, a father in his mid-fifties, sees the mobile phone and pager as a kind of “umbilical cord,” since they allow him greater contact with his children:

**Guy:** But we also used it, now less, it used to be a lot like an umbilical cord with the kids. The kids could call us... Now it’s less important... they’re 19 and 20 now. They both have pagers. Bruno who didn’t want one, we twisted his arm to get him to have one, so we could get in touch with him.

Parents may also insist on their children calling them, as we can see in the following discussion between Louis (age 10) and his parents, Gerry
and Madeleine (in their 40s) that lend him their cell phone to reach them:

**Researcher:** Do you call your parents often?

**Louis:** Well, yes. Even when I’m going to school.

**Gerry:** Let’s say you don’t call, it’s because we tell you to call...

**Researcher:** Why do you call them, for example?

**Louis:** Well! Sometimes when it’s important or something that uh...

**Madeleine:** But he doesn’t call us. We have to insist on him calling us.

**Gerry:** In fact, it’s because we are starting to leave him at home alone a little. So we tell him, “before you go, you call.”

Children also can perceive the mobile communication device more as a kind of “electronic leash” that allows their parents to contact them at any time:

**Barry (19 years old):** It is a pager heu.. (...) and then afterwards there, it happened, what we call.. it becomes a bit like an electronic leash for my mother...

**Researcher:** An electronic leash?

**Barry:** For my mother and then so... It lets her call me all the time and then uh... any time.

**Andrée (mother, age 50):** Well, it’s true, I appreciate it.

**Barry:** Yeah, she finds it very useful.

**Andrée:** I can reach him everywhere because he has it and it’s reliable, you always have it?

**Barry:** I alw... I almost have it all the time on me. Sometimes I forget but otherwise it is always on, always, always.

The image of the cellular phone as a piece of emergency equipment is another recurrent pattern of meaning in parents’ accounts of the reasons they introduced cell phones. Parents and children often construct narratives of hypothetical dangers and imagined scenarios in which having a mobile phone helps the owner resolve a problematic situation. The emergency discourse is actually one of the most recurrent themes in explanations of why the mobile phone came into informants’ family and how they were supposed to use it:

**Researcher:** You told me you’d have a cellular?

**Louis (son, age 10):** Yes.

**Madeleine (mother age 40):** When did we talk to you about having a cellular?

**Louis:** When we were in the car.

**Gerry (father, age 45):** That’s right.

**Louis:** To call each other in emergencies.

**Gerry:** That is we will lend him one of our cell phones so that when he is on the mountain, if ever something happens, that he would get lost, like when he went to blue mountain and he got lost, well he would have his cellular and it is going to be programmed, because, you know, you can program the cell phone, so he will have to program the number.

**Louis:** At Green Mountain I had it.
Growing Up Wireless

Gerry: Had you lent it to him?

Madeleine: Yes I remember.

As these examples show, the use and the functions of mobile phones are shaped by typical features of cultural model of parenting characteristic of contemporary western society. Exerting control over children, ensuring that they are safe, handling emergencies, managing time to create family moments, assuming responsibility toward children, supervising children’s life out of the home, and mutual coordination to be in touch are all behaviours consistent with the cultural definition of being a parent. From this point of view, remote parenting (Caronia & Caron, 2004; Rakow & Navaro, 1993) seems to be nothing more than a new way to perform old functions and to act according to established models of fulfilling parental roles.

Our hypothesis is that mobile communication devices are not only an expression of an existing family culture and social organization, they are also ways to create them. By tracking their children’s movements, finding out who they are spending time with, claiming to know that their children are safe, reminding their children when they have to be back or scolding them if they are late, parents realize the rights and duties involved in “being a parent.” By participating in these remote parenting interactions, children are socialized in the commitments and responsibilities of being members of the family. Mobile communication devices’ practical uses are thus meaningful actions: they establish and confirm family boundaries, they state “who makes family with whom” and what behaviours belong to family members. They make the link between relatives permanent and work as teaching-learning strategies on the rights and duties governing family community life. Through the courses of action implicit in mobile phone use, parents do more than exert their role: they construct culture by legitimizing the definitions of what counts as “being a parent,” “being a child,” or “being a family” inscribed in their mobile phone mediated actions.

The following example from our ethnographic fieldwork on mobile use in the family sheds light on the cultural and social consequences hidden behind the most visible functions of remote parenting.

Scene: It is Saturday afternoon in Bologna. Silvia, a divorced mother in her 40s, is talking on the land phone to her friend, participant researcher Laura. Mafalda, Silvia’s oldest daughter, age 13, is in Milan at her father’s house. Silvia’s mobile phone rings:

1. Silvia to Laura: Wait, just a minute, it’s “Serafini-Milano.” (reading on the display)
2. Laura: Okay.
3. Silvia to Mafalda: Yes, sweetheart, I’m on the phone, talking with Laura.
5. Silvia: “Back?” (English in original), it means “at the rear” or “been returned,” It depends. You have to consider the sentence.
6. Silvia: “Appear?” (English in the original), I don’t know, wait, I’ll ask Laura...
7. Silvia to Laura on the land phone: Laura, what does it mean, “appear?” A-P-P-E-A-R?
8. Laura: “To have an outward aspect.”
9. Silvia to Mafalda: “To have an outward aspect.” Laura said that it means to have an outward aspect.
10. Silvia: “Fail” (English in original), I don’t know, I’ll ask Laura.
11. Silvia to Laura: And “fail?” (English in original), F-A-I-L?
12. Laura: To deceive, fail, to not succeed in doing something.
13. **Silvia to Mafalda:** To not succeed, okay sweetheart? Is it correct? I love you.

14. **Silvia to Laura:** Hey, many thanks, many thanks from Mafalda, too. It’s fantastic, I never do that, helping Mafalda with her homework in this way. She’s in Milano and I’m in Bologna and you, you’re at home, it’s great!

Remote parenting is more than an easy way to attain practical purposes or carry out typical functions related to the parental role. Through this mobile phone mediated interaction, Silvia is not only helping her daughter do her English homework. The sequence of her “mobile” actions is a meaning making devices.

Consider first the opening sequence of this multiparty telephone conversation. Silvia interrupts her conversation with Laura to give priority to her daughter’s call (turn 1.). “It is Serafini-Milano”: reading aloud the identity of the caller appeared on the display, she tells Laura whose needs come first. In this family culture “Serafini-Milano” is a shortcut for “daughters when they are at their father’s house.” Sharing this background local knowledge, Laura accepts Silvia’s shift to her daughter’s call (turn 2.). Acceptance is an action: through this action Laura legitimizes her being put in standby position. Then, Silvia does more than merely shift her attention to her daughter. After addressing Mafalda with some instances of intimate talk, she formulates this move with words (turn 3). Describing in words what one is doing is one of the linguistic moves through which participants negotiate the meaning of what is going on (Garfinkel & Sacks, 1970) and construct a shared definition of the event and its implications. This can be summarized as: “if children call, their mother is available and their needs come first.”

The second part of the conversation is a typical mother-child scaffolding interaction: the mobile phone guarantees a direct, always open access to the caregiver and makes it possible to carry out this kind of joint action despite physical distance.

In the closing sequence, Silvia formulates what happened as a new, original way to perform as a parent (turns 13 and 14).

The actions performed in and through this technologically mediated conversation are culture building activities and socialization devices. By doing “being a parent” in certain ways, the mother locally constructs and proposes dimensions defining her cultural model of parenting: being always available, giving priority to children’s needs over adults’ needs, interrupting the ongoing course of action to open up a parallel one, using intimate talk to address one’s own children, and giving children a scaffolding to overcome their difficulties.

At the same time, the mother’s actions convey a cultural model of the child: a child is a demanding individual whose needs come first. He or she has the right to expect his or her parent to divert attention from an ongoing adult-adult interaction to take care of the children.

What about the other participants? By participating in such an interaction, Mafalda is learning more than the meaning of some foreign words: she is being socialised in the cultural models of “being a mother” and “being a child” that are at stake in this family. Accepting her role as a collateral participant, Laura legitimizes the definition, under construction, of “what is going on and why.”

The participants officially involved in this interaction, are jointly constructing and ratifying, at least locally, a shared definition of “being a parent” and “being a child.” That is, they are constructing a cultural model of parenting as a technologically mediated achievement.

If “reciprocal availability” can be considered a trait of an existing culture of parenting, how does mobile phone shape this trait?

Mobile communication devices are distinctive because they allow anytime and anywhere reciprocal availability. This is nothing more than a suggested way of acting, a “possible world” inscribed in the technology. It is through everyday and ordinary ways of using the mobile phone that
this cultural model becomes a (technologically mediated) accomplishment.

A pre-existing cultural definition of being a parent has clearly shaped parents’ and children’s use of the mobile phone far beyond the management of urgency, safety, and control. In very reflexive ways, the use of this technology has created a new original way to be a parent. The possibility of remote parenting has been turned into hyper-parenting.

Through their everyday mobile interactions, parents and children have transformed physical distance into relational proximity; they have overcome the spatial and temporal constraints of face-to-face or traditional telephone interactions, and transformed almost every moment into an opportunity for coconstructing joint actions and care-giving. Family relationships seem to perfectly mirror the contemporary paradox of a wireless world producing hyperlinked people.

**LINKING MACRO AND MICRO: SOCIO-CULTURAL CHANGES IN FAMILY EDUCATION**

One of the most relevant contributions to the construction of the contemporary cultural model of parenting has been the historical change in the notion of parental authority. Since the end of the 17th Century, western societies have progressively moved from a political model of authority based on the concept of natural inequality and on the related notions of power and obedience to a definition of authority legitimised by a social consensus among equals. According to the political model, the pater familias’ supreme authority over his children was analogous to that exerted by a sovereign over his subjects. Power and submission were the expected behaviours defining parents’ and children’s reciprocal and naturally unequal status. This notion of authority was profoundly questioned by Locke and Rousseau according to the principle of the natural equality of all human beings. Obedience to the authority does not stem from the presumed inferior status of some individuals. Rather, it derives from the social contract. Individuals have to obey the law because it expresses the will of all the people concerned.

Since Toqueville, and throughout the 19th Century, this model of authority has strongly affected western societies’ macrohistory, politics, and laws. While in a slow often inconsistent way, it has also brought major changes to microhistory: it has affected the cultural models of all social relationships including those typical of the private family universe. The patria potestas no longer has a natural foundation, and negotiation is presumed to be at the core of family members’ distribution of authority. The translation of this consensus-based model into actions and interaction is less obvious with respect to the parent-child relationship. Here, a “natural inequality” (now referred to as “asymmetry”) is at stake: it defines the psycho-physical dependency of children on their caregivers. The gap in competences, skills, and knowledge is precisely what defines the reciprocal status of parents and children. Parents’ authority—whatever that means—is a tool to overcome this gap, a necessary condition for children’s development. Yet this necessity is no longer an argument for a power-based definition of parental authority.

At the end of the 20th Century, the inner logic defining parental authority was completely reversed. Until at least a century ago, parents had almost absolute power over their children, who were not considered to have rights. Now it is parents that have duties toward children. Most western societies have substituted the notion of patria potestas with those of parental cares and responsibilities, protection and supervision. The United Nations Convention on the Rights of the Child, introduced in 1989, emphasized that children have their own rights; adults’ “authority” is clearly defined in terms of duties, obligations, and responsibilities that parents have over their children. The notion of power as the probability
of obtaining obedience no longer defines the contemporary model of parenting.

How can this new image of a child as a subject that is no longer expected to obey be reconciled with the notion of parental authority and governance? How can authority be invoked without power? How does one cope with a child that is considered both a vulnerable and dependent individual and an autonomy-oriented person with rights?

Traditionally, parents had the right to exert power over children who had the obligation to obey. Aside from any other consideration, this model was inherently consistent. It offered a clear distribution of complementary rights and duties and traced a path for mutually coordinated actions.

The change in the definition of parental authority has broken the inner consistency of the traditional model. Now, children’s rights and parents’ duties often appear incompatible, and family education practices need to be conceived as ways to cope with the inherent paradoxes defining contemporary democratic education.

It may sound hazardous to relate these macro cultural, historical, and political changes to everyday life and social practices. Yet it is in the micro-order of ordinary life that cultural changes are both reflected and accomplished. The cultural changes in the status of children and in the notion of parental authority have directly and indirectly affected family education practices.

Aside from tragic exceptions, mainstream parents and children in contemporary western societies interact according to the social consensus framework. While recognizing the difficulties of creating such a consensus, sometimes shifting to or mythically evoking the simplicity of the authoritarian traditional model, contemporary parents have assumed the basic principles of democratic education.

Negotiation more than obedience, competence more than power, trust more than authority are the basic principles underlying parents’ and children’s reciprocal interactions. Mobile communication devices have been shaped by such a cultural framework. They have been appropriated as unexpected and efficient tools to negotiate parents’ and children’s often conflicting perspectives on children’s developmental needs, and as ways to articulate their often incompatible rights and obligations.

In other words, mobile communication devices play a role in coping with the slightly paradoxical nature of the contemporary model of family education.

PARENTS’ AND CHILDREN’S INCOMPATIBLE RIGHTS: MOBILE PHONES AS A NEGOTIATION TOOL

One of the domains where the paradoxical nature of parents’ and children’s reciprocal status emerges the most is children’s gradual shift towards the peer universe.

As they grow up, children multiply their universes of references and have to negotiate their progressive belonging to multiple socio-cultural worlds. Family and peer community are different, often conflicting, demanding worlds.

It is mostly at this point in their developmental trajectory that pre-adolescents start demanding autonomy, freedom, and the right to make their own decisions, choices, and even mistakes. Moreover, it is then that they construct social links beyond their parents’ filter. Not surprisingly, it is at this moment that parents officially enforce their responsibility, their obligation, or even their right to exert control and supervision. Less than 10 years ago, these conflicting perspectives were managed in two ways: talking with children about the where, when, what, and with whom of their extra-family life and negotiating the limits of time spent outside the home. These educational practices are rarely mutually exclusive. Depending on the family’s pedagogical model and on
children’s behaviours and attitudes, the transition to the peer universe may be more dialogic-oriented or more control-oriented. In either case, borders are clearly identified and the transition becomes a field where parents’ and children’s differing perspectives often conflict.

As mobile phones became part of the family’s technological equipment, they are interpreted as a means of coping with children’s belonging to multiple socio-cultural worlds. They have opened a new arena to manage the transition from family universe to that of peers. Crossing the boundaries of these two worlds, mobile phones become tools to negotiate children’s right to develop autonomy and parents’ right to control a still dependent child.

Consider first the arrival of a mobile phone in children’s life. Often, parents offer their children a mobile phone at some ritual milestone of their development. This gift-giving is a meaningful symbolic practice: parents recognize that their children have attained a stage of relative autonomy and allow them to privatize their social contacts. In contemporary societies, mobile phone gifts are rites of passage marking the (culturally perceived) beginning of adolescence. Like other goods provided by parents that symbolically mark the beginning of children’s autonomy, the mobile phone marks also children’s dependence on their parents for a wide set of needs and activities. Children’s dependence on their parents for mobile phone use seems even more obvious when we look at management of the related costs. As some adolescents, age 15, explain:

Researcher: Generally, among your friends who have mobile phones, who pays?

All: Our parents!

Mishan: Well, I think it is half and half because teenagers want to have a little independence so they pay half. But they can’t pay for the whole cost so their parents pay half.

Since children or even adolescents do not have the means to cover the costs, parents pay the fees. As soon as they are able, adolescents want to express their independence and give themselves some freedom by taking responsibility for part of the cost. Yet when parents are paying all or most of the related costs, they acquire the right to set rules on mobile phone use. This economic leash defines the boundaries of children’s autonomy. If the mobile phone is a bridge connecting children with the outside family universe, the bridge is built by parents who partially control access to this universe. Allowing for an economically controlled independency, mobile phones are used as cultural objects to mediate and gradually modulate children’s construction of a life outside of family boundaries and constraints.

Besides the strategic use of costs, the role of the mobile phone as a mediating device emerges from the way it is used both by parents and children.

As a 15-year-old girl told us, parents often take advantage of the fact that their children have mobile phones to keep an eye on them, watch over them from a distance, and even control where they go:

Karine (age 15): Well, it’s because my parents, it’s become like they really want to know where I am, so my parents always want to contact me, they’re always afraid when I’m outside. When I’m out they can’t contact me because there’s no phone, when I’m at someone’s it’s okay but if I go somewhere and I don’t call when I’m going, well they start freaking out, so… I need one.

Anxiety when children go out is an emotional experience strictly related to parenting. Mobile phones allow parents to cope with such a common experience in a totally original way: they do not need to choose between either allowing children be out of supervision and enduring their own anxiety, or radically limiting children’s social life to avoid painful apprehension. The mobile phone thus opens an alternative course of action:
**Pénélope (age 15):** Often there are, well I know some where it’s the parents who want to know where their kids are...

**Researcher:** Ah?

**Pénélope:** It’s a form of security for them, like, you know, parents buy it for their kids to give them, to give the kids some freedom, but at the same time the parents can know where the kids are any time.

For parents, the function at stake is not only to reduce their own apprehension. By tracking their children’s movements and finding out with whom they are spending time, they fulfil the duties and rights related to their parental role while respecting the children’s right to live an autonomous life. As we have seen in the extract above, adolescents seem to be quite aware of the dual nature of mobile phone contact. It is exactly this feature that allows them to use the technology in very strategic ways to negotiate their right to autonomy.

Adolescents usually accept that parents use cell phones to exert parental control. The duty to inform parents is generally well integrated in young people’s specific culture: this ritual practice is commonly assumed to be a way to gain more permission:

**Sophie (age 15):** It’s safer, not just for us, but for our parents too... Sometimes there are families that are separated; in ours, we’re all together, but even so my mother likes to be able to call me...

**Antoine (age 17):** In that sense, it’s sure that it’s another advantage, maybe to be able to get more permission to go out because you tell them something like “hey, you can call me any time, there won’t be any problems.”

**Sophie:** “If there’s anything, I’ll call you, Mom, Dad...”

**Karine (age 15):** Because some people go out a lot, they have a really big social life and for their parents, it would help them a little.

**Researcher:** To be able to contact them?

**Karine:** To contact them, yeah, so the parents won’t freak out, so they won’t be there going “Aaaack!”

As this discussion among adolescents shows, mobile phone has opened a totally new arena for negotiating children’s belonging to both family and peer worlds. Allowing users to reach and be reachable all time, the phone creates a symbolic space where parents and children can take into account the rights of the counterpart. When provided with a mobile phone, children are willing to accept the parents’ right to know where their children are, and they are willing to attend to and cope with their parents’ anxiety (It’s a form of security for them; It’s safer not just for us, but for our parents too.). Conversely, helping them manage their own right to apprehension, mobile phones help parents cope with their children’s right to go out and have a “really big social life:”

**Layla (age 15):** Why did you get a mobile phone?

**Jean (age 15):** Well, one, to communicate, like to have more independence. You know, when your parents tell you, like in a mall, you have something, a means of communicating, to contact you. Like with your friends, let’s say we say, “okay, let’s meet like at the movie theatre.”

**Layla (age 15):** Okay.

**Carl (age 15):** Me, it’s about the same too. It’s like the parent-child relationship. It’s sure that you know if, if you’re going to be late, you’re on your way, so then you just have to call your parents on
Growing Up Wireless

your mobile and then you tell them, “I’m coming, I’m about 15 minutes late, uh, I’m just in front of such-and-such a place, I’m coming.” Then they say, “oh, okay, that’s fine.”

Children consider autonomy, freedom, and peer life coordination the fundamental reasons for owning a mobile. However it is not surprising that they strategically focus on safety reasons when impressing on parents the need to get one. Grasping the unique opportunities they offer, adolescents use mobile phones as a means to act in ways that are consistent both with their needs and rights and with those of their parents.

Camera phones have amplified the repertoire of parents’ and children’s mediating tools. They provide parents and children with a more sophisticated strategy to negotiate their incompatible rights and to construct a bridge that connects the worlds of family and peers:

Layla (age 15): Then you say, “yes, Mom, see my friends,” then you take a picture with your phone. It’s so your mom can see that you’re really with your friends.

Researcher: Could you repeat what you just said?

Layla: It’s because I say to myself, okay, let’s say I call my mother, then my mother really wants to know if I’m somewhere or if I’m really with my friends, you take a picture, then you say, “yes, Mom, I’m with my friends, look.”

Researcher: So you’ve got proof.

Layla: Yeah, I’ve got proof.

Aside from their impressive role in creating a community of peer where instant pictures circulate and are shared by members, camera phones fit perfectly into parents’ and children’s typical interactions. It would be easy to invoke the image of Bentham’s panoptikon and wonder if this kind of visual remote parenting is nothing more than a contemporary version of power and control dynamics. Rather, we propose a different interpretation that focuses on the strategic use of this otherwise controlling device: the dialogic use of mobile phones. By letting their parents enter their peer world, by giving them visual proof of what they probably have stated in words, adolescents establish a contract of trust with their parents. Gaining in trust implies gaining in freedom and autonomy. Adolescents have turned the constraints of remote parenting to their advantages as in peer culture gaining more freedom is an advantage. Less hidden then it once used to be, adolescents’ underground life with respect to family can be strategically and at least partially shared with parents. The new sharable quality makes peer community experience a negotiable affair.

Sending photos via camera phone to parents may thus be seen as a paradox-resolving practice. In and through this process, parents and children articulate their symmetric and opposite rights, while creating much more room for negotiation and for consensus construction.

Mobile phones are also used to transgress this dialogic model. Transgressing family norms, pushing the boundaries of what has been consensually established as legitimate, and eventually breaking the terms of the trust contract, are all typical dimensions of adolescents’ growing up process. Mobile phones can be strategically turned off (i.e., when children do not want to be reached by their parents) or simply ignored if the caller ID device signals that parents are calling:

Tania (age 15): It’s like, I don’t really like that. You’re with your friends and then your mother calls you.

Researcher: So, you’d rather not have one? It’s your mother who insists?
Tania: Yeah, but it’s really like, uh, to know where I am, if I’m going to be late or something.

Researcher: So how do you deal with it?

Tania: I turn it off. [Laughs]

Researcher: You take it but you turn it off…

Tania: Well, I turn it off, yeah, or else I say I was in the subway.

The following is another example of the strategies used by adolescents to filter parental control calls. In this case an additional function of the technology enables Sandrine to transgress the rule:

Delphine (15 years old): On top of that, I don’t have call display, so I have no choice but to answer.

Sandrine (15 years old): I have call display, you know, when it’s someone, let’s say I’m somewhere and it’s my parents and I don’t want to talk to them, I don’t want them to bug me, so I don’t answer.

Turning off the mobile phone and not answering if parents are calling are behaviours that have to be justified or accounted for: no signal and low battery are the arguments commonly used by children to justify their being unreachable. The need for explanations defines these behaviours as exceptional transgressions. Invariably, transgression reveals and confirms the rule at stake. In this case, the rule is dialogic use of the mobile phone, a pattern of interaction legitimizing both parents’ right and duty to supervise their children and children’s right to be autonomous.

PARENTS’ AND CHILDREN’S DIALOGICAL USE OF MOBILE PHONES: CONCLUSIONS

Although they are incorporated in existing cultures of parenting and strongly dependent on each family moral economy, mobile communication devices nurture these worlds of meaning. Culture and praxis create each other. Everyday uses of mobile phone are no exception: they participate in the process whereby people constantly create and recreate their cultural ways of living their lives. Entering the family’s and teens’ everyday life and allowing new forms of interaction (such as remote parenting), this device works as a culture making object. It plays a major role in the rise of new cultural models of “being a parent” and “being a child.” Hyper-parenting is one such model.

Beside allowing coordination of children and working parents, besides facilitating single parents’ multitasking or connecting divorced parents to their children living away from their home, mobile phones are used to create and constantly confirm social and affective links among parents and children. Building upon traits of a shared, pre-existing model of parenting and seizing the opportunities of mobile phone, parents in contemporary western societies go beyond its practical functions. They have transformed the “reaching children and being reachable” dimension into anytime and everywhere reciprocal availability. Wireless parents and children perform as hyper-linked members of a family. Beyond any practical purposes or topic of mobile conversations, it is the contexts of mobile phone use and the ways in which it is used that give their interactions meaning. Their mobile verbal exchanges are meaningful actions that define their social and affective ties as relevant and prior to almost any other course of action. Simply put, mobile phones have magnified and overstated a totally cultural and unnatural parental model: children come first. It may sound obvious, yet it is not.
Growing Up Wireless

Mobile phones uses confirm, naturalize, and literally objectivize what is nothing more than a socially constructed definition of “being a parent.” These technologies participate in the silent and almost invisible process in and through which individuals create their cultural world as a quasi natural one.

The same process underlies the use of the mobile phone as a bridge connecting family and peer worlds. As we have seen, contemporary parents must contend with a definition of parental authority and children’s rights that make family education almost paradoxical. Mobile phone use has been totally integrated in a dialogical model of exerting parenthood. Thanks to its engineering, it leaves room for negotiating the symmetric and opposite rights defining the status of contemporary children and parents.

The mobile phone has opened a symbolic space to manage the transition from family universe to that of peers and to cope with paradoxes of the developmental process such as the typical autonomy-dependency dimension. Parents and children use the technology to blur the boundaries of the different socio-cultural universes to which children belong, and to make a smooth supported transition from family culture to the peer world. In particular, the mobile phone is used by family members to negotiate the often conflicting perspectives of parents and children with respect to the developmental needs and to articulate an often incompatible system of reciprocal rights and duties.

In a social and historical context where parental governance is no longer legitimized by power and obedience, mobile communication devices are used as an educational tool consistent with a consensus-based notion of parental authority. Performing according to such a cultural and even normative model of being a parent is a way to constantly recreate it. Through a dialogic use of mobile phones, parents and children participate in the process of defining a contemporary model of family education as a democratic social practice.

ENDNOTES

1 This is the famous slogan of Chicago World's Fair in 1933.
2 The notion of intentionality as the human competence in making sense of reality and in creating the crucial dimensions of people’s life-world was introduced by Brentano and Husserl at the beginning of the 20th Century. It is perhaps one of the more heuristic notions of XX century philosophy.
3 Aside from any theoretical consideration, the relevance of talk-in-interaction in meaning making and culture construction has strong methodological consequences. Notably, it legitimizes the analysis of discourse as a social practice per se (Wetherell, et al., 2001). According to this framework, we conceive and analyze the uses of mobile communication devices as well as the discourses on such devices, as ways to make sense of them.
4 This chapter draws on data from a 7-year multiple research project on the appropriation of communication and information technologies in families' and adolescents' worlds (Caronia & Caronia, 2001, 2007; Caronia, 2005; Caronia & Caron, 2004). We used different yet complementary methodological and recording devices: family interviews and participant observation, log books on everyday practices, focus groups with adolescents, ethnographic case studies among natural groups of adolescents, analysis of naturally occurring mobile conversations and SMS exchanges. These studies have been conducted jointly with André H. Caron (Department of Communication, University of Montreal, Montreal), with financial support from CITÉ (Center for Interdisciplinary Research on Emerging Technologies, University of Montreal). I wish to thank my colleague André H. Caron for the support and the suggestions he gave me. Most of the ideas and interpretation proposed in this chapter have emerged from the joint analysis of data.
5 In some countries the diffusion and appropriation of mobile phone by young people is an important social phenomenon. In Europe, 23% of children ages 8 to 10 have a mobile phone. In Italy, one in three children between ages 5 and 12 has and uses a personal mobile phone. At age 9, 28% own a mobile phone. Among 14 and 18-year-olds, the percentage of mobile use and ownership is around 100% (Doxa Junior, 2005). In Norway, nearly 80% of children ages 9 to 12 have and use a mobile phone. The percentage rises at 13 (around 96%) to reach 100% at 16 (Ling, 2006). In Britain, 49% of children ages 8-11 and 82% of 12-15 year-olds own a mobile phone (Withers, 2006). The phenomenon is less apparent in Canada but is still growing. According to Statistics Canada, 17.5% of children in primary school have a cell phone and 42.8% of high school students have one (Dunfield, 2004).
6 The following verbatim come from family interviews made during a larger ethno-

2673
graphic research on the integration of new communication technologies in family everyday life (Caron & Caronia, 2001).

From an empirical point of view, we have strong evidences of remote parenting as a new way to perform the parental role. Whether it is considered as a way to dissimulate adults’ escape from their responsibility or as a way to manage the contemporary parents’ multitask life, strictly depends on the actors’ points of view and cultural models of “what counts as good parenting.” I advance the hypothesis that the common sense shared cultural model of “good parenting” is strictly anchored on notions as “face-to-face interaction” and “physical contact.” On the basis of such a cultural model, remote parenting may be considered as not consistent with the ideal-typical behaviour of a “good parent.” This is the point: are not these new communication technologies participating in the change of the cultural models we live by?

All the following transcripts come from conversational focus groups with adolescents on their uses of mobile phones (Caron & Caronia, 2004).

ABSTRACT

This chapter describes how social politeness is relevant to computer system design. As the Internet becomes more social, computers now mediate social interactions, act as social agents, and serve as information assistants. To succeed in these roles computers must learn a new skill—politeness. Yet selfish software is currently a widespread problem and politeness remains a software design “blind spot.” Using an informational definition of politeness, as the giving of social choice, suggests four aspects: 1. respect, 2. openness, 3. helpfulness, and 4. remembering. Examples are given to suggest how polite computing could make human-computer interactions more pleasant and increase software usage. In contrast, if software rudeness makes the Internet an unpleasant place to be, usage may minimize. For the Internet to recognize its social potential, software must be not only useful and usable, but also polite.

INTRODUCTION

Social Computing

Computers today are no longer just tools that respond passively to directions or input. Computers are just as mechanical as cars, but while a car inertly reflects its driver’s intentions, computers now ask questions, request information, suggest actions, and give advice. Perhaps this is why people often react to computers as they would to a person, even though they know it is not (Reeves & Nass, 1996). Miller notes that if I accidentally hit my thumb with a hammer, I blame myself not the hammer, yet people may blame an equally mechanical computer for errors they initiate (Miller, 2004). Software it seems, with its ability to make choices, has crossed the threshold from inert machine to interaction participant as the term human-computer interaction (HCI) implies. Nor are computers mediating a
social interaction, like e-mail, simply passive, as the software, like a facilitator, affects the social interaction possibilities (Lessig, 1999). As computers evolve, people increasingly find them active collaborators and participators rather than passive appliances or media. In these new social roles, as agent, assistant, or facilitator, software has a new requirement—to be polite.

To treat machines as people seems foolish, like talking to an empty car, but words seemingly addressed to cars on the road actually to their drivers. While the cars are indeed machines, their drivers are people. Likewise, while a computer is a machine, people “drive” the programs interacted with. Hence, people show significantly more relational behaviours when the other party in computer mediated communication is clearly human than when it is not (Sheetman & Horowitz, 2003), and studies find that people do not treat computers as people outside the mediation context (Goldstein, Alsio, & Werdenhoff, 2002)—just as people do not usually talk to empty cars. Reacting to a software installation program as if to a person is not unreasonable if the program has a social source. Social questions like: “Do I trust you?” and “What is your attitude to me?” now apply. If computers have achieved the status of semi-intelligent agents, it is natural for people to treat them socially, and thus expect politeness.

A social agent is taken as an interacting entity that represents another social entity in an interaction, either person or group, for example, if an installation program represents a company (a social entity), the installation program is a social agent, if it interacts with the customer on behalf of the company. The interaction is social even if the social agent is a computer, and an install creates a social contract even though the software is not a social entity itself. In the special case where a software agent is working for the party it is interacting with, it is a software assistant, working both for the user and to the user. In such cases of human-computer interaction (HCI), social concepts like politeness apply.

If software can be social it should be designed accordingly. A company would not let a socially ignorant person represent it to important clients. Yet, often, today’s software interrupts, overwrites, nags, changes, connects, downloads, and installs in ways that annoy and offend users (Cooper, 1999). Such behaviour is probably not illegal, but it is certainly impolite.

**Selfish Software**

The contrast to polite software is “selfish software.” Like a selfish person who acts as if only he or she exists, so selfish software acts as if it were the only application on your computer. It typically runs itself at every opportunity, loading at start-up and running continuously in the background. It feels free to interrupt you any time, to demand what it wants, or announce what it is doing, for example, after installing new modem software, it then loaded itself on every start-up and regularly interrupted me to go online to check for updates to itself. It never found any, even after many days, so finally after yet another pointless “Searching for upgrades” message I (first author) decided to uninstall it. As in “The Apprentice” TV show, one reaction to assistants that do not do what you want is: “You’re fired!”

Selfish software is why after 2-3 years Windows becomes “old.” With computer use, the Windows taskbar soon fills with icons, each an application that finds itself important enough to load at start-up and run continuously. Such applications always load, even if you never use them, for example, I never use Windows messenger but it always loads itself onto my taskbar. When many applications do this, it slows down the computer considerably, and taskbar icon growth is just the tip of the iceberg of what is happening to the entire computer. Because selfish programs put files wherever they like, uninstalled applications are not removed cleanly, and overtime Windows accretes an ever increasing “residue” of files and registry records left-over from previous installs. Giving
selfish applications too much freedom degrades performance until eventually only reinstalling the entire operating system can recover system performance.

**Polite Computing**

Polite computing is about how software design can support HCI politeness. It is not about how people should be polite to people online, which various “online etiquette” guides cover. This chapter aims to define, specify, and illustrate an information vision of polite computing.

Politeness is distinct from both usefulness and usability requirements. Usefulness addresses a system’s functionality, while usability concerns how people use that functionality. The first focuses on what the computer does, and the second on how the user gets the computer to do that. Polite computing, however, is not about what the computer does, nor how one can better get it to do it. It is about social relations rather than computer power or cognitive ease. It enables software that “plays well” in a social setting and encourages users to do the same. It addresses the requirements for social interaction, enabling better social collaboration, rather than better tool use. The contexts differ, so software could be easy to use yet rude, or polite but hard to use. While usability reduces training and documentation costs, only politeness lets a software agent work with a competent user without frustration. Both usability and politeness, however, fall under the rubric human-centred design.

**BACKGROUND**

The Oxford English Dictionary (http://dictionary.oed.com) defines politeness as:

... behaviour that is respectful or considerate to others

Considering and respecting others, a critical success factor in physical society, is equally relevant to online society. The predicted effect of polite computing is better human-computer interactions. While one may mistrust a polite door-to-door salesman as much as an impolite one, the polite one will get more “air time” because interacting with them is more pleasant. If politeness makes social interaction more pleasant, a polite society is a nicer place to be than an impolite one, and its people will be more willing to interact beneficially with others. Polite computing can contribute to computing by:

1. Increasing legitimate interactions.
2. Reducing anti-social attacks.
3. Increasing synergistic trade.
4. Increasing software use.

There is nothing to stop programmers faking politeness, just as nothing stops people in the physical world from doing so, but when people behave politely, cognitive dissonance theory finds they also tend to feel more polite (Festinger, 1957). Likewise, if programmers design for politeness, the overall effect will be positive, even though some may pretend.

**Politeness Supports Legitimate Interactions**

Legitimate interactions, defined as those that are both fair and in the common good, have been proposed as the complex social source of civilized prosperity (Whitworth & deMoor, 2003) and a core requirement for any prosperous and enduring community (Fukuyama, 1992). Conversely, societies where win-lose corruption and conflicts still reign are among the poorest in the world (Transparency-International, 2001). Legitimate interactions offer all parties a fair choice and are in the public good, while anti-social interactions, like theft or murder, give the “victim” little choice
Politeness as a Social Computing Requirement

and harm society overall. In contrast, polite acts are more than fair. To do as the law requires is not politeness precisely because it is required, for example, one does not thank a driver who stops at a red light, yet one thanks the driver who stops to let you into a line of traffic. While laws specify what citizens should do, politeness is about what they could do. If politeness involves offering more choices in an interaction than the law requires, then it begins where fixed laws end. If criminal acts fall below the law, then polite acts rise above it, and polite, legitimate, and anti-social acts can be ordered by the degree of choice offered to the other party or parties (Figure 1). In this view politeness increases social “health,” just as criminality poisons it.

Politeness Reduces Anti-Social Attacks

Polite computing may have value, but should not it take a back seat to security issues? Is politeness relevant if we are under attack? Yet upgrading security every time an attack exploits another loophole, is a never-ending cycle. An alternative is to develop strategies to reduce motivation to attack (Rose, Khoo, & Straub, 1999). Politeness can help one common source of attacks—resentment or anger against a system where the powerful are perceived to predate the weak (Power, 2000). Often hacking is vengeance against a person, a company, or the capitalist society in general (Forester & Morrison, 1994). Politeness contradicts the view that since everyone takes what they can, so can I. That some people are polite and give choice to others, may cause those neutral to society to copy, or those against society to become neutral. Politeness and security seem two sides of the same coin of social health. By analogy, a gardener defends his or her crops from weeds but does not wait for every weed to be killed before fertilizing. If politeness grows a better society, one should not wait to use it until every threat is purged. If security reduces anti-social acts, and politeness encourages social acts, they are complementary not mutually exclusive functions.

Politeness Increases Prosperity

Over thousands of years, as physical society became more “civilized,” this has created enormous prosperity, so for the first time in history some economies now produce more food than their people can eat (as their obesity epidemics testify). The bloody history of humanity seems to represent a social evolution from zero-sum (win-lose) interactions, such as war, to non-zero-sum (win-win) interactions, such as trade (Wright, 2001). Scientific research illustrates this social synergy, as for researchers to freely give their hard earned knowledge to all seems at first foolish, but when a critical mass do this, people gain more than they could have by working alone. Synergy means that when many people give to each other, they gain more than is possible by selfish activity. The success of the open source software (OSS) movement illustrates this, as open source products like Linux now compete with commercial products like Windows. The mathematics of social synergy are that while individual gains increase linearly with group size, synergy gains increase geometrically, as they depend on the number of interactions not the number of group members. The Internet illustrates social synergy, as we each only “sow” a
small part of it, but from it can “reap” the world’s knowledge interactions.

**Politeness Increases Software Use**

A study of reactions to a computerized Chinese word-guessing game found that when the software apologized after a wrong answer by saying “We are sorry that the clues were not helpful to you” the game was rated more enjoyable than when the computer simply said “This is not correct” (Tzeng, 2004). Brusque and often incomprehensible error messages like the “HTTP 404—File not Found” response to an unavailable Web page can imply a user fault, while a message like: “Sorry I could not find file xxxxx.” does not. Accusatory error messages can rub users the wrong way, especially if it is a software error in the first place.

In general, politeness improves the social interactions of a society, which makes it a nicer place to be. The reader can judge for him or herself whether the world wide Web is currently a nice place to be or whether its “dark side” which includes spam, spyware, viruses, hackers, pop-up ads, nagware, identity theft, solicitations, pornography, spoofers, and worms (Power, 2000), means it could benefit from polite computing. If software were more polite, people might be more willing to use it and less willing to abuse it.

**AN INFORMATION DEFINITION OF POLITENESS**

**Reinventing Politeness Online**

To apply politeness to computer programming, it must be defined in information terms. If politeness is “considering others,” then since different societies “consider” differently, what is polite in one culture can be rude in another. Given no universal “polite behaviour,” there seems no basis to apply politeness to the logic of programming. Yet while different countries have different laws, the goal of fairness that underlies the law can be attributed to every society (Rawls, 2001). Likewise, different cultures could have different “etiquettes” but a common goal of politeness. Figure 2 distinguishes the goals of Figure 1 from their specific implementations. In this view, while each society may “implement” a different etiquette, politeness remains the common “design goal,” just as legitimacy is the “spirit” behind laws that vary in detail between societies.

If politeness can take different forms in different societies, to ask which implementation applies online is to ask the wrong question. The right question is how to “reinvent” politeness in each specific online case, whether for chat, wiki, e-mail, or other groupware. Just as each different physical society develop local etiquettes and laws, so different applications may need a different politeness implementation based on a general design “pattern,” specifying politeness in information terms (Alexander, 1964).

**Informational Politeness**

If the person considered knows what is “considerate” for them, politeness can be defined abstractly as *the giving of choice to another in a social interaction*. Doing this is then always considerate if the other knows what is good for them, though the latter assumption may not always be true, for example, a young baby. In a conversation, where the locus of channel control passes back and forth between parties, it is polite to give control to the
other party, for example, it is impolite to interrupt someone, as that removes their choice to speak, and polite to let them finish talking, as they then choose when to stop.

An information definition of politeness is:

... any unrequired support for situating the locus of choice control of a social interaction with another party to it, given that control is desired, rightful and optional. (Whitworth, 2005)

Unrequired means the choice given is more than required by the law, as a required choice is not politeness. Optional means the polite party has the ability to choose, as politeness must be voluntary. Desired by the receiver means giving choice is only polite if the other wants it. “After you” is not polite when facing a difficult task. Politeness means giving desired choices, not forcing the locus of control, with its burden of action, upon others. Finally, rightful means that consideration of someone acting illegally is not polite, for example, to considerately hand a gun to a serial killer about to kill, is not polite.

**Other Definitions**

Some define politeness as “being nice” to the other party (Nass, 2004) and argue that when another says “I think I’m a good teacher; what do you think?” polite people respond “You’re great,” even if they do not think so. In this view, agreeing with another’s self praise is considered one of the “most fundamental rules of politeness” (Nass, 2004). Yet while agreeableness may often accompany politeness, it does not define it if one can be both agreeably impolite and politely disagreeable. One can politely refuse, beg to differ, respectfully object, and humbly criticize, that is, disagree but still be polite. Conversely, one can give charity to others yet be impolite, that is, be kind but rude.

Being polite is different from being kind, for example, kind parents may not give an infant many choices, but politeness does not apply to young children who are considered to not yet know what they really want. Do software creators consider software users to be like little children, unable yet to exercise choice properly? While inexperienced users may happily let software do as it thinks is best, when children grow up they want more choice (as teenagers illustrate). The view that “software knows best” is hard to justify for the majority of today’s computer-literate users. Perhaps once computer users were child-like, but today they want respect and choices from their software.

**Impolite Computing**

Impolite computing has a long history. Spam, for example, fills inboxes with messages users do not want (Whitworth & Whitworth, 2004) and is impolite because it takes choice away from e-mail receivers. Pop-up windows are impolite, as they “hijack” the user’s cursor or point of focus and take away the user choice of what they want to look at. Users do not like this, so many browsers prevent pop-ups. Impolite computer programs can:

1. **Use your computer’s services.** Software can use your hard drive to store information cookies or your long distance phone service for downloads.
2. **Change your computer settings.** Like browser home page, e-mail preferences or file associations.
3. **Spy on what you do online.** Spyware, stealthware, or software back doors that gather information from your computer without your knowledge or record your mouse clicks as you surf the Web and, even worse, exchange your private information with others.

For example, Microsoft’s Windows XP Media Player, was reported to quietly record the DVDs it played and use the user’s computer’s connection
to “phone home,” that is, send data back to Microsoft (Editor, 2002). Such problems differ from security threats, where hackers or viruses break in to damage information. This problem concerns those invited into our information home, not those who break in, for example, “software bundling,” where users choose to install one product but are forced to get many:

When we downloaded the beta version of Triton [AOL’s latest instant messenger software], we also got AOL Explorer—an Internet Explorer shell that opens full screen, to AOL’s AIM Today home page when you launch the IM client—as well as Plaxo Helper, an application that ties in with the Plaxo social-networking service. Triton also installed two programs that ran silently in the background even after we quit AIM and AOL Explorer. (Larkin, 2005)

Likewise, Yahoo’s “typical” installation of their IM also downloads their Search Toolbar, anti-spyware and anti-pop-up software, desktop and system tray shortcuts, as well as Yahoo Extras, which inserts Yahoo links on your browser. It also alters the users’ home page and auto-search functions to point to Yahoo by default. Even Yahoo employee, Jeremy Zawodny dislikes this:

I don’t know which company started using this tactic, but it is becoming the standard procedure for lots of software out there. And it sucks. Leave my settings, preferences and desktop alone. (http://jeremy.zawodny.com/blog/archives/005121.html)

A similar scheme is to use security updates to install new products, for example:

Microsoft used the January 2007 security update to induce users to try Internet Explorer 7.0 whether they wanted to or not. But after discovering they had been involuntarily upgraded to the new browser, they next found that application incompatibility effectively cut them off from the Internet. (Pallatto, 2007)

Security cannot defend against people one invites in, especially if it is the security system taking advantage! However, in a connected and free society, social influence can be very powerful. In physical society the withering looks given to the impolite are not toothless, as what others think of you affects how they behave towards you. In old societies banishment was often considered worse than a death sentence. Likewise, what online users think of a company that creates a software agent can directly impact sales. A reputation for riding roughshod over computer user’s rights is not good for business.

**SPECIFYING SOFTWARE AGENT POLITENESS**

The widespread problem of software that is rude, inconsiderate, or selfish is a general software design “blind spot” (Cooper, 1999). The specification of politeness in information terms is in its infancy, but previous work (Whitworth, 2005) suggests polite software should:

1. **Respect the other’s rights.** Polite software respects the user, does not pre-empt user choices, and does not act on or copy information without its owner’s permission.
2. **Openly declare itself.** Polite software does not sneak or change things in secret, but openly declares what it does, who it represents, and how they can be contacted.
3. **Help the other party.** Polite software helps users make informed choices, giving useful and understandable information when needed.
4. **Remember the interaction.** Polite software remembers past user choices in future interactions.
Respect includes not taking another’s rightful choices. If two parties jointly share a resource, one party’s choices can deny the other’s, for example, if I delete a shared file, you can no longer print it. Polite software should not preempt rightful user information choices regarding common HCI resources like the desktop, registry, hard drive, task bar, file associations, quick launch, and other user configurable settings. Pre-emptive acts, like changing a browser home page without asking, act unilaterally on a mutual resource and so are impolite.

Information choice cases are rarely simple, for example, a purchaser can use the software but not edit, copy, or distribute it. Such rights can be specified as privileges, in terms of specified information actors, methods, and objects (Table 1). To apply politeness in such cases requires a legitimacy baseline, for example, a software provider has no right to unilaterally upgrade a computer the user owns (though the Microsoft Windows Vista End User License Agreement (EULA) seems to imply this). Likewise, users have no right to unilaterally upgrade, as this edits the product source code. In such cases politeness applies, for example, the software suggests an update and the user agrees, or the user requests an update and the software agrees (for the provider). Similarly, while a company that creates a browser owns it, the same logic means users own data they create with the browser, for example, a cookie. Hence, software cookies require user permission, and users should be able to view, edit, or delete “their” cookies.

A respectful assistant does not interrupt unnecessarily, while selfish software, like a spoilt child, repeatedly does, for example, Windows Update advises me when it starts, as it progresses, and when it finishes its update. Its modal window interrupts what I am doing, seizing the cursor, and loses my current typing. Since each time Update only needs me to press OK, this is like being repeatedly interrupted to pat a small child on the head. The lesson of Mr. Clippy, that software serves the user not the other way around, seems still unlearned at Microsoft.

It is hard for selfish software to keep appropriately quiet, for example, Word can generate a table of contents from a document’s headings. However, if one sends the first chapter of a book to someone, with the book’s table of contents (to show its scope), every table of contents heading line without a page number loudly declares: “ERROR! BOOKMARK NOT DEFINED.” This, of

course, completely spoils the sample document impression, and even worse, this is not apparent until the document is received. Why could the software not just quietly put a blank instead of a page number? Why must it announce its needs so rudely? What counts is not what the software needs, but what the user needs.

Open

Part of a polite greeting in most cultures is to introduce oneself and state one’s business. Holding out an open hand, to shake hands, shows that the hand has no weapon and that nothing is hidden. Conversely, to act secretly behind another’s back, to sneak or to hide ones actions, for any reason, is impolite. Secrecy in an interaction is impolite because the other has no choice regarding things they do not know about. Hiding your identity reduces my choices, as hidden parties are un-touchable and unaccountable for their actions. When polite people interact, they declare who they are and what they are doing.

If polite people do this, polite software should do the same. Users should see who is doing what on their computer. However, when Windows Task Manager shows cryptic process like CTSysVol.exe, attributed to the user, it could be system critical process or one left over from a long un-installed product.

An operating system Source Registry could link all online technical processes to their social sources, giving contact and other details. “Source” could be a property of every desktop icon, context menu item, taskbar icon, hard drive file, or any other resource. A user could delete all resources allocated by a given source without concern that they were system critical. Windows messages could also state their source so users know who a message is from. Source data could be optional, making it backward compatible. Applications need not disclose themselves, but users will prefer sources that do. Letting users know the actions of their computer’s inhabitants could help the marketplace create more polite software.

Helpful

A third politeness property is to help the user by offering understandable choices, as a user cannot properly choose from options they do not understand. Offering options that confuse is inconsiderate and impolite, for example, a course text Web site offers the choices:

- OneKey Course Compass
- Content Tour
- Companion Web site
- Help Downloading
- Instructor Resource Centre

It is unclear how the “Course Compass” differs from the “Companion Web site,” and why both seem to exclude “Instructor Resources” and “Help Downloading.” Clicking on these choices, as is typical for such sites, leads only to further confusing menu choices. The impolite assumption is that users enjoy clicking links to see where they go. Yet information overload is a serious problem for Web users, who have no time for hyperlink merry-go-rounds.

Yet to not offer choices at all, on the grounds that users cannot understand them, is also impolite. Installing software can be complex, but so is installing satellite TV technology. In both cases users expect to hear their choices in an understandable way. Complex installations are simplified by choice dependency analysis of how choices are linked, as Linux’s installer does. Letting a user choose to install an application they want minus a critical system component is not a choice but a trap. Application-critical components are part of the higher choice to install or not, for example, a user’s permission to install may imply access to hard drive, registry, and start menu, but not to desktop, system tray, favourites, or file associations.
Remember

Finally, it is not enough to give choices now but forget them later. If previous responses are forgotten, the user must redo them, which is inconsiderate. Hence, software that actually listens and remembers past user choices is a wonderful thing. Polite people remember previous encounters, yet each time I open Explorer it fills its preferred directory with files I do not want to see, then returns the cursor to me to select the directory I want to look at, which is never the one displayed. Each time, Explorer acts as if it were the first time I had used it, yet I am the only person it has ever known. Why can it not remember where I was last time and return me there? The answer is simply that it is impolite by design.

Such “amnesia” is a trademark of impolite software. Any document processing software could automatically open the user’s last document and put the cursor where they left off, or at least give that option (Raskin, 2000). The user logic is simple: “If I close the file I am finished, but if not, put me back where I was last time.” Yet most software cannot even remember what we were doing last time we met. Even within an application, like Outlook’s e-mail, if one moves from inbox to outbox and back, it “forgets” the original inbox message and one must scroll back to it.

If a choice repeats, to ask the same question over and over, for the same reply, is to pester or nag like the “Are we there yet?” of children on a car trip. This forces the other party to again and again give the same choice reply, for example, uploading a batch of files creates a series of overwrite questions, and software that continually asks “Overwrite Y/N?” forces the user to continuously reply “Yes.” Hence, most copy software also offers the “Yes to All” meta-choice that remembers for the choice set. Offering choices about choices (meta-choices) reduces information overload, as users need only set repeated access permissions once, for example:

1. Always accept
2. Always reject
3. Let me choose

A general meta-choice console (GMCC) would give users a common place to see or set all meta-choices (Whitworth, 2005).

IMPLEMENTATION CASES

The Impolite Effect

In HCI interactions, impoliteness can cause a social failure every bit as damaging as a logic failure, for example, the first author’s new 2006 computer came with McAfee Spamkiller, which when activated overwrote my Outlook Express mail server account name and password with its own values. When checking why I could no longer receive mail, I retyped in my mail server account details and fixed the problem. However, next time the system rebooted, McAfee rewrote over my mail account details again. The McAfee help person explained that Spamkiller was protecting me by taking control and routing all my e-mail through itself. To get my mail I had to go into McAfee and tell it my specific e-mail account details. That this did not work is less the issue than why this well known software:

a. Felt entitled to overwrite the e-mail account details a user had typed in
b. Could not copy my account details, which it wrote over, to create its own account

deep this same software also “took charge” whenever Outlook started, forcing me to wait as it did a slow foreground check for e-mail spam. Yet in 2 weeks of use, it never found any spam at all! I (first author) concluded it was selfish software, and uninstalled it.
Politeness as a Social Computing Requirement

Interaction Situations

Other human computer interactions where politeness applies include:

1. **Errors.** Polite error messages say we have an error rather than you have an error. While computers tend to take charge when things go well, when they go wrong, software seems to universally agree that the user is in fact “in charge.” To ask what “we” (rather than you) want to do about an error implies the computer should also suggest solution options. Studies of users in human-computer tutorials show significant differences based on how politely the computer addresses the user, that is, users respond differently to “Click the Enter button” vs. “Let’s click the Enter button” (Mayer, Johnson, Shaw, & Sandhu, 2006).

2. **Advice and Notifications.** To interrupt impolitely disturbs the user’s train of thought. For complex work, like programming, even short interruptions can cause a mental “core dump,” as the user drops one thing to attend to another. The real interruption effect is then not just the interruption time, but also the user recovery time (Jenkins, 2006), for example, if a user takes three minutes to refocus after an interruption, a 1 second interruption every 3 minutes can reduce productivity to zero. Mr. Clippy, Office ‘97’s paper clip assistant, had this problem, since as one user noted: “It wouldn’t go away when you wanted it to. It interrupted rudely and broke your train of thought.” (Pratley, 2004). Searching the Internet for “Mr. Clippy” gives comments like “Die, Clippy, Die!” (Gauze, 2003), yet its Microsoft designer wonders: “If you think the Assistant idea was bad, why exactly?” (Pratley, 2004). To answer simply, he was impolite, and in XP, is replaced by polite smart tags.

3. **Action requests.** Asking permission is polite because it gives the other choice and does not pre-emptively act on a common resource, such as a zip extract product that puts the files it extracted as icons onto the desktop, without asking! Such software tends to be used only once.

4. **Information requests.** If software asks for and gets choices from a user, it should remember them. Polite people do not ask “What is your name?” every time they meet, yet software often has no interaction memory whatsoever, for example, when reviewing e-mail offline in Windows XP, actions like using Explorer trigger a “Do you want to connect?” request every few minutes. No matter how often one says “No!” it keeps asking, because the software has no interaction memory.

5. **Installations.** Installation programs are notorious for pre-emptive acts, for example, the Real-One Player adds desktop icons and browser links, installs itself in the system tray, and can commandeer all video and sound file associations. Customers resent such invasions, which while not illegal, are impolite. An installation program changing your PC settings is like furniture deliverers rearranging your house because they happen to be in it. Software upgrades continue the tradition, for example, Internet Explorer upgrades that make MSN your browser home page without asking. Polite software does not do this.

Online Learning

Online learning software, like WebCT or Blackboard, illustrates how politeness issues vary with channel type. While channel richness (rich vs. lean) was once thought the main property of computer-mediated communication (Daft & Lengel, 1986), channel properties like linkage (one-to-one,
Politeness as a Social Computing Requirement

One-to-few or one-to-many) and interactivity (one-way or two-way) now also seem relevant (Whitworth, Gallupe, & McQueen, 2001). For example, instructor-student online communications, like e-mail, text messaging, chat, podcasts, cell phone, or video-computer interaction are usually one-to-one and two-way. In contrast, instructor-class communications are one-to-many and one-way. The rich-lean dimension is orthogonal to this distinction, for example, an instructor can post lean text assignments, graphical lecture slides, or rich video-lessons. E-mail still plays a major role in online learning, though it remains largely plain text, because it is interactive. Online learning system’s e-mail and chat functions unnecessarily duplicate existing e-mail services, like Hotmail. Having a separate e-mail for each class taken or taught requires students or instructors to check each class e-mail, in addition to their normal e-mail. For online learning systems to create normal e-mail lists would be much more user considerate, as then students would only have to check their normal e-mail.

In 1:1 two-way communications, like e-mail, “the conversation channel” is the shared resource. Yet while physical society recognizes the joint ownership of communication channels and offers everyone the right not to interact (e.g., to remain silent, to not receive junk mail, to not answer the phone, etc.), the core e-mail system gives all senders the right to put any message into any receiver’s inbox. This unfairly gives all rights to the sender and none to the receiver and enables the ongoing spam epidemic that plagues us all.

A more fundamental problem with e-mail in online learning is that one-to-one teacher-student interactions do not scale well (Berners-Lee, 2000). While one can as easily post lessons to a large class as to a small one, handling e-mails for classes over 50 can be difficult. The legitimacy baseline is that students have paid for class tuition, not one-to-one on-demand tuition. Experienced instructors often restrict the use of e-mail to personal requirements, like arranging meetings. They discourage its use for course content, for example, “Sorry I could not make the last class, what did I miss?” is a real student e-mail that I discouraged. Politeness in an interaction works two-ways, so training students to be e-mail polite is a valid learning goal, for example, polite e-mails are:

1. **Signed.** Give your name clearly—e-mails from nicknames like “fly-with-wind” are often unanswered.
2. **Understandable.** Give course/class number in the e-mail title so the instructor knows the context.
3. **Personal.** Use personal e-mail for personal issues, not issues that affect the entire class, for example, an online instructor may paste a “When is the exam?” e-mail into an online discussion board and answer it there, so other students can see the answer.

Class to instructor interactions, like an online assignment submission box, illustrate many-to-one one-way communication. For multi-choice quizzes, the computer can also grade the submissions and give student feedback. This is scalable as the computer can handle any class size, and can remember previous tests, telling the student if he/she is improving or not. However, while online exams do not need politeness, as students must take them, voluntarily online learning is a different matter. The distinction is:

a. **Formal testing quizzes.** Usually begin and end at a fixed time, shuffle questions and options to prevent cheating, and give little content feedback. Being mandatory, politeness applies only minimally.

b. **Informal learning quizzes.** Offer choices like pausing to restart later, optional tips, answer feedback, and choice of difficulty level. Being voluntary, politeness can help involve the student in the learning process.
Politeness as a Social Computing Requirement

If learning means changing one’s own processing, a case can be made that all learning is voluntary. If so, polite interaction may help engage students in voluntarily online learning. The difference between a forced online quiz and an online learning experience may be politeness and respect. Online quizzes can support face-to-face lessons, for example, if students answer online questions on a textbook chapter the week before lecture. This questioning encourages them to actively find information from the textbook, and prepares them for the weekly face-to-face class. Unlike a testing quiz, which is given after the class, and is graded by percentage correct, a “learning participation” quiz occurs before the taught class, and any reasonable participation (e.g., 30+) gets full points. However, the quiz must be done in the week stated, and there are no “resits” for weekly participations. The quiz answers are not released until the week finishes, and students can do or redo the quiz any time in the given week. In practice, those who do poorly in testing quizzes also tend to omit the learning quizzes. However, the good students find them an excellent way to learn.

Most online learning systems seem designed to give information to teachers rather than students, who get learning feedback only with difficulty, for example, Figure 3a shows a “View Scores” button, which when clicked gives Figure 3b, that shows a score. Few students then realize that clicking the underlined “1” gives feedback on the right answers. While online teachers can “see” everything, like when and for how long students are online, students struggle to see what could help them learn in online software.

Figure 3. Getting quiz feedback in WebCT
Class-to-class FAQ boards, where students answer each other’s questions, are many-to-many, two-way interactions that scale well to all class sizes. Respecting and using class member knowledge is not only popular with students but for fast changing subjects, like Web-programming, almost essential. If young people learn mainly from their peers, involving their peers in online learning seems sensible, and polite computing could enable this.

Polite computing suggests voluntary choice is a new online learning dimension. Its application however, requires a complete redesign of current teacher focused systems like WebCT. The online classroom must move from what is essentially a software supported dictatorship to a system that invites voluntary student participation, based on a balance of rights and choices.

FUTURE TRENDS

Polite computing suggests computers will increasingly:

1. Remember interaction data rather than object data.
2. Become human assistants or agents rather than independent actors.
3. Support politeness rather than selfishness in online interaction.

Remember the Interaction

It is astounding that major software manufacturers like Microsoft gather endless data on users, but seem oblivious to data on how their software interacts with the user. Like Peter Sellers in the film “Being There,” such software “likes to watch,” but cannot relate to people. To spy on users at every opportunity is not a user relationship. For example, Mr. Clippy watched your document actions but could not see his interactions with you, and so was oblivious to the rejection and scorn he evoked. Most software today is in the same category, and modern airport toilets seem more aware of their users than the average personal computer. Hopefully tomorrow’s software will make HCI memory its business, as its primary role will be to work for people, not for itself.

Computers as Assistants or Agents

There are several reasons why people should control computers, not the reverse. Firstly, while computers manage vast amounts of data with ease, they handle context changes poorly, and outside their fixed parameters can seem very stupid. So-called “smart” computing (Kurzweil, 1999) usually needs a human “minder.” Secondly, computers are not accountable for what they do, as they have no “self” to bear any loss. If society makes people accountable for what computers do, as it does, people need control over computer choices. Thirdly, the resistance of people to computer domination is predictable. Software designers should not underestimate the importance of user choice. In human history, freedom and choice are the stuff of revolutions, and a grass-roots Internet movement against impolite software is not inconceivable.

Fortunately, the future of computers probably lies not in becoming so clever or powerful that people are obsolete, nor in being passive human tools, but in contributing to a human-computer combination that performs better than either people or computers alone. The runaway IT successes of the last decade (cell-phones, Internet, e-mail, chat, bulletin boards, etc.) all support people rather than supplant them. As computers develop this co-participant role, politeness will be a critical success factor. These arguments suggest that if the role of computers is to assist, they should learn to be polite.
Online Politeness Will Grow

Today, many users feel at war with their software: removing things they did not want added, resetting changes they did not want changed, closing windows they did not want opened, and blocking e-mails they did not want to receive, and so forth. User weapons in this unnecessary war include third party blockers, cleaners, and filters of various sorts, whose main aim is to put users back in charge of their computer estate. Such applications are the most frequent accesses at Internet download sites. Like all wars, if software declares war on user choice, everyone will lose in the long run. If the Internet is a battlefield, no-one will want to go there. Some compare the Internet to the U.S. Wild West, and others talk of the “hunter-gatherers of the information age” (Meyrowitz, 1985). Yet the Stone Age and the U.S. Wild West evolved into civil society, and so perhaps it is time to introduce civility to the Internet. What took physical society thousands of years may occur online in only a few years for example, Wikipedia began with few rules and one leader, but now to combat “trolls” who trash data, has many rules (including copyright) and many roles, like “Steward,” “Bureaucrat,” and “Sysop” (Whitworth, Aldo de Moor, & Liu, 2006). Yet the real force behind Wikipedia is the majority’s enjoyment of working together considerately, not its ability to deal with the anti-social minority.

Many successful online traders find politeness profitable. eBay’s customer reputation feedback gives users optional access to valued information relevant to their purchase choice, which by the previous definition is polite. Amazon gives customers information on the books similar buyers buy, not by pop-up ads but as a view option below. Rather than a demand to buy, it is a polite reminder of same-time purchases that could save the customer postage. Politeness is not about selling but improving the customer relationship that leads to sales. By giving customers choice, polite companies win business because customers given choices come back. Perhaps one reason the Google search engine swept all before it was that its simple white interface, without annoying flashing or pop-up ads, made it pleasant to interact with. Google ads sit quietly at screen right, as options not demands. Yet while many online companies know that politeness pays, for others the lesson is still being learned, and for still others, hit-and-run rudeness is an online way of life.

FUTURE RESEARCH

The users of modern software increasingly choose whether to use it or not, for example, President Bush’s 2001 decision not to use e-mail because he did not trust its privacy. The ability of software to hold users hostage to its power may be declining. Where customers choose their software, a simple prediction is made: Polite software will be used more and deleted or disabled less than impolite software.

An experimental test of polite computing value requires a comparison of polite versus impolite applications on measures like willingness to use, attitude to the software, willingness to purchase, and user satisfaction. Politeness here is defined to apply not just to language, conversations, or people, but also to human-computer interactions. Research can show if computer users really value politeness in HCI interactions like application installations, user help, online learning, e-mail, messaging, and bulletin boards, to mention a few. This politeness is not just the words used, but also the software actions taken. The relative value of the proposed politeness sub-aspects (respect, openness, helpfulness, and remembering) can also be compared. Correlational studies could compare rated application politeness with market success. Longitudinal studies could determine if
successful applications become more polite over time. Ethnographic studies could explore how users perceive polite and impolite software.

The scope of online politeness also bears investigation. The definition implies that young or inexperienced users will tolerate impolite agents like Mr. Clippy more than experienced users. Also, it has been proposed that for interactions mandated by law, or other coerced acts, politeness will apply less. Other individual differences including gender, age, and culture, may also mediate the user reaction to impolite software. Cultural differences in polite computing raise highly complex issues of roles and social structures and may affect the boundary between what is required and what is polite.

CONCLUSION

Polite software asks before it allocates computer resources, openly declares itself and its acts, does not unnecessarily interrupt or draw attention to itself, offers understandable choices, and remembers past interactions. Conversely, impolite software acts without asking, does things secretly, interrupts unnecessarily, offers confusing choices, and has no recall of its past interactions with you.

If polite software attracts users, impolite software can drive them away. This implies a new type of IS error—social error. A program syntax error fails to support the needs of the computer technology. A software usability error fails to support the psychological needs of the computer user. However, a social error means the software fails to support the equally critical needs of human social interaction. While users misunderstand systems designed with poor usability, they understand impolite software all too well, and that is why they walk away from the interaction. Whether a system fails because the computer cannot run it, the user cannot run it, or the user will not run it, makes no difference. The end effect is still that the application does not run. A software social error gives the same outcome as a software crash or user failure. Indeed, social errors may be even worse, as it is in the nature of people to actively seek retribution against those who wrong others in social interactions.

A future is envisaged where software politeness is a critical requirement for socio-technical system success, especially where user willingness to participate counts. Polite computing could be taught in system design classes, along with other system requirements. A “politeness seal” could credit applications that give rather than take user choice. If physical society in general sees the value of politeness, online society should follow that lead. As software becomes not only useful and usable but also polite, the Internet may at last recognize its social potential.

ACKNOWLEDGMENT

Many thanks to Guy Kloss, Massey University, for his very useful comments and insights.

Neo-Symbiosis: The Next Stage in the Evolution of Human Information Interaction

Douglas Griffith

ABSTRACT

The purpose of this article is to re-address the vision of human-computer symbiosis as originally expressed by J.C.R. Licklider nearly a half-century ago and to argue for the relevance of this vision to the field of cognitive informatics. We describe this vision, place it in some historical context relating to the evolution of human factors research, and observe that the field is now in the process of re-invigorating Licklider’s vision. A central concept of this vision is that humans need to be incorporated into computer architectures. We briefly assess the state of the technology within the context of contemporary theory and practice, and we describe what we regard as this emerging field of neo-symbiosis. Examples of neo-symbiosis are provided, but these are nascent examples and the potential of neo-symbiosis is yet to be realized. We offer some initial thoughts on requirements to define functionality of neo-symbiotic systems and discuss research challenges associated with their development and evaluation. Methodologies and metrics for assessing neo-symbiosis are discussed.

BACKGROUND

In 1960, J.C.R. Licklider wrote in his paper “Man-Machine Symbiosis,”

The hope is that in not too many years, human brains and computing machines will be coupled together very tightly, and that the resulting partnership will think as no human brain has ever thought and process data in a way not approached by the information-handling machines we know today (p. 5).
This statement is breathtaking for its vision — especially considering the state of computer technology at that time, that is, large mainframes, punch cards, and batch processing. The purpose of this article is to re-address Licklider’s vision and build upon his ideas to inform contemporary theory and practice within the broader field of human factors as well as to offer a historical perspective for the emerging field of cognitive informatics.

It is curious to note that Licklider did not use the term symbiosis again, but he did introduce more visionary ideas in a symbiotic vein. A paper he co-authored with Robert Taylor, titled “The Computer As a Communication Device,” made the bold assertion, “In a few years, men will be able to communicate more effectively through a machine than face to face” (p. 21). Clearly the time estimate was optimistic, but the vision was noteworthy. Licklider and Taylor described the role of the computer in effective communication by introducing the concept of “On-Line Interactive Vicarious Expediter and Responder” (OLIVER), an acronym that by no coincidence was chosen to honor artificial intelligence researcher and the father of machine perception, Oliver Selfridge. OLIVER would be able to take notes when so directed, and would know what you do, what you read, what you buy and where you buy it. It would know your friends and acquaintances and would know who and what is important to you. This paper made heavy use of the concept of “mental models,” relatively new to the psychology of that day. The computer was conceived of as an active participant rather than as a passive communication device. Remember that when this paper was written, computers were large devices used by specialists. The age of personal computing was off in the future.

Born during World War II, the field of human factors engineering (HFE) gained prominence for its research on the placement of controls — commonly referred to as knobology within the field of HFE, which was an unjust characterization. Many important contributions were made to the design of aircraft, including controls and displays. With strong roots in research on human performance and human errors, the field gained prominence through the work of many leaders in the field who came out of the military: Alphonse Chapanis, a psychologist and a Lieutenant in the U.S. Air Force; Alexander Williams, a psychologist and naval aviator; Air Force Colonel Paul Fitts; and J.C.R. Licklider. Beginning with Chapanis, who realized that “pilot errors” were most often cockpit design errors that could be corrected by the application of human factors to display and controls, these early educators were instrumental in launching the discipline of aviation psychology and HFE that led to worldwide standards in the aviation industry. These men were influential in demonstrating that the military and aviation industry could benefit from research and expertise of the human factors academic community; their works (Fitts, 1951a) were inspirational in guiding research and design in engineering psychology for decades. Among the most influential early articles in the field that came out of this academic discipline was George Miller’s (1956) “The Magical Number Seven, Plus or Minus Two: Some Limits on Our Capacity to Process Information,” which heralded the field of cognitive science and application of quantitative approaches to the study of cognitive activity and performance.

An early focus of HFE was to design systems informed by known human information processing limitations and capabilities — systems that exploit our cognitive strengths and accommodate our weaknesses (inspired by the early ideas represented in the Fitts’ List that compared human and machine capabilities; Fitts, 1951b). While the early HFE practice emphasized improvements in the design of equipment to make up for human limitations (reflecting a tradition of machine centered computing), a new way of thinking about human factors was characterized by the design of the human-machine system, or more generally, human- or user-centered computing (Norman &
Draper, 1986). The new subdiscipline of interaction design emerged in the 1970s and 1980s that emphasizes the need to organize information in ways to help reduce clutter and “information overload” and to help cope with design challenges for next-generation systems that will be increasingly complex while being staffed with fewer people. Emphasis on human cognitive processes, and on the need to regard the human-machine system as a joint cognitive system, represented a further refinement that has been called cognitive systems engineering (Hollnagel & Woods, 1983).

Fundamental to all of these approaches and perspectives on HFE is the overriding principle to “know your user.” In a recent critical essay, Don Norman (2005) asks us to re-assess the human-centered design perspective: Developed to overcome the poor design of software products, human-centered design emphasized the needs and abilities of users and improved the usability and understandability of products. But despite these improvements, software complexity is still with us. Norman goes on to ask why so many designs of everyday things work so well, even without the benefit of user studies and human-centered design. He suggests that they all were “developed with a deep understanding of the activities that were to be performed (p.14).” Successful designs are those that fit gracefully into the requirements of the underlying activity. Norman does not reject human-centered design, but rather encompasses it within a broader perspective of activity-centered design. Further, he questions a basic tenet of human-centered design that technology should adapt to the human, rather than vice versa. He regards much of human behavior as an adaptation to the “powers and limitations of technology.” Activity-centered design aims to exploit this fact.

Other perspectives suggest that the focus of design should be on human-information interaction rather than human-computer interaction. Gershon (1995) coined the term Human-Information Interaction (HII) to focus attention on improving the way people “find, interact with, and understand information.” As such, HII includes aspects of many traditional research efforts, including usability evaluation methods and cognitive task analysis, but also design concepts that address the ethnographic and ecological environment in which action takes place. Examples of work in this area include distributed cognition (Zhang & Norman, 1994), naturalistic and recognition-primed decision making (Zsombok, 1997); and information foraging and information scent (Pirolli & Card, 1999).

In summary, over the last half century or so, the field of human factors has evolved through a series of modest perspective shifts and insights that have yielded a fair degree of success in approaches, methods, and techniques for design and evaluation of systems that are created to support and enhance human-information interaction. The many labels that have been applied to the field (cognitive engineering, human-centered computing, participatory design, decision centered design, etc.) are all “differently hued variants of the same variety” (Hoffman, Feltovich, Ford, Woods, Klein & Feltovich, 2002).

Engineering psychology and human factors are moving to a more encompassing scope of the field. Raja Parasuraman (2003) married neuroscience with ergonomics and termed it neuroergonomics. Don Norman (2004) incorporated affect (emotion) into the field with his book, Emotional Design: Why We Love (or Hate) Everyday Things. Hancock, Pepe and Murphy (2005) are developing the concept of hedonomics. They have developed a hierarchy of ergonomics and hedonic needs derived from Maslow’s (1970) hierarchy of needs: safety, the prevention of pain, forms the foundation of this pyramid; next comes functionality, the promulgation of process; then usability, the priority of preference (the transition from ergonomics to hedonomics begins at the usability layer); the next layer is pleasurable experience; and the apex of the pyramid comprises individuation and personal perfection. So the field is beginning to address the enhancement of individual potential.
Recent research in the emerging field of cognitive informatics (Wang, 2005a, b) addresses Maslow’s hierarchy of needs within a formal model that attempts to capture the relationships among human factors and basic human needs.

Recently a new research thrust has emerged that aims to shift the focus once more to not only enhancing the interaction environment, which is the aim of cognitive systems engineering, but also to enhance the cognitive abilities of the human operators and decision makers themselves. The Augmented Cognition program (Schmorrow & Kruse, 2004) within the DARPA Information Processing Technology Office (IPTO) aims to monitor and assess the user’s cognitive state through behaviorally and neurologically derived measures acquired from the user while interacting with the system and then to adapt or augment the computational interface to improve performance of the user-computer system. Schmorrow and McBride (2005) explain that this research is based on the view that the weak link in the human-computer system may be attributed to human information processing limitations, and that human and computer capabilities are increasingly reliant on each other to achieve maximal performance. Much of the research within the augmented cognition program seeks to further our understanding of how information processing works in the human mind so that augmentation schemes might be developed and exploited more effectively — in a variety of domains from clinical restoration of function to education to worker productivity to warfighting superiority. Thus, as described by Schmorrow and McBride: “the DARPA Augmented Cognition program at its core is an attempt to create a new frontier, not by optimizing the friendliness of connections between human and computer, but by reconceptualizing a true marriage of silicon- and carbon-based enterprises [International of Journal Human Computer Interaction, p. 128].”

While augmented cognition exploits neuroscience research as a path toward symbiosis of humans and machines, research in cognitive informatics embraces neuroscience research as a potential model and point of departure for “brain-like” machine-based cognitive systems that may someday exhibit human-like properties of sensation, perception, and other complex cognitive behaviour (Anderson, 2005a, b). We believe that neo-symbiosis provides a strong contextual framework to organize and guide research in cognitive informatics.

**NEO-SYMBIOSIS**

Once more, then, we are on the threshold of resurrecting a vision of symbiosis — but today we have the advantage of far greater computational resources and decades of evolution in the field of human factors/cognitive engineering. Licklider’s notion of symbiosis does require updating. First, the term “man/machine symbiosis” is politically incorrect and would be more appropriately termed “human/machine symbiosis.” Then there is a problem with the term symbiosis itself. Symbiosis implies co-equality between mutually supportive organisms. However, we contend that the human must be in the superordinate position. The Dreyfuses (Dreyfus, 1972, 1979, 1992; Dreyfus & Dreyfus, 1986) have made compelling arguments that there are fundamental limitations to what computers can accomplish, limitations that will never be overcome (Dreyfus & Dreyfus, 1986). In this case, it is important that the human remain in the superordinate position so that these computer limitations can be circumvented. On the other hand, Kurzweil has argued for the unlimited potential of computers (Kurzweil, 1999). But should it be proven that computers do, indeed, have this unlimited potential, then some attention needs to be paid to Bill Joy and his nightmarish vision of the future should technology go awry (Joy, 2000). In this case, humans would need to be in the superordinate position for their own survival.

Griffith (2005a) has suggested the term neo-symbiosis for this updated vision of symbiosis.
The augmented cognition research community is taking Licklider’s vision quite literally in exploring technologies for acquiring, measuring, and validating neurological cognitive state sensors to facilitate human-information interaction and decision-making. Neurobiologically inspired forms of symbiosis, while consistent with the metaphor that Licklider used, were not a focus of Licklider’s vision; but the possibilities for enhanced cognitive performance are enticing. Clearly, however, much work is required to achieve a brain-computer interface that might be called neo-symbiotic. Much of the effort in this field to date has focused on cognitive activity that tends to be more oriented toward attention and perception processes, and less toward decision making and thinking. In this sense, augmented-cognition neurological inputs can help to approach neo-symbiosis by providing information to the computer that can in turn be fed back to the human in the form of adaptive displays and interactions or other functions aimed to mitigate the effects of stress or information overload. More ambitious goals of increasing total cognitive capacity through augmented cognition technologies are still on the horizon of this research program and recent offshoots of augmented cognition R&D such as DARPA’s Neurotechnology for Intelligence Analysts program. Our interest, similarly, is in the current potential for enhanced human-computer collaboration that will achieve a level of performance that is superior to either the human or the computer acting alone.

The principal reason that the beginning of the 21st century is so propitious for the reinvigoration of Licklider’s vision is the result of advancements in computer technology and psychological theory. Therefore, one of our major objectives is to increase the human’s understanding, accuracy, and effectiveness by supporting the development of creative insights. Understanding involves learning about the problem area and increasing the variety of contexts from which the problem can be understood. Enhanced accuracy/effectiveness can be achieved by endowing the computer with a variety of means to support the task or activity. Revisiting thoughtful prescriptions for such computer-based intelligent support capabilities from two decades ago, we find examples such as knowledge of the user’s goals and intentions, contextual knowledge (Croft, 1984), and “cognitive coupling” (Fitter & Sime, 1980) functions that include (Greitzer, Hershman & Kaiwi, 1985) the ability to inform the user about the status of tasks, remind the user to perform certain tasks, advise the user in selecting alternative actions, monitor progress toward the goal, anticipate requests to display or process information, and test hypotheses. In the context of information analysis tasks, examples of such neo-symbiotic contributions by the computer include considering alternative hypotheses, assessing the accuracy of intelligence sources, and increasing the precision of probability estimates through systematic revision. These types of activity-based support functions, enhanced by cognitive models, are the concepts that we believe will put us more solidly on the path to the original vision of Licklider, a neo-symbiosis where there is a greater focus on cognitive coupling between the human user and the computer.

**NEO-SYMBIOSIS RESEARCH AGENDA**

**Requirements: Implementing Neo-Symbiosis**

How should neo-symbiosis be implemented? Fortunately, Kahneman (2002, 2003) and Kahneman and Frederick (2002) has provided guidance through a theoretical framework. In his effort to organize seemingly contradictory results in studies of judgment under uncertainty, he has advanced the notion of two cognitive systems introduced by Sloman (1996, 2002) and others (Stanovich, 1999; Stanovich & West, 2002). System 1, termed Intuition, is fast, parallel, automatic, effortless,
associative, slow learning, and emotional. System 2, termed Reasoning, is slow, serial, controlled, effortful, rule-governed, flexible, and neutral. The cognitive illusions, which were part of the work for which he won the Nobel Prize, as well as perceptual illusions, are the results of System 1 processing. Expertise is primarily a resident of System 1. So are most of our skilled performance such as recognition, speaking, driving, and many social interactions. System 2, on the other hand, consists of conscious operations, such as what is commonly thought of as thinking. Table 1 summarizes these characteristics and relationships. The upper portion of the table describes human information processing characteristics and strengths, interpreted within Kahneman’s (2003) System 1/System 2 conceptualization. The bottom portion of the table represents an update of traditional characterizations of functional allocation based on human and computer capabilities, such as the original Fitts’ List (Fitts, 1951b), cast within the System 1/System 2 framework.

System 1 is effective presumably due to evolutionary forces, massive experience, and by constraining context. Most of the time, it is quite effective. System 1 uses nonconscious heuristics to achieve these efficiencies, so occasionally it errs and misfires. Such misfires are responsible for perceptual and cognitive errors. One of the roles of System 2 is to monitor the outputs of System 1 processes. It is the System 2 processes that require computer support, not only with respect to the pure drudgery and slowness of human System 2 processes, but also with respect to the monitoring of System 1 processes. In most cases, however, it is a mistake to assign System 1 processes to the computer. This was the fundamental error in many automatic target recognition and image interpretation algorithms that attempted to automate the human out of the loop. Even to this day, computer technology has been unsuccessful in modeling human expertise in System 1 domains. The perceptual recognition processes of most humans are excellent. System design should capitalize upon these superb processes and provide support to other areas of human information processing such as search (there is a tendency to overlook targets); interpretation keys to provide a check and support for the recognition process; analysis and synthesis (e.g., to augment reasoning processes); support to facilitate adjusting to changes in context (e.g., to maintain situational awareness); and computational support (e.g., to make predictions). The bottom portion of Table 1 exhibits examples of how human and computer contributions can be allocated to System 1 and System 2 processing in a neo-symbiotic system.

Greitzer (2005b) has discussed the importance of identifying cognitive states in real-world decision-making tasks. A critical question here is, what are the cognitive states that need to be measured? What are the cognitive states that, if identified and measured, could enhance neo-symbiosis? Clearly it would be beneficial to identify neurological correlates for System 1 and System 2 processes. It would be especially beneficial to identify neurological correlates of System 2 while monitoring System 1 processing. Perhaps there is a neurological signature when potential errors are detected in System 1 processing. It is conceivable that some of these errors remain below the threshold of consciousness. If these errors were detectable in the neurological stream, computers could assist in this error monitoring process.

As was mentioned previously, the identification of neurological correlates is not a requirement, nor is it the only enabler for neo-symbiosis. Griffith (2005b) has argued that neo-symbiosis can be achieved over a wide range of technological sophistication. Overviews and tutorials can be presented on basic human information processing capabilities, limitations, and biases. A software agent, or avatar, can pop up at strategic times with reminding prompts or checklists. Of course, the capability to monitor the human’s cognitive state through neurological correlates will enhance the ability of the avatar to pop up at strategic times. It might also be possible to monitor the content

of the interactions with the computer to identify potential processing problems. Differences in processing time present is yet another potential source of information for detecting errors and biases.

In our view, the thrust of the HII research agenda should be targeted at enhancing neo-symbiosis. A major focus of HII research today is aimed at visualization technology that processes and seeks to represent massive data in ways that facilitate insight and decision making. Data visualization technology seeks to facilitate visual thinking to gain an understanding of complex information, and perhaps most particularly to gain insights that would otherwise not be apparent from other data representations. A famous example of a successful visualization is the periodic table of elements (conceived by Mendeleev and published in 1869), which not only provided a simple display of known data but also pointed out gaps in knowledge that led to discoveries of new elements. However, creating novel visualizations of complex data (information visualization) does not guarantee success; there are arguably more examples of visualizations that have not lived up to expectations than success stories. A leap of faith is required to expect that a given scientific visualization will produce the “aha!” moment that leads to an insightful solution to a difficult problem. We assert that the key to a successful scientific visualization is its effectiveness in fostering new ways of thinking about a problem — in the System 1 sense as exemplified in Table 1 (e.g., seeing contextual shifts, recognizing new patterns, finding creative insights). This view stresses that the interaction component of HII needs to be emphasized. The human should not be regarded as simply a passive recipient of information display, however creative that information display might be. The human needs to be able to manipulate and interact with the information. The ability to manipulate information and view it in different contexts is key to the elimination of cognitive biases and to the achievement of novel insights (e.g., finding the novel intelligence in massive data). The goal is a neo-symbiotic interaction between the human and the information.

Thus, requirements should be defined so that a neo-symbiosis can be achieved between humans and their technology. Questions to guide the requirements definition process for neo-symbiotic systems designed to facilitate HII include:

- **How can such systems be designed to mitigate or eliminate cognitive biases?** Detecting/recognizing possible bias is one part of the challenge; an equally critical R&D goal is to define mitigation strategies. What types of interventions will be effective, and how should interventions be managed? We suggest that a mixed-initiative solution will be required that maintains the supervisory control of the human.

- **How can such systems be designed to leverage the unique processing skills of humans?** A prerequisite here is to identify the unique processing skills of humans. Technologies and approaches for developing idiosyncratic user models would be most useful. Moreover, expert users can identify and contribute their own unique skills: Consider an image interpretation system in which an expert with knowledge of a certain area could correct and elaborate upon outputs of image interpretation algorithms.

- **How can such systems be designed to facilitate collaboration?** One aim is to realize the assertion made by Licklider and Taylor (1968) that people will be able to communicate more effectively through a machine than face to face.

- **How can such systems promote a more pleasurable experience?** The goal here is to address some of the objectives outlined by Hancock et al. (2005).

- **How can such systems help someone to leverage personal potential or overcome a personal deficit (e.g., through augmenta-
Neo-Symbiosis

tive/assistive technology? A major area of interest for neurally-based symbiotic studies is the use of implant technology in which a connection is made between technology and the human brain or nervous system. Important medical applications include restoring lost functionality in individuals due to neurological trauma or a debilitating disease, or for ameliorating symptoms of physical impairment such as blindness or deafness. Other applications that do not address medical needs but instead aim to enhance or augment mental or physical attributes provide a rich area of research in the growing area of augmented cognition. Warwick and Gasson (2005) review the field of research and describe his research and experiences as a researcher and experimental subject who is the first human to have a computer chip inserted into his body that enabled bidirectional information flow and demonstration of control of a remote robot hand using the subjects’ own neural signals (Gasson, Hutt, Goodhew, Kyberd & Warwick, 2002; Warwick & Gasson, 2005). Warwick and Gasson (2005) observe:

By linking the mental functioning of a human and a machine network, a hybrid identity is created. When the human nervous system is connected directly with technology, this not only affects the nature of an individual’s ... identity, ... but also it raises serious questions as to that individual’s autonomy.

It should be appreciated, however, that assistive technology need not necessarily entail implants or any involvement with neurology. Indeed a great deal has already been accomplished via adaptive software and input and output devices (Griffith, 1990; Griffith, Gardner-Bonneau, Edwards, Elkind & Williges, 1989).

What are implications and requirements for computer architectures to achieve neo-symbiosis? A central point underlying neo-symbiosis is that humans need to be included in the computer architecture or system design. It is anathema to the concept of neo-symbiosis that computers and humans be regarded in isolation. They need to be considered together with the objective of each exploiting the other’s potential and compensating for the other’s weaknesses. Ideally the interaction between the two will achieve a multiplicative effect, a true leveraging.

Metrics: Measuring Success

An important question is how to identify neo-symbiotic design and how to assess it. It is important to recognize instances of neo-symbiotic design that are already among us in the form of productivity enhancement tools or job aids. For example, spell checking in contemporary word processors compensate for memory and perceptual/motor shortcomings; thesauruses leverage communicative abilities. Various creativity tools, such as concept mapping, leverage creative potential. In the augmented cognition domain, various neurologically-based “cognitive state sensors” are emerging as indicators of cognitive load and as potential cognitive prosthetics for medical purposes. In each of these cases, particularly the most recent developments that aim to enhance cognitive functions and effectiveness, evaluation methods and metrics are needed to guide research and facilitate deployment of technologies. For more advanced development of neo-symbiotic designs that aim to enhance human information processing and decision making (e.g., intelligence analysis performance) or knowledge/skill acquisition (e.g., training applications), we recognize the need for more rigorous evaluation methods and
metrics that reflect the impact of the technology on performance.

Of course, standard subjective measures can readily be expanded to include neo-symbiotic potential. Many subjective measures are interpreted in terms of usability. There are several sources of established guidelines for usability testing (e.g., Nielsen, 1993). Commonly used criteria include efficiency, ability to learn, and memorability. Usability measures the address of the experience of users; whether or not they found the tool useful, easy to learn, easy to use, and so forth. Often, users are asked to provide this sort of feedback using qualitative measures obtained through verbal (“out loud”) protocols and/or post-hoc comments (via questionnaires, interviews, ratings). Likert scales, in which respondents indicate their degree of agreement or disagreement with particular statements using numerical ratings, can use question stems such as: “Using this application/system enhanced my performance”; or “Using this application/system compensated for my information processing shortcomings.”

Subjective measures such as these are designed to assess the acceptance by users of the system. It is unfortunate that the term subjective is used in a pejorative sense and that subjective measures are all too often regarded as second rate measures. Whether or not a system is perceived favorably and judged to be useful are central questions in evaluating the system’s value. Especially relevant to neo-symbiosis is the user’s assessment of the extent to which his or her potential has been enhanced.

It is possible to use magnitude estimation to assess the subjective amount, or lack of, neo-symbiosis in an application/system. In magnitude estimation (Stevens, 1975), stimuli are evaluated with respect to a standard stimulus, or modulus. That standard stimulus is assigned a value, and other stimuli are evaluated proportionate to it. So if the modulus was assigned a value of 50, and the stimulus being rated was regarded as half of whatever the rating dimension was, it would be rated 25. Were it regarded as having twice the value on the rating dimensions, it would be rated 100. A given version of Microsoft Word™ could be assigned a value of 50. If someone regarded another word processor as being twice as neo-symbiotic as this version of Word, it would be rated 100. Were it regarded to be only half as neo-symbiotic, it would be rated 25. A desirable property of magnitude estimation methods is that they produce ratio scales. Magnitude estimation is a remarkably robust methodology. Its validity has been demonstrated with stimuli ranging from the loudness of tones to the seriousness of crimes. It uses an anchor to a standard that allows proportional assessments of where an issue, item, stimulus stands with respect to that standard. Thus, statements can be made that a product is 20% better than a related product, 40% worse, and so forth. These ratings are more meaningful and interpretable than many other subjective rating techniques.

Whenever feasible, subjective measures should be supplemented with objective measures. Greitzer (2005a) has argued for development of measures of effectiveness based on performance impact in addition to the continued use of traditional subjective usability measures. User satisfaction is a necessary, but not sufficient measure. Behavioral measures are needed to address more cognitive factors and the utility of tools or technologies: Does technology X improve the throughput of cognitive tasks of type Y? Does it yield more efficient or higher quality output for certain types of tasks? Quantitative measures that assess utility may include efficiency in completing the task (time, accuracy, completeness). These will be most useful in comparing the utility of alternative tools or assessing the utility of a given tool vs. baseline performance without the tool. For example, in information analysis tasks, it has been observed (Scholtz, Morse & Hewett, 2004) that analysts tend to spend more time in data collection and report generation than in analysis activity (hence a kind of “bathtub curve” as described by Wilkins
of the work in human factors and ergonomics has been empirical. Only occasionally has the field drawn upon theory. The field of HII has been primarily technology driven. Programs and systems are developed on the bases of intuitions and what is regarded as cool and challenging by the developer, rather than from considerations of the information processing shortcomings and potential of the users. Very often techniques are not even subject to empirical assessment. But a strategy of generating an idea and then evaluating it empirically will not prove successful in the long run. HII requirements need to be developed not only on the basis of what a given system is being designed to accomplish, but also on the basis of theory and data in cognitive science and neuroscience.

To sum up, we have argued that the field of HII is on the threshold of realizing a new vision of symbiosis — one that embraces the concept of mutually supportive systems, but with the human in a leadership position, and that exploits the advances in computational technology and the field of human factors/cognitive engineering to yield a level of human-machine collaboration and communication that was envisioned by Licklider, yet not attained. As we have described, the field of human factors/HII is not static, but rather must inexorably advance. With advances in computer technology, cognitive science, and neuroscience, human potential and fulfillment can be leveraged more, yielding a spiral of progress: As human potential is raised, then that new potential can be leveraged even further. We think this vision provides a useful framework for cognitive informatics.

**ENDNOTES**

1 A research program at DARPA, Neurotechnology for Intelligence Analysts, seeks to identify robust brain signals that may be recorded in an operational environment and that are correlated with imagery data of potential interest to the analyst. Investigations of visual neuroscience mechanisms have indicated that the human brain is capable of responding to visually salient objects significantly faster than an individual’s visuomotor response—i.e., essentially before the human indicates awareness. The program seeks to develop information processing triage methods to increase the speed and
Neo-Symbiosis

As Anderson (2005b) has observed, human expertise in System I domains has been very difficult to model in computers, and many researchers (connectionists, behavior-based roboticists) have used this to argue that digital computer metaphor is flawed.

This work was previously published in the International Journal of Cognitive Informatics and Natural Intelligence, edited by Y. Wang, Volume 1, Issue 1, pp. 39-52, copyright 2007 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).
Emerging pervasive computing scenarios involve client applications that dynamically collect information directly from the local environment. The sophisticated distribution and dynamics involved in these applications place an increased burden on developers that create applications for these environments. The heightened desire for rapid deployment of a wide variety of pervasive computing applications demands a new approach to application development in which domain experts with minimal programming expertise are empowered to rapidly construct and deploy domain-specific applications. This chapter introduces the DAIS (Declarative Applications in Immersive Sensor networks) middleware that abstracts a heterogeneous and dynamic pervasive computing environment into intuitive and accessible programming constructs. At the programming interface level, this requires exposing some aspects of the physical world to the developer, and DAIS accomplishes this through a suite of novel programming abstractions that enable on-demand access to dynamic local data sources. A fundamental component of the model is a hierarchical view of pervasive computing middleware that allows devices with differing capabilities to support differing amounts of functionality. This chapter reports on our design of the DAIS middleware and highlights the abstractions, the programming interface, and the reification of the middleware on a heterogeneous combination of client devices and resource-constrained sensors.
INTRODUCTION

As networked computing capabilities become increasingly ubiquitous, we envision an instrumented environment that can provide varying amounts of information to applications supporting mobile users immersed within the network. While such a scenario relies on low-cost, low-power miniature sensors, it deviates from existing deployments of sensor networks, which are highly application-specific and generally funnel information to a central collection service for a single purpose. Instead, solutions for ubiquitous computing must target future scenarios in which multiple mobile applications leverage networked nodes opportunistically and unpredictably. To date, most application development for ubiquitous computing has been limited to academic circles. One significant barrier to the widespread development of ubiquitous computing applications lies in the increased complexity of the programming task when compared to existing distributed or even mobile situations. Sensor nodes, which provide computational platforms embedded in the environment, are severely resource-constrained, in terms of both computational capabilities and battery power, and therefore, application development must inherently consider low-level design concerns. This complexity, coupled with the increasing demand for ubiquitous applications, highlights the need for programming platforms (i.e., middleware) that simplify application development.

As will be described in more detail in later sections, much existing work in simplifying programming in sensor networks focuses on application-specific networks where the nodes are statically deployed for a particular task. Ubiquitous computing requires a more futuristic (but not unrealistic) scenario in which sensor networks become more general-purpose and reusable. While the networks may remain domain-specific, ubiquitous computing applications that will be deployed are not known \textit{a priori} and may demand varying capabilities from the environment. Finally, existing applications commonly assume that sensor data is collected at a central location to be processed and used in the future and/or accessed via the Internet. Applications for ubiquitous computing, however, involve users immersed in a network environment who access locally sensed information on demand. This is exactly the vision of pervasive computing environments (Weiser, 1991), in which sensor networks must play an integral role (Estrin, Culler, Pister, & Sukhatme, 2002).

While this style of interaction is common in many application domains, we will refer to applications from the first responder domain, which provides a unique and heterogeneous mix of embedded and mobile devices. The former includes fixed sensors in buildings and environments that are present regardless of crises and ad hoc deployments of sensors that responders may distribute when they arrive. Mobile devices include those moving within vehicles, carried by responders, and even autonomous robots that may perform exploration and reconnaissance.

In this chapter, we will first demonstrate that immersive networks built of tiny sensing and actuating devices are an essential component of the vision of ubiquitous computing. We will carefully define what we mean by immersive networks and highlight how the definition differs from traditional uses of such technologies. Because these networks deviate so significantly from existing application environments, constructing tailored, adaptive applications necessary for ubiquitous computing is difficult. We will demonstrate this complexity through a handful of example applications and then provide a detailed survey of existing approaches to simplifying the development of ubiquitous computing applications that rely on immersive sensor networks. Following this survey of existing technologies, we will introduce a new paradigm for programming ubiquitous immersive networks that not only simplifies the programming task, but also improves the performance of
enabling programmable ubiquitous computing environments

the supportive network in terms of battery life, communication overhead, and latency.

the next section describes the operating environment of immersive sensor networks for supporting ubiquitous computing and provides a comparative analysis of existing approaches to simplifying programming for ubiquitous computing. We then introduce a new programming paradigm for immersive sensor networks that combines communication abstractions with high-level programming constructs.

background

in ubiquitous computing applications that rely on immersive sensor networks, users with client devices need to interact directly with devices (or sensors) embedded in their environments. this allows the client applications to operate over information collected directly from the local area (as shown in Figure 1(b)). this is in contrast to existing sensor network deployments in which sensor networks are commonly accessed through a central collection point (as shown in Figure 1(a)). More directly, immersive sensor networks support ubiquitous computing applications, not remote distributed sensing. in this type of environment, we differentiate client devices (those on which ubiquitous computing applications run) from sensors (devices embedded in the environment). the former commonly support users and have increased computational power, while the latter are heavily resource-constrained.

Figure 1. Comparison of (a) existing operational environments and (b) immersive sensor networks for ubiquitous computing

(a) (b)
Supporting Ubiquitous Computing: An Operating Environment

The style of interaction apparent in ubiquitous computing and depicted in Figure 1(b) differs from common uses of sensor networks. First and foremost, applications require direct local interactions with embedded devices present in the immediately accessible environment. Second, the area from which an application desires to draw information is subject to the device user’s movement. These mobility-induced dynamics demand a constant reevaluation of the sensors participating in ongoing interactions. Third, networks must support general classes of applications. Few a priori assumptions can be made about the needs or intentions of applications, requiring a middleware to handle unpredictable coordination. Finally, in immersive sensor networks, the programming complexity is drastically increased due to the above concerns coupled with traditional concerns associated with distributed, embedded computing. In addition, the desire to provide end-user applications (as opposed to more database-oriented data collection) increases the demand for applications and the number of programmers that will need to construct them.

Ubiquitous computing applications from domains such as intelligent construction sites (Hammer et al., 2006), aware homes (Kidd et al., 1999), and pervasive office environments (Voida, Maynatt, & MacIntyre, 2002) involve users immersed in the network who access locally sensed information on demand. Such application scenarios motivate a view of the ubiquitous computing environment that is device-agnostic. That is, applications, in general, do not care about devices embedded in the environment, but instead about information and resources available locally. Logically, the ubiquitous environment appears as a world of embedded information available for immersed applications. To support this view, it is essential to allow developers to distance themselves from explicit knowledge of devices and communication capabilities of the underlying pervasive computing network and instead focus on dynamically changing, locally available information.

Sensor networks for these environments will also need to provide reusability. Current efforts offer solutions that are specific to a particular application (e.g., once the sensor network has been tasked to do habitat monitoring, that is all it is expected to do), but the future will see multipurpose networks deployed to support numerous applications whose natures may not be known at the time the network is deployed. The cost of physically visiting each sensor to program it is prohibitive, and therefore, the ability to remotely and dynamically tailor sensor networks to particular applications will be essential.

The data collection schemes used in existing deployments of sensor networks commonly require sensors to relay raw data to sink nodes to perform further processing. For the sensing devices, communication is much more expensive than local computation; thus, the approaches used in existing deployments lead to short network lifetimes. Furthermore, the throughput at each node decreases as the network scales due to redundant broadcasts, leading to inefficient use of the network bandwidth. To support ubiquitous environments, sensor networks will need to perform complicated tasks and in-network processing to seamlessly transform raw data.

Related Work: Simplifying Programming for Ubiquitous Computing

It is largely recognized that constructing applications for ubiquitous computing environments is a significant undertaking. Several approaches have made strides in simplifying the kind of programming necessary for immersive networks. This section provides a thorough comparative analysis of these approaches.
investigation into these existing techniques, from middleware solutions to toolkits and programming languages.

**Ubiquitous Computing Middleware**

One strong example of a middleware for ubiquitous computing, Gaia (Roman et al., 2002), introduces *active spaces* as a programmable environment, by encapsulating the heterogeneity of devices that are located in them. It abstracts user data and applications into a *user virtual space* that has a dynamic mapping to the resources in the current environment. Users always have their virtual space available, even as they move across different active spaces. Furthermore, they can simultaneously interact with multiple devices, dynamically reconfigure applications, pause and resume applications, and use context attributes to program application behaviors (Roman et al., 2002). However, this model assumes a centralized system structure which is in direct opposition to the goal of deploying large numbers of applications over a widely dispersed immersive sensor networks.

**Blackbox Abstractions**

In contrast, projects targeted directly for sensor networks more directly address the desire to reduce computational and power requirements and to operate in a more distributed fashion. Two demonstrative examples that have explored representing the sensor network as a database are TinyDB (Madden, Franklin, Hellerstein, & Hong, 2005) and Cougar (Yao & Gehrke, 2002). Generally, these approaches enable applications to generate data requests that flow out from a central point (i.e., a base station) and create routing trees that funnel replies back to this root (in a manner similar to that shown in Figure 1(a)). Much of the work in these approaches focuses on performing intelligent in-network aggregation and routing to reduce the overall energy cost while still keeping the semantic value of data high. Each node processes streams of sensor data much like the processing of streams in a database. In both approaches, data aggregation is specified using an SQL-like language over homogeneous data types. Ubiquitous computing applications often require the use of many nearby sensors, ultimately aggregating these disparate pieces of data into a cohesive piece of information for the application or user. Therefore, despite the fact that moving data across the network in approaches such as TinyDB and Cougar still requires centralized algorithms, they have much to offer in support of ubiquitous computing applications in immersive sensor networks. REED (Abadi, Madden, & Lindner, 2005) is an extension to TinyDB that supports joins between sensor data and static tables built outside the sensor network. Users can express queries with complex time- and location-varying predicates over multiple conditions using join predicates over these different attributes. REED organizes nodes into groups and stores a part of the predicate table at each group member, reducing storage costs at remote nodes. This in-network application of *join* can significantly reduce the communication overhead in the network. However, since the group members contain parts of an external table, they are all required to be in radio range of one another.

State-centric programming (Liu, Chu, Liu, Reich, & Zhao, 2003) mediates between an application developer’s model of physical phenomena and the distributed execution of sensor network applications. It uses the notion of collaboration of groups to abstract common patterns in application-specific communication and resource allocation. Furthermore, it takes a signal processing and control theory approach, where dynamically created collaboration groups provide the input to applications written by application developers as algorithms for state update and retrieval. Consequently, the resulting software is more modular.
Enabling Programmable Ubiquitous Computing Environments

and can be ported to different platforms as these programs are less affected by system configuration changes. However, the state-centric programming implementation and evaluation relies on the software environment, PIECES (developed in Java and Matlab), which, unlike most other network simulators, does not simulate network behavior all the way down to the packet level (it only verifies the algorithms at the collaboration group level). While the implementation of collaboration groups needs to be distributed in real-world deployments, collaborations groups are implemented as centralized objects in PIECES. The Abstract Task Graph (ATaG) (Bakshi, Prasanna, Reich, & Larner, 2005) methodology provides system-level support for architecture-independent sensing application development. ATaG uses a combination of imperative and declarative programming styles and has a data-driven program flow. For example, in an environment monitoring application, it allows the periodic computation and logging of the maximum pressure in the system, and the periodic monitoring of temperature. However, it cannot combine these two different types of data to arrive at an abstracted measurement.

Virtual Machines and Code Generation

Other approaches have focused more specifically on the programmability of ubiquitous computing environments. VM* (Koshy & Pandey, 2005) is a virtual machine approach that can scale software components depending on the constraints of each device. This allows application developers to better manipulate unpredictable environments with a wide variety of devices, but has limitations in that the virtual machine must know about the applications in advance to be able to optimize resource usage. TinyGALS (Cheong, Liebman, Liu, & Zhao, 2003) allows programmers to represent applications in terms of relatively high-level components, which are subsequently synthesized into the low-level, lightweight, efficient programs that are deployed on the nodes. This eases the programming task but does not allow arbitrary applications to access the immersive sensor network and immediately start to use it. MiLAN (Heinzelman, Murphy, Carvallo, & Perillo, 2004) aims to enable applications to control the network’s resource usage and allocation optimally to tune the performance of an entire sensor network through the definition of application policies that are enacted on the network. MiLAN tries to maximize network lifetime as well as meet the application’s quality-of-service requirements. While such approaches are highly beneficial when the application is known and the networks are relatively application-specific, they do not map well to immersive sensor networks where the nodes must be able to service a variety of unpredictable applications.

Toolkits and Development Suites

More generalized approaches attempt to provide integrated suites of tools that enable simplified programming of sensor networks. For example, EmStar (Girod et al., 2004) provides a suite of libraries, development tools, and application services that focus on coordinating microservers (e.g., sensing devices with computational power equivalent to a PDA). However, EmStar functions only on Linux-based platforms such as the Stargate. The Sensor Network Application Construction Kit (SNACK) (Greenstein, Kohler, & Estrin, 2004) consists of a set of libraries and a compiler that makes it possible to write very simple application descriptions that specify sophisticated behavior using components written in nesC (the TinyOS programming language that runs on sensor motes). While EmStar and SNACK are programming environments for individual nodes, Agilla (Fok, Roman, & Lu, 2005) is an agent-based middleware that allows applications to inject agents into the sensor network that coordinate through local tuple spaces and migrate intelligently to carry out the applications’ tasks. Multiple autonomous applications
can run simultaneously over the sensor network. However, Agilla does not use any mechanisms for authenticating agent activities.

**Coordination Approaches**

One approach that does map well to the operational picture shown in Figure 1(b) is TinyLIME (Curino et al., 2005), a tuple space based middleware that enables mobile computing devices to interact with sensor data in a manner decoupled in both space and time. Applications create tuple templates to subscribe for data that is of interest to them. The tuple spaces of a pair of devices are temporarily federated whenever the devices are within a single hop of one another. TinyLIME allows client devices to connect to sensors available in the immediate environment, but does not enable multihop communication or aggregation. Another adaptation of the LIME model, TeenyLIME (Costa, Mottola, Murphy, & Picco, 2006), uses the abstraction of a shared tuple space that contains the data of the local device and its one-hop neighbors. Since TinyLIME targets sensor networks where users with mobile devices request data from sensors immediately around them, the applications are deployed on the client devices and the sensing devices are only data producers without any tuple spaces. On the other hand, TeenyLIME applications are deployed directly on the sensing devices that have their own tuple spaces and play an active role in distributed coordination.

**Location-Dependent Approaches**

EnviroTrack (Abdelzaher et al., 2004) is an object-based and data-centric middleware designed specifically for embedded tracking applications. EnviroTrack associates a context-label with each entity. Upon initial detection of the entity, the context-label is dynamically created and logically follows the entity’s movement through the sensor field. Application developers directly interact with the context label instead of a continuously changing collection of nodes that detect the entity, through the help of a directory service based on a geographic hash table. EnviroTrack relies on embedded sensors with precise knowledge of their locations to locate and track mobile objects.

**Macroprogramming Approaches**

Finally, Kairos (Gummadi, Gnamiali, & Govindan, 2005) is a macroprogramming model that allows the specification of the network’s global behavior through a centralized model. As such, it is not adaptive or general-purpose, requiring deployment-time knowledge of the intended application(s). Regiment (Newton & Welsh, 2004) also employs a macroprogramming approach to program sensor networks. A user writes a single program that is then distributed and run across the sensor network. Kairos provides abstractions to facilitate this task, while Regiment focuses on the suitability of functional programming to the sensor network domain.

In summary, while these systems for ubiquitous computing have addressed components of the problems associated with the operating environment described above, other components of the problem definition are not completely satisfied by these existing systems. Overall, the projects focus on specific facets of enabling application development in ubiquitous computing or sensor networks, but none take a holistic approach. We claim that any middleware for simplifying the creation of ubiquitous computing applications must provide constructs tailored to this unique and dynamic environment. These constructs must consider both communication and coordination aspects of tying together embedded devices as well as the application-level operations that are available to instruct these dynamic networks. In the next section, we introduce a new paradigm for immersive sensor networks targeted directly towards the application of such networks to the challenges posed by ubiquitous computing applications and their operating environments.
Enabling Programmable Ubiquitous Computing Environments

A NEW MIDDLEWARE PARADIGM FOR IMMERSIVE NETWORKS

In this section, we introduce a new programming paradigm for immersive sensor networks that combines communication abstractions with high-level programming constructs. We argue that such knowledge about the communication environment by the programmer is essential to mediating performance and efficiency concerns, and our approach minimizes the complexity of knowing about communication using a pair of intuitive grouping abstractions, the scene, and the virtual sensor.

Scenes: Abstractions of Local Data

In an immersive sensor network, a user’s operational context is highly dynamic. As the user moves through the environment, the set of embedded devices he interacts with should change accordingly. Furthermore, if the sensor network is well connected, the client device will be able to reach vast amounts of raw information that must be filtered to be usable. To enable efficient solutions, the application must be able to limit the scope of its interactions to include only the data that matches its needs. Therefore, an application developer must be conscious of the communication tasks required to satisfy his desired application behaviors.

In the middleware paradigm this chapter describes, such specification of the operating context is encapsulated in an abstraction called a scene (Kabadayi & Julien, 2007). Applications define scenes according to their needs, and each scene constrains which particular sensors may influence the application. The constraints may be on properties of hosts (e.g., battery life), of network links (e.g., bandwidth), and of data (e.g., type).

The declarative specification defining a scene allows an application programmer to flexibly describe the type of scene he wants to create. Multiple constraints can be used to define a single scene. The programmer only needs to specify three parameters to define a constraint:

- **Metric:** A property of the network or environment that defines the cost of a connection (i.e., a property of hosts, links, or data)
- **Path cost function:** A function (such as sum, average, minimum, maximum) that operates on a network path to calculate the cost of the path
- **Threshold:** The value a path’s cost must satisfy for that sensor to be a member of the scene.

Thus, a scene, $S$, is specified by one or more constraints, $C_1, C_2, \ldots, C_n$:

$$C_i = \langle M_i, F_i, T_i \rangle, \quad C_2 = \langle M_2, F_2, T_2 \rangle, \ldots, \quad C_n = \langle M_n, F_n, T_n \rangle$$

where $M$ denotes a metric, $F$ denotes a path cost function, and $T$ denotes a threshold.

Figure 2 demonstrates the relationships between these components. This figure is a simplification that shows only a one-constraint scene and a single network path. The cost to a particular node in the path (e.g., node $i$) is calculated by applying the scene’s path cost function to the metric. The metric can combine information about the path so far ($p_i$) and information about this node. Nodes along a path continue to be included in the scene until the path hits a node whose cost (e.g., $c_k$) is greater than the scene’s threshold. This functionality is implemented in a dynamic distributed algorithm that can calculate (and dynamically recalculate) scene membership. The application’s messages carry with them the metric, path cost function, and threshold, which are sufficient for each node to independently determine whether it is a member of the scene. Each node along a network path determines whether it lies within the scene, and if so, forwards the message. It is possible for a node to qualify to be within the scene based on
multiple paths. These network paths correspond to branches of a routing tree that is set up as part of the distributed calculation of the scene. When a certain data source needs to relay a reply back to the user, the reverse of the path on the routing tree the message took to get to that node can be used. If a node receives a scene message that it has already processed, and the new metric value is not shorter, the new message is dropped. If the new message carries a shorter metric, then the node forwards the information again because it may enable new nodes to be included in the scene.

Scene construction can be formalized in the following way:

*Given a client node $\alpha$, a metric $M$, and a positive threshold $T$, find the set of all hosts $S_\alpha$ such that all hosts in $S_\alpha$ are reachable from $\alpha$ and, for all hosts $\beta$ in $S_\alpha$, the cost of applying the metric on some path from $\alpha$ to $\beta$ is less than $T$. Specifically:*

$$S_\alpha = \langle \text{set } \beta : M(\alpha, \beta) < T :: \beta \rangle$$

In the three-part notation: $= \langle \text{op quantified_variables : range :: expression} \rangle$, the variables from quantified_variables take on all possible values permitted by range. Each instantiation of the variables is substituted in expression, producing a multiset of values to which op is applied, yielding the value of the three-part expression. If no instantiation of the variables satisfies range, then the value of the three-part expression is the identity element for op, e.g., *true* if op is $\forall$, or $\emptyset$ if op is set.

The scene concept conveys a notion of locality, and each application decides how “local” its interactions need to be. A first responder team leader coordinating the team spread throughout the site may want to have an aggregate view of the smoke conditions over the entire site. On the other hand, a particular responder may want a scene that contains readings only from nearby sensors or sensors within his path of movement. The scene for the leader would be “all smoke sensors within the site boundaries,” while the scene for the responder might be “all smoke sensors within 5m.” As a responder moves through the site, the scene specification stays the same, but the data sources belonging to the scene may change.

In the ubiquitous computing scenarios we target, embedded nodes can come and go either because new devices are introduced to the environment, existing devices stopped functioning, or devices moved. Although existing systems treat such situations as exceptional conditions, they must be treated as commonplace. For this reason, the scene abstraction is specifically designed to handle such dynamics. Using the distributed
computation detailed above, the scene implementation automatically recalculates and reconstructs an application’s scene in response to such changes. This adjustment occurs automatically and seamlessly using the application’s provided scene specification (which is now imprinted in the sensor network) and does not involve the application or user directly. Instead, the scene (or the set of devices with which the application interacts) automatically adjusts to reflect the application’s changing operational environment.

To maintain the scene for continuous queries, each member sends periodic beacons advertising its current value for the metric. Each node also monitors beacons from its parent in the routing tree, whose identity is provided as previous hop information in the original scene message. If a node has not heard from its parent for three consecutive beacon intervals, it disqualifies itself from the scene. This corresponds to the node falling outside of the span of the scene due to client mobility or other dynamics. In addition, if the client’s motion necessitates a new node to suddenly become a member of the scene, this new node becomes aware of this condition through the beacon it receives from a current scene member.

Table 1 shows examples of how scenes may be specified. These examples include restricting the scene by the maximum number of hops allowed, the minimum allowable battery power on each participating node, or the maximum physical distance. As one example, SCENE_HOP_COUNT effectively assigns a value of one to each network link. Therefore, using the built-in SCENE_SUM path cost function, the application can build a hop count scene that sums the number of hops a message takes and only includes nodes that are within the number of hops as specified by the threshold. The scene can be further restricted using latency as a second constraint.

Intelligent Virtual Sensors

Our middleware paradigm also defines a virtual sensors model (Kabadayi, Pridgen, & Julien, 2006). Virtual sensors provide indirect measurements of abstract conditions (that, by themselves are not physically measurable) by combining sensed data from a group of heterogeneous physical sensors. As an example, the intelligent construction site domain that consists of users with mobile devices distributed over the site and sensors embedded in equipment presents substantial challenges to pervasive computing. For example, users may desire safe load indicators on cranes that determine if a crane is exceeding its capacity. Such a virtual sensor (as shown in Figure 3) would take measurements from physical sensors that monitor boom angle, load, telescoping length, two-block conditions, wind speed, etc. (Neitzel, Seixas, & Ren, 2001). Signals from these individual sensors are used in calculations within the virtual sensor to determine if the crane has exceeded its safe working load. With the virtual sensors model, an application interacts with a combination of physical and virtual devices embedded in the environment.

The physical sensors are the components of the model that provide the physical data types required to compute the desired abstract measurement. Creating a virtual sensor requires defining a group of physical sensors that have some locality relationship (i.e., belong to a local region, where “local” is defined by some property of the network or environment). The resulting virtual sensor has an interface similar to that of a physical sensor (from the application’s perspective).

The virtual sensor hides the explicit data sources from the application, making them appear as one data source that provides the same type of interface as a physical sensor. Our approach to creating a virtual sensor’s declarative specification assumes applications and sensors share knowledge of a naming scheme for the low-level data types the sensor nodes can provide (e.g., “location,” “temperature,” etc.). The types of sensors deployed in a network determine the

Figure 3. An example of a virtual sensor for safe working load
available data types. The programmer, then, only needs to specify the following four parameters for the virtual sensor:

- **Input data types**: Physical (low-level) data types required to compute the desired abstract measurement. Each input data type also includes the number of different sensors (which could be one, two, all, etc.) the virtual sensor would like to obtain this data type from. For example, in deciding if a slab of concrete on a construction site is ready for use, a virtual sensor could combine measurements from concrete heat sensors and strain sensors. The specification of the number of different sensors of a certain type allows us to differentiate between requests for “all of the concrete heat sensors” and “one concrete heat sensor.” The “all” count allows the virtual sensor’s heterogeneous aggregation (over heat and strain sensors) to be combined with homogeneous aggregation (over heat sensors).

- **Aggregator**: A generic function defined to operate over the specific (possibly heterogeneous) input data to calculate the desired measurement.

- **Resulting data type**: The abstract measurement type that is a result of the aggregation.

- **Aggregation frequency**: The frequency with which this aggregation should be made. This frequency determines how consistent the aggregated value is with actual conditions (i.e., more frequently updated aggregations reflect the environment more accurately but generate more communication overhead.). This is similar to the sample frequency of a physical sensor. At each aggregation frequency, the virtual sensor “samples” each physical sensor that it uses and aggregates these results.

By providing these virtual sensor specifications, an application delegates physical sensor discovery to the virtual sensor (and to the framework that supports the virtual sensor). Therefore, if the data sources that support the virtual sensor change over time, the virtual sensor adapts, but the application is not disrupted. This concept of data sources changing over time will be discussed in more detail in the following subsections.

In our model, the input data types carry simply the nature of the physical measure (e.g., “temperature”) provided by a sensor. There could be a data type that is sometimes provided by a physical sensor and is sometimes provided by a virtual sensor (e.g., location provided by GPS (physical sensor) or by triangulation (virtual sensor)). From the application’s perspective, this is only a single data type, and our model uses a data ontology (that may be application domain-specific) to describe these data types. The ontology is basically a simple listing of types. The application programmer can also insert new data types into the ontology to update or augment it over time. Before accessing sensors in the immersive network, the application checks the ontology to determine first if the type can be provided by a physical sensor and, if not, what virtual sensor needs to be deployed to provide the type.

As stated in the introduction, our goal is to support locality of interactions and access to local data. Thus, it is necessary to define the region from which it is allowable to select physical sensors to support a virtual sensor. This allows us to limit the reach of a virtual sensor to some small portion of the network in the immediate vicinity of the client device. When a virtual sensor construction is requested, the necessary scene is created first, and then the virtual sensor is constructed.

After specifying the constraints that build the scene (which consist of a metric definition and a maximum permissible cost for that metric), a client application would like to construct the
virtual sensor using physical sensors from within the scene. That is:

Given the set of hosts \( S_\alpha \) in the scene, the required physical data types \( D_1, D_2, ..., D_n \), the aggregation function \( F \), and the resulting data type, \( D_{\text{res}} \), the virtual sensor can be formalized as:

\[
D_{\text{res}} = F(D_1, D_2, ..., D_n) \text{ where } \langle \forall D_i : 1 \leq i \leq n : (\exists S : |S| = D_i.\text{count} \land (\forall s \in S : s \in S_\alpha \land D_i.\text{type} (\triangleright s)) \rangle
\]

The “\( D_i.\text{type} (\triangleright s) \)” construct denotes the fact that “sensor \( s \) can provide the data type specified in \( D_i.\text{type} \).” In the above definition, the set \( S \) is the subset of \( S_\alpha \) that defines which physical devices contribute to the virtual sensor. If the construct in the last line of the definition evaluates to false, it is not possible to construct the specified virtual sensor.

As stated in the scene definition, the input data types (\( D_1, D_2, ..., D_n \)) are defined by the type of data they request and the number of independent readings of that type that are required. We assume the former is expressed as \( D_i.\text{type} \) and the latter is expressed as \( D_i.\text{count} \). For example, the virtual sensor shown in Figure 3 requires two data types and one sensor of each type: a single crane base position and a single crane boom position. On the other hand, a virtual sensor that generates the average temperature of a curing pad of concrete requires temperature values from \( n \) temperature sensors. In this case, only one \( D \) is provided, and its count value reflects the number of sensors to be polled. As we described previously, the count value included in the declaration of the virtual sensor can be a number (e.g., one as in the case of the crane sensor above) or \( \text{all} \), indicating that all matching sensors in the scene should be polled. In the latter case, the count value for the data type is set to be exactly the cardinality of the scene, \( |S_\alpha| \).

To summarize, the virtual sensor aggregation function \( (F) \) operates on the input data that is of the specified type to yield the specified output data type. This function evaluation takes place at every interval specified by the aggregation frequency.

Dynamic sensor discovery, that is the discovery of the virtual sensor by the application, takes place on the basis of the virtual sensor specification. Virtual sensors provide the same interface to the user as physical sensors. The data type ontology that was mentioned above exists at this interface and defines the data types available to the application. A domain expert can create complex virtual sensors by hand and add their types to the ontology. Most importantly, the application does not have to know that it is discovering a virtual sensor instead of a physical sensor. The developer selects a data type listed in the ontology from a scene. If a physical sensor can provide that data type, no virtual sensor construction is necessary. Otherwise, the virtual sensor is activated and searches for supporting physical sensors in the scene. The ontology provides this mapping so that the application developer using virtual sensors must do nothing more than select the virtual sensor associated with the type in the ontology and request its deployment. This is handled automatically by the middleware at the time an application requests data of a particular type.

If a virtual sensor is being used to obtain periodic responses, it needs to be dynamically refreshed. At every refresh interval specified by the virtual sensor’s aggregation frequency, the virtual sensor gets new measurements from each physical sensor contributing to it and recalculates the virtual measurement. During its lifetime, some sensors contributing to a virtual sensor may deplete their battery power and become nonfunctional. In this case, the virtual sensor attempts to discover a new sensor that can provide the data that sensor was providing; if another such sensor does not exist in the scene, the virtual sensor fails.

Furthermore, while the sensor nodes used in pervasive environments are embedded (hence stationary), the application interacting with them runs on a device carried by a mobile user.
Therefore, the device’s connections to particular sensors and the area from which the application desires to draw information (i.e., the scene) are subject to constant change. These changes need to be seamlessly handled without revealing the underlying dynamics to the user. The dynamics associated with user movement may cause the physical sensors that comprise the virtual sensor to change locations or become unavailable.

Figure 4. The dynamics associated with user movement

Figure 5. Abstract depiction of a virtual sensor that uses n physical nodes: (a) n physical sensors, aggregated into a virtual sensor which runs locally, (b) n physical sensors, aggregated into a virtual sensor which runs remotely
Enabling Programmable Ubiquitous Computing Environments

to change and are handled by the scene abstraction (see Figure 4). Since the physical data sources that can contribute to a virtual sensor are restricted by the scene, any data source that satisfies the data requirements from that scene is a valid data source for the virtual sensor.

To summarize, this dynamic maintenance allows the user to interact directly with a changing set of local information sources. The virtual sensor hides the underlying complexity from the user.

Figure 5 abstractly depicts n physical sensors, aggregated into a virtual sensor which can run (a) locally (on the client) or (b) remotely (in the network). The physical sensors are illustrated using circles, and the different shadings indicate their heterogeneous nature. The sensors inside the large dashed circle contribute to the virtual sensor, but only a few have been shown with arrows representing the data they send back, for ease of presentation. The virtual sensor code can either run locally on the client device or be deployed to a resource-constrained sensor within the network. When deployed remotely, this code will be dynamically received by a listener on the remote sensor and executed. If all of the physical sensors are in a cluster, and that cluster is several hops away from the user’s device, then it may make sense to send the virtual sensor out to the cluster. On the other hand, if each of the sensors that make up the virtual sensor is within one hop of the user, then the virtual sensor should run on the user’s device. With respect to the application interface, it does not matter if the virtual sensor is deployed on the client’s device or remotely in the network, but it might improve performance to use a certain option depending on the application’s situation.

Benefiting from Middleware in Ubiquitous Computing

In this section, we present a complete middleware solution, the DAIS middleware model, which incorporates the scene and virtual sensor abstractions, adheres to the requirements enumerated in the previous section, and provides a cohesive environment for ubiquitous computing application development. Figure 6 shows the DAIS architecture, which consists of a handheld component (running on, for example, a laptop or a PDA) and the immersive sensor environment (defined by a community of sensors). The figure shows DAIS’s explicit hierarchical model which enables more powerful devices (i.e., client devices) to support more of the middleware’s functionality than resource-constrained devices (e.g., physical sensors). As Figure 6 shows, a client application runs with the support of the two key abstractions introduced in the previous sections, namely scenes and virtual sensors. The types of queries possible in DAIS can be classified into one-time queries (which return a single result from each participating sensor) and persistent queries (which return periodic responses from participating sensors). To support these types, we provide two different methods for posing queries to the network. We also include versions of these two methods that request processing of the retrieved data before the result is handed back to the application.

In the remainder of this section, we describe the use of the strategy pattern to perform communication protocol encapsulation, how queries come from the application, and what happens as these queries travel through the middleware depicted in Figure 6. Figure 7 shows a simplified object diagram of the DAIS middleware layers. The names of the layers on the right of the figure correspond to the layers in Figure 6.

Strategy Pattern Interface

As shown in Figure 7, our middleware makes use of the strategy pattern (Gamma, Helm, Johnson, & Vlissides, 1995), a software design pattern in which algorithms (such as strategies for query dissemination) can be chosen at runtime depending on system conditions. The strategy pattern provides a means to define a family of algorithms,
Figure 6. The DAIS high-level architecture. The left-hand side shows the components comprising the model on the component carried by the user (e.g., PDA or laptop), and the right-hand side shows the DAIS components on the sensors.

Figure 7. DAIS object diagram
Encapsulate each one as an object, and make them interchangeable. Such an approach allows the algorithms to vary independently from clients that use them.

In DAIS, the clients that employ the strategies are the queries, and the different strategies are the SceneStrategy algorithms. These algorithms determine how a query is disseminated to the scene and how the QueryResult is returned. If a particular dissemination algorithm other than the default is required for a specific application, an appropriate SceneStrategy algorithm is instantiated.

Two principle directives of object-oriented design are used in the strategy pattern: encapsulate the concept that varies, and program to an interface, not to an implementation. Using the strategy pattern, we decouple the Query from the code that runs it so we can vary the query dissemination algorithm without modifying the Query class. The loose coupling that the strategy pattern enables between the components makes the system easier to maintain, extend, and reuse.

For now, we provide only a single implementation of the strategy, the BasicScene. This is a simple, greedy scheme in which all data aggregation is performed locally. We have chosen this as a first step to provide a quick prototype of the entire middleware. Other communication approaches can be swapped in for the BasicScene (for example, one built around TinyDB (Madden et al., 2005) or directed diffusion (Intanagonwiwat, Govindan, Estrin, Heideman, & Silva, 2003), although the implementations of these approaches on the sensors may have to be modified slightly to accommodate scene construction). By defining the SceneStrategy interface, we enable developers who are experts in existing communication approaches to create simple plug-ins that use different query dissemination and/or aggregation protocols. Different communication paradigms can be used in different environments or to support different application domains depending on the resource constraints or domain-specific capabilities of the devices in a particular domain.

Each SceneStrategy interacts with the javax.comm package to provide the DAIS abstraction protocols that allow the portion of the middleware implemented in Java (described above) to interact with the sensor hardware. Each SceneStrategy requires not only a high-level portion implemented on the handheld device, but also a low-level portion that runs on the sensors. Next, we briefly discuss our BasicScene implementation that runs on the sensor nodes that respond to a client application’s queries. Complete details of this implementation can be found in (Kabadayi & Julien, 2007). This serves as just one example of a particular implementation of the SceneStrategy.

In DAIS, we have developed the sensor components for the Crossbow MICA2 mote platform (Crossbow, 2007). Our initial implementation is written for TinyOS (Hill et al., 2000) in the nesC language (Gay et al., 2003) and helps the BasicScene strategy conform to the SceneStrategy interface.

Building Scenes

In nesC, an application consists of modules wired together via shared interfaces to form configurations. We have created several components that form the fundamental functionality of the Scene configuration. Figure 8 abstractly depicts the necessary components and the interfaces they share.

This implementation functions as a routing component on each node, receiving each incoming message from the radio and processing it as our protocol dictates. In this picture, we show components as rounded rectangles and interfaces as arrows connecting components. A component provides an interface if the corresponding arrow points towards it and uses an interface if the arrow points away from it. If a component provides an
interface, it must implement all of the commands in the interface, and if a component uses an interface, it can call any commands in the interface and must handle all events generated by the interface. In short, the SceneM component uses the messages sent as part of the scene construction protocol to determine whether the local node is contained within the specified scene. If so, the application-level message is propagated to the application layer on the sensor, and the scene construction message is propagated to the neighbors to allow includes of additional nodes.

Determining whether or not it is part of a scene may require the SceneM component to access local context information (through the ContextSources in Figure 8). For example, if a scene is defined based on physical locations, each node must access a location context sensor to determine the node’s physical location.

When a node is part of a scene over which persistent queries have been issued, a Beacon message proactively maintains the connectivity among the scene members. If, in the exchange of these Beacon messages and monitoring the ContextSources that are in use, a node discovers that it no longer qualifies to be a member of the scene (e.g., the scene is based on physical location and the client device has moved), the node removes itself from the scene and ceases this proactive behavior.

Enabling Programmable Ubiquitous Computing Environments

Processing Dynamic Queries:
A Step-By-Step Example

To describe the DAIS model and how it works, we follow a query from the application developer’s hands all the way into the network to a participating sensor and back. To present the steps involved in the process, we use a single, specific application example taken from the intelligent construction site domain. In the example we have selected, the application’s user would like to receive a notification if any crane load reading within 100m exceeds a safe threshold. The user would like this information to be updated every 10 seconds to ensure he has the most current information.

• **Step 1: Create a Virtual Sensor.** As depicted in Figure 3, whether or not a crane load is safe depends on several conditions and is not simply a factor of the weight of a load. In a simple scenario, we assume that the safety of a load depends on the position of the load on the crane arm (e.g., heavier loads should be kept closer to the center of the crane), the tension on the boom (e.g., heavier loads and windier conditions both imply greater tensions, which can increase danger), and the acceleration of the crane (e.g., moving heavier loads quickly is dangerous). An application domain expert (with knowledge about crane safety) can create a virtual sensor that collects these aspects of the crane environment and generates a crane safety value (“safe” or “unsafe”). The following code would define the virtual sensor:

```java
VirtualSensor craneVS = new VirtualSensor({new CraneArmTension(),
    new CraneBoomPosition(),
    new CraneAcceleration()},
    new LoadAggregator(),
    new CraneSafety(),
    1);
```

Within this definition, the first argument to the constructor contains an array of the virtual sensor’s input data types. We omit the count for each type for brevity; in this example, the virtual sensor requires only one data reading of each type. The second argument contains a function definition that dictates how these values should be combined to generate the crane safety type. The third argument specifies the return type of the virtual sensor; in this case, whether or not the crane is safe. The final argument, an integer, gives the desired aggregation frequency for this virtual sensor. In this example, the physical sensors supporting the virtual sensor should send updates of their values every second. The application domain expert must define the code for the `LoadAggregator` and the meaning of the `CraneSafety` type; the other types are assumed to be physical measures that can be provided within the deployed network. The definition of this virtual sensor must also be added to the data ontology so applications needing to query the network can locate its type and automatically deploy it when it is needed. This is accomplished through the following code, which associates the `CraneSafety` type with the `craneVS` virtual sensor definition.

```java
ontology.add({new CraneSafety(), craneVS});
```

This allows applications searching the data ontology to locate the virtual sensor functionality when they request the `CraneSafety` type.

• **Step 2: Declare a Scene.** This is the first step is performed by an application developer when creating and interacting with an immersive sensor network through the programming interface. Nothing happens involving network communication until the application actually uses the scene,
enabling programmable ubiquitous computing environments

Reducing communication overhead. For our application example, the developer uses the following code to invoke the constructor of a Scene object that defines a scene that includes every sensor (not just those measuring crane load safety) within 100m of the declaring device:

```java
Scene s = new Scene(new Constraint(Scene.SCENE_DISTANCE, Scene.SCENE_DFORMULA, new IntegerThreshold(100)));
```

When the application subsequently needs to query the constructed scene, it calls the `getSceneView()` method, which returns a handle to a SceneView. The application can then use this SceneView to send a query over the scene.

- **Step 3: Issue a Query.** This step is performed by the application developer using the SceneView instance created and accessed in the previous step. In our example application, the developer must first create the query:

```java
Query q = new Query(new Constraint("CraneSafety", Query.EQUALS_OPERATOR, "unsafe"));
```

In this case, the Query is defined by a single Constraint that requires returns any crane safety value of “unsafe” within 100m to be returned to the developer. After creating the Query above and a ResultListener r to receive the results (omitted for brevity), the application developer dispatches it using the SceneView:

```java
SceneView sv = s.getSceneView();
int receipt = sv.registerQuery(q, r, 10);
```

where 10 refers to the fact that the application wishes to sense the safety of crane loads every 10 seconds. Upon receiving any query request, the SceneView object adjusts its state in several ways. First, for every query, a table within the SceneView is updated with a mapping from a unique query id generated for the query to the ResultListener handle provided with the query. In addition, for persistent queries, this unique id is returned as a receipt of registration that can be used in subsequent interactions to, for example, deregister the query.

- **Step 4: Initialize Necessary Virtual Sensors.** Before dispatching the query to the scene, the middleware checks the data ontology to determine if the request type (in this case CraneSafety) is a primitive type in this network (i.e., it can be provided by a physical sensor), or if it is a virtual type for which a virtual sensor must be deployed. In the latter case (and in the case of this example), it is at this instant that the middleware creates the virtual sensor in the network. It is possible that multiple virtual sensors could be supported within the scene (e.g., in our scenario, it is possible that there are multiple cranes within 100m). For now, our implementation assumes that only a single virtual sensor is constructed in the scene; the final section of this chapter discusses the potential research necessary in this area in more detail. In our current implementation, the virtual sensor is “deployed” locally (as in Figure 5(a)), and this step connects the remote physical sensors to the local virtual sensor. The virtual sensor is now present within the scene and can be discovered by subsequent queries (from this node or other nodes). It is available to the QueryProcessor as one of the Sensors shown in Figure 9 and described below.
• **Step 3: Create Local Data Proxy.** Control has passed from the application developer to the middleware, which is now responsible for ensuring that the application’s `ResultListener` is called with the appropriate data at the appropriate times. DAIS creates a local proxy dedicated to handling return calls for this query. The local data proxy is especially important in facilitating the translation between the low-level language spoken by the sensors (nesC in our implementation) in the network and the high-level language the application uses (Java).

• **Step 4: Construct and Distribute Protocol Query.** The local data proxy with the DAIS middleware transforms the application’s request into a protocol data unit for the scene implementation in use. As was shown in Figure 7, several different protocols can provide the communication functionality as long as they adhere to the specified strategy pattern interface. The scene implementations must handle both persistent and one-time queries, as dictated by the strategy pattern interface. In our current implementation of the scene protocol (Kabadayi & Julien, 2007), the scene protocol message carries the information about scene membership constraints and the data query at the same time. This reduces the communication overhead by constructing the scene on demand. The details of the communication protocol are omitted here (see the referenced paper); it suffices to say that, by its definition, the protocol ensures that the data query is delivered to exactly the set of sensor nodes that satisfy the scene’s constraints. In our example application, this
Enabling Programmable Ubiquitous Computing Environments

means that every sensor within 100m will receive the data query constructed above. Every sensor receiving this query (i.e., all sensors within 100m) that supports the requested type (i.e., that have a CraneSafety sensor) periodically evaluates the query, but responds only if and when the sensor returns exactly the value unsafe.

- **Step 5: Process Scene Query on Remote Sensor.** We use TinyOS to implement functionality on the sensors; when the communication protocol receives and processes a scene message, if it determines that the node is within the scene, it passes the received message up to the application layer. In DAIS, the QueryProcessor, implemented in TinyOS, defines this application layer. This is essentially a slimmed down version of our middleware that is capable of running on the resource-constrained device. An abstract representation of the TinyOS implementation of the QueryProcessor is shown in Figure 9, which uses the same notational conventions used in Figure 8.

In our implementation, the QueryProcessor component provides the functionality shown at the top layer of the sensor portion of the architecture in Figure 6. The query arrives in the QueryProcessor through the receive event of the Receive interface. If the query is a one-time query (as indicated by a field in the TinyOS message), then the QueryProcessor simply connects to the onboard sensor that can provide the requested data type (depicted as Sensor in the figure). If the data request is for a sensor type that is not supported on this device (i.e., the sensor table stored in the QueryProcessor has no mapping to a sensor that can provide the specified data type), then the message is ignored. This sensor table includes both physical and virtual sensors available at this node. Even if the node ignores the application layer message because it cannot satisfy the data query, the node is still included in the scene because it may be a necessary routing node connecting the requester to another node that does have the required sensor.

If the query is persistent (as in our safe crane load example), then in addition to immediately returning the requested value if the query is satisfied, the QueryProcessorM module also initializes a QueryTimer using the request frequency specified in the data portion of the received message. When the timer fires, QueryProcessorM retrieves a value from the sensor and sends it back to the initial requester using the SendMsg interface of the QueuedSend module.

When a node is no longer in a scene (either because it moved, the client moved, or something happened in between to cause the scene membership requirement to no longer be satisfied), the scene communication implementation creates a null message that it sends to the QueryProcessor through the Receive interface. The QueryProcessor takes this message as a sign to cease streaming data back to the requester and stops the QueryTimer.

- **Step 6: Reply from Query Processor.** If the query processor possessed the correct sensor and the other components of the query are also satisfied (e.g., the constraints on the data value), the query processor replies (and continues to reply periodically to a persistent query). In our specific application scenario, every sensor node in the scene (i.e., within 100m) receives the Query for the CraneSafety type. In this case, only one of the sensors, the one supporting the virtual sensor, can actually provide the type. This QueryProcessor on this sensor monitors the values the virtual sensor generates over time (every 10 seconds) and returns a message to the application if the
CraneSafety value is ever “unsafe.” If the value is “safe,” the node does not reply to the client application. Replies are sent through the SendMsg interface shown in Figure 9 and use basic multihop routing to return to the original requester.

- **Step 7: Distribute Result to Client Device.** After propagating through the underlying communication substrate, query replies will arrive at the client device’s sensor network interface. At the client device, the result is demultiplexed by the Request Processor (shown in Figure 6) and handed off to the appropriate local proxy. Again, the local proxy is automatically generated and managed by the middleware. It translates the low-level query reply into a high-level Result and invokes the application’s registered resultReceived() method. It is important to note that, as shown in Figure 7, multiple queries may be active over a single scene at any given time. For each scene, the SceneView controls all of these queries and connects them to the underlying implementation via the strategy pattern interface. When the result is passed off to the ResultListener, control transfers back to the application which handles the query’s results (or queries’ results if multiple matches existed). For persistent queries, as more results arrive, the same process occurs until the application deregisters the query.

This complete example demonstrates the few steps the application developer must accomplish to be able to leverage the automatic capabilities of the DAIS middleware. By simply interacting with the straightforward APIs the middleware provides, the application developer can define virtual sensors, create scenes over which to interact with a network, and dispatch queries. The persistent query capabilities of the DAIS middleware enable the application to monitor potentially dynamic situations as the user moves through an immersive sensor network. Both the scene and virtual sensor abstractions are capable of automatically adjusting to such changes and making the application’s perspective on the world reflect the instantaneous operating conditions.

By coupling communication constructs (through the scene communication protocol) in addition to programming abstractions (through the virtual sensors and scene programming interfaces), the DAIS middleware exposes significant expressiveness to the application developer while accepting the burden of implementing the complex interactions in the ubiquitous computing network. From the application developer’s perspective, the most complicated portions of interacting with the DAIS middleware lie in properly defining the virtual sensors and creating meaningful queries to issue over scenes. Both of these aspects require significant domain-specific knowledge, and the simple APIs we have designed allow domain experts to easily encode this knowledge which the DAIS middleware can subsequently translate to low-level code to run in the sensor network.

**CONCLUSION**

Given the extreme demands for simplified programming of ubiquitous computing applications, it is obvious that programming environments tailored to this domain are required. In this chapter, we have first argued that immersive sensor networks are essential to the future success of ubiquitous computing. We have then surveyed existing work in the area of providing simplified programming constructs for application developers working in both sensor networks and ubiquitous computing. Finally, the chapter has presented a new paradigm for immersive sensor networks that combines traditional sensor network technologies with the vision of ubiquitous computing.

Because any middleware for immersive environments must operate at least to some degree on resource-constrained devices, it is important to achieve reasonable performance with respect to
battery lifetimes and communication overhead. Our work on the scene protocol (Kabadayi & Julien, 2007) has shown that, by localizing communication to a region surrounding the application in question (as depicted in Figure 1(b)), we greatly reduce the energy and communication impact on other devices in the network. In addition, this approach provides a localized view of the world, which is invaluable to ubiquitous computing applications. A similar performance characterization of the query processing capabilities on the sensor nodes themselves is underway; here we must ensure that responses (especially those indicating anomalous conditions) can be returned to client applications in a timely fashion.

Finally, the example application given in the previous section demonstrates the ease with which application developers can interact with the DAIS middleware constructs. By employing a few straightforward middleware interfaces, applications can easily define regions of interactions that expand and contract in response to context properties of the environment. Applications can also define expressive queries that the middleware dispatches to the network, allowing in-network query resolution, which can reduce communication overhead and latency.

Given the systems available as the current state of the art, we are lacking the ability to quickly and easily design, develop, and deploy expressive applications that allow localized interaction and coordination among users immersed in ubiquitous computing environments and the environments themselves. The DAIS middleware, presented in this chapter, takes a first step towards providing such an environment that focuses on localized interactions that are based on relative notions of locations between devices.

**FUTURE DIRECTIONS**

As our survey of existing research has indicated, there is a significant lack of availability of tools and development environments that enable application development in ubiquitous computing environments. Clearly, significant progress must be made in this area before applications can be rapidly and reliably created for ubiquitous computing environments. Such tools should be motivated directly by the characteristics specific to ubiquitous computing environments as detailed in this chapter, and they must provide support for coordination among users immersed in the environment. Such tools must allow applications to remain highly expressive while embedding much of the complexity within a middleware that eases the development burden.

Evaluation of the results of this research must also come to the forefront. Testing and evaluation of development constructs is inherently difficult; ubiquitous computing environments add extra concerns to the mix. New mechanisms for supporting easy and correct evaluation and testing must be developed that are tailored to the ubiquitous computing environment. Specifically, in addressing the above development environments, we must be able to evaluate the quality of the abstractions with respect to aiding application development.

Finally, in evaluating the coordination requirements for ubiquitous computing environments, an obvious central theme is the ability to group embedded nodes based on relative physical and logical properties. The scene abstraction is one example of this, and it is a natural approach to defining regions of coordination around an immersed application user. We have also used this scene approach to support the virtual sensor abstraction, but it is not as natural in this case. To enable abstractions such as the virtual sensor to accurately reflect an environment, new neighborhood abstractions must be developed that enable sensor nodes to self-organize in response to application queries.

In conclusion, while many positive steps have been made in enabling technologies for immersive sensor network support of ubiquitous computing
Applications, several research aspects remain open and must be addressed before we will see widespread adoption of ubiquitous computing networks and applications.
