- **Roles**: The actors take on roles (e.g., team leader), which may change during the project.

Figure 1. Overview of the flow and main products of the design process
Socio-Cognitive Engineering

- **Stage:** Each box represents one stage of the project.
- **Methods:** Each stage can be carried out by one or more methods of analysis and design, which need to be specified before starting the stage.
- **Tools:** Each method has associated tools (for activity analysis, software specification, systems design, and evaluation) in order to carry out the method.
- **Outcomes:** Each stage has outcomes that must be documented, and these are used to inform and validate the system design.
- **Measures:** Each design decision must be validated by reference to outcomes from one of the stages.

The general sequence for socio-cognitive engineering is as follows:

1. Form a project team.
2. Produce General Requirements for the project.
3. Decide which methods and tools will be used for each stage of the project.
4. Decide how the process and outcomes will be documented.
5. Decide how the project will be evaluated.
6. Carry out each stage of the project, ensuring that the requirements match the design.
7. Carry out a continuous process of documentation and evaluation.

The process starts by specifying the **General Requirements** for the system to be designed. These provide broad yet precise initial requirements and constraints for the proposed system in language that designers and customers can understand. They are used to guide the design and to provide a reference for validation of the system. The requirements normally should indicate:

- The scope of the project;
- The main actors involved in designing, deploying, using, and maintaining the system;
- The market need and business case; and
- General attributes and constraints of the proposed system (i.e., whether it aims to support individual or collaborative working).

The requirements will be extended and made more precise as the project progresses.

This leads to two parallel studies: a theory-based study of the underlying cognitive processes and social activities, and an investigation into how everyday activities are performed in their normal contexts. The **Theory of Use** involves an analysis of relevant literature from cognitive psychology, social sciences, and business management to form a rich picture of the human knowledge and activity. It is essential that this should offer a clear guide to system design. Thus, it must be relevant to the intended use of the system and extend the requirements in a form that can be interpreted by software designers and engineers.

The aim of carrying out **Field Studies** is to uncover how people interact with current technology in their normal contexts. The role of the fieldworker is both to interpret activity and to assist technology design and organizational change. This addresses the widely recognized problem of ethnographic approaches that, while they can provide an understanding of current work practices, are not intended to explore the consequences of socio-technical change.

Table 1 shows a multi-level structure for field studies, with level 1 consisting of a survey of the existing organizational structures and schedules, levels 2 and 3 providing an analysis of situated practices and interactions of those for whom the technology is intended, and level 4 offering a synthesis of the findings in terms of designs for new socio-technical systems. The four levels give an overview of activity, leading to a more detailed investigation of particular problem areas, with each level illuminating the situated practices and also providing a set of issues to be addressed for the next level. These piece together into a composite picture of how people interact with technology.
in their everyday lives, the limitations of existing practices, and ways in which they could be improved by new technology.

The outcomes of these two studies are synthesized into a Task Model. This is a synthesis of theory and practice related to how people perform relevant activities with their existing technologies. It is the least intuitive aspect of socio-cognitive engineering; it is tempting to reduce it to a set of bullet-point issues, yet it provides a foundation for the systems design. It could indicate:

- The main actors and their activity systems;
- How the actors employ tools and resources to mediate their interaction and to externalize cognition;
- How the actors represent knowledge to themselves and to others;
- The methods and techniques that the actors employ, including differences in approach and strategy;
- The contexts in which the activities occur;
- The implicit conventions and constraints that influence the activity; and
- The actors’ conceptions of their work, including sources of difficulty and breakdown in activity and their attitudes toward the introduction of new technology.

The Design Concept needs to be developed in relation to the Task Model. It should indicate how the activities identified by the Task Model could be transformed or enhanced with the new technology. It should:

- Indicate how limitations from the Task Model will be addressed by new technology;

- Outline a system image (Norman, 1986) for the new technology;
- Show the look and feel of the proposed technology;
- Indicate the contexts of use of the enhanced activity and technology; and
- Propose any further requirements that have been produced as a result of constructing the Design Concept.

The Design Concept should result in a set of detailed design requirements and options that can be explored through the design space.

The relationship between the Task Model and Design Concept provides the bridge to a cycle of iterative design that includes:

- Generating a space of possible system designs, systematically exploring design option and justifying design decisions;
- Specifying the functional and non-functional aspects of the system;
- Implementing the system; and
- Deploying and maintaining the system.

Although these stages are based on a conventional process of interactive systems design (see Preece, Rogers, & Sharp [2002] for an overview), they give equal emphasis to cognitive and organizational factors as well as to task and software specifications. The stages shown in Figure 1 are an aid to project planning but are not sufficiently detailed to show all the design activities. Nor does the figure make clear that to construct a successful integrated system requires the designers to integrate software engineering with design for human cognition, social interaction, and organizational management. The “building-block diagram in Table 2 gives a more detailed picture of the system’s design process.

The four “pillars” indicate the main processes of software, task, knowledge, and organizational engineering. Each “brick” in the diagram shows
one outcome of a design stage, but it is not necessary to build systematically from the bottom up. A design team may work on one pillar (e.g., knowledge engineering) up to the stage of system requirements, or it may develop an early prototype based on a detailed task analysis but without a systematic approach to software engineering. How each activity is carried out depends on the particular application domain, actors, and contexts of use.

The design activities are modular, allowing the designer to select one or more methods of conducting the activity according to the problem and domain. For example, the usability evaluation could include an appropriate selection of general methods for assessing usability, or it could include an evaluation designed for the particular domain.

It should be emphasized that the blocks are not fixed entities. As each level of the system is developed and deployed, it will affect the levels that follow (e.g., building a prototype system may lead to revising the documentation or re-evaluating the human-computer interaction; deploying the system will create new activities). These changes need to be analyzed and supported through a combination of new technology and new work practices. Thus, the building blocks must be revisited both individually to analyze and update the technology in use, and through a larger process of iterative redesign.

Although Table 1 shows system evaluation as a distinct phase, there also will be a continual process of testing to verify and validate the design, as shown in Figure 1. Testing is an integral part of the entire design process, and it is important to see it as a lifecycle process (Meek & Sharples, 2001) with the results of testing early designs and prototypes being passed forward to provide an understanding of how to deploy and implement the system, and the outcomes of user trials being fed back to assist in fixing bugs and improving the design choices.

The result of the socio-cognitive engineering process is a new socio-technical system consisting of new technology, its associated documentation, and proposed methods of use. When this is deployed in the workplace, home, or other location, it not only should produce bugs and limitations that need to be addressed but also engender new patterns of work, social, and organizational structures that become contexts for further analysis and design.

FUTURE TRENDS

The computer and communications industries are starting to recognize the importance of adopting a human-centered approach to the design of new socio-technical systems. They are merging their existing engineering, business, industrial design, and marketing methods into an integrated process, underpinned by rigorous techniques to capture requirements, define goals, predict costs, plan activities, specify designs, and evaluate outcomes. IBM, for example, has developed the method of User Engineering to design for the total user experience (IBM, 2004). As Web-based technology becomes embedded into everyday life, it increasingly will be important to understand and design distributed systems for which there are no clear boundaries between people and technology.

CONCLUSION

Socio-cognitive engineering forms part of an historic progression from user-centered design and soft systems analysis toward a comprehensive and rigorous process of socio-technical systems design and evaluation. It has been applied through a broad range of projects for innovative human technology and is still being developed, most recently as part of the European MOBIlearn project.
REFERENCES

KEY TERMS

**Activity System**: The assembly and interaction of people and artefacts considered as a holistic system that performs purposeful activities. See http://www.edu.helsinki.fi/activity/pages/chatanddwr/activitysystem/

**Human-Centred Design**: The process of designing socio-technical systems (people in interaction with technology) based on an analysis of how people think, learn, perceive, work, and interact.

**Socio-Technical System**: A system comprising people and their interactions with technology (e.g., the World Wide Web).

**Soft Systems Methodology**: An approach developed by Peter Checkland to analyze complex problem situations containing social, organizational, and political activities.

**System Image**: A term coined by Don Norman (1986) to describe the guiding metaphor or model of the system that a designer presents to users (e.g., the desktop metaphor or the telephone as a “speaking tube”). The designer should aim to create a system image that is consistent and
familiar (where possible) and enables the user to make productive analogies.

**Task Analysis:** An analysis of the actions and/or knowledge and thinking that a user performs to achieve a task. See [http://www.usabilitynet.org/tools/taskanalysis.htm](http://www.usabilitynet.org/tools/taskanalysis.htm)

**User-Centered Design:** A well-established process of designing technology that meets users’ expectations or that involves potential users in the design process.

**User Engineering:** A phrase used by IBM to describe an integrated process of developing products that satisfy and delight users.
Chapter 2.20
On the Cognitive Processes of Human Perception with Emotions, Motivations, and Attitudes

Yingxu Wang
University of Calgary, Canada

ABSTRACT

An interactive motivation-attitude theory is developed based on the Layered Reference Model of the Brain (LRMB) and the object-attribute-relation (OAR) model. This paper presents a rigorous model of human perceptual processes such as emotions, motivations, and attitudes. A set of mathematical models and formal cognitive processes of perception is developed. Interactions and relationships between motivation and attitude are formally described in real-time process algebra (RTPA). Applications of the mathematical models of motivations and attitudes in software engineering are demonstrated. This work is a part of the formalization of LRMB, which provides a comprehensive model for explaining the fundamental cognitive processes of the brain and their interactions. This work demonstrates that the complicated human emotional and perceptual phenomena can be rigorously modeled and formally treated based on cognitive informatics theories and denotational mathematics.

INTRODUCTION

A variety of life functions and cognitive processes has been identified in cognitive informatics (Wang, 2002a, 2003a, 2003b, 2007b) and cognitive psychology (Payne & Wenger, 1998; Pinel, 1997; Smith, 1993; Westen, 1999; Wilson & Keil, 1999). In order to formally and rigorously describe a comprehensive and coherent set of mental processes and their relationships, an LRMB has been developed (Wang & Wang, 2006; Wang, Wang, Patel, & Patel, 2006) that explains the functional mechanisms and cognitive processes of the brain and the natural intelligence. LRMB encompasses 39 cognitive processes at six layers known as the sensation, memory, perception, action, meta and higher cognitive layers from the bottom up.
Definition 1: Perception is a set of internal sensational cognitive processes of the brain at the subconscious cognitive function layer that detects, relates, interprets, and searches internal cognitive information in the mind.

Perception may be considered as the sixth sense of human beings since almost all cognitive life functions rely on it. Perception is also an important cognitive function at the subconscious layers that determines personality. In other words, personality is a faculty of all subconscious life functions and experience cumulated via conscious life functions. It is recognized that a crucial component of the future generation computers known as the cognitive computers is the perceptual engine that mimic the natural intelligence (Wang, 2006a, 2007c).

The main cognitive processes at the perception layer of LRMB are emotion, motivation, and attitude (Wang et al., 2006). This article presents a formal treatment of the three perceptual processes, their interrelationships, and interactions. It demonstrates that complicated psychological and cognitive mental processes may be formally modeled and rigorously described. Mathematical models of the psychological and cognitive processes of emotions, motivations, and attitudes are developed in the following three sections. Then, interactions and relationships between emotions, motivations, and attitudes are analyzed. Based on the integrated models of the three perception processes, the formal description of the cognitive processes of motivations and attitudes will be presented using RTPA (Wang, 2002b, 2003c, 2006b, 2007a). Applications of the formal models of emotions, motivations, and attitudes will be demonstrated in a case study on maximizing strengths of individual motivations in software engineering.

THE HIERARCHICAL MODEL OF EMOTIONS

Emotions are a set of states or results of perception that interprets the feelings of human beings on external stimuli or events in the binary categories of pleasant or unpleasant.

Definition 2: An emotion is a personal feeling derived from one’s current internal status, mood, circumstances, historical context, and external stimuli.

Emotions are closely related to desires and willingness. A desire is a personal feeling or willingness to possess an object, to conduct an interaction with the external world, or to prepare for an event to happen. A willingness is the faculty of conscious, deliberate, and voluntary choice of actions.

According to the study by Fischer, Shaver, and Carnochan (1990) and Wilson and Keil (1999), the taxonomy of emotions can be described at three levels known as the sub-category, basic, and super levels as shown in Table 1.

It is interesting that human emotions at the perceptual layer may be classified into only two opposite categories: pleasant and unpleasant.

Table 1. Taxonomy of emotions

<table>

</tr>
<tr>
<td></td>
<td>Horror, worry</td>
</tr>
</tbody>
</table>
Various emotions in the two categories can be classified at five levels according to its strengths of subjective feelings as shown in Table 2 (Wang, 2005), where each level encompasses a pair of positive/negative or pleasant/unpleasant emotions.

Definition 3: The strength of emotion $|E_m|$ is a normalized measure of how strong a person’s emotion on a five-level scale identified from 0 through 4, that is:

$$0 \leq |E_m| \leq 4 \quad (1)$$

where $|E_m|$ represents the absolute strength of an emotion regardless whether it is positive (pleasant) or negative (unpleasant), and the scope of $|E_m|$ is corresponding to the definitions of Table 2.

It is observed that an organ known as hypothalamus in the brain is supposed to interpret the properties or types of emotions in terms of pleasant or unpleasant (Payne & Wenger, 1998; Pinel, 1997; Smith, 1993; Wang et al., 2006; Westen, 1999).

Definition 4: Let $T_e$ be a type of emotion, $ES$ the external stimulus, $IS$ the internal perceptual status, and $BL$ the Boolean values true or false. The perceptual mechanism of the hypothalamus can be described as a function, that is:

$$T_e : ES \times IS \rightarrow BL \quad (2)$$

It is interesting that the same event or stimulus $ES$ may be explained in different types, in terms of pleasant or unpleasant, due to the difference of the real-time context of the perceptual status $IS$ of the brain. For instance, walking from home to the office may be interpreted as a pleasant activity for one who likes physical exercise, but the same walk due to car breakdown will be interpreted as unpleasant. This observation and the taxonomy provided in Tables 1 and 2 leads to the following Theorem.

Theorem 1: The human emotional system is a binary system that interprets or perceives an external stimulus and/or internal status as pleasant or unpleasant.

Although there are various emotional categories in different levels, the binary emotional system of the brain provides a set of pairwise universal solutions to express human feelings. For example, angry may be explained as a default solution or generic reaction for an emotional event when there is no better solution available; otherwise, delight will be the default emotional reaction.

THE MATHEMATICAL MODEL OF MOTIVATIONS

Motivation is an innate potential power of human beings that energizes behavior. It is motivation that triggers the transformation from thought (information) into action (energy). In other words, human behaviors are the embodiment of motivations. Therefore, any cognitive behavior is driven by an individual motivation.

Definition 5: A motivation is a willingness or desire triggered by an emotion or external stimulus to pursue a goal or a reason for triggering an action.

As described in LRMB (Wang et al., 2006), motivation is a cognitive process of the brain at the perception layer that explains the initiation, persistence, and intensity of personal emotions and desires, which are the faculty of conscious, deliberate, and voluntary choices of actions.

Motivation is a psychological and social modulating and coordinating influence on the direction, vigor, and composition of behavior. This influence arises from a wide variety of internal, environmental, and social sources, and is manifested at many levels of behavioral and neural organizations.

The taxonomy of motives can be classified into two categories known as learned and unlearned (Wittig, 2001). The latter is the primary motives such as the survival motives (hunger, thirst, breath, shelter, sleep, and eliminating pain). The former are the secondary motives such as the need for achievement, friendship, affiliation, dominance of power, and relief anxiety, which are acquired and extended based on the primary motives.

Definition 6: The strength of motivation $M$ is a normalized measure of how strong a person’s motivation on a scale of 0 through 100, that is:

$$0 \leq M \leq 100$$ (3)

where $M = 100$ is the strongest motivation and $M = 0$ is the weakest motivation.

It is observed that the strength of a motivation is determined by multiple factors (Westen, 1999; Wilson & Keil, 1999) such as:

a. The absolute motivation $|E_m|$: The strength of the emotion.

b. The relative motivation $E - S$: A relative difference or inequity between the expectancy of a person $E$ for an object or an action towards a certain goal and the current status $S$ of the person.

c. The cost to fulfill the motivation $C$: A subjective assessment of the effort needed to accomplish the expected goal.

Therefore, the strength of a motivation can be quantitatively analyzed and estimated by the subjective and objective motivations and their cost as described in the following theorem.

**Theorem 2:** The strength of a motivation $M$ is proportional to both the strength of emotion $|E_m|$ and the difference between the expectancy of desire $E$ and the current status $S$, of a person, and is inversely proportional to the cost to accomplish the expected motivation $C$, that is:

$$M = \frac{2.5 \cdot |E_m| \cdot (E-S)}{C}$$ (4)

where $0 \leq |E_m| \leq 4$, $0 \leq (E,S) \leq 10$, $1 \leq C \leq 10$, and the coefficient 2.5 makes the value of $M$ normalized in the scope of [0 .. 100].

In Theorem 2, the strength of a motivation is measured in the scope $0 \leq M \leq 100$. When $M > 1$, the motivation is considered being a desired motivation, because it indicates both an existing emotion and a positive expectancy. The higher the value of $M$, the stronger the motivation.

According to Theorem 2, in a software engineering context, the rational action of a manager of a group is to encourage individual emotional desire, and the expectancy of each software en-
engineer and to decrease the required effort for the employees by providing additional resources or adopting certain tools.

**Corollary 1:** There are super strong motivations toward a resolute goal by a determined expectancy of a person at any cost.

It is noteworthy that a motivation is only a potential mental power of human beings, and a strong motivation will not necessarily result in a behavior or action. The condition for transforming a motivation into a real behavior or action is dependent on multiple factors, such as values, social norms, expected difficulties, availability of resources, and the existence of alternative goals.

The motivation of a person is constrained by the attitude and decision-making strategies of the person. The former is the internal (subjective) judgment of the feasibility of the motivation, and the latter is the external (social) judgment of the feasibility of the motivation. Attitude and decision-making mechanisms will be analyzed in the following subsections.

### THE MATHEMATICAL MODEL OF ATTITUDES

As described in the previous section, motivation is the potential power that may trigger an observable behavior or action. Before the behavior is performed, it is judged by an internal regulation system known as the attitude.

Psychologists perceive attitude in various ways. Fazio (1986) describes an attitude as an association between an act or object and an evaluation. Eagly and Chaiken (1992) define that an attitude is a tendency of a human to evaluate a person, concept, or group positively or negatively in a given context. More recently, Wittig (2001) describes attitude as a learned evaluative reaction to people, objects, events, and other stimuli. Attitudes may be formally defined as follows.

**Definition 7:** An attitude is a subjective tendency towards a motivation, an object, a goal, or an action based on an intuitive evaluation of its feasibility.

The modes of attitudes can be positive or negative, which can be quantitatively analyzed using the following model.

**Definition 8.** The mode of an attitude $A$ is determined by both an objective judgment of its conformance to the social norm $N$ and a subjective judgment of its empirical feasibility $F$, that is:

$$A = \begin{cases} 1, & N = 1 \land F = 1 \\ 0, & N = 1 \lor F = 1 \end{cases} \quad (5)$$

where $A = 1$ indicates a positive attitude; otherwise, it indicates a negative attitude.

### INTERACTIONS BETWEEN MOTIVATION AND ATTITUDE

This section discusses the relationship between the set of interlinked perceptual psychological processes such as emotions, motivations, attitudes, decisions, and behaviors as formally modeled in the preceding sections. A motivation/attitude-driven behavioral model will be developed for formally describing the cognitive processes of motivations and attitudes.

It is observed that motivation and attitude have considerable impact on behavior and influence the ways a person thinks and feels (Westen, 1999). A reasoned action model is proposed by Fishbein and Ajzen (1975) that suggests human behavior is directly generated by behavioral intensions, which are controlled by the attitude and social norms. An initial motivation before the judgment by an attitude is only a temporal idea; with the
judgment of the attitude, it becomes a rational motivation (Wang et al., 2006), also known as the behavioral intention.

The relationship between an emotion, motivation, attitude, and behavior can be formally and quantitatively described by the Motivation/Attitude-Driven Behavior (MADB) model as illustrated in Figure 1. In the MADB model, motivation and attitude have been defined in Equations 4 and 5. The rational motivation, decision, and behavior can be quantitatively analyzed according to the following definitions. It is noteworthy that, as shown in Figure 1, a motivation is triggered by an emotion or desire.

Definition 9: A rational motivation $M_r$ is a motivation regulated by an attitude $A$ with a positive or negative judgment, that is:

$$M_r = M \cdot A = \frac{2.5 \cdot |\varepsilon_m| \cdot (E-S)}{C} \cdot A$$  \hspace{1cm} (6)

Definition 10: A decision $D$ for confirming an attitude for executing a motivated behavior is a binary choice on the basis of the availability of time $T$, resources $R$, and energy $P$, that is:

$$D = \begin{cases} 1, & T \land R \land P = T \land R \land P = 1 \\ 0, & T \lor R \lor P = T \lor R \lor P = 0 \end{cases}$$  \hspace{1cm} (7)

Definition 11. A behavior $B$ driven by a motivation $M_r$ and an attitude is a realized action initiated by a motivation $M$ and supported by a positive attitude $A$ and a positive decision $D$ toward the action, that is:

$$B = \begin{cases} 1, & M_r \cdot D = \frac{2.5 \cdot |\varepsilon_m| \cdot (E-S)}{C} \cdot A \cdot D > 1 \\ 0, & \text{otherwise} \end{cases}$$  \hspace{1cm} (8)

**FORMAL DESCRIPTION OF COGNITIVE PROCESSES OF MOTIVATION AND ATTITUDE**

The formal models of emotion, motivation, and attitude have been developed in previous sections. This section extends the models and their relationship into detailed cognitive processes based on the OAR model (Wang, 2007d) and using RTPA (Wang, 2002b, 2003c, 2006b, 2007a), which enable more rigorous treatment and computer simulations of the MADB model.
The Cognitive Process of Motivations

The mathematical model of rational motivation is described in Equation 6. Based on Equation 6, the cognitive process of motivation is presented in Figure 2. The motivation process is divided into four major sub-processes known as: (1) to form motivation goal; (2) to estimate strength of motivation; (3) to form rational motivation; and (4) to stimulate behavior for the motivation.

The MADB model provides a formal explanation of the mechanism and relationship between motivation, attitude, and behavior. The model can be used to describe how the motivation process drives human behaviors and actions, and how the attitude as well as the decision-making process help to regulate the motivation and determines whether the motivation should be implemented.

The Cognitive Process of Attitudes

The mathematical model of attitude has been described in Equation 5. Based on Equation 5, the cognitive process of attitude is presented in Figure 3. The attitude process is divided into three major sub-processes known as: (1) to check the mode of attitude; (2) to determine physical availability; and (3) to stimulate behavior for the motivation.

The Integrated Process of Motivation and Attitudes

According to the MADB model and the formal description of the motivation and attitude processes as shown in Figures 1 through 3, the cognitive processes of motivation and attitude are interleaved. An integrated process that combines both motivation and attitude is given in Figure 4 via the following sub-processes: (1) to form motivation goals; (2) to estimate strength of motivation; (3) to check the mode of attitude; (4) to form rational motivation; (5) to determine physical availability; and (6) to stimulate behavior for the rational motivation.

MAXIMIZING STRENGTHS OF INDIVIDUAL MOTIVATIONS

Studies in sociopsychology provide a rich theoretical basis for perceiving new insights into the organization of software engineering. It is noteworthy that in a software organization, according to Theorem 2, the strength of a motivation of individuals $M$ is proportional to both the strength of emotion and the difference between the expectancy and the current status of a person. At the same time, it is inversely proportional to the cost to accomplish the expected motivation $C$.

The job of management at different levels of an organization tree is to encourage and improve $E_m$ and $E$, and to help employees to reduce $C$.

**Example 1:** In software engineering project organization, the manager and programmers may be motivated to the improvement of software quality to a different extent. Assume the following factors as shown in Table 3 are collected from a project on the strengths of motivations to improve the quality of a software system, analyze how the factors influence the strengths of motivations of the manager and the programmers.

According to Theorem 2, the strengths of motivations of the manager $M_1$ and the programmers $M_2$ can be estimated using Equation 4, respectively:

$$M_{1}(\text{manager}) = \frac{2.5 \cdot | E_m | \cdot (E-S)}{C}$$

$C = 2.5 \cdot 4 \cdot (8 - 5)$

$= 10.0$

and

$$M_{2}(\text{programmer}) = \frac{2.5 \cdot 3.6 \cdot (8 - 6)}{8}$$

$= 2.3$
### The Motivation Process

\[ \Rightarrow \text{Memorization} (\text{OAR ST}) \]

---

**Figure 4. The integrated process of motivation and attitude**
The results show that the manager has much stronger motivation to improve the quality of the software system than that of the programmers in the given project. Therefore, the rational action for the manager is to encourage the expectancy of the programmers or to decrease the required effort for the programmers by providing additional resources or adopting certain tools.

According to sociopsychology (Wiggins, Eiggins, & Zanden, 1994), social environment, such as culture, ethical norms, and attitude greatly influences people's motivation, behavior, productivity, and quality towards collaborative work. The chain of individual motivation in a software organization can be illustrated as shown in Figure 5.

Cultures and values of a software development organization helps to establish a set of ethical principles or standards shared by individuals of the organization for judging and normalizing social behaviors. The identification of a larger set of values and organizational policy towards social relations may be helpful to normalize individual and collective behaviors in a software development organization that produces information products for a global market.

Another condition for supporting creative work of individuals in a software development organization is to encourage diversity in both ways of thinking and work allocation. It is observed in social ecology that a great diversity of species and a complex and intricate pattern of interactions among the populations of a community may confer greater stability on an ecosystem.

**Definition 12:** Diversity refers to the social and technical differences of people in working organizations.

Diversity includes a wide range of differences between people such as those of race, ethnicity, age, gender, disability, skills, educations, experience, values, native language, and culture.

**Theorem 3:** The diversity principle states that the more diversity of the workforce in an organization, the higher the opportunity to form new relations and connections that leads to the gain of the system fusion effect.

Theorem 3 is particularly useful for software development organizations where creative work products are engineered. System theory indicates that if the number of components of a system reaches a certain level—the critical mass—then the functionality of the system may be dramatically increased (Wang, 2007a). That is, the increase of diversity in a system is the condition to realize the system fusion effect, which results in a more powerful system with newly created relations and behaviors that only belong to the system as a whole.
CONCLUSION

This article has described the perceptual processes of emotions, motivations, and attitudes based on which complicated psychological and mental processes may be formally modeled and rigorously explained. Relationships and interactions between motivation and attitude have been formally described in RTPA. It has been recognized that the human emotional system is a binary system that interprets or perceives an external stimulus and/or internal status as in the categories of pleasant or unpleasant. It has revealed that the strength of a motivation is proportional to both the strength of the emotion and the difference between the expectancy of desire and the current status of a person and is inversely proportional to the cost to accomplish the expected motivation. Case studies on applications of the interactive motivation-attitude theory and cognitive processes of motivations and attitudes in software engineering have been presented.

This work has demonstrated that the complicated human emotional and perceptual phenomena, as well as their natural drives and constraints, can be rigorously modeled in denotational mathematics and be formally treated and described. This work has been based on two fundamental cognitive informatics models: the LRMB and the OAR model. The former has provided a blueprint to exploring the natural intelligence and its mechanisms. The latter has established a contextual foundation to reveal the logical representation of information, knowledge, and skills in the perceptual space of the brain.

Chapter 2.21
Sociotechnical System Design for Learning: Bridging the Digital Divide with CompILE

Benjamin E. Erlandson
Arizona State University, USA

ABSTRACT

CompILE is a sociotechnical “comprehensive interactive learning environment” system for personal knowledge management and visualization that represents the growing collective knowledge an individual gathers throughout his or her lifespan. A network of intelligent agents connects the user and his or her inhabited knowledge space to external information sources and a multitude of fellow users. Following a brief perspective on educational technology, concepts of human-computer interaction, and a description of CompILE, this chapter will introduce CompILE as a sociotechnical system supported by an enriched design process. From an educational perspective, CompILE can bridge the digital divide by creating community, embracing culture, and promoting a learning society.

INTRODUCTION

This chapter begins with a brief perspective on educational technology, concepts of human-computer interaction, and a description of the Comprehensive Interactive Learning Environment (CompILE) as a knowledge management system controlled using a network of intelligent software agents. Strategies for bridging the digital divide using CompILE will be presented using the four-part framework of the “Wheel of Policy Instruments” constructed by van Dijk (2005).

The effect of CompILE on society will be approached from the standpoint of lifelong learning and usability engineering. CompILE will create a sense of community via participatory research, scenario-based design, and heuristic evaluation. In terms of culture, CompILE will rely heavily
upon ethnography to refine its ability to facilitate cross-cultural communication, and a distinct effort to achieve functional beauty as an interactive system should help its participants achieve a higher level of appreciation for the aesthetics of “culture” from a philosophical perspective. Globalization can be addressed by CompILE in terms of ubiquitous computing, the mobile user, visual literacy, and just-in-time translation. The chapter will conclude with a description of CompILE as a hybrid entity, and the essence of CompILE as a sociotechnical system.

This chapter has two specific objectives:

• Introducing CompILE as a sociotechnical system supported by an enriched design process
• Using CompILE to bridge the digital divide by creating community, embracing culture, and promoting a learning society.

BACKGROUND

One trait of humans that makes us advanced social creatures is our ability to create artificial devices or artifacts that expand our capabilities (Norman, 1993). Throughout history, many of these artifacts have been perceived as the final piece to the ultimate puzzle of technological advancement; the last thing humans would create to meet all their future needs. The automobile, the airplane, the telephone, the television, the microwave, the Internet; the list goes on. While no single invention can actually be that final puzzle piece, major technological advancements cannot be denied as a driving force of society. Norman (1993) agrees, noting the essential nature of technology for growth of human knowledge and mental capabilities.

An important consideration to be made when designing any new interface is the anticipated impact it will have on human activity. In fact, most significant consequences of design are based on impact to human activity. In an effort to reduce occurrence of these consequences, the design process should include a well-managed team of participants with a variety of knowledge and skills, willing to completely deconstruct any particular problem that may arise (Carroll, 1991). Why are these consequences so important? These consequences have the power to make technology completely redundant, existing merely for entertainment.

This breakpoint of redundancy is paramount in education, which, upon clarification, is essentially a purposed form of communication between one or more individuals, intended to facilitate learning and knowledge construction. Using a learning-centric approach, the application of technology to the processes of teaching and learning can be seen as an amplification of the channels of communication. There is no point in seeking to improve the educational communication process with technology if all efforts result in glamorous toys with no effect beyond distraction. Computers cannot be placed in schools for an administration to show that it is on the forefront with cutting-edge educational technology. Technology must be carefully integrated with curricula to be used as tools, or artifacts, fundamental to the learning process.

This concept extends beyond the classroom geographically and temporally. Students using the technology must be wholly engaged in the content of the curriculum, using the technology as a mechanism of that engagement. Kling (2000) reinforces this notion of engagement when describing such an application of technology as the development of a “sociotechnical system,” or an information technology system that cannot separate its existence from the social context of its users. Once this point of engagement is reached, the technology available today and tomorrow can create amazing opportunities for experience and growth within and beyond the classroom. To reach this point, a sociotechnical system must be designed and developed, with an eye toward
the inseparable bond between human, machine, and use.

**HUMAN-COMPUTER INTERACTION**

There are four main sources of knowledge underlying information systems design: (1) systematic empirical evidence of user-interface relations, (2) models and theories of human cognition and artificial systems, (3) field studies of how humans cope with tasks in real-world settings, and (4) specific work domain knowledge derived from textbooks, interviews with experts, and analytical methods such as task analysis (Rasmussen, Anderson, & Bernsen, 1991). The diversity of these sources underscores the interdisciplinary nature of the studies and practices involved with human-computer interaction (HCI), including but not limited to the natural sciences, engineering, the social sciences, and humanities.

One might assume that the foundations of HCI are purely objective, due to the binary nature of information systems. Computers are objective machines based on logic, but humans are interacting with them; this completely unbalances the equation. HCI research and development must take into account human knowledge, decision-making and planning, current mental representations of the user based on causal and intentional relationships, and the fact that interactive behavior is influenced by the environment in which it takes place (Beehtel, 1997; Gifford, 1997; Sommer, 1969).

It is increasingly inadequate for system designers to consider the modules of the information system in isolation from each other (Rasmussen et al, 1991). Increasingly numerous applications working in seamless integration on the same computer (and across networks) becomes more feasible with each new cycle in computer processing technology. Modules can no longer be designed around the requirements of a narrow group of users (Rasmussen et al, 1991). As greater numbers of users become cognizant of the true potential of personal computing, the “narrow” user groups formerly associated with modules and applications in information systems are expanding rapidly. The expansion presents an enormous challenge to designers; accounting for so much more variety when building interfaces for their products. Accounting for variety involves the careful specification of user communities in tandem with a thorough identification of tasks. With novice users, the most success with this dual process can be found through reliance on several measurable criteria: time taken to learn specific functions, speed of task performance, rate of human error, subjective user satisfaction, and human retention of functions over time (Shneiderman, 1993).

The less time users must spend learning a system, the more time they can spend being productive. In man-made environments (interfaces), there are two phases of activity: adaptation and adapted. During adaptation, a user’s activity is being guided by exploratory behavior. Once adapted, a user’s behavioral patterns have reached a state of equilibrium, or a *satisfactory state of transparency* between user input and system output (Rasmussen et al., 1991). The characteristics of any particular workplace and the type of work being done determine the priority of the two phases.

**COMPREHENSIVE INTERACTIVE LEARNING ENVIRONMENTS**

The “workplace” of most interest to those designing interfaces for educational technology would be the transitioning traditional classroom, which can be propelled beyond the 21st century with CompIILE. CompIILE relies heavily upon provision of access to information to all students at all stages of the educational process, as well as continual facilitation of mediated communication between humans and machines. This is accom-
plished through a network of intelligent agents whose existence is focused entirely upon two processes: (1) facilitation of learning for the user and (2) constantly learning about the user. These two processes are inseparable, as an integral part of the agents' facilitation of learning processes for each user is learning the “quirks” of each user’s processes in situations of learning (both formal and informal). To create a personal knowledge management system, agents must know the personality of the user almost better than the user knows himself or herself.

As a system for personal knowledge management and visualization, CompILE can be considered an inhabited information space, or IIS (Snowdon, Churchill, & Frécon, 2004), that represents the growing collective knowledge an individual gathers throughout his or her lifespan. To be more specific, CompILE connects the user and his or her inhabited knowledge space (IKS). This IKS can be navigated individually by the user or collaboratively with additional individuals. Any number of interfaces could be used to access this IKS. Most of these interfaces would function as intermediaries between the internal knowledge architecture, external information sources, the user(s), and associated intelligent agents.

These agents can permanently link education and technology into a symbiotic relationship. Agents have become fairly reliable forms of autonomous software, intertwined more actively with the social lives of humans than any technology ever before, playing “an increasingly critical role in the organization, in particular the self-organization, of social life” (Brown & Duguid, 2000). Education is a highly socialized activity, with constant interaction between people a fundamental part of learning. A positive attribute of software agents is their ability to deal with the increasingly intimidating amounts of information that people are forced to deal with on a daily basis (Brown & Duguid, 2000). This ability would enable agents to assist students with keeping track of much larger amounts of information.

Agents that exist today (mainly for consumer purposes) can be broken down into three categories: information brokering, product brokering, and merchant brokering. Information brokers are agents that gather information from a wide variety of resources, and perform operations with the gathered information. Product broker agents are designed to track their owner’s history (usually shopping habits) and alert that person to the availability of particular products in various venues. Agents that perform merchant brokering are essentially price comparison agents, trying to find the best possible “buy” for their owner. No successful negotiation agents (a fourth category) have ever been created (Brown & Duguid, 2000). Humans negotiate through nonverbal behavior in order to accommodate themselves to one another; constructing and adjusting the social fabric, but software agents have yet to be built with this capacity.

Information brokering agents would have the most direct crossover into education, being resourceful for students, teachers, and administrators; taking the form of research agents. Product brokering agents would translate to learning agents, tracking learning styles and suggesting individual supplements and alternative approaches to the basic curriculum for each student. Merchant brokering agents would not necessarily be feasible in an educational environment on a regular basis, but a similar concept can be realized in terms of brokering a user’s time. Time management agents can assist the user by calculating approximate durations for activities, with a focus on multitasking and efficiency. Negotiation agents are an integral part of the CompILE system, facilitating intercommunication amongst all types of participants, with the agents dutifully negotiating with each other on the users’ behaviors as the users themselves go about their daily routines. As a networked system of these four types of agents, CompILE could prove to be a vital instrument to help our society bridge the “digital divide.”
THE DIGITAL DIVIDE: WHEEL OF POLICY INSTRUMENTS

Van Dijk (2005) addresses the “digital divide” with a four-part strategy called the “Wheel of Policy Instruments,” which denotes four perspectives for access to information and communication technology (ICT): motivational, material, skills, and usage. Motivational access features increasing surplus values and user-friendliness of ICTs, organizing user trust by regulation, promoting useful applications of ICTs, and providing specific services for underserved groups. In terms of surplus value and user-friendliness, every use of CompILE must be beneficial for the user, with little or no margin for “user errors” that do nothing but frustrate the user, decreasing user confidence in the reliability of the CompILE system. Additionally, certain agents can focus upon the “add-on value” of a user’s current actions within CompILE, giving suggestions for efficiency that the user may or may not have noticed; thus, increasing the surplus value of the system.

Regulation and promotion of ICTs can be seen as a symbiotic relationship. Government and corporate institutions can work together to promote useful applications of CompILE by upholding regulations in an open, trustworthy manner that promotes the benefits of CompILE (and other applications and services) to the user. A democratic, user-centric approach to legislation of regulations can serve as a valuable promotional tool as well. CompILE can help eliminate “underserved groups” using special agents designed to find information and services specifically targeted to the individual demographics of the agents’ owner/user, such as cultural groups, gender- and age-specific information, or sociopolitical, health, and spiritual or secular information.

Material access features universal service, access to basic provisions, promotion of broadband access, support of competition, interconnectivity amongst media, conditional subsidies to lagging groups, and creation of public access points. As insinuated, much of materials access improvement involves government and corporate institutions cooperating to provide equal access to ICT services for all citizens. A good start would be the deprivatization of broadband Internet access into a public utility, much like public water and sewer service or electricity co-ops. Furthermore, public access points for broadband Internet connectivity (both wired and wireless) would be a fundamental element for the complete operation of CompILE. A combination of passive RFID tags and agents would allow for user identity and seamless integration from one access point to another, with just-in-time delivery of information to the user. This should all be available free of charge as part of a public broadband infrastructure.

Skills access features connecting all schools, libraries, hospitals, and cultural centers, adapting curricula for operational, instrumental, and strategic skills, creating better educational software and better digital teaching skills, teaching both basic and advanced skills to everyone, extending adult education to learning digital skills, and an emphasis upon distance education at home and in local classes or meetings. Adaptation of curricula for operational, instrumental, and strategic ICT skills would help users “meet” advancing technology at a “middle ground” of usability and user-friendliness. This should also lead to an increased knowledge base and skill sets for those who will be maintaining and supporting the CompILE system on a regular basis.

CompILE can reduce the need for purposed standalone educational software applications by providing such a dynamic, comprehensive digital teaching and learning environment. Additionally, CompILE can improve digital teaching skills with the assistance of special agents for preservice teachers while they are still in training. These agents can be carried over with these teachers into the in-service environment for professional development to expand technological skills and knowledge.
As opposed to a somewhat narrowed emphasis on “distance education” at home and in local classes, an emphasis should be made on a broader inclusion of self-paced, asynchronous collateral/supplemental learning and inquiry. The path of learning should extend throughout the waking hours of each individual’s day. The formation of networked learning groups could supplement the current formal education system, leading to a “cottage industry” of sorts in the field of education and training. CompILE could facilitate these encounters both synchronously and asynchronously, both in-person and across distances via ICTs.

Usage access features support for learning on the job and at home, more hardware and software designed for underserved groups, special content for minorities and socially deprived groups, open access to all public and scientific information and major cultural events, support for competition in software and services, promotion of open-source software, lifelong learning and circulation of applications in jobs and education, and the full integration of ICTs into social and user environments. The success of CompILE depends (perhaps most heavily) upon open access to all public and scientific information. This information must be available to all who wish to learn, reflecting back upon the users’ trust of the system—CompILE’s agents must be able to deliver all the pertinent information related to a subject of inquiry. Also, upon completion of an initial performance or showing, major cultural events should be released into the public domain. The option should be available for immediate, free access to any cultural event, in appropriate digital format via the Internet.

The CompILE application will be open source software. With the source code available for public development, advanced users would be able to modify CompILE with add-ons or “plug-ins” that can increase the benefits of CompILE use. Similar to other open source software projects, these add-ons will be shared with other users across the Internet. In addition to extending the basic internal functionality of the main CompILE application, the add-ons would allow CompILE to communicate with an increasing number of current (and future) software applications. This would allow for a much fuller integration of ICTs into social and user environments, based on the intended widespread use of CompILE as a tool set for learning. The increased user-friendliness and surplus value realized with better communication between CompILE, and other applications would promote lifelong learning and the circulation of useful software applications in jobs and education.

CompILE AND SOCIETY

The concept of “lifelong learning” has its official origination in the 1973 UNESCO “Faure Report” (Faure, Herrera, Kaddoura, Lopos, Petrovsky, Rahnema, & Ward, 1972), which indicates the world’s transition to a “learning society” and a “knowledge economy.” Since then, many definitions of lifelong learning have surfaced. Smith and Spurling (1999) approach lifelong learning from a holistic perspective, with empirical and moral elements. Concerned with the scope of lifelong learning, the empirical element includes continuity, intention, and unfolding strategy as keys to the learning process. The moral element deals with the character of the learner, in terms of personal and social commitment, respect of others, and respect of the truth. Most importantly, Smith and Spurling give a wide berth to the activities that fall within the realm of lifelong learning, including formal, informal, and self-directed learning.

Crick (2005) hints toward the autonomy of the learner, noting that learning and metacognition are activities that we must do for ourselves, leading to a stronger self-awareness of and responsibility for learning. Fischer (2001) maintains that the arena for lifelong learning is highly contextualized and driven by the specific yet flexible demands of
these situations of context. Considering the wide range of learning activities, learner autonomy, and highly contextual situations of learning, it’s no surprise that humans must embrace the concept of a “learning society.”

One approach to understanding this concept of a “learning society” is in terms of a social learning system, which can be understood as a “constellation” of communities of practice (Wenger, 2000). However, from a sociopolitical perspective, Lambeir (2005) suggests that “lifelong learning has become a new kind of power mechanism,” highlighting two important trends: (1) a shift from a “knowledge-based” society to an information society, with learning having an emphasis upon the retrieval, dissemination, and evaluation of information; and (2) the increasing autonomy of the learner. With or without consideration of the politics involved, how can technology be applied to such a socially expansive concept?

The Open University Knowledge Network is under development as a software environment for lifelong learners’ community knowledge network, based on Wenger’s community of practice framework (McAndrew, Clow, Taylor, & Aczel, 2004). The designers chose to use evolutionary design methods, building only essential elements into the software, to be improved with user feedback. From their experiences with the OU Knowledge Network, they conclude that knowledge management software is an excellent tool for the collection of resources and experiences within a community, only if great care is taken when introducing the system and in maintaining existing work practices.

Koper and Tattersall (2004) note four main characteristics of lifelong learning to be considered when developing ICT support networks:

- Self-direction of learners
- Mobile access to distributed information
- Heterogeneity of learners
- Necessity for the maintenance of individual records of growth in competence

Their “Learning Network” (Koper & Sloep, 2003), developed exclusively with open source software, is currently in the pilot stages, also at the Open University of the Netherlands. Designed to support “seamless, ubiquitous access” to learning facilities at work, home, and schools, this architecture helps lower the access barriers to lifelong learning (Koper & Tattersall, 2004).

Two crucial areas of research taking place simultaneously at the Center for Lifelong Learning and Design (L3D) are knowledge-based systems (KBS) and human-computer communication (HCC), with the idea that success cannot fully be realized in either area without substantial progress in the other (Fischer, 2001). All of these projects surrounding the application of technology in support of lifelong learning have similar indications, working with information, autonomy and heterogeneity of the learner, improvement through user feedback, maintaining existing work practices, and the inseparability of KBS and HCC, lead to a necessary focus upon the absolute importance of the usability of applied technology.

**USABILITY**

There are five distinct attributes of usability: learnability, efficiency, memorability, errors, and satisfaction. An interface should be simple enough to learn that users can quickly become productive with the application. Efficiency is also essential, as a user should be able to maintain high levels of productivity with the application upon learning the interface. The interface should be easy to remember, so those users that are not constantly in contact with the application can easily reorient themselves when necessary. User error should be kept to a minimum, and errors that are unavoidable should have easy avenues of recovery. The interface should be enjoyable for the user, creating a sense of satisfaction with the application (Nielsen, 1993).
The “common sense” foundation of usability makes it quite easy for a designer to forget the actual level of importance that usability has in the design process. The concepts become second nature, and because of this may become “second-rate.” Also, it may seem as though an interface designer for a fairly complex system would have to choose between ease of use (learnability) and productivity (efficiency). This choice can be avoided by providing multiple interaction styles along with user action accelerators (Nielsen, 1993). Through a purposed focus upon multiple interaction styles, accelerators, or both, CompILE must compensate completely for learnability and efficiency. Not only should this focus increase endearment of the user population to CompILE, it should create a general increase in the appreciation of the usability design process amongst members of this user community.

**CompILE AND COMMUNITY**

The discovery-based design process inherent in sociotechnical systems effectively integrates the designers as participants within the system itself. This integration indicates a need for change within educational research as well. Geelan (2006) would agree, noting that the time has come for drastic changes in the methods of educational research, with the need for a highly participatory approach. This can be accomplished with an appropriate combination of scenario-based design, heuristic evaluation, and a better understanding of individual human participatory roles within CompILE.

**SCENARIO-BASED DESIGN**

While most engineering methods seek to control the complexity and fluidity of design using filtering and decomposition techniques, scenario-based design techniques seek to exploit the complexity and fluidity of design by learning more about the structure and dynamics of the problem domain. This process of exploitation promotes diverse views of the situation at hand, as well as intimate interaction with the concrete elements of that problem domain (Carroll, 2000). To exemplify this scenario-based process, consider an ambitious educational administration that wishes to implement CompILE across its entire school system. The problem domain of CompILE consists of all the individual schools within the system and the “usual” issues that these separate schools face: curricular consistency, communication, funding, staffing, regulations, parental involvement, and so forth.

There are two fundamental premises of the scenario-based approach that make it such an attractive design option. First, descriptions of how people accomplish tasks are a primary working design representation. Second, each context in which humans experience and act provides detailed constraint for the development and application of information technologies (Carroll, 2000). Considering these two premises, it is easy to see how a scenario-based approach for designing CompILE would radically differ from the same type of approach for designing an accident prevention program for a nuclear power plant.

Scenarios are contexts of interaction that highlight key aspects of a particular problem domain or system: goals suggested by the appearance and behavior of the system; what people try to do with the system; what procedures are adopted or not adopted, carried out successfully or erroneously; and reflections of system participants. In addition, these scenarios are comprised of four characteristic elements: setting, or the place and its props; agents/actors, or the people operating within the system; goals/objectives, or the changes an agent/actor wishes to achieve in the circumstances of the setting; and plot, including sequences of actions and events that can facilitate, obstruct, or be irrelevant to the given goals/objectives (Carroll, 2000).
Creating and using scenarios pushes designers beyond simple static answers. The emphasis on raising questions makes it easier for designers to integrate reflection and action into their own design practice. The process creates constant integration between the designers and the constituents of the problem domain by evoking reflection, contrasting the simultaneously concrete and flexible nature of scenarios, promoting work orientation, and melding abstraction with categorization. Scenarios also allow analysts and designers to visually sketch interactions in order to probe relationships (Carroll, 2000). It is precisely the nuances revealed through these questions and sketches that hold the keys to progress within the design of a system like CompILE. In addition, much of the reflection/action paradox is resolved by scenarios, as they provide a language for action that invokes reflection (Carroll, 2000). For example, a designer concerned with the implementation of stand-alone Web-browsing functionality within the global navigation menu of the CompILE interface would have a much easier time making a primary decision if he or she knew the current classroom dynamic between students, teachers, and the integration of Web content as a daily part of the curriculum.

Scenarios of use reconcile concreteness and flexibility by embodying concrete design actions that evoke concrete move testing by designers, and by facilitating open-ended exploration of design requirements and possibilities (Carroll, 2000). This approach is perfect for a project such as CompILE, because many decisions would be cut-and-dry, based on preceding projects within the same vein, but the specific needs of any school system would call for the refreshment of open-ended exploration. Exploration of this nature would help avoid overapplication of technology, as would the practical approach to interface use and analysis; heuristic evaluation.

**HEURISTIC EVALUATION**

Heuristic evaluation is the process of a person viewing an interface and making value judgments based on the 10 heuristics of usability, using his or her own common sense or intuition. Nielsen (1993) provides the following 10 heuristics of usability:

- Simple and natural dialog
- Speak the users’ language
- Minimize user memory load
- Consistency
- Feedback
- Clearly marked exits
- Shortcuts
- Good error messages
- Error prevention
- Help and documentation

One of the best ways to find mistakes and problems in interfaces is to “use” the interface and look for them. Evaluators should work individually, only communicating after completion, including written or recorded reports following inspection (Nielsen, 1993). This lowers the probability of biased evaluations. For CompILE, individualized evaluation might not work, since students would be using the interface in close proximity to each other within the classroom environment. Even though the results would likely be biased for these group evaluation sessions, the bias itself would be an integral part of the feedback loop in designing CompILE. Examining “off-line” communication between students would be essential for creating seamless computerized intercommunication functionality.

Observers are a necessity for evaluating CompILE, since the evaluators would include young children, incapable of successfully completing comprehensive written evaluations. However, the “observer method” would still have its shortcomings, as much of the responsibility for interface content analysis still falls upon the evaluator. Due
to the inexperience that most children would have with such an evaluation, the fact that observers are free to give ample hints for interface operation would be crucial to successful testing of CompILE. The short attention spans of most school-aged children combined with the complex nature of the CompILE interface would necessitate the series of short, small-scope evaluation sessions (as opposed to one marathon session). The product of a heuristic evaluation of any interface is a list of problems about that interface, directly referencing the 10 heuristics. When designers receive the report, the dots between problem and solution are mostly connected.

Unfortunately, many children might have difficulty remembering the 10 heuristics. There are at least three solutions to compensate for this difficulty: (1) place posters or reference cards of the heuristics near the child evaluator; (2) provide simple training for any child who would be heuristically evaluating the interface; or (3) create a third role within the evaluation process, a “supporter.” A supporter would be an observer with more “clout,” helping the child with his or her analysis as opposed to merely recording it. However, this supporter role does not have to be entirely fulfilled by humans. Supporters could manifest as “quality feedback” agents, similar to many software applications already in existence. Instead of the typical reactionary role that most of these quality feedback agents play, CompILE’s supporter agents would assume a highly proactive role, providing an almost constant link between the users (from all roles of participation) and the processes of scenario-based design and heuristic evaluation.

**ROLES OF PARTICIPATION**

How can these agents specifically benefit the current and future individuals involved in the educational system: students, teachers, parents, administrators, researchers, and designers? Students could benefit from research agents, tutoring agents, archival agents, and communication agents. Research agents could constantly scour the infinite resources of the World Wide Web, reporting back to the student (or another agent) whenever any relative information is discovered. Tutoring agents would be highly customizable personal agents that grow with the student. Much like the aforementioned product brokering agents, these personal tutoring agents would remember the learning history of the student, keeping track of patterns of learning. This would enable the tutor to create a custom-built learning package that would cater directly to the child’s learning style.

Archival agents could track the student throughout the day, digesting every idea communicated (and piece of work created) by the student into a digital archive. In the CompILE environment, every interaction in the classroom would be recorded in digital format. These records would be readily available, produced quickly and quietly by the archival agents. If a student cannot remember exactly what a teacher said or wrote at the beginning of the day, he or she would no longer need to worry, with everything available on a permanent basis. Issues of storage would need to be considered, but a half-sufficient remedy could be the use of a single storage facility (accessible by all the students in the class) for all in-class communication. Communication agents representing each student could queue up for the teacher, and he or she could answer the questions in the order in which they were received. This would work much like the “spooling” process for a networked printer. A student could place the requests and continue working on some other task while his or her communication agent representative waited to be served.

The teacher could employ several intelligent teaching assistant agents to deal with the overload of student questions. Many students would likely repeat the same question, so one of these assistant agents could be created specifically to tackle this issue, essentially replicating the teacher’s original
answer for each of the students. Teachers could employ grading agents to assist them with grading exams, especially the objective evaluations. This portion of the grading process could be an automatic function of CompILE, with the teacher’s “grading” agents merely collecting the data from the system for the teacher’s records. Observational agents that track the student’s progress and individual learning styles could compare notes with the teacher’s lesson plan preparation agents (primarily used like research agents) to create customized lessons for the class that compensated for each student’s current position within the learning spectrum. It is even possible that these agents could continue working while the lesson is being presented, providing real-time diagnostics for the teacher, giving him or her the ability to change the speed or direction of the lesson on the fly!

As parents would have easy, secure access to CompILE, teachers could send conference requests via agents. As opposed to unanswered e-mails or phone calls that might have arrived at a time inconvenient to the parent, agents would be willing to wait indefinitely for a response, dutifully delivering it back to the teacher immediately upon receipt. Parents could also create agents to request progress reports on their children, or to create conferencing agents of their own, if they wished to speak with the teacher. Messenger agents could provide a way for parents to alert their children (and the teachers and administration) to any sudden change of plans that might arise on any particular day. This would be particularly helpful if the family has more than one child in the same school system, but different facilities (one in elementary school, one in middle school), or in entirely different systems. One agent could carry the message to all the different constituents involved.

In addition to progress report agents, parents could create agents that gathered their children’s homework assignments for the day (or week), creating a chart for easy time management, helping the children finish their homework efficiently and effectively. The homework agents could also serve as tutoring assistance agents, gathering information to assist the parent who might need a “refresher” on the fundamentals to be learned in the homework. These agents could report back to the teacher on the following day, giving a brief evaluation of the previous evening’s proceedings.

Administrators would have many uses for agents. In addition to agents already mentioned, the administration could employ agents to monitor teachers, creating periodical “evaluations” that indicate the progress of the students; one indication of the teacher’s ability to teach. Financial agents could help the administration cope with more political issues, such as which departments need more funding for equipment or textbooks, with research agents in turn scouring the resources of the Internet for the best options. Communication agents could serve the administration by contacting other school systems with similar demographic issues and comparing notes.

Researchers could employ the assistance of statistical agents that would perform data collection, sorting, and statistical analysis. Observation agents could continually observe the actions of different types of participants, searching for recognizable patterns of use of the CompILE system. As with administrators, communication agents could assist researchers by linking to the research taking place at other school systems with similar and different circumstances, performing trend comparisons and facilitating the collaboration of researchers on pertinent issues.

Design teams could rely heavily upon testing agents for the initial alpha testing of upgrades and new modules to be added to the CompILE application tool set, as the purpose of alpha testing is to find all possible ways to “break” software, and agents are the perfect digital drones for simulating endless combinations of user actions in an organized fashion. Role-playing agents could assist designers by demonstrating alternative
solutions in the scenario-based design approach. Documentation agents could be responsible for tracking and archiving each iteration within the design team’s process, allowing for appropriate reflection upon completion of a project.

Special care should be given when CompILE is implemented to prevent oversaturation of agents within the “cybersphere.” Most agents should be able to multitask. Or it is possible that the better solution would involve millions of minimalist agents designed to complete one simple task and dispose of themselves. In either case, the possibilities abound for agent use in education, and the main purpose of their existence should be to allow humans to perform their roles in a manner that embodies valid participation in the educational community. Additionally, the persistence of researchers and designers “on the scene” in schools should raise the comfort level of other participants (especially children) due to familiarity. Perhaps increased exposure to research and design processes for other participant roles would cause an increased general appreciation of these processes. More importantly, though, researchers would likely gain more honest insight into participant processes, especially on the qualitative level.

CompILE AND CULTURE

Ethnography is the process of identifying the customs, habits, and key differences between different races, cultures, and groups of people. Due to its small focus and personalized nature, ethnography is known for its rich descriptions providing historical depth and contextual perspective, tracing social processes within groups (Howard, 2002). The rich descriptions and contextual perspective can provide the foundation for the new form of education that accommodates comprehensive interactive learning environments. In terms of communication, ethnography is concerned with patterns and functions of communication, the nature and definition of speech community, the components of communicative competence, and linguistic and social universals and inequalities (Saville-Troike, 2003).

Patterns of communication exist on the societal, group, and individual level. The interconnectedness of these patterns largely affects the roles of individuals in society in general, as well as within an educational setting. If a person was unaware that the patterns differ from one group of people to the next, it would be easy to misunderstand the implications of a particular attempt at communication by someone from a different group or culture. The fact that our schools are becoming increasingly multicultural opens a floodgate of potential misconception.

The classroom can be viewed as a model for societal structure in the sense that it can serve as a microcosm of the communicative situations that exist in our society. Considering this, the need for more attentiveness to the context of the discourse makes sense, but is not always possible at the time the discourse takes place. Teachers have too many other things to think about, and the context of discourse cannot possibly always be their main concern. Teachers can have more time to explain the context of discourse to students, thanks to the streamlined efficiency of CompILE. Addressing this context “in the moment” can reinforce an open-mindedness in students that leads to a broader appreciation of all cultures.

In addition to a broader appreciation of the diversity of human cultures, CompILE can also foster an overall appreciation for “culture” from a more philosophical perspective, one that considers aesthetic beauty. Adler (1981) refers to the subjective side of beauty as “enjoyable beauty,” and the objectivity of beauty as “admirable beauty.” Gelernter (1998) takes the concept of admirable beauty and refines it into a more fitting term for the technological world: “machine beauty,” which can be considered a keen symmetry of simplicity and power. Conceptually, CompILE exemplifies this marriage of simplicity and power, providing access to so much information in such an organ-
nized, efficient way. However, its development falls under the shadow of the “beauty paradox”: (1) most computer technologists are oblivious to beauty; (2) the best are obsessed with it; (3) the public has a love-hate relationship with beauty in computing; (4) beauty is the most important quality that exists in the computer world, when all is said and done (Gelernter, 1998). The subjectivity of the love-hate relationship between users and computers is the biggest hindrance to the development of simple yet powerful applications such as CompILE. An application can be admirably beautiful to all its users, but some will not experience its enjoyable beauty, at first. A deeper appreciation for the admirable beauty can lead to a newfound appreciation and enjoyment.

FUTURE TRENDS: CompILE AND GLOBALIZATION

The globalization of our learning society will come about with the increased ubiquity of ICTs (including those yet to be realized), which is leading to the disappearance of the traditional “brick-and-mortar classroom space.” CompILE must be designed in a way to facilitate participants’ responses to this removal in a seamless, “beautiful” manner. A core of visual communication and literacy (Dondis, 1973), backed by a network of translation agents, will advance the intercultural community that would thrive in this global learning society, based entirely upon open access to information by all participants.

As mobile inhabitants of a global society, lifelong learners should not be held stationary by any sociotechnical system. A learner must be able to collaborate effectively, sharing the contents of his or her IKS with others using a sophisticated visualization interface. As we begin working across national and cultural boundaries with higher frequency, verbal communication in a “common language” might not resonate clearly, but recognition of patterns in other’s knowledge spaces, using basic elements of visual form could transcend this issue altogether. If we as a society were to become visually literate, would a common “visual language” lead to better understanding, communication, and cooperative learning? Perhaps this visual communication process could initially be augmented by translation agents, a specialized form of negotiation agents that augment the verbal communication between people who cannot find a common spoken language between them. These agents would be reliant upon the advent of highly accurate voice recognition technology, and instantaneous translation would be paramount to provide seamless assistance during conversation.

CONCLUSION

As a sociotechnical system, CompILE must manifest as a hybrid system in at least two ways. First, its users, in all forms of participation, would in fact be de facto designers. Second, CompILE would combine reality and virtual environments in a manner conducive to constructive learning practices, taking full advantages of the added dimensionality provided by this combination. Imagine a learner interested in Greek civilization, standing in modern-day Greece, able to augment his or her current visual field with images of classic Greek structures overlaid precisely upon those structures in their current form. Upon the request of the user, these augmenting images could animate, showing the degradation of the structures over time, highlighting access to information about specific historic events that had direct impact on the process. This is just one example of how CompILE could embody the careful integration of ICT as a tool fundamental to the learning process.

The agents of CompILE can help promote higher levels of information literacy amongst its users, which in time should lead to a more informed consumer society, which will provide
society with a more appropriate mindset to create community, embrace all cultures, and become a true learning society. The CompILE system, obviously, is a continuous work in progress, still in its infancy. Much more discussion must take place concerning theories and applications as a continuing predevelopment phase. It is precisely such a discussion, as well as the continued involvement in its design and development, that will empower users of CompILE to cross the digital divide.

Chapter 2.22
Problem Frames for Sociotechnical Systems

Jon G. Hall
The Open University, UK

Lucia Rapanotti
The Open University, UK

ABSTRACT

This chapter introduces Problem Frames as a framework for the analysis of sociotechnical problems. It summarizes the Problem Frames approach, its techniques and foundations, and demonstrates, through theory and examples, how it can be applied to simple sociotechnical systems. The chapter continues with the description of an extended Problem Frame framework that allows the treatment of more general sociotechnical problems. This extension covers social components of a system — individuals, groups or organisations — bringing them within the remit of the design activity. The aim of the chapter is to make the Problem Frames framework more accessible to the software practitioner, especially those involved in the analysis of sociotechnical problems, as these problems have so far received only scant coverage in the Problem Frames literature.

INTRODUCTION

By sociotechnical system we mean a collection of interacting components in which some of the components are people and some are technological. In this chapter we focus on the requirements analysis of sociotechnical systems in which some of the technological subsystems are computer-based, these systems forming the largest part of modern software design problems.

More precisely, there are two (not necessarily disjoint) sub-classes of sociotechnical systems that we will treat in this chapter. The first sub-class contains those systems in which existing components or sub-systems (that is, domains) are to be allowed, through software, to interact. An example from this first class might be the problem of designing software for the operator of heavy machinery. The larger second class contains those systems for which software, a user interface, and user instruction are to be designed to enable a new process or service. An example
of this second class might be the development of a new customer call centre.

The use of Problem Frames (PFs) underpins our requirements analysis process. As described in Jackson (1998), PFs are a concretization of the ideas of Michael Jackson and others in the separation of machine and its environment’s descriptions. This separation is generally accepted as being a useful principle for requirements analysis. We will have cause, later in the chapter, in dealing with a more general class of sociotechnical problems, to further detail this separation, but nothing we do compromises its fundamental status.

The usual representation of the separation of machine and environment descriptions is as the “two ellipse” model, illustrated in Figure 1. In that figure world knowledge $W$ is a description of the relevant environment; $R$ is the statement of requirements; $S$ is the specification that mediates between environment and machine; $M$ is the description of the machine; and $P$ is the program that, on machine $M$, implements the specification $S$. The role of $W$ is to bridge the gap between specification $S$ and requirements $R$. More formally (Gunter, Gunter, Jackson, & Zave, 2000; Hall & Rapanotti, 2003; Zave & Jackson, 1997), $W,S \models R$.

One of the aims of the PF framework is to identify basic classes of problems that recur throughout software development. Each such class should be captured by a problem frame that provides a characterization for the problem class. Sociotechnical systems are an important class of problems and so should be representable within the PF framework, possibly with their own (collection of) problem frame(s).

In a fundamental sense, of course, the PF framework already deals with sociotechnical systems: problem frames are an attempt to allow customer and developer to come together to match real-world problems and technological solutions. There are many examples in Jackson (2001) as to how this relationship can be facilitated using problem frames.

We observe, however, that the application of problem frames to particular sociotechnical problems remains under-explored. Currently some discussion of HCI appears in Jackson (2001), and some analysis appears in Jackson (1998), but otherwise there is little in-depth coverage of how to apply problem frames in this context. In this chapter we show, in some detail, how problem frames can be applied to sociotechnical systems.

Our development is threefold. We first show how the problem of representing interaction with (and not just control of) technology can be represented within the PF framework. To do this we introduce two new basic problem frames, the User Interaction Frame and the User Commanded Behaviour Frame, each dealing with the class of user-interaction problems.

Secondly we show how architectural artifacts can be used to guide the analysis of sociotechnical problems. To do this we discuss the notion of an Architectural Frame (AFrame for short), a new PF artifact that can be used to guide problem decomposition in the light of particular solution expertise as might, for instance, exist in a software development company. As an exemplar of AFrames and their use, we define and apply an AFrame corresponding to the Model View Controller (MVC) architectural style (Bass, Clements, & Kazman, 1998).

Lastly we adapt the PF framework to meet the needs of representing the problems of more

---

**Figure 1. The requirements analysis model**

![Figure 1. The requirements analysis model](image)
Problem Frames for Sociotechnical Systems

complex sociotechnical systems, including those in which, as well as user-machine interaction, user training needs to be addressed. This causes us to consider a reification of the two-ellipse model into three ellipses to represent machine, environment, and user descriptions. Consequently, by interpreting this third ellipse in the PF framework, we discover a new type of PF domain—the knowledge domain—to represent a user’s knowledge and their “instruction” needs, and argue that this leads to a more general PF framework for sociotechnical systems.

Chapter Overview

In the major part of this chapter we will use a well-known chemical reactor problem (Dieste & Silva, 2000; Leveson, 1986) as an example for illustration of techniques. Later we briefly describe the design of a “cold-calling” system. The chemical reactor is a sociotechnical system and is representative of the class of operator-controlled safety-(and mission-)critical systems. A schematic for the chemical reactor hardware appears in Figure 2.

A statement of the problem is as follows:

A computer system is required to control the safe and efficient operation of the catalyst unit and cooling system of a chemical reactor. The system should allow an operator to issue commands for activating or deactivating the catalyst unit, and to monitor outputs. Based on the operator’s commands, the system should instruct the unit accordingly and regulate the flow of cooling water. Attached to the system is a gearbox: whenever the oil level in the gearbox is low, the system should alert the operator and halt execution.

The chapter is organized as follows. The next section develops the problem frame representation of the chemical reactor problem and uses this to recall the basis of problem representation in the PF framework. The section on problem classification provides a small taxonomy of problem classes, including those of relevance to sociotechnical systems. The next section addresses problem decomposition, both in the classical PF framework and through AFrames. The section on requirements analysis models for sociotechnical systems details our separation into three of the various domain descriptions and uses this to motivate a new type of PF domain, the knowledge domain. The final section concludes the chapter.

PROBLEM REPRESENTATION

We first consider the PF representation of the chemical reactor problem. Within the PF framework problems are represented through problem diagrams. A problem diagram defines the shape

Figure 2. The chemical reactor schematic (adapted from Dieste & Silva, 2000)
of a problem: it records the characteristic descriptions and interconnections of the parts (or domains) of the world the problem affects; it places the requirements in proper relationship to the problem components; it allows a record of concerns and difficulties that may arise in finding its solution.

For the chemical reactor, there are a number of domains, including those that appear in the schematic of Figure 2. Also the operator will play an important role in issuing commands to control the catalyst and cooling systems. Placing all of these domains in their correct relationship to each other leads to the problem diagram shown in Figure 3.

The components are:

- **Operation machine**: The machine domain, that is, the software system and its underlying hardware. The focus of the problem is to build the Operation machine.

- **Other boxes** (Cooling System, Catalyst, and so forth): Given domains representing parts of the world that are relevant to the problem.

- **Shared phenomena**: The ways that domains communicate. These can include events, entities, operations, and state information. In Figure 3, for example, the connection between the Operation machine and the Cooling System is annotated by a set $e$, containing the events $\text{increase}_{\text{water}}$ and $\text{decrease}_{\text{water}}$, and a set $f$, containing the phenomenon $\text{water}_{\text{level}}$. Phenomena in $e$ are controlled by the Operation machine; this is indicated by an abbreviation of the domain name followed by $!$, that is, $\text{OM}!$. Similarly the phenomenon in $f$ is controlled by the Cooling System, indicated by the $\text{CS}!$.

- The dotted oval. **Safe and efficient operation**: The requirement, that is, what has to be true

---

**Figure 3. The chemical reactor problem diagram**

```
- $a: \{\text{open}_{\text{catalyst}}, \text{close}_{\text{catalyst}}\}$
- $b: \{\text{catalyst}_{\text{status}}, \text{water}_{\text{level}}\}$
- $c: \{\text{open}_{\text{catalyst}}, \text{close}_{\text{catalyst}}\}$
- $d: \{\text{is}_{\text{open}}, \text{is}_{\text{closed}}\}$
- $e: \{\text{increase}_{\text{water}}, \text{decrease}_{\text{water}}\}$
- $f: \{\text{water}_{\text{level}}\}$
- $g: \{\text{oil}_{\text{level}}\}$
```
of the world for the (operation) machine to be a solution to the problem.

- In the connections between the requirement and the domains, a dotted line indicates that the phenomena are referenced (that is, an object of) the requirement, while a dotted arrow indicates that the phenomena are constrained (that is, a subject for the requirement). In Figure 3, for instance, the oil level in the gear box is referenced while the cooling system’s water level is constrained.

- Phenomena at the requirement interface (for example, those of sets \( f \) or \( d \)) can be, and usually are, distinct from those at the machine domain interface (for example, those of sets \( c \) and \( e \)). The former are called requirement phenomena; the latter, specification phenomena. The intuition behind this distinction is that the requirement is expressed in terms of elements of the problem, while the specification (that is, what describes a machine domain) is expressed in terms of elements of the solution.

Other artifacts that are not represented on the problem diagram but are related to it are domain and requirement descriptions. Such descriptions are essential to the analysis of a problem and address relevant characteristics and behaviours of all given domains, the machine domain, and the requirement.

An important distinction in the PF framework is that of separating two types of descriptions: indicative and optative. Indicative descriptions are those that describe how things are; optative descriptions describe how things should be. In this sense, in a problem diagram, given domain descriptions are indicative, while requirement and machine descriptions are optative. In other words, things that have to do with the problem domain are given, while things that have to do with the solution domain can be chosen. For instance, in the chemical reaction problem indicative descriptions of the Catalyst, Cooling System, and Gear Box should include characteristics of the domains that are of interest in the specification of the machine, say, the mechanics of opening the catalyst, or of changing the water level in the cooling system, or the oil level in the gear box. On the other hand the requirement should express some constraints on the status and operations of those domains that, when satisfied, result in their safe and efficient operation. Finally the machine specification should describe how we would like the control system to behave and interact with the given domains so that the requirements are met.

Indeed not all domains share the same characteristics. There is a clear difference between a cooling system and an operator. In a cooling system there exist some predictable causal relationships among its phenomena. For instance, it could be described as a state machine, with a set of clearly identified states and predictable transitions between them. A domain with such characteristics is known as a causal domain. On the other hand, an operator’s phenomena lack such predictable causal relationships. We can describe the actions an operator should be allowed to do but cannot guarantee that they will be executed in any particular order, or not at all, or that some other (unpredicted) actions will not be executed instead. A domain with such characteristics is known as biddable.

The distinction between causal and biddable domains is an important one, as it has ramifications for the type of descriptions we can provide and the assumptions we can make in discharging proof obligations during the analysis of a problem, as we will see in the following sections.

Of course there exist other types of domains, each with its own characteristics. An exhaustive domain classification is beyond the scope of this chapter and can be found in, for example, Jackson (1995), Jackson (1998) and Jackson (2001).
PROBLEM CLASSIFICATION

One of the intentions of the PF framework is to classify problems. An initial problem classification is given in Jackson (2001). Therein are identified five basic problem frames. They are basic because they represent relatively simple, recurrent problems in software development. In describing the basis of problem frames, the intention is not to be exhaustive in its classification of problems. Indeed there are other frames by Jackson (see, for example, Jackson, 1998) that do not make it into that classification.

In this section we present a simple taxonomic development, beginning with the simplest of all problem frames and adding domain types (modulo topology). As each type has different characteristics, the resulting problem frames represent different classes of problems. In doing so we introduce a new basic problem frame, the User Interaction Frame, which is novel in the problem class it represents within the PF framework (but not, of course, within software engineering). The taxonomy is summarized in Figure 4.

Programs

The simplest form of problem representable in problem frames is that of producing a program from a given specification. This is illustrated in Figure 5. Although this is a sub-problem of all software engineering problems, it is not a very interesting problem class to be analyzed using problem frames: nothing exists outside the machine. Other techniques, such as JSD (Jackson, 1997) or design patterns (Gamma, Helm, Johnson, & Vlissides, 1995), are probably more appropriate to tackle this problem class. Indeed the PF framework does not include a problem frame for this class of problems.

Embedded Controllers

For a problem class to be purposefully analyzed in PFs, some given domain(s) of interest must exist outside the machine. An interesting problem class is identified in Jackson (2001) by introducing a single causal domain. The problem frame is known as the Required Behaviour Frame, and its characterizing problem is that of building a machine that controls the behaviour of some part of the physical world so that it satisfies certain conditions. Some software engineers may find it easy to identify this problem with that of building an embedded controller (although it does apply also to more general software problems).

The Required Behaviour Frame is illustrated in Figure 6. The frame has a topology that is captured by a frame diagram (that of the illustration).

The frame diagram resembles a problem diagram, but it also includes some further annotation.
This provides an indication of the characteristics of the domains and phenomena involved in problems of the class. For the Required Behaviour Frame:

- The **Controlled domain** is causal (the C annotation in the figure). Its phenomena are also causal (indicated by C on the arcs) — they are directly caused or controlled by a domain and may cause other phenomena in turn.
- The **Control machine** has access to causal phenomena of the **Controlled domain** (in C2) and controls another set of phenomena, which are also shared with the **Controlled domain** (in C1). Intuitively phenomena in C1 are used by the machine to control the domain, while phenomena in C2 are used to obtain information and feedback on the functioning and state of the domain.
- The requirement, **Required behaviour**, is expressed in terms of a set (C3) of causal phenomena of the **Controlled domain**.

When a problem of a particular class is identified, it can be analyzed through the instantiation of the corresponding frame diagram. The instantiation is a process of matching problem and frame’s domains and their types, as well as problem and frame’s phenomena types. The result of the instantiation is a problem diagram, which has the same topology of the frame diagram but with domains and phenomena grounded in the particular problem.

Let us return to the chemical reactor problem and consider the problem of regulating the water level in isolation. This can be regarded as a required behaviour problem (Figure 7) with some safety requirement on the water level.

For a problem to be fully analyzed, the instantiation of a problem frame is only the first step of the process. Suitable domain and requirement descriptions (see the section on problem representation) need to be provided and the frame concern needs to be addressed. The frame concern is an overall correctness argument, common to all the problems of the class. It is the argument that must convince you, and your customer, that the specified machine will produce the required behaviour once combined with the properties of the given domains. Each problem frame comes with a particular concern whose structure depends on the nature of the class problem. For

![Water Level Regulation Diagram](image)

```
e:{increase_water,decrease_water}
f:{water_level}
```
the Required Behaviour Frame, the argument is outlined in Figure 8.

**User Interaction**

Another interesting class of problems can be obtained by including a single biddable domain outside the machine, which represents the user of the system. We call the resulting problem frame the *User Interaction Frame*, and its characterizing problem is that of building a machine that enforces some rule-based interaction with the user. The frame diagram for the User Interaction Frame is given in Figure 9.

The *Interaction machine* is the machine to be built. The *User* is a biddable domain representing the user who wants to interact with the machine. The requirement gives the rules that establish legal user/machine interactions.

The manifestation of the user/machine interaction is through exchanges of causal phenomena (in $C_1$) controlled by the user and symbolic phenomena (in $Y_1$) controlled by the machine. Intuitively the user issues commands in $C_1$ and the machine provides feedback through $Y_1$. The interaction rules specify the legal correspondence of user and machine phenomena.

In the chemical reactor problem we can isolate the operator/machine interaction as a user interaction problem as illustrated in Figure 10, where the requirement establishes some rules on the relationship between operator’s commands and system feedback, say, that an *open_catalyst* command cannot be issued when the *water_level* value is below a set threshold. Note that this would be the perspective of a User Interface (UI) designer, whose main concern is the user interacting with a black box system. Indeed, in the wider problem analysis of the chemical reactor problem, machine responses to user commands depend on a faithful representation of the internal state of, say, the catalyst or the cooling system.
Figure 11 illustrates the frame concern for the User Interaction Frame.

**User Commanded Behaviour**

The Required Behaviour and the User Interaction Frames are representative of relatively simple problems, albeit often recurring in software development. It is possible, and indeed likely, that other interesting problem classes could be identified by considering single given domains of some other type (see discussion at the end of the section on problem representation). However we do not pursue this any further here. We look, instead, at what happens when there are two given domains outside the machine.

As for the single domain case, other interesting classes of problems emerge. In fact the remaining four basic problem frames introduced in Jackson (2001) are all of this form.

If we add a biddable domain to the Requirement Behaviour Frame, we obtain a User Commanded Behaviour Frame, which is illustrated in Figure 12. Its characterizing problem is that of building a machine that will accept the user’s commands, impose control on some part of the physical world accordingly, and provide suitable feedback to the user. Jackson (2001) introduces a subclass of this frame, the Commanded Behaviour Frame, which does not require the user to receive any feedback.

1. Given this set of machine phenomena, when the user causes this phenomena (it may or may not be sensible or viable)...  
2. if sensible or viable the machine will accept it...  
3. resulting in this set of machine phenomena...  
4. thus achieving the required interaction in every case.
In the chemical reactor problem, we can apply the User Commanded Behaviour Frame to analyze how the catalyst is controlled by the operator. The corresponding problem diagram is given in Figure 13.

A possible description of the interaction rules could be as follows. The machine shall allow the user to control the catalyst under the following constraints:

1. *catalyst_status* is a faithful representation of the state of the catalyst
2. the initial state of the catalyst is *catalyst_closed*
3. possible user commands are *open_catalyst* or *close_catalyst*
4. state transitions are represented in Figure 14.

The frame concern for the User Commanded Behaviour Frame is given in Figure 15. From the figure you will notice that the argument has two parts: satisfying the required behaviour of the domain (from 1 to 4) and providing suitable feedback to the user (5 and 6).

**PROBLEM DECOMPOSITION**

Most real problems are too complex to fit basic problem frames. They require, rather, the structur-
Problem Frames for Sociotechnical Systems

In this section we discuss two ways of decomposing problems within the PF framework. The first, classical decomposition, proceeds through sub-problem identification and problem frame instantiation. The second, our novel approach, combines sub-problem identification with guided architectural decomposition using AFrames.

Classical Decomposition

In classical PF decomposition a problem is decomposed into simpler constituent sub-problems that
Problem Frames for Sociotechnical Systems

can then be analysed separately. If necessary each sub-problem can be decomposed further, and so forth, until only very simple sub-problems remain. Decomposition proceeds through the identification of sub-problems that fit a recognised problem class and the instantiation of the corresponding problem frame. We illustrate the process on the chemical reactor problem.

There are three sub-problems:

1. a user-commanded behaviour problem, for the operator to control the catalyst;
2. a required behaviour problem, for regulating the water flow in the cooling system; and
3. a sub-problem to issue a warning (and halt the system) when there is an oil leak in the gearbox.

Addressing sub-problems 1 and 2 means instantiating the corresponding problem frames to derive problem diagrams for each sub-problem. These were depicted in Figures 13 and 7, respectively.

The third sub-problem has no standard problem frame to represent it. The closest fit would be the Information Display Frame (Jackson, 2001), but this requires a decision on how the alarm will be raised. Here we have made an arbitrary choice of introducing a Bell domain, and assume that it will

Figure 16. Raising the alarm as an instance of the information display problem

![Diagram of raising the alarm as an instance of the information display problem]

h: \{ring_bell\}  i: \{bell_ringing\}  g: \{oil_level\}

Figure 17. Further decomposition of the user Commanded Behaviour sub-problem

![Diagram of further decomposition of the user Commanded Behaviour sub-problem]

a: \{open_catalyst, close_catalyst\}  b: \{catalyst_status\}  c: \{open_catalyst, close_catalyst\}  d: \{is_open, is_closed\}
ring when the oil level in the gearbox is below a certain threshold. The resulting sub-problem diagram is shown in Figure 16.

Finally we already know from the simple taxonomy in the third section that sub-problem one can be decomposed further, resulting in a required behaviour and a user interaction sub-problem. These are shown in Figure 17.

**AFrames**

AFrame decomposition complements classical decomposition in providing guidance and decomposition and recomposition rules. The rational behind AFrames is the recognition that solution structures can be usefully employed to inform problem analysis.

AFrames characterise the combination of a problem class and an architectural class. An AFrame should be regarded as a problem frame for which a “standard” sub-problem decomposition (that implied by an architecture or architectural style) exists. AFrames are a practical tool for sub-problem decomposition that allow the PF practitioner to separate and address, in a systematic fashion, the concerns arising from the intertwining of problems and solutions, as has been observed to take place in industrial software development (Nuseibeh, 2001). Further motivation for, and other examples of, AFrames can be found in Rapanotti, Hall, Jackson, & Nuseibeh (2004).

The MVC (short for Model-View-Controller) (see, for example, Bass et al., 1998) is a way of structuring a software solution into three parts — a model, a view, and a controller — to separate and handle concerns related, respectively, to the modeling of a domain of interest, the visual feedback to the user, and the user input. The controller interprets user inputs and maps them into commands to the model to effect the appropriate change. The model manages one or more data elements, responds to queries about its state, and responds to instructions to change state. The view is responsible for feedback on the model’s state to the user. Standard communication patterns (for example, the Observer pattern (Gamma et al., 1995)) apply between the MVC parts.

Here we introduce the MVC AFrame as applied to the User Commanded Behaviour Frame. This represents the class of user commanded behaviour problems for which an MVC solution is to be provided.

The intention of using the MVC in the solution space is recorded through an annotation of the machine as illustrated in Figure 18. Guidance on decomposition is in the form of decomposition templates, which are applied to obtain sub-problem diagrams. The decomposition templates for the MVC AFrame are given in Figure 19. It can be seen from the figure that the original problem is decomposable into two sub-problems, whose

---

*Figure 18. MVC annotation of the User Commanded Behaviour Frame*
machine domains are the View and Controller machines (in the MVC sense). Also a Model domain is introduced that represents an abstraction of the real-world domain to be controlled. This is a designed domain (Jackson, 2001), that is, one that we have the freedom to design, as it will reside inside the solution machine. The resulting sub-problems are then: that of building a View machine to display the Model’s representation of the state of the controlled domain and that of building a Controller machine that acts on the Model, which will pass on the commands to the controlled domain. In PF terms the Model acts as a connection domain between the real-world domain and presentation and control subsystems.

The application of the MVC AFrame to the sub-problem of controlling the catalyst (see Figure 13) results in the decomposition of Figure 20.

We see at least two strengths of AFrames. The first is that they suggest how a problem would need to be restructured for a particular solution form. For instance, in the MVC case, that an abstract model of the catalyst needs to be produced (or, for that matter, a connection domain between Operator and Gearbox — a Bell — would be needed).

The second is that they help the recomposition of sub-problem solutions into the original problem. Recomposition is facilitated by the fact that AFrame decomposition is regularized through the application of the AFrame templates. For the MVC this is through the identification of the links among its architectural elements. The recomposition diagram for the MVC AFrame is illustrated in Figure 21 and its frame concern in Figure 22. In Figure 21 the recomposition of the model, view, and controller domains follows the MVC architectural rules.
Problem Frames for Sociotechnical Systems

![MVC decomposition diagram]

Figure 21. MVC recomposition

![MVC recomposition diagram]

A REQUIREMENTS ANALYSIS MODEL FOR SOCIOTECHNICAL SYSTEMS

The consideration of more sophisticated human-machine relationships is our next concern. To be specific we now wish to look at users’ behaviour as being the subject of requirements statements, admitting that users are the source of much of the flexibility in sociotechnical systems. In short we wish to allow the design of human instruction to be the subject of the requirements engineering process addressed through problem frames alongside that of the program.

Paraphrasing this we might say that the human, as well as the machine, is to be the subject of
Problem Frames for Sociotechnical Systems

Figure 22. Discharging the correctness argument in MVC recomposition

1. Given a choice of commands in the current state, when the user issues this command (it may or may not be sensible)...
2. If sensible or viable, the machine will cause these events...
3. Resulting in this state or behaviour...
4. Which satisfies the requirement...
5. And which the machine will relate to the user...
6. Thus satisfying the requirement in every case.

optative descriptions. Foundationally this means the separation of the description of the world from that of the human who is the subject of the design. This leads to the reification of the original ellipse model shown in Figure 23. In it we have three ellipses – that for the Human $H$ with knowledge $K$, that for the Machine $M$ with program $P$, and that for the remaining Environment $W$ with requirements $R$. Of course, just as machines outside the design process have indicative descriptions in $W$, so do humans.

With the introduction of the human $H$, we identify and separate two new areas of interest, which now form explicit foci for design:

- the specification $UI$, anonymous in the $S$ region in the original model, which determines the Human-Machine interface; and
- the specification $I$, missing from the original model, which determines the knowledge and behaviour that is expected of the human as a component of the sociotechnical system.

As in the original model the description $W$ has the role of bridging the gaps between the requirement $R$ and the specification $S$, in our extension $W$ has the role of bridging the gaps between the requirement $R$ and the instruction $I$, human-machine interface $UI$ and specification $S$ together. More precisely we assert that $S$, $I$, $UI$, and $W$ must be sufficient to guarantee that the requirements of the sociotechnical system are satisfied. More formally:
Problem Frames for Sociotechnical Systems

A Problem Frame Interpretation

In the PFs framework the machine domain represents the machine for which the specification $S$ must be designed. By analogy a new domain type will be required to represent the human for which the instruction $I$ has to be designed. To this end we introduce into the PF framework the notion of a knowledge domain to represent that domain. In a problem diagram a knowledge domain should be represented as a domain box with a double bar on the right-hand side (to distinguish it from the machine domain).

The most general form of a sociotechnical problem, as a problem diagram, is shown in Figure 24. In the figure both Knowledge and Machine domains are subjects of design, as are their shared user interface phenomena.

An example of how a real-world sociotechnical problem could be treated in the new model is that of designing a “cold-calling” system to allow an interviewee to be telephoned and for their responses to certain questions, asked by an interviewer, to be recorded in a database for future analysis. The problem is to design both the technical subsystem (the machine domain) and the instructions that guide the interaction of the interviewer (the knowledge domain) with the interviewee. The interviewee sits firmly in the environment (as a biddable, indicative domain). The interaction with the database is a machine task.

The outcome of the design process, in addition to the specification for the technical subsystem, might be a script for the interviewer and the human-machine interface as used by the interviewer.
The problem diagram for this example is outlined in Figure 25.

CONCLUSION

In their classical form problem frames happily represent interactions between a user and a machine, as might be characteristic of simple sociotechnical systems. In this chapter we have presented an enrichment of the PF framework to allow the representation and analysis of more complex sociotechnical systems. To do this we have introduced two new problem frames, the User Interaction and User Commanded Behaviour Frames. Although not exhaustive in their treatment of socio-technological interaction problems, they hopefully will provide a sound basis for a richer taxonomy of user interaction within the PF framework.

One of the as-yet under-developed areas within the PF framework is the treatment of problem decomposition, in particular from the perspective of how to do it in practice. We are currently exploring the development and use of A Frames. An A Frame offers guidance in problem decomposition on the basis of solution space structures. In this chapter we have shown how basic sociotechnical interaction problems can be decomposed when the target architecture is to be the MVC style.

Although both these enrichments are new in the PF framework, they do not move outside of its original conceptual basis in the two-ellipse model of requirements analysis. In contrast we have seen in this chapter that the development of general sociotechnical systems raises challenges for the PF framework. We have suggested solutions to these challenges in the reification of the two-ellipse model to a three-ellipse version, in which social sub-systems – individuals, groups, and organisations – can also be considered as the focus of the design process. With the introduction of the knowledge domain, the manifestation of this extension in problem frames, we aim to bring the sociotechnical system problems under the design remit of the PF framework.

ACKNOWLEDGMENT

We acknowledge the kind support of our colleagues, especially Michael Jackson and Bashar Nuseibeh in the Department of Computing at the Open University.

Integrating Semantic Knowledge with Web Usage Mining for Personalization

Honghua Dai
DePaul University, USA

Bamshad Mobasher
DePaul University, USA

ABSTRACT

Web usage mining has been used effectively as an approach to automatic personalization and as a way to overcome deficiencies of traditional approaches such as collaborative filtering. Despite their success, such systems, as in more traditional ones, do not take into account the semantic knowledge about the underlying domain. Without such semantic knowledge, personalization systems cannot recommend different types of complex objects based on their underlying properties and attributes. Nor can these systems possess the ability to automatically explain or reason about the user models or user recommendations. The integration of semantic knowledge is, in fact, the primary challenge for the next generation of personalization systems. In this chapter we provide an overview of approaches for incorporating semantic knowledge into Web usage mining and personalization processes. In particular, we discuss the issues and requirements for successful integration of semantic knowledge from different sources, such as the content and the structure of Web sites for personalization. Finally, we present a general framework for fully integrating domain ontologies with Web usage mining and personalization processes at different stages, including the preprocessing and pattern discovery phases, as well as in the final stage where the discovered patterns are used for personalization.

INTRODUCTION

With the continued growth and proliferation of e-commerce, Web services, and Web-based information systems, personalization has emerged as a critical application that is essential to the success of a Website. It is now common for Web users to encounter sites that provide dynamic recommendations for products and services, tar-
geted banner advertising, and individualized link selections. Indeed, nowhere is this phenomenon more apparent as in the business-to-consumer e-commerce arena. The reason is that, in today’s highly competitive e-commerce environment, the success of a site often depends on the site’s ability to retain visitors and turn casual browsers into potential customers. Automatic personalization and recommender system technologies have become critical tools, precisely because they help engage visitors at a deeper and more intimate level by tailoring the site’s interaction with a visitor to her needs and interests.

Web personalization can be defined as any action that tailors the Web experience to a particular user, or a set of users (Mobasher, Cooley & Srivastava, 2000a). The experience can be something as casual as browsing a Website or as (economically) significant as trading stocks or purchasing a car. Principal elements of Web personalization include modeling of Web objects (pages, etc.) and subjects (users), categorization of objects and subjects, matching between and across objects and/or subjects, and determination of the set of actions to be recommended for personalization. The actions can range from simply making the presentation more pleasing to anticipating the needs of a user and providing customized information.

Traditional approaches to personalization have included both content-based and user-based techniques. Content-based techniques use personal profiles of users and recommend other items or pages based on their content similarity to the items or pages that are in the user’s profile. The underlying mechanism in these systems is usually the comparison of sets of keywords representing pages or item descriptions. Examples of such systems include Letizia (Lieberman, 1995) and WebWatcher (Joachims, Freitag & Mitchell, 1997). While these systems perform well from the perspective of the end user who is searching the Web for information, they are less useful in e-commerce applications, partly due to the lack of server-side control by site owners, and partly because techniques based on content similarity alone may miss other types of semantic relationships among objects (for example, the associations among products or services that are semantically different, but are often used together).

User-based techniques for personalization, on the other hand, primarily focus on the similarities among users rather than item-based similarities. The most widely used technology user-based personalization is collaborative filtering (CF) (Herlocker, Konstan, Borchers & Riedl, 1999). Given a target user’s record of activity or preferences, CF-based techniques compare that record with the historical records of other users in order to find the users with similar interests. This is the so-called neighborhood of the current user. The mapping of a visitor record to its neighborhood could be based on similarity in ratings of items, access to similar content or pages, or purchase of similar items. The identified neighborhood is then used to recommend items not already accessed or purchased by the active user. The advantage of this approach over purely content-based approaches that rely on content similarity in item-to-item comparisons is that it can capture “pragmatic” relationships among items based on their intended use or based on similar tastes of the users.

The CF-based techniques, however, suffer from some well-known limitations (Sarwar, Karypis, Konstan & Riedl, 2000). For the most part these limitations are related to the scalability and efficiency of the underlying algorithms, which requires real-time computation in both the neighborhood formation and the recommendation phases. The effectiveness and scalability of collaborative filtering can be dramatically enhanced by the application of Web usage mining techniques.

In general, Web mining can be characterized as the application of data mining to the content, structure, and usage of Web resources (Cooley, Mobasher & Srivastava, 1997; Srivastava, Cooley, Deshpande & Tan, 2000). The goal of Web min-
Integrating Semantic Knowledge with Web Usage Mining for Personalization

The goal of Web usage mining, in particular, is to capture and model Web user behavioral patterns. The discovery of such patterns from the enormous amount of data generated by Web and application servers has found a number of important applications. Among these applications are systems to evaluate the effectiveness of a site in meeting user expectations (Spiliopoulou, 2000), techniques for dynamic load balancing and optimization of Web servers for better and more efficient user access (Pitkow & Pirolli, 1999), and applications for dynamically restructuring or customizing a site based on users’ predicted needs and interests (Perkowitz & Etzioni, 1998).

More recently, Web usage mining techniques have been proposed as another user-based approach to personalization that alleviates some of the problems associated with collaborative filtering (Mobasher et al., 2000a). In particular, Web usage mining has been used to improve the scalability of personalization systems based on traditional CF-based techniques (Mobasher, Dai, Luo & Nakagawa, 2001, 2002).

However, the pure usage-based approach to personalization has an important drawback: the recommendation process relies on the existing user transaction data, and thus items or pages added to a site recently cannot be recommended. This is generally referred to as the “new item problem”. A common approach to resolving this problem in collaborative filtering has been to integrate content characteristics of pages with the user ratings or judgments (Claypool et al., 1999; Pazzani, 1999). Generally, in these approaches, keywords are extracted from the content on the Website and are used to either index pages by content or classify pages into various content categories. In the context of personalization, this approach would allow the system to recommend pages to a user, not only based on similar users, but also (or alternatively) based on the content similarity of these pages to the pages the user has already visited.

Keyword-based approaches, however, are incapable of capturing more complex relationships among objects at a deeper semantic level based on the inherent properties associated with these objects. For example, potentially valuable relational structures among objects such as relationships between movies, directors, and actors, or between students, courses, and instructors, may be missed if one can only rely on the description of these entities using sets of keywords. To be able to recommend different types of complex objects using their underlying properties and attributes, the system must be able to rely on the characterization of user segments and objects, not just based on keywords, but at a deeper semantic level using the domain ontologies for the objects. For instance, a traditional personalization system on a university Website might recommend courses in Java to a student, simply because that student has previously taken or shown interest in Java courses. On the other hand, a system that has knowledge of the underlying domain ontology might recognize that the student should first satisfy the prerequisite requirements for a recommended course, or be able to recommend the best instructor for a Java course, and so on.

An ontology provides a set of well-founded constructs that define significant concepts and their semantic relationships. An example of an ontology is a relational schema for a database involving multiple tables and foreign keys semantically connecting these relations. Such constructs can be leveraged to build meaningful higher-level knowledge in a particular domain. Domain ontologies for a Website usually include concepts, subsumption relations between concepts (concept hierarchies), and other relations among concepts that exist in the domain that the Web site represents. For example, the domain ontologies of a movie Website usually include concepts such as “movie,” “actor,” “director,”
“theater,” and so forth. The genre hierarchy can be used to represent different categories of movie concepts. Typical relations in this domain may include “Starring” (between actors and movies), “Directing,” “Playing” (between theaters and movies), and so forth.

The ontology of a Website can be constructed by extracting relevant concepts and relations from the content and structure of the site, through machine learning and Web mining techniques. But, in addition to concepts and relations that can be acquired from Web content and structure information, we are also interested in usage-related concepts and relations in a Website. For instance, in an e-commerce Website, we may be interested in the relations between users and objects that define different types of online activity, such as browsing, searching, registering, buying, and bidding. The integration of such usage-based relations with ontological information representing the underlying concepts and attributes embedded in a site allows for more effective knowledge discovery, as well as better characterization and interpretation of the discovered patterns.

In the context of Web personalization and recommender systems, the use of semantic knowledge can lead to deeper interaction of the visitors or customers with the site. Integration of domain knowledge allows such systems to infer additional useful recommendations for users based on more fine-grained characteristics of the objects being recommended, and provides the capability to explain and reason about user actions.

In this chapter we present an overview of the issues related to and requirements for successfully integrating semantic knowledge in the Web usage mining and personalization processes. We begin by providing some general background on the use of semantic knowledge and ontologies in Web mining, as well as an overview of personalization based on Web usage mining. We then discuss how the content and the structure of the site can be leveraged to transform raw usage data into semantically-enhanced transactions that can be used for semantic Web usage mining and personalization. Finally, we present a framework for more systematically integrating full-fledged domain ontologies in the personalization process.

**BACKGROUND**

**Semantic Web Mining**

Web mining is the process of discovering and extracting useful knowledge from the content, usage, and structure of one or more Web sites. Semantic Web mining (Berendt, Hotho & Stumme, 2002) involves the integration of domain knowledge into the Web mining process.

For the most part the research in semantic Web mining has been focused in application areas such as Web content and structure mining. In this section, we provide a brief overview and some examples of related work in this area. Few studies have focused on the use of domain knowledge in Web usage mining. Our goal in this chapter is to provide a road map for the integration of semantic and ontological knowledge into the process of Web usage mining, and particularly, in its application to Web personalization and recommender systems.

Domain knowledge can be integrated into the Web mining process in many ways. This includes leveraging explicit domain ontologies or implicit domain semantics extracted from the content or the structure of documents or Website. In general, however, this process may involve one or more of three critical activities: domain ontology acquisition, knowledge base construction, and knowledge-enhanced pattern discovery.

**Domain Ontology Acquisition**

The process of acquiring, maintaining and enriching the domain ontologies is referred to as “ontology engineering”. For small Web sites with only static Web pages, it is feasible to construct a domain knowledge base manually or semi-
Integrating Semantic Knowledge with Web Usage Mining for Personalization

manually. In Loh, Wives and de Oliveira (2000), a semi-manual approach is adopted for defining each domain concept as a vector of terms with the help of existing vocabulary and natural language processing tools.

However, manual construction and maintenance of domain ontologies requires a great deal of effort on the part of knowledge engineers, particularly for large-scale Websites or Websites with dynamically generated content. In dynamically generated Websites, page templates are usually populated based on structured queries performed against back-end databases. In such cases, the database schema can be used directly to acquire ontological information. Some Web servers send structured data files (e.g., XML files) to users and let client-side formatting mechanisms (e.g., CSS files) work out the final Web representation on clients. In this case, it is generally possible to infer the schema from the structured data files.

When there is no direct source for acquiring domain ontologies, machine learning and text mining techniques must be employed to extract domain knowledge from the content or hyperlink structure of the Web pages. In Clerkin, Cunningham, and Hayes (2001), a hierarchical clustering algorithm is applied to terms in order to create concept hierarchies. In Stumme, Taouil, Bastide, Pasquier and Lakhal (2000) a Formal Concept Analysis framework is proposed to derive a concept lattice (a variation of association rule algorithm). The approach proposed in Maedche and Staab (2000) learns generalized conceptual relations by applying association rule mining. All these efforts aim to automatically generate machine understandable ontologies for Website domains.

The outcome of this phase is a set of formally defined domain ontologies that precisely represent the Website. A good representation should provide machine understandability, the power of reasoning, and computation efficiency. The choice of ontology representation language has a direct effect on the flexibility of the data mining phase. Common representation approaches are vector-space model (Loh et al., 2000), descriptive logics (such as DAML+OIL) (Giugno & Lukasiewicz, 2002; Horrocks & Sattler, 2001), first order logic (Craven et al., 2000), relational models (Dai & Mobasher, 2002), probabilistic relational models (Getoor, Friedman, Koller & Taskar, 2001), and probabilistic Markov models (Anderson, Domingos & Weld, 2002).

Knowledge Base Construction

The first phase generates the formal representation of concepts and relations among them. The second phase, knowledge base construction, can be viewed as building mappings between concepts or relations on the one hand, and objects on the Web. The goal of this phase is to find the instances of the concepts and relations from the Website’s domain, so that they can be exploited to perform further data mining tasks. Learning algorithms play an important role in this phase.

In Ghani and Fano (2002), a text classifier is learned for each “semantic feature” (somewhat equivalent to the notion of a concept) based on a small manually labeled data set. First, Web pages are extracted from different Websites that belong to a similar domain, and then the semantic features are manually labeled. This small labeled data set is fed into a learning algorithm as the training data to learn the mappings between Web objects and the concept labels. In fact, this approach treats the process of assigning concept labels as filling “missing” data. Craven et al. (2000) adopt a combined approach of statistical text classification and first order text classification in recognizing concept instances. In that study, learning process is based on both page content and linkage information.

Knowledge-Enhanced Web Data Mining

Domain knowledge enables analysts to perform more powerful Web data mining tasks. The ap-
Applications include content mining, information retrieval and extraction, Web usage mining, and personalization. On the other hand, data mining tasks can also help to enhance the process of domain knowledge discovery.

Domain knowledge can improve the accuracy of document clustering and classification and induce more powerful content patterns. For example, in Horrocks (2002), domain ontologies are employed in selecting textual features. The selection is based on lexical analysis tools that map terms into concepts within the ontology. The approach also aggregates concepts by merging the concepts that have low support in the documents. After preprocessing, only necessary concepts are selected for the content clustering step. In McCullum, Rosenfeld, Mitchell and Ng (1998), a concept hierarchy is used to improve the accuracy and the scalability of text classification.

Traditional approaches to content mining and information retrieval treat every document as a set or a bag of terms. Without domain semantics, we would treat “human” and “mankind” as different terms, or, “brake” and “car” as unrelated terms. In Loh et al. (2000), a concept is defined as a group of terms that are semantically relevant, for example, as synonyms. With such concept definitions, concept distribution among documents is analyzed to find interesting concept patterns. For example, one can discover dominant themes in a document collection or in a single document; or find associations among concepts.

Ontologies and domain semantics have been applied extensively in the context of Web information retrieval and extraction. For example, the ARCH system (Parent, Mobasher & Lytinen, 2001) adopts concept hierarchies because they allow users to formulate more expressive and less ambiguous queries when compared to simple keyword-based queries. In ARCH, an initial user query is used to find matching concepts within a portion of concept hierarchy. The concept hierarchy is stored in an aggregated form with each node represented as a term vector. The user can select or unselect nodes in the presented portion of the hierarchy, and relevance feedback techniques are used to modify the initial query based on these nodes.

Similarly, domain-specific search and retrieval applications allow for a more focused and accurate search based on specific relations inherent in the underlying domain knowledge. The CiteSeer system (Bollacker, Lawrence & Giles, 1998) is a Web agent for finding interesting research publications, in which the relation “cited by” is the primary relation discovered among objects (i.e., among published papers). Thus, CiteSeer allows for comparison and retrieval of documents, not only based on similar content, but also based on inter-citation linkage structure among documents.

CiteSeer is an example of an approach for integrating semantic knowledge based on Web structure mining. In general, Web structure mining tasks take as input the hyperlink structure of Web pages (either belonging to a Website or relative to the whole Web), and output the underlying patterns (e.g., page authority values, linkage similarity, Web communities, etc.) that can be inferred from the hypertext co-citations. Another example of such an approach is the PageRank algorithm, which is the backbone of the Google search engine. PageRank uses the in-degree of indexed pages (i.e., number of pages referring to it) in order to rank pages based on quality or authoritativeness. Such algorithms that are based on the analysis of structural attributes can be further enhanced by integrating content semantics (Chakrabarti et al., 1998). Web semantics can also enhance crawling algorithms by combining content or ontology with linkage information (Chakrabarti, van den Berg & Dom, 1999; Maedche, Ehrig, Handschuh, Volz & Stojanovic, 2002).

The use of domain knowledge can also provide tremendous advantages in Web usage mining and personalization. For example, semantic knowledge may help in interpreting, analyzing, and reasoning about usage patterns discovered in the mining
Integrating Semantic Knowledge with Web Usage Mining for Personalization

phase. Furthermore, it can enhance collaborative filtering and personalization systems by providing concept-level recommendations (in contrast to item-based or user-based recommendations). Another advantage is that user demographic data, represented as part of a domain ontology, can be more systematically integrated into collaborative or usage-based recommendation engines. Several studies have considered various approaches to integrate content-based semantic knowledge into traditional collaborative filtering and personalization frameworks (Anderson et al., 2002; Claypool et al., 1999; Melville, Mooney & Nagarajan, 2002; Mobasher, Dai, Luo, Sun & Zhu, 2000b; Pazzani, 1999). Recently, we proposed a formal framework for integrating full domain ontologies with the personalization process based on Web usage mining (Dai & Mobasher, 2002).

WEB USAGE MINING AND PERSONALIZATION

The goal of personalization based on Web usage mining is to recommend a set of objects to the current (active) user, possibly consisting of links, ads, text, products, and so forth, tailored to the user’s perceived preferences as determined by the matching usage patterns. This task is accomplished by matching the active user session (possibly in conjunction with previously stored profiles for that user) with the usage patterns discovered through Web usage mining. We call the usage patterns used in this context aggregate usage profiles since they provide an aggregate representation of the common activities or interests of groups of users. This process is performed by the recommendation engine which is the online component of the personalization system. If the data collection procedures in the system include the capability to track users across visits, then the recommendations can represent a longer term view of user’s potential interests based on the user’s activity history within the site. If, on the other hand, aggregate profiles are derived only from user sessions (single visits) contained in log files, then the recommendations provide a “short-term” view of user’s navigational interests. These recommended objects are added to the last page

Figure 1. General Framework for Web Personalization Based on Web Usage Mining — The Offline Pattern Discovery Component
Integrating Semantic Knowledge with Web Usage Mining for Personalization

in the active session accessed by the user before that page is sent to the browser.

The overall process of Web personalization based on Web usage mining consists of three phases: data preparation and transformation, pattern discovery, and recommendation. Of these, only the latter phase is performed in real-time. The data preparation phase transforms raw Web log files into transaction data that can be processed by data mining tasks. A variety of data mining techniques can be applied to this transaction data in the pattern discovery phase, such as clustering, association rule mining, and sequential pattern discovery. The results of the mining phase are transformed into aggregate usage profiles, suitable for use in the recommendation phase. The recommendation engine considers the active user session in conjunction with the discovered patterns to provide personalized content.

The primary data sources used in Web usage mining are the server log files, which include Web server access logs and application server logs. Additional data sources that are also essential for both data preparation and pattern discovery include the site files (HTML, XML, etc.) and meta-data, operational databases, and domain knowledge. Generally speaking, the data obtained through these sources can be categorized into four groups (see also Cooley, Mobasher, & Srivastava, 1999; Srivastava et al., 2000).

- **Usage data:** The log data collected automatically by the Web and application servers represents the fine-grained navigational behavior of visitors. Depending on the goals of the analysis, this data needs to be transformed and aggregated at different levels of abstraction. In Web usage mining, the most basic level of data abstraction is that of a pageview. Physically, a pageview is an aggregate representation of a collection of Web objects contributing to the display on
a user’s browser resulting from a single user action (such as a clickthrough). These Web objects may include multiple pages (such as in a frame-based site), images, embedded components, or script and database queries that populate portions of the displayed page (in dynamically generated sites). Conceptually, each pageview represents a specific “type” of user activity on the site, e.g., reading a news article, browsing the results of a search query, viewing a product page, adding a product to the shopping cart, and so on. On the other hand, at the user level, the most basic level of behavioral abstraction is that of a server session (or simply a session). A session (also commonly referred to as a “visit”) is a sequence of pageviews by a single user during a single visit. The notion of a session can be further abstracted by selecting a subset of pageviews in the session that are significant or relevant for the analysis tasks at hand. We shall refer to such a semantically meaningful subset of pageviews as a transaction. It is important to note that a transaction does not refer simply to product purchases, but it can include a variety of types of user actions as captured by different pageviews in a session.

• **Content data:** The content data in a site is the collection of objects and relationships that are conveyed to the user. For the most part, this data is comprised of combinations of textual material and images. The data sources used to deliver or generate this data include static HTML/XML pages, image, video, and sound files, dynamically generated page segments from scripts or other applications, and collections of records from the operational database(s). The site content data also includes semantic or structural meta-data embedded within the site or individual pages, such as descriptive keywords, document attributes, semantic tags, or HTTP variables. Finally, the underlying domain ontology for the site is also considered part of content data. The domain ontology may be captured implicitly within the site, or it may exist in some explicit form. The explicit representation of domain ontologies may include conceptual hierarchies over page contents, such as product categories, structural hierarchies represented by the underlying file and directory structure in which the site content is stored, explicit representation of semantic content and relationships via an ontology language such as RDF, or a database schema over the data contained in the operational databases.

• **Structure data:** The structure data represents the designer’s view of the content organization within the site. This organization is captured via the inter-page linkage structure among pages, as reflected through hyperlinks. The structure data also includes the intra-page structure of the content represented in the arrangement of HTML or XML tags within a page. For example, both HTML and XML documents can be represented as tree structures over the space of tags in the page. The structure data for a site is normally captured by an automatically generated “site map” which represents the hyperlink structure of the site. A site mapping tool must have the capability to capture and represent the inter- and intra-pageview relationships. This necessity becomes most evident in a frame-based site where portions of distinct pageviews may represent the same physical page. For dynamically generated pages, the site mapping tools must either incorporate intrinsic knowledge of the underlying applications and scripts, or must have the ability to generate content segments using a sampling of parameters passed to such applications or scripts.

• **User data:** The operational database(s) for the site may include additional user profile information. Such data may include demo-
graphic or other identifying information on registered users, user ratings on various objects such as pages, products, or movies, past purchase or visit histories of users, as well as other explicit or implicit representation of users’ interests. Obviously, capturing such data would require explicit interactions with the users of the site. Some of this data can be captured anonymously, without any identifying user information, so long as there is the ability to distinguish among different users. For example, anonymous information contained in client-side cookies can be considered a part of the user’s profile information, and can be used to identify repeat visitors to a site. Many personalization applications require the storage of prior user profile information. For example, collaborative filtering applications, generally, store prior ratings of objects by users, though, such information can be obtained anonymously, as well.

For a detailed discussion of preprocessing issues related to Web usage mining see Cooley et al. (1999). Usage preprocessing results in a set of \( n \) pageviews, \( P = \{ p_1, p_2, \ldots, p_n \} \), and a set of \( m \) user transactions, \( T = \{ t_1, t_2, \ldots, t_m \} \), where each \( t \) in \( T \) is a subset of \( P \). Pageviews are semantically meaningful entities to which mining tasks are applied (such as pages or products). Conceptually, we view each transaction \( t \) as an \( l \)-length sequence of ordered pairs:

\[
t = \left( \left( p_{t_1}, w(p_{t_1}) \right), \left( p_{t_2}, w(p_{t_2}) \right), \ldots, \left( p_{t_l}, w(p_{t_l}) \right) \right)
\]

where each \( p_{t_j} = p_j \) for some \( j \) in \( \{1, \ldots, n\} \), and \( w(p_j) \) is the weight associated with pageview \( p_j \) in transaction \( t \), representing its significance (usually, but not exclusively, based on time duration).

For many data mining tasks, such as clustering and association rule discovery, as well as collaborative filtering based on the \( k \)-NN technique, we can represent each user transaction as a vector over the \( n \)-dimensional space of pageviews. Given the transaction \( t \) above, the transaction vector \( \tilde{t} \) is given by: \( \tilde{t} = \{ w_{p_1}, w_{p_2}, \ldots, w_{p_n} \} \), where each \( w_{p_j} = w(p_j) \), for some \( j \) in \( \{1, \ldots, n\} \), if \( p_j \) appears in the transaction \( t \), and \( w_{p_j} = 0 \), otherwise. Thus, conceptually, the set of all user transactions can be viewed as an \( m \times n \) transaction-pageview matrix, denoted by \( TP \).

Given a set of transactions as described above, a variety of unsupervised knowledge discovery techniques can be applied to obtain patterns. These techniques such as clustering of transactions (or sessions) can lead to the discovery of important user or visitor segments. Other techniques such as item (e.g., pageview) clustering and association or sequential pattern discovery can be used to find important relationships among items based on the navigational patterns of users in the site. In each case, the discovered patterns can be used in conjunction with the active user session to provide personalized content. This task is performed by a recommendation engine.

**Requirements for Semantic Web Usage Mining**

In this section, we present and discuss the essential requirements in the integration of domain knowledge with Web usage data for pattern discovery. Our focus is on the critical tasks that particularly play an important role when the discovered patterns are to be used for Web personalization. As a concrete example, in the last part of this section we discuss an approach for integrating semantic features extracted from the content of Web sites with Web usage data, and how this integrated data can be used in conjunction with clustering to perform personalization. In the next section, we go beyond keyword-based semantics and present a more formal framework for integrating full ontologies with the Web usage mining and personalization processes.
Representing Domain Knowledge as Content Features

One direct source of semantic knowledge that can be integrated into mining and personalization processes is the textual content of Web site pages. The semantics of a Web site are, in part, represented by the content features associated with items or objects on the Web site. These features include keywords, phrases, category names, or other textual content embedded as meta-information. Content preprocessing involves the extraction of relevant features from text and meta-data.

During the preprocessing, usually different weights are associated with features. For features extracted from meta-data, feature weights are usually provided as part of the domain knowledge specified by the analyst. Such weights may reflect the relative importance of certain concepts. For features extracted from text, weights can normally be derived automatically, for example as a function of the term frequency and inverse document frequency (tf.idf) which is commonly used in information retrieval.

Further preprocessing on content features can be performed by applying text mining techniques. This would provide the ability to filter the input to, or the output from, other mining algorithms. For example, classification of content features based on a concept hierarchy can be used to limit the discovered patterns from Web usage mining to those containing pageviews about a certain subject or class of products. Similarly, performing learning algorithms such as, clustering, formal concept analysis, or association rule mining on the feature space can lead to composite features representing concept categories or hierarchies (Clerkin, Cunningham, & Hayes, 2001; Stumme et al., 2000).

The integration of content features with usage-based personalization is desirable when we are dealing with sites where text descriptions are dominant and other structural relationships in the data are not easy to obtain, e.g., news sites or online help systems, etc. This approach, however, is incapable of capturing more complex relations among objects at a deeper semantic level based on the inherent properties associated with these objects. To be able to recommend different types of complex objects using their underlying properties and attributes, the system must be able to rely on the characterization of user segments and objects, not just based on keywords, but at a deeper semantic level using the domain ontologies for the objects. We will discuss some examples of how integrated content features and usage data can be used for personalization later in this Section.

Representing Domain Knowledge as Structured Data

In Web usage mining, we are interested in the semantics underlying a Web transaction or a user profile which is usually composed of a group of pageview names and query strings (extracted from Web server logs). Such features, in isolation, do not convey the semantics associated with the underlying application. Thus, it is important to create a mapping between these features and the objects, concepts, or events they represent.

Many e-commerce sites generate Web pages by querying operational databases or semi-structured data (e.g., XML and DTDs), from which semantic information can be easily derived. For Web sites in which such structured data cannot be easily acquired, we can adopt machine learning techniques to extract semantic information. Furthermore, the domain knowledge acquired should be machine understandable in order to allow for further processing or reasoning. Therefore, the extracted knowledge should be represented in some standard knowledge representation language.

DAML+OIL (Horrocks & Sattler, 2001) is an example of an ontology language that combines
the Web standards from XML and RDF, with the reasoning capabilities from a description logic \textit{SHIP(DL)}. The combinations of relational models and probabilistic models is another common approach to enhance Web personalization with domain knowledge and reasoning mechanism. Several approaches to personalization have used Relational Models such as Relational Markov Model (Anderson et al., 2002). Both of these approaches provide the ability to represent knowledge at different levels of abstraction, and the ability to reason about concepts, including about such relations as subsumption and membership.

In Dai & Mobasher (2002), we adopted the syntax and semantics of another ontology representation framework, \textit{SHOQ(D)}, to represent domain ontologies. In \textit{SHOQ(D)}, the notion of \textit{concrete datatype} is used to specify literal values and \textit{individuals} which represent real objects in the domain ontology. Moreover, \textit{concepts} can be viewed as sets of individuals, and \textit{roles} are binary relations between a pair of concepts or between concepts and data types. The detailed formal definitions for concepts and roles are given in Horrocks & Sattler (2001) and Giugno & Lukasiewicz (2002). Because our current work does not focus on reasoning tasks such as deciding subsumption and membership, we do not focus our discussion on these operations. The reasoning apparatus in \textit{SHOQ(D)} can be used to provide more intelligent data mining services.

Building “Mappings” Between Usage-Level and Domain-Level Instances

During usage data preprocessing or post processing, we may want to assign domain semantics to user navigational patterns by mapping the pageview names or URLs (or queries) to the instances in the knowledge base. To be more specific, instead of describing a user’s navigational path as: “\(a_1, a_2, \ldots, a_n\)” (where \(a_i\) is a URL pointing to a Web resource), we need to represent it using the instances from the knowledge base, such as: “\(\text{movie(name=Matrix)}, \text{movie(name=Spiderman)}, \ldots, \text{movie(name=Xman)}\).” With the help of a pre-acquired concept hierarchy, we may, for example, be able to infer that the current user’s interest is in the category of “Action\&Sci-Fi.” We refer to this “semantic” form of usage data as “Semantic User Profiles.” These profiles, in turn, can be used for semantic pattern discovery and online recommendations. In the context of personalization applications, domain-level (semantic) instances may also need to be mapped back to Web resources or pages. For example, a recommendation engine using semantic user profiles may result in recommendations in the form of a movie genre. This concept must be mapped back into specific pages, URLs, or sections of the site relating to this genre before recommendations can be relayed to the user.

Using Content and Structural Characteristics

Classification algorithms utilizing content and structural features from pages are well-suited for creating mappings from usage data to domain-level instances. For example, in Craven et al. (2000) and Ghani & Fano (2002) classifiers are trained that exploit content or structural features (such as terms, linkage information, and term proximity) of the pageviews. From the pageview names or URLs we can obtain the corresponding Web content such as meta-data or keywords. With help from text classification algorithms, it is possible to efficiently map from keywords to attribute instances (Ghani & Fano, 2002).

Another good heuristics used in creating semantic mappings is based on the anchor text associated with hyperlinks. If we can build the complete user navigational path, we would be able to acquire the anchor text for each URL or pageview name. We can include the anchor text as part of the content features extracted from the body of documents or in isolation. However,
whereas the text features in a document represent the semantics of the document, itself, the anchor text represents the semantics of the document to which the associated hyperlink points.

Using Query Strings

So far, we have overlooked the enormous amount of information stored in databases or semi-structured documents associated with a site. Large information servers often serve content integrated from multiple underlying servers and databases (Berendt, & Spiliopoulou, 2000). The dynamically generated pages on such servers are based on queries with multiple parameters attached to the URL corresponding to the underlying scripts or applications. Using the Web server query string recorded in the server log files it is possible to reconstruct the response pages. For example, the following are query strings from a hypothetical online bookseller Web site:

http://www.xyz.com/app.cgi?action=viewitem&item=1234567&category=1234

http://www.xyz.com/app.cgi?action=search&searchtype=title&searchstring=web+mining

http://www.xyz.com/app.cgi?action=order&item=1234567&category=1234&couponid=3456

If the background database or semi-structured documents are available, then we can access the content of the instances in the response pages via the name-value pairs from the query strings. This enriches our knowledge base of user interest. In the above bookseller Web site example, if we were able to access background database, we would be able to get the content of item “1234567” in category “1234”. In this case, we could have the book name, price, author information of this item. We could recommend other books in the same content category or written by the same author. More generally, in well-designed sites, there is usually an explicitly available semantic mapping between query parameters and objects (such as products and categories), which would obviate the need to reconstruct the content of dynamic pages.

Levels of Abstraction

Capturing semantic knowledge at different levels of abstraction provides more flexibility both in the mining phase and in the recommendation phase. For example, focusing on higher-level concepts in a concept hierarchy would allow certain patterns to emerge which otherwise may be missed due to low support. On the other hand, the ability to drill-down into the discovered patterns based on finer-grained subconcepts would provide the ability to give more focused and useful recommendations.

Domain knowledge with attributes and relations requires the management of a great deal more data than is necessary in traditional approaches to Web usage mining. Thus, it becomes essential to prune unnecessary attributes or relations. For example, it may be possible to examine the number of distinct values of each attribute and generalize the attributes if there is a concept hierarchy over the attribute values. In Han & Fu (1995) a multiple-level association rule mining algorithm is proposed that utilizes concept hierarchies. For example, the usage data in our hypothetical movie site may not provide enough support for an association rule: “Spiderman, Xmen → Xmen2”, but mining at a higher level may result in obtaining a rule: “Sci-Fi&Action, Xmen → Xmen2”. In Anderson et al. (2002) relational Markov models are built by performing shrinkage (McCallum et al., 1998) between the estimates of parameters at all levels of abstractions relative to a concept hierarchy. If a pre-specified concept hierarchy does not exist, it is possible to automatically create such hierarchies through a variety of machine learning techniques, such as hierarchical agglomerative clustering (Stumme et al., 2000).
Integration of Semantics at Different Stages of Knowledge Discovery

The semantic information stored in the knowledge base can be leveraged at various steps in the knowledge discovery process, namely in the preprocessing phase, in the pattern discovery phase, or during the post-processing of the discovered patterns.

Preprocessing Phase

The main task of data preprocessing is to prune noisy and irrelevant data, and to reduce data volume for the pattern discovery phase. In Mobasher, Dai, Luo, & Nakagawa (2002), it was shown that applying appropriate data preprocessing techniques on usage data could improve the effectiveness of Web personalization. The concept level mappings from the pageview-level data to concepts can also be performed in this phase. This results in a transformed transaction data to which various data mining algorithms can be applied. Specifically, the transaction vector $t$ given previously can be transformed into a vector $t' = \{w'_o, w'_o, \ldots, w'_o\}$, where each $o_j$ is a semantic object appearing in one of the pageviews contained in the transaction, and is a weight associated with that object in the transaction. These semantic objects may be concepts appearing in the concept hierarchy or finer-grained objects representing instances of these concepts.

Pattern Discovery Phase

Successful utilization of domain knowledge in this phase requires extending basic data mining algorithms to deal with relational data to concept hierarchies. As an example, consider a distance-based data mining technique such as clustering. The clustering of flat single-relation data (such as Web user transactions) involves the computation of similarities or distance among transaction vectors. In such cases, normally simple vector-based operations are used. However, in the presence of integrated domain knowledge represented as concept hierarchies or ontologies, the clustering algorithms will have to perform much more complex similarity computations across dimensions and attributes. For example, even if the two user transactions have no pageviews in common, they may still be considered similar provided that the items occurring in both transactions are themselves “similar” based on some of their attributes or properties. The integration of domain knowledge will generate “semantic” usage patterns, introducing great flexibility as well as challenges. The flexibility lies in the pattern discovery being independent of item identities. The challenge is in the development of scalable and efficient algorithms to perform the underlying computational tasks such as similarity computations. We discuss this issue further below.

Post-Processing Phase

Exploiting domain knowledge in this phase can be used to further explain usage patterns or to filter out irrelevant patterns. One possibility is to first perform traditional usage mining tasks on the item-level usage data obtained in the preprocessing phase, and then use domain knowledge to interpret or transform the item level user profiles into “domain-level usage profiles” (Mobasher & Dai, 2002) involving concepts and relations in the ontology. The advantage of this approach is that we can avoid the scalability issues that can be endemic in the pattern discovery phase. The disadvantage is that some important structural relationships may not be used during the mining phase resulting in lower quality patterns.

Aggregation Methods for Complex Objects

To characterize patterns discovered through data mining techniques, it is usually necessary to de-
derive aggregate representation of the patterns. An example of this situation is clustering applications. In the context of Web user transactions, clustering may result in a group of sessions or visitors that are considered similar because of their common navigational patterns. The vector representation of these transactions facilitates the aggregation tasks: the centroid (mean vector) of the transaction cluster acts as a representative of all of the transactions in that cluster. However, in the case of semantically enhanced transactions, the aggregation may have to be performed independently for each of the attributes associated with the objects contained in the cluster.

For example, clustering may result in a group of users who have all visited pages related to several movies. To be able to characterize this group of users at a deeper semantic level, it would be necessary to create an aggregate representation of the collection of movies in which they are interested. This task would require aggregation along each dimension corresponding to the attributes of “movie” instances, such as “genre”, “actors”, “directors”, etc. Since each of these attributes require a different type of aggregation function depending on the data type and the domain, it may be necessary to associate various aggregation functions with the specification of the domain ontology, itself. In the next section we present one approach for solving this problem.

**Measuring Semantic Similarities**

Measuring similarities (alternatively, distances) among objects is a central task in many data mining algorithms. In the context of Web usage mining this may involve computing similarity measures among pageviews, among user transactions, or among users. This also becomes a critical task in personalization: a current user’s profile must be matched with similar aggregate profiles representing the discovered user patterns or segments. As in the case of the aggregation problem discussed above, when dealing with semantically enhanced transactions, measuring similarities poses additional challenges. This is because the similarity of two transactions depends on the similarities of the semantic objects contained within the transactions.

Let us again consider the static vector model for representing a Web transaction $t$ (or a user profile): $t = \langle w'_1, w'_2, \ldots, w'_p \rangle$. Computing similarity between two such vectors is straightforward and can be performed using measures such as cosine similarity, Euclidean distance, Pearson correlation (e.g., in case the weights represent user ratings).

When such vectors are transformed according to the underlying semantics, however, the computation of similarities will involve the computation of semantic similarities among the concepts or objects, possibly using different domain-specific similarity measures. Let $A$ and $B$ be two transformed transactions, each represented as a set of semantic objects in a site:

$A = \{a_1, a_2, \ldots, a_m\}$ and $B = \{b_1, b_2, \ldots, b_l\}$.

The computation of vector similarity between $A$ and $B$, $Sim(A,B)$, is dependent on the semantic similarities among the component objects, $SemSim(a_i,b_j)$. For instance, one approach might be to compute the weighted sum or average of the similarities among object pairs, such as in:

$$Sim(A,B) = \sum_{a_i \in A} \sum_{b_j \in B} \frac{SemSim(a_i,b_j)}{|A||B|}$$

In general, computing the semantic similarity, $SemSim(a,b)$, is domain dependent and requires knowledge of the underlying structure of among objects. If both objects can be represented using the same vector model (e.g., pages or documents represented as bags of words), we can compute their similarity using standard vector operations. On the other hand, if their representation includes attributes and relations specified in the domain ontology, we need to first make sure that the ob-
jects can be classified under a common ontological schema and then measure similarities along the different dimensions corresponding to each attribute. The notion of semantic matching among objects and classes has been a subject of considerable study recently (Rodriguez & Egenhofer, 2003; Palopoli, Sacca, Terracina, & Ursino, 2003; Ganesan, Garcia-Molina, & Widom, 2003).

For example, such an approach was used in Jin & Mobasher (2003) in the context of collaborative filtering with movies. In this work, association analysis was first performed on the “genre” attribute to define a genre hierarchy. Furthermore, the “year” attribute was discretized into intervals, while other attributes, such as “cast”, were treated as a bag of words. These preprocessing steps allowed for the definition of appropriate similarity measures for each attribute. Finally, the semantic similarity between two movies, $i$ and $j$, was defined as a linear combination of attribute-level similarities:

$$
SemSim(i, j) = \alpha_1 \ast CastSim(i, j) + \alpha_2 \ast DirectorSim(i, j) + \alpha_3 \ast GenreSim(i, j) + \ldots
$$

where, $\alpha_i$ are predefined weights for the corresponding attributes.

**Example: Using Content Features for Semantic Web Usage Mining**

As an example of integrating semantic knowledge with the Web usage mining process, let us consider the especial case of using textual features from the content of Web pages to represent the underlying semantics for the site. As noted earlier, each pageview $p$ can be represented as a $k$-dimensional feature vector, where $k$ is the total number of extracted features (words or concepts) from the site in a global dictionary. This vector can be given by:

$$p = \{fw(p, f_1), fw(p, f_2), \ldots, fw(p, f_k)\}$$

where $fw(p, f_j)$ is the weight of the $j$th feature in pageview $p$, for $1 \leq j \leq k$. For the whole collection of pageviews in the site, we then have an $n \times k$ pageview-feature matrix $PF = \{p_1, p_2, \ldots, p_n\}$.

There are now at least two basic choices as to when content features can be integrated into the usage-based personalization process: pre-mining integration or post-mining integration.

The pre-mining integration involves the transformation of user transactions, as described earlier, into “content-enhanced” transactions containing the semantic features of the pageviews. While, in practice, there are several ways to accomplish this transformation, the most direct approach involves mapping each pageview in a transaction to one or more content features. The range of this mapping can be the full feature space, or feature sets (composite features) which in turn may represent concepts and concept categories. Conceptually, the transformation can be viewed as the multiplication of the transaction-pageview matrix $TP$, defined earlier, with the pageview-feature matrix $PF$. The result is a new matrix $TF = \{t_1, t_2, \ldots, t_n\}$, where each $t_i$ is a $k$-dimensional vector over the feature space. Thus, a user transaction can be represented as a content feature vector, reflecting that user’s interests in particular concepts or topics.

Various data mining tasks can now be performed on the content-enhanced transaction data. For instance, if we apply association rule mining to such data, then we can get a group of association rules on content features. As an example, consider a site containing information about movies. This site may contain pages related to the movies themselves, actors appearing in the movies, directors, and genres. Association rule mining process could generate a rule such as: (“British”, “Romance”, “Comedy” $\Rightarrow$ “Hugh Grant”), suggesting that users who are interested in British romantic comedies may also like the actor Hugh Grant (with a certain degree of confidence). During the online recommendation phase, the user’s active session (which is also transformed into a feature vector) is compared with the discovered
rules. Before recommendations are made, the matching patterns must be mapped back into Web pages or Web objects. In the above example, if the active session matches the left hand side of the association rule, the recommendation engine could recommend other Web pages that contain the feature “Hugh Grant”.

The post-mining integration of semantic features involves combining the results of mining (performed independently on usage and content data) during the online recommendation phase. An example of this approach was presented in Mobasher et al. (2000b), where clustering algorithms were applied to both the transaction matrix $TP$ and the transpose of the feature matrix $PF$. Since both matrices have pageviews as dimensions, the centroids of the resulting clusters in both cases can be represented as sets of pageview-weight pairs where the weights signify the frequency of the pageview occurrence in the corresponding cluster. We call the patterns generated from content data “content profiles”, while the patterns derived from usage data are called “usage profiles”. Though they share the same representation, they have different semantics: usage profiles represent a set of transactions with similar navigational behavior, while content profiles contain groups of Web pages with (partly) similar content.

Specifically, given a transaction cluster (respectively, a feature cluster) $cl$, we can construct the usage (respectively, content) profile $pr_{ci}$ as a set of pageview-weight pairs by computing the centroid of $cl$:

$$pr_{ci} = \{(p, weight(p, pr_{ci}))\mid weight(p, pr_{ci}) \geq \mu\}$$

where:

- $w(p,s)$ is the weight of page $p$ in transaction (respectively, feature) vector $s$ in the cluster $cl$; and
- the threshold $\mu$ is used to focus only on those pages in the cluster that appear in a sufficient number of vectors in that cluster.

Each such profile, in turn, can be represented as a vector in the original $n$-dimensional space of pageviews. This aggregate representation can be used directly in the recommendation phase: given a new user, $u$ who has accessed a set of pages, $P_u$, so far, we can measure the similarity of $P_u$ to the discovered profiles, and recommend to the user those pages in matching profiles which have not yet been accessed by the user. Note that this approach does not distinguish between recommendations emanating from the matching content and usage profiles. Also note that there are many other ways of combining usage profiles and content profiles during the online recommendation phase. For example, we can use content profiles as the last resort in the situation where usage profiles can not provide sufficient number of recommendations.

**A FRAMEWORK FOR ONTOLOGY-BASED PERSONALIZATION**

At a conceptual level, there may be many different kinds of objects within a given site that are accessible to users. At the physical level, these objects may be represented by one or more Web pages. For example, our hypothetical movie site may contain pages related to the movies, actors, directors, and studios. Conceptually, each of these entities represents a different type of semantic object. During a visit to this site, a user may implicitly access several of these objects together during a session by navigating to various pages containing them. In contrast to content features, ontological representation of domain knowledge contained in the site makes it possible to have a...
uniform architecture to model such objects, their properties, and their relationships. Furthermore, such a representation would allow for a more natural mapping between the relational schema for the backend databases driving Web applications and the navigational behavior of users.

In this section we will present a general framework for utilizing domain ontologies in Web usage mining and personalization. Figure 3 lays out a general process for such an integrated approach. In keeping with our earlier discussion, it is composed of three main phases: preprocessing, pattern discovery and online recommendation. Each of these phases must take into account the object properties and their relationships as specified in a domain ontology.

We assume that the site ontology is already available (either specified manually, or extracted automatically using ontology learning techniques). The goal of the preprocessing phase is to transform users’ navigational transactions into “semantic transactions” by mapping accessed pages and resource to concepts and objects of the specified ontology. The goal of the pattern discovery phase is to create aggregate representation of groups of semantic objects that are implicitly accessed by similar users, thus providing a semantic characterization of user segments with common behavior or interests. Finally, in the recommendation phase, the discovered semantic patterns are utilized in conjunction with an ongoing record of a current user’s activity (including, possibly the user’s stored profile) to recommend new resources, pages, or objects to that user.

Knowledge Representation

General ontology representation languages such as DAML+OIL (Horrocks, 2002) provide formal syntax and semantics for representing and reasoning with various elements of an ontology. These elements include “individuals” (or objects), “concepts” (which represent sets of individuals), and “roles” (which specify object properties). In DAML+OIL, the notion of a concept is quite general and may encompass a heterogeneous set of objects with different properties (roles) and structures. We, on the other hand, are mainly

Figure 3. A General Framework for Personalization Based on Domain Ontologies
interested in the aggregate representations for groups of objects that have a homogenous concept structure (i.e., have similar properties and data types). For example, we may be interested in a group of movie objects, each of which has specific values for properties such as “year”, “genre”, and “actors.” We call such a group of objects a class. Thus, in our framework, the notion of a class represents a restriction of the notion of a concept in DAML+OIL. It should be noted, however, that the users of a Web site, in general, access a variety of objects belonging to different classes. Thus, this homogeneity assumption would imply that semantic objects within user transactions must first be classified into homogenous classes as a preprocessing step.

More specifically, we define a class \( C \) as a set of objects together with a set of attributes. These attributes together define the internal properties of the objects in \( C \) or relationships with other concepts that involve the objects in \( C \). Thus attributes of a class correspond to a subset of the set of roles in the domain ontology. We denote the domain of values of an attribute \( a \) as \( D_a \). Furthermore, because we are specifically interested in aggregating objects at the attribute level, we extend the notion of a role to include a domain-specific combination function and an ordering relation.

More formally, a class \( C \) is characterized by a finite set of attributes \( AC \), where each attribute \( a \) in \( AC \) is defined as follows.

**Definition:** Let \( C \) be a class in the domain ontology. An attribute \( a \) \( AC \) is a 4-tuple, where \( a = (T_a, D_a, \prec_a, \psi_a) \)

- \( T_a \) is the type for the values for the attribute \( a \).
- \( D_a \) is the domain of the values for \( a \);
- \( \prec_a \) is an ordering relation among the values in \( D_a \); and
- \( \psi_a \) is a combination function for the attribute \( a \).

The “type” of an attribute in the above definition may be a concrete datatype (such as “string” or “integer”) or it may be a set of objects (individuals) belonging to another class.

In the context of data mining, comparing and aggregating values are essential tasks. Therefore, ordering relations among values are necessary properties for attributes. We associate an ordering relation \( \prec_a \) with elements in \( D_a \) for each attribute \( a \). The ordering relation \( \prec_a \) can be null (if no ordering is specified in the domain of values), or it can define a partial or a total order among the domain values. For standard types such as values from a continuous range, we assume the usual ordering. In cases when an attribute \( a \) represents a concept hierarchy, the domain values of \( a \) are a set of labels, and \( \prec_a \) is a partial order representing the “is-a” relation.

Furthermore, we associate a data mining operator, called the combination function, \( \psi_a \), with each attribute \( a \). This combination function defines an aggregation operation among the corresponding attribute values of a set of objects belonging to the same class. This function is essentially a generalization of the “mean” or “average” function applied to corresponding dimension values of a set of vectors when computing the centroid vector. In this context, we assume that the combination function is specified as part of the domain ontology for each attribute of a class. An interesting extension would be to automatically learn the combination function for each attribute based on a set of positive and negative examples.

Classes in the ontology define the structural and semantic properties of objects in the domain which are “instances” of that class. Specifically, each object \( o \) in the domain is also characterized by a set of attributes \( A_o \) corresponding to the attributes of a class in the ontology. In order to more precisely define the notion of an object as an instance of a class, we first define the notion of an instance of an attribute.
Definition: Given an attribute \( a = \langle T_a, D_a, \prec_a, \psi_a \rangle \) and an attribute \( b = \langle T_b, D_b, \prec_b, \psi_b \rangle \), \( b \) is an instance of \( a \), if \( D_b \subseteq D_a \), \( T_b = T_a \), \( \psi_b = \psi_a \), and \( \prec_b \) is a restriction of \( \prec_a \) to \( D_b \). The attribute \( b \) is a null instance of \( a \), if \( D_b \) is empty.

Definition: Given a class \( C \) with attribute set \( A_C = \{ a_1^C, a_2^C, \ldots, a_n^C \} \), we say that an object \( o \) is an instance of \( C \), if \( o \) has attributes \( A_o = \{ a_1^o, a_2^o, \ldots, a_n^o \} \) such that each is a, possibly null, instance of \( a_i^C \).

Based on the definitions of attribute and object instances, we can now provide a more formal representation of the combination function \( \psi_a \). Let \( C \) be a class and \( \{ o_1, o_2, \ldots, o_m \} \) a set of object instances of \( C \). Let \( a \in A_C \) be an attribute of class \( C \). The combination function \( \psi_a \) can be represented by:

\[
\psi_a \left( \left\{ \langle a_1^o, w_1 \rangle, \langle a_2^o, w_2 \rangle, \ldots, \langle a_n^o, w_n \rangle \right\} \right) = \left\{ \langle a_{agg}, w_{agg} \rangle \right\}
\]

where each \( o_i \) belonging to object \( o_i \) is an instance of the attribute \( a_i \), and each \( w_i \) is a weight associated with that attribute instance (representing the significance of that attribute relative to the other instances). Furthermore, \( a_{agg} \) is a pseudo instance of \( a \) meaning that it is an instance of \( a \) which does not belong to a real object in the underlying domain. The weight \( w_{agg} \) of \( a_{agg} \) is a function of \( w_1, w_2, \ldots, w_n \).

Given a set of object instances, of a class \( C \), a domain-level aggregate profile for these instances is obtained by applying the combination function for each attribute in \( C \) to all of the corresponding attribute instances across all objects \( o_1, o_2, \ldots, o_m \).

**Ontology Preprocessing**

The ontology preprocessing phase takes as input domain information (such as database schema and metadata, if any) as well as Web pages, and generates the site ontology. For simple Web sites, ontologies can be easily designed manually or derived semi-automatically from the site content. However, it is more desirable to have automatic ontology acquisition methods for a large Web site, especially in Web sites with dynamically generated Web pages. E-commerce Web sites, for instance, usually have well-structured Web content, including predefined metadata or database schema. Therefore it is easier to build automatic ontology extraction mechanisms that are site-specific.

There have been a number of efforts dealing with the ontology learning problem (Clerkin et al., 2001; Craven et al., 2000; Maedche & Staab, 2000). A wide range of information, such as thesauri, content features, and database schema can help to identify ontologies. Many of these approaches have focused on extracting ontological information from the Web, in general. In Berendt et al. (2002) the notion of “Semantic Web Mining” was introduced, including a framework for the extraction of a concept hierarchy and the application of data mining techniques to find frequently occurring combinations of concepts.

**An Example**

As an example, let us revisit our hypothetical movie Web site. The Web site includes collections of pages containing information about movies, actors, directors, etc. A collection of pages describing a specific movie might include information such as the movie title, genre, starring actors, director, etc. An actor or director’s information may include name, filmography (a set of movies), gender, nationality, etc. The portion of domain ontology for this site, as described, contains the classes Movie, Actor and Director (Figure 4). The collection of Web pages in the site represents a group of embedded objects that are the instances of these classes.

In our example, the class Movie has attributes such as Year, Actor (representing the relation
“acted by”), Genre, and Director. The Actor and Director attributes have values that are other objects in the ontology, specifically, object instances of classes Actor and Director, respectively. The attribute Year is an example of an attribute whose datatype is positive integers with the usual ordering. The attribute Genre has a concrete datatype whose domain values in $D_{genre}$ are a set of labels (e.g., “Romance” and “Comedy”). The ordering relation $\prec_{genre}$ defines a partial order based on the “is-a” relation among subsets of these labels (resulting in a concept hierarchy of Genres, a portion of which is shown in Figure 4).

Figure 5 shows a Movie instance “About a Boy” and its related attributes and relations extracted from a Web page. The schema of the class Movie is shown at the bottom left portion of the figure. Here we treat the classes Genre and Year as attributes of the class Movie. The instances of the ontology are shown at the bottom right of the figure. The Genre attribute contains a partial order among labels representing a concept hierarchy of movie genres. We use a restriction of this partial order to represent the genre to which the Movie instance belongs. The diagram also shows a keyword bag containing the important keywords in that page.

An attribute $a$ of an object $o$ has a domain $D_a$. In cases when the attribute has unique a value for an object, $D_a$ is a singleton. For example, consider an object instance of class Movie, “About a Boy” (see Figure 5). The attribute Actor contains two objects “H. Grant” and “T. Collette” that are instances of the class Actor (for the sake of presentation we use the actors’ names to stand for the object instances of Actor). Therefore, $D_{Actor} = \{“H. Grant”, “T. Collette”\}$. Also, a real object may have values for only some of the attributes. In this case the other attributes have empty domains. For instance, the attribute Director in the example has an empty domain and is thus not depicted in the figure. We may, optionally, associate a weight with each value in the attribute domain $D_a$ (usually in the range $[0,1]$). This may be useful in capturing the relative importance of each attribute value.

For example, in a given movie the main actors should have higher weights than other actors in the cast. In our example, the object “H. Grant” has weight 0.6 and the object “Toni Collette” has weight 0.4. Unless otherwise specified, we assume that the weight associated with each attribute value is 1. In the object $o$ shown in Figure 5, the domain for the attribute Genre is the set of labels {Genre-All, Action, Romance, Comedy, Romantic Comedy, Black Comedy, Kids & Family}. The ordering relation $\prec_{genre}$ is a restriction of $\prec_{genre}$.
to the subset \{Genre-All, Comedy, Romantic Comedy, Kids & Family\}.

**Pattern Discovery**

As depicted in Figure 3 domain ontologies can be incorporated into usage preprocessing to generate semantic user transactions, or they can be integrated into pattern discovery phase to generate semantic usage patterns. In the following example, we will focus on the latter approach.

Given a discovered usage profile (for example, a set of pageview-weight pairs obtained by clustering user transactions), we can transform it into a domain-level aggregate representation of the underlying objects (Dai & Mobasher, 2002). To distinguish between the representations we call the original discovered pattern an “item-level” usage profile, and we call the new profile based on the domain ontology a “domain-level” aggregate profile. The item-level profile is first represented as a weighted set of objects: $pr = \{(o_1, w_1), (o_2, w_2), ..., (o_n, w_n)\}$ in which each $o_i$ is an object in the underlying domain ontology and $w_i$ represents $o_i$‘s significance in the profile $pr$. Here we assume that, either using manual rules, or through supervised learning methods, we can extract various object instances represented by the pages in the original page- or item-level usage profile. The transformed profile represents a set of objects accessed together frequently by a group of users (as determined through Web usage mining). Objects, in the usage profile, that belong to the same class are combined to form an aggregated pseudo object belonging to that class. An important benefit of aggregation is that the pattern volume is significantly reduced, thus relieving the computation burden for the recommendation engine. Our goal is to create an aggregate representation of this weighted set of objects to characterize the common interests of
the user segment captured by the usage profile at the domain level.

Given the representation of a profile \( pr \) as a weighted set of objects, the objects in \( pr \) may be instances of different classes \( C_1, C_2, \ldots, C_k \) in the ontology. The process of creating a domain-level aggregate profile begins by partitioning \( pr \) into collections of objects with each collection containing all objects that are instances of a specified class (in other words, the process of classifying the object instances in \( pr \)). Let \( G_i \) denote the elements of \( pr \) that are instances of the class \( C_i \).

Having partitioned \( pr \) into \( k \) groups of homogeneous objects, \( G_1, \ldots, G_k \), the problem is reduced to creating aggregate representation of each partition \( G_i \). This task is accomplished with the help of the combination functions for each of the attributes of \( C_i \), some of whose object instances are contained in \( G_i \). Once the representatives for every partition of objects are created, we assign a significance weight to each representative to mark the importance of this group of objects in the profile. In our current approach the significance weight for each representative is computed as the weighted sum of all the object weights in the partition. However, significance weight can be computed using other numeric aggregation functions.

Examples Continued: Generating Domain-Level Aggregate Profiles

To illustrate the semantic aggregation process, let us return to our movie site example. The aggregation process requires that a “combination function” be defined for each attribute of an object in the domain ontology. Figure 6 and 8 show an example of such process. Each movie object has attribute “Name”, “Actor”, “Genre” and “Year”. For the attribute Name, we are interested in all the movie names appearing in the instances. Thus we can define \( \psi_{\text{Name}} \) to be the union operation performed on all the singleton Name attributes of all movie objects. On the other hand, the attribute Actor contains a weighted set of objects belonging to class Actor. In fact, it represents the relation “Starring” between the actor objects and the movie object. In such cases we can use a vector-based weighted mean operation as the combination function. For example, we will determine the aggregate weight of an actor object \( o \) by:

\[
w_o = \left( \sum_i w_i \cdot w_n \right) / \sum_i w_i.
\]

Applying \( \psi_{\text{Actor}} \) in our example will result in the aggregate actor object \( \{ (S, 0.58), (T, 0.27), (U, 0.09) \} \). As for the attribute Year, the combination function may create a range of all the Year values appearing in the objects. Another possible solution is to discretize the full Year range into decades and find the most common decades that are in the domains of the attribute. In our example, using the range option, this may result in an aggregate instance [1999, 2002] for the Year attribute.

The attribute Genre of Movie contains a partial order representing a concept hierarchy among different Genre values. The combination function, in this case, can perform tree (or graph) matching to extract the common parts of the conceptual hierarchies among all instances. Extracting the common nodes from this hierarchy may also depend on the weights associated with the original objects leading to different weights on the graph edges. For example, given that the higher weight Movies 1 and 2 have “Romance” in common, this node may be selected for the aggregate instance, even though it is not present in Movie 3. However, the weight of “Romance” may be less than that of “Comedy” which is present in all three movies.

Figure 6 shows the item-level usage profile and its representation as a weighted set of objects, as well as the resulting domain-level aggregate profile. Note that the original item-level profile gives us little information about the reasons why these objects were commonly accessed together. However, after we characterize this profile at the domain-level, we find some interesting patterns:
they all belong to Genre “Comedy” (and to a lesser degree “Romance), and the actor S has a high score compared with other actors.

Online Recommendation Phase

In contrast to transaction-based usage profiles, semantic usage profiles capture the underlying common properties and relations among those objects. This fine-grained domain knowledge, captured in aggregate form enables more powerful approaches to personalization. As before, we consider the browsing history of the current user, i.e., active session, to be a weighted set of Web pages that the user has visited. The same transformation described in the last subsection can be used to create a semantic representation of the user’s active session. We call this representation the current user profile.

Figure 7 presents the basic procedure for generating recommendations based on semantic profiles. The recommendation engine matches the current user profile against the discovered domain-level aggregate profiles. The usage profiles with matching score greater than some pre-specified threshold are considered to represent this user’s potential interests. A successful match implies that the current user shares common interests with the group of users represented by the profile. The matching process results in an extended user profile which is obtained by applying the aggregation process described above to the domain-level profiles and the original user profile.

The recommendation engine then instantiates the user’s extended profile to real Web objects and will recommend them to the user. We can also exploit structural relationships among classes during the recommendation process. For example, if a concept hierarchy exists among objects, and the recommendation engine can not find a good match for a user profile at a certain concept level, then it can generalize to a more abstract level (e.g., from “romantic comedy” to “romance”).

This approach has several advantages over traditional usage-based personalization. First, it retains the user-to-user relationships that can be captured by the discovered usage profiles. Secondly, in contrast to standard collaborative
filtering, it provides more flexibility in matching aggregate usage profiles with the current user’s activity because the matching process involves comparison of features and relationships, not exact item identities. Thirdly, the items do not have to appear in any usage profiles in order to be recommended, since fine-grained domain relationships are considered during the instantiation process. The previous example shows that this approach can also be used to solve the “new item” problem. Furthermore, it can alleviate the notorious “sparsity” problem in collaborative filtering systems by allowing for “fuzzy” comparisons between two user profiles (or ratings). The basis for matching profiles does not have to be similar ratings on the same items. The comparison can be based on showing interest in different objects with similar properties (for example, purchasing items that have the same brand). Therefore, even if the raw transaction or rating data is sparse, the semantic attributes of items or users can be used to indirectly infer potential interest in other items.

CONCLUSION

We have explored various approaches, requirements, and issues for integrating semantic knowledge into the personalization process based on Web usage mining. We have considered approaches based on the extraction of semantic features from the textual content contained in a site and their integration with Web usage mining tasks and personalization both in the pre-mining and the post-mining phases of the process. We have also presented a framework for Web personalization based on full integration of domain ontologies and usage patterns. The examples provided throughout this chapter reveal how such a framework can provide insightful patterns and smarter personalization services.

We leave some interesting research problems for open discussion and future work. Most important among these are techniques for computing similarity between domain objects and aggregate domain-level patterns, as well as learning techniques to automatically determine appropriate combination functions used in the aggregation process.

More generally, the challenges lie in the successful integration of ontological knowledge at every stage of the knowledge discovery process. In the preprocessing phase, the challenges are in automatic methods for the extraction and learning of the ontologies and in the mapping of users’ activities at the clickstream level to more abstract concepts and classes. For the data mining phase, the primary goal is to develop new approaches that take into account complex semantic relationships such as those present in relational databases with multiple relations. Indeed, in recent years, there has been more focus on techniques such as those based relational data mining. Finally in the personalization stage, the challenge is in developing techniques that can successfully and efficiently measure semantic similarities among complex objects (possibly from different ontologies).
In this chapter we have only provided an overview of the relevant issues and suggested a road map for further research and development in this area. We believe that the successful integration of semantic knowledge with Web usage mining is likely to lead to the next generation of personalization tools which are more intelligent and more useful for Web users.

Chapter 2.24
Modeling Variant User Interfaces for Web-Based Software Product Lines

Suet Chun Lee
BUSINEX, Inc., USA

ABSTRACT

Software product line (SPL) is a software engineering paradigm for software development. SPL is important in promoting software reuse, leading to higher productivity and quality. A software product within a product line often has specific functionalities that are not common to all other products within the product line. Those specific functionalities are termed “variant features” in a product line. SPL paradigm involves the modeling of variant features. However, little work in SPL investigates and addresses the modeling of variant features specific to UI. UML is the de facto modeling language for object-oriented software systems. It is known that UML needs better support in modeling UIs. Thus, much research developed UML extensions to improve UML support in modeling UIs. Yet little of this work is related to developing such extensions for modeling UIs for SPLs in which variant features specific to user interfaces (UI) modeling must be addressed. This research develops a UML extension, WUIML, to address these problems. WUIML defines elements for modeling variant features specific to UIs for Web-based SPLs. The model elements in WUIML extend from the metaclass and of the UML2.0 metamodel. WUIML integrates the modeling of variant features specific to UIs to UML. For example, in a Web-based patient registration SPL, member products targeting British users may use British date format in the user interface, while member products targeting United States users may use United States date format in the user interface. Thus, this is a variant feature for this product line. WUIML defines a model element, XOR, to represent such exclusive or conditions in a product line user interface model. WUIML would reduce SPL engineers’ efforts needed in UI development. To validate the WUIML research outcome, a case study was conducted. The results of this empirical study indicate that modeling UIs for Web-based SPLs using WUIML is more effective and efficient than using standard UML.
INTRODUCTION

Software product line (SPL) (Chastek, Donohoe, Kang, & Thiel, 2001; Clements & Northrop, 2002; SEI, 2005a) is a software engineering paradigm to develop software products. One important step in the SPL paradigm is the modeling of the functional features of software products across the product line. The features are called common core. An even more important step in the SPL paradigm is the modeling of the specific functional features within a particular member product in a product line. These specific functional features are called variant features because they are the features that differentiate member products in the product line. Then based on the model, a product is “assembled” by reusing the common core and selected variant features.

Unified Modeling Language (UML) (OMG, 2003b, 2004; Rumbaugh, Jacobson, & Booch, 2005) is a standard object-oriented modeling language. UML includes multiple views and diagram types to capture software functionalities from user perspective. However, UML seems to have not been developed for modeling user interface specific issues (Kovacevic, 1998; Silva & Paton, 2003). One of the usages of user interface models is that, in model-based user interface management systems (MB-UIMSs) (Griffiths et al., 2001; Szekey, Sukaviriya, Castells, Muthukumarasamy, & Salcher, 1996), user interface models can be used to generate user interface codes. There are extensions of UML (Blankenhorn & Jeckle, 2004; Nunes, 2003; Silva, 2002) to make UML better support user interface modeling. Yet, these extensions often assume the modeling of a single system instead of a SPL. On the other hand, although standard UML (OMG, 2003b, 2004) seems to have not been developed to support the modeling of SPLs, there are works (Gomaa, 2004; Gomaa & Gianturco, 2002; Ziadi, Héléouët, & Jézéquel, 2004) on extending UML to improve UML supports in modeling SPLs. Yet, these works do not focus on user interface modeling. Currently, many software products are Web-based. However, some (Silva, 2002) observe that there are specific modeling challenges for modeling user interfaces of Web-based software systems.

Thus, it is not clear how to model variant features for user interface specific issues in Web-based software product lines. This is an important barrier to overcome if software product line development of Web-based products is to take greater advantage of software reuse objectives: increased quality, decreased effort, or decreased time to market. Therefore, this paper is concerned with reporting research about developing a UML extension, Web User Interface Modeling Language (WUIML) that decreases effort by increasing effectiveness and efficiency needed in using UML to model user interfaces for Web-based software product lines. User interface development has been found (Myers, 1989) to account for a significant amount of overall software development work. WUIML would improve SPL software engineering paradigm in the user interface development perspective by reducing engineers’ efforts needed in user interface modeling.

BACKGROUND AND RELATED WORK

Unified Modeling Language

Unified Modeling Language (UML) (Booch, Rumbaugh, & Jacobson, 1999; OMG, 2003b, 2004; Scott, 2004) is a graphical language for specifying software systems. UML is a standard of the Object Management Group (OMG; see http://www.omg.org). The most current version for UML is UML 2.0 (OMG, 2003b, 2004). This research considers UML in UML 2.0 context.

UML is a standardized notation for object-oriented development. UML consists of views, diagrams, model elements, and general mechanisms. Views are used to present different aspects of complex systems from both the “system” in the
problem and the “system” in the solution. Tacitly, UML defaults to “system” as meaning the system in the solution. This is consistent with the classical use cases modeling and design process model. Therefore, whenever the term “system” is used in this paper, this usual UML use cases default as “system in the solution” is implied. Moreover, each view requires a number of diagrams, such as use case diagram, class diagram, and interaction diagrams. Each diagram captures a particular aspect of a system. Views that are often used with UML include: use case view, logical view, implementation view, process view, and deployment view. Use case views describe the functionality a system should deliver from external actors’ point of view. An actor is a human user or another system external to the system. A use case is often used to describe functions requested for a system. Logical views are used to describe a system’s functionality. Use cases are often the first set of models being created for a system. However, some found common pitfalls in use cases for one who is new to use case modeling (Lilly, 2000; Rosenberg & Scott, 2001).

Modeling concepts are captured in model elements. Example model elements are class, object, state, node, package, and component (Eriksson, Penker, Lyons, & Fado, 2004). Model elements are used in diagrams. A model element can have a visual representation. There are rules that limit types of model elements for different diagrams. Relationships between model elements are specified by relationships, such as association, generalization, dependency, and aggregation.

Additional information that cannot be represented using model elements is represented using UML general mechanisms, such as adornments, comments, tagged values, and properties (Eriksson et al., 2004). Adornments are used to add visual impact to the element. For example, “underline” an instance of a type is an adornment. Comments can be placed anywhere in a diagram. Comments often contain explanations or questions to resolve issues at a later time. Model elements have properties to store data values about an element. A property is defined with a name and a value called a tagged value. Properties are used to add additional specifications about element instances that are not normally shown in the diagram.

UML can be extended or adapted by its extension mechanisms: stereotype, tagged values, and constraints. A stereotype defines a new kind of model element based on existing model elements. A stereotype is described by placing its name as a string and within a pair of guillemots. For example, a class with the stereotype <<Radio>> is read as “a class of the Radio stereotype,” meaning that it is a radio type of class. The particular characteristics of a Radio class must have been defined when the stereotype is defined. A constraint is a restriction on an element that limits the usage of the elements. A constraint is enclosed in a curly bracket, for example, {student = “Dorothy”}. Alternatively, constraints can be written in Object Constraint Language (OCL) (OMG, 2003a). A UML profile (OMG, 2003b) is a stereotyped package that contains model elements that have been customized for a specific purpose using extension mechanisms, such as stereotypes, tagged values, and constraints. A profile can only extend an existing UML model element using stereotypes, tagged values, or constraints. A profile cannot create new model elements that were not previously defined in the UML 2.0 infrastructure specification (OMG, 2003b).

UML 2.0 is defined in Meta-Object-Facility (MOF) (OMG, 2002). MOF is an abstract language for defining modeling languages. Therefore, another way to extend UML is using MOF. MOF extends UML by defining new metamodel elements. This approach is often called metamodel approach. In metamodel approach, new model elements can be created. With metamodel approach, one can also create model elements that change UML symbols and semantics.
Software Product Line

Software product line (SPL) (SEI, 2005a) is a software engineering paradigm (SEI, 2005b). The paradigm mainly includes two software engineering processes: product line engineering and member product engineering. The product line engineering process involves a number of techniques in software engineering, such as domain analysis, requirements engineering, product architecture, and component development (Clements & Northrop, 2002). The product engineering process involves the configuration (“assemble”) of member products from the product line assets. The SPL paradigm depends on the notion of variability and variability mechanisms. In SPL, the term variability is used to indicate the extent of differences in user visible software properties among member products. A user visible software property is a feature. A feature of a member product that is different from other member products is a variant feature. Therefore, a variant feature is a feature only to one or more (but not all) products in a SPL. Variability mechanisms are a set of methods and steps that can be applied to develop variant features for SPLs.

The user interface of member products of a SPL may vary in one or more user interface specific features. Examples of user interface specific features are the layout of the user interface, the functionality of the user interface, the interaction of the user interface to and from the user, and so forth. The user interface specific variant features, like other non-user interface specific features, also need to be captured in a SPL model.

It seems that issues in user interface developments have been largely ignored by the SPL researches. It is not clear how to go about applying the software product line paradigm in user interface modeling. WUIML developed in this research is differentiated from other related works (Gomaa, 2004; Gomaa & Gianturco, 2002; Shin, 2002; Webber, 2001; Ziadi et al., 2004) in SPL researches in that WUIML is addressing the modeling of user interfaces in a SPL using UML. It is known (Silva & Paton, 2003) that UML needs better support in modeling user interfaces. The related works extend UML to improve support on modeling SPL, yet those works have not addressed the modeling issues in user interfaces for SPL. User interface development has been found (Myers, 1989) to account for a significant amount of overall software development work. WUIML would improve SPL software engineering paradigm in the user interface development perspective by reducing engineers’ efforts needed in user interface modeling.

Web User Interface Modeling

User interface is a computer-based media to facilitate communication between users and a software system (Marcus, 2002). Early user interfaces in software systems are text or form-based. Modern software systems however use graphical user interfaces (GUI) implemented according to programming packages, such as Java Swings classes (Eckstein, Loy, & Wood, 1998). More recently, HTML is used to create Web-based user interfaces that can be rendered by Internet browsers (Sommerville, 2001).

The user interfaces of a Web-based software product are called Web user interface (WUI) in this research. The modeling of a WUI is the development of an abstract understanding of the requirements of the WUI and represents it in an abstract notation. The modeling of WUI using WUIML does not provide a visual look of a WUI, thus, WUI modeling is not the design of a WUI. Currently, a major use of WUI modeling is to provide inputs for WUI code generation. In particular, WUI models resulting from WUI modeling are fed into a model-based tool. The tool either auto-generates (or semi-auto-generates) WUI implementations for the WUI models (Behrens, Ritter, & Six, 2003; Gómez & Cachero, 2003).
UML-Based User Interface Modeling

One approach to user interface modeling and specification methods is to extend UML notations (Behrens et al., 2003; Blankenhorn & Jeckle, 2004; Hennicker & Koch, 2001; Jacobson, Christerson, Jonsson, & Overgaard, 1992; Nunes, 2003; Phillips, Kemp, & Kek, 2001; Scogings & Phillips, 2001; Silva & Paton, 2003).

A Web UI development method is proposed in Behrens et al. (2003). The method consists of two tasks: UI requirements modeling and mapping UI requirements model to UI architecture. The modeling of UI requirements includes the specification of use cases (called “work units” in the paper), and then the work units are modeled using user-defined UML stereotypes representing user interface elements. A UI element is modeled as a \texttt{<<scene>>}. A \texttt{<<scene>>} may consist of zero or more \texttt{<<class view>>}. A user interface is then the composition of different \texttt{<<scene>>} elements. The navigations between user interfaces are based on the parent-child relationship between the user interfaces, domain requirements, and usability aspects. In Hennicker and Koch (2001), a UML profile for modeling user interfaces for Web applications is proposed. The UML profile includes UML stereotypes to model the presentation (“look and feel”) and navigation aspects of Web UIs. The Object-Oriented Hypermedia (OO-H) Method (Gómez & Cachero, 2003) extends UML with a set of new views for modeling Web user interface models. In Silva and Paton (2003), a UML extension, UMLi, was developed to support user interface modeling for interactive systems. However, UMLi has yet to address Web UI as indicated in Silva (2002) that there are additional user interface modeling properties for Web applications.

The major difference between this work and the related works (Behrens et al., 2003; Gómez & Cachero, 2003; Hennicker & Koch, 2001; Jacobson et al., 1992; Silva, 2002; Silva & Paton, 2003) in user interface modeling is that WUIML addresses the modeling of user interfaces for SPLs and the related works focus on the modeling of user interfaces for a single system. In addition, the modeling elements in WUIML capture the Web user interface properties specific to Web software products according to important Web standards (Axelsson, Epperson, Ishikawa, McCarron, Navarro, & Pemberton, 2003; Bos, Celik, Hickson, & Lie, 2004; Dubinko, Leigh, Klotz, Merrick, & Raman, 2002; Lie & Bos, 1999; Meyer, 2000; W3C). WUIML improves SPL software engineering paradigm by reducing efforts needed by SPL engineers in user interface modeling for SPLs.

WEB USER INTERFACE MODELING LANGUAGE (WUIML)

WUIML improves UML support on user interface modeling for Web-based software product lines. User interface modeling falls into the scope of user interface development. The user interface models specified in WUIML form one generic user interface software product line asset for the entire main software product line. The idea is to have user interface models as core assets. Then to develop user interfaces for member products, one would reuse all common user interface components and reuse selectively the variant user interface components.

In this research, the requirements analysis process for user interfaces is as follows. Given software requirements for a software product line, user interface related use cases from product line requirements are derived. A use case that is user interface related can be developed into many user interface scenarios. Each scenario is due to one or more variant user interface aspects. A user interface scenario involves one or more user interfaces. Any interaction between a human user and a user interface or between a user interface and a backend application is also captured in the use case scenario. Once the user interfaces are identified, one can decide on the user interface components. After eliciting and describing the scenarios, the
next step is to identify the relationships between user interfaces. The interacting relationships between user interfaces are captured in extended activity diagrams where nodes in the activity diagrams can represent variant user interfaces. The extended activity diagram shows the variant interactions between user interfaces.

In order to specify common and variant features for user interfaces, WUIML defines stereotyped relationships between modeling elements. These new relationships are selected syntheses and extensions from Jacobson, Griss, and Jonsson (1997) and Anastasopoulos and Gacek’s (2001) variability mechanisms. In addition, the variant notations and rules of the FODA (Cohen, Stanley, Peterson, & Krut, Jr., 1992) technique have been adopted and incorporated into WUIML. In addition, this research developed a new variability mechanism called WUIML. WUIDefinition models a WUI that is an aggregation of different parts of other WUIs. For example, a portal WUI is a WUIDefinition of a number of other WUIs. The difference between WUIDefinition and the UML aggregation is that WUIDefinition limits its aggregated components to be instances of WUIComposite or specific WUIElements while the standard UML aggregation does not have this restriction. This restriction helps modelers on deciding what components are appropriate for the aggregation. The variability mechanisms are used to generate variants on user interface aspects. User interface aspects include (but not limited to) user functional requirements, style, presentation, layout, events, data model, and constraints.

The structural contents of WUIML are built from various World Wide Web Consortium (W3C; see http://www.w3c.org) specifications: XHTML (Altheim & McCarron, 2001; Altheim, Boumphrey, McCarron, Schnitzendomer, & Wugofski, 2001; Altheim & McCarron, 2001; Axelsson et al., 2003; Powell, 2003; Raggett, Hors, & Jacobs, 1999; Sauers & Wyke, 2001; W3C, 2002), XForms (Dubinko, 2003; Dubinko et al., 2002; Khare, 2000), and Cascading Style Sheets (CSS) (Bos et al., 2004; Lie & Bos, 1999; Meyer, 2000, 2003; Schengili-Roberts, 2004; Schmitt, 2003).

WUIML is also built on the UML 2.0 specifications (OMG, 2003b, 2004) and is an extension to the metamodeling approach of the UML 2.0. In particular, WUIML extends metaclass and BasicActivity of the UML 2.0 metamodel. The metaclass extension is achieved via stereotype extension mechanism. The extension to the BasicActivity is achieved via MOF.

A WUI structurally consists of multiple user interface elements, such as user interface visual elements (such as a button, a checkbox, etc.), hypertext links, images, text, and so forth. These elements are “mapped” to stereotyped UML classes that extend the UML2.0 metaclass.

Events (sometimes termed “triggers”) occur when user interface elements interact with user actions. Actions are mapped to UML interfaces. An interface defines a set of operations triggered by events. Events and actions characterize a user interface interaction and are modeled as operations of metamodel elements. Interactions between user interfaces are modeled using UML activity diagrams. In addition, UML activity diagram is extended to model variant interactions in WUIML.

Basic WUIML Elements

Figure 1 defines the Basic WUIML Elements in UML 2.0 notations. These model elements extend from the metaclass of the UML2.0 metamodel. These model elements have attributes and operations. The attributes are used to model the static features of user interfaces; for example, an attribute can be used to describe the background color of a user interface element. The operations are used to model the dynamic aspects of user interfaces, for example, events (e.g., a user clicks a button can be tracked by an event listener) and actions (e.g., an error message box popup can be implemented by a method) can be modeled.
Modeling Variant User Interfaces for Web-Based Software Product Lines

Figure 1. Basic WUIML elements

as operations. Figure 2 shows the class diagram of the WUIElement and the Command model elements.

A WUI is modeled as a WUITemplate. A WUITemplate may be composed of one or more of WUIComposite. A WUITemplate may also be composed of one or more WUIElement and one or more WUIComposite. A WUIComposite has one or more specific WUI modeling elements (such as Submit, Input, etc.) that extend from the WUIElement. The style, layout, and position within a WUI of a WUIElement can be described using the StyleDecorator model element. A StyleDecorator composes of a number of Dimension element, Position element, and the Style element. The Dimension (how large or small the WUI element is), Position (where the WUI element is positioned within a WUI), and Style (such as what is the foreground color of the WUI element) elements together model abstractly the style of a WUI element. A set of StyleDecorator elements forms a StyleStrategy. A StyleStrategy element describes the style of a WUIComposite element. A set of StyleStrategy elements models the style of a WUITemplate.

These WUIML elements integrate Web properties according to important Web standards (Axelsson et al., 2003; Bos et al., 2004; Dubinko et al., 2002; Lie & Bos, 1999; Meyer, 2000; W3C) to the modeling of Web-based user interfaces for
SPLs. With regard to the modeling of the static aspects of user interfaces, what WUIML adds to the standard UML is like what application programming interfaces (APIs) add to a programming language. For example, the Swing API (Eckstein et al., 1998) provides the building blocks for programmers to code user interfaces. Similarly, WUIML provides the building blocks for modelers to model user interfaces. When using Swing, a programmer does not have to construct fundamental user interface elements, such as textboxes, radio buttons, and so forth. The programmer would just use them. Similarly, when using WUIML, a modeler does not have to model the fundamental user interface elements, such as textboxes, radio buttons, and so forth. When using standard UML, those fundamental user interface elements must be modeled first. In addition, WUIML provides a way to conveniently model the layout, size, and position (where it is within a user interface) for a particular user interface element. Currently, there is no standard way in using UML to model the layout and style of a Web-based user interface. WUIML defines a way for modeling the layout and style of a Web-based user interface.
Example I: Web User Interface Modeling Using Basic WUIML Elements

In a SPL, a user interface feature may vary among the member products. For example, consider a SPL of online patient registration systems. A member product to be deployed for U.S. customers would have a user interface customized for the U.S. address format. On the other hand, member products to be deployed for Hong Kong customers would have a user interface customized for the Hong Kong address format.

Figure 3 shows a product line Web user interface model that consists of instances of <<WUIComposite>> elements. An instance of <<WUIComposite>> may compose of a number of fundamental user interface elements (such as a textbox, an input box, a listbox, etc.) but they are not shown in Figure 3. A <<WUIComposite>> can be considered as a portion of a user interface called user interface fragment in this research. A user interface is composed of a number of user interface fragments.

Modeling Variant Interactions

WUIML defines elements to model the different interactions between a user interface and its back-end process. If an MVC architecture (Gamma, Helm, Johnson, & Vlissides, 1995) is the example, then the back-end application is the controller and the model. For the same functional task, such as a WUI for remittance of an online banking service SPL, each member product may implement it in a slightly different way. The difference would lead to differences in the WUI related to the task among member products. The differences in WUI would in turn lead to different patterns of user interactions to the WUI as well as different implementation of back-end processes. For example, to send money to a foreign country, the WUI must collect the destination country (as country code) and currency (currency code) information from the user. On the other hand, to send money...
domestically within the U.S., the WUI does not need to collect country code or currency information. The different user interactions to a user interface in a SPL are called variant interactions. User actions, such as clicking a submit button in a WUI, may trigger transitions between WUls. In this research, UML activity diagram is used to model the interactions between WUls.

WUIML defines two new metamodel elements using MOF to model variant interactions. The two new elements are VariantAction and SPLAction. In UML, a node in an activity diagram is represented by the ActivityNode element. The ActivityNode element has three children: ExecutableNode, ObjectNode, and ControlNode. Object Nodes represent the objects involved in the activity diagram. The ControlNode signifies the control flow on the activity diagram; for example, a fork bar is a ControlNode. The ExecutableNode has a child, the Action element. The Action element in UML is the representation of a node that characterized by one or more actions. Since interactions are characterized by actions, WUIML extends the UML Action element to model variant interactions.

Figure 4 shows the new metamodel elements, VariantAction and SPLAction, and how they relate to other elements in the activity class diagram. The VariantAction element is a specialization of the UML Action element. The SPLAction is a specialization of the Element metamodel element from the UML2.0 kernel package. A SPLAction element contains one or many Variant Action elements. A UML Activity is now also consisting of one or more of the SPLAction and VariantAction elements.

Suppose we have an activity called “submit order.” The “submit order” activity is very common in Web-based shopping applications because a user must submit an order so that the order can be processed. But there are variants in the “submit order” activity. For example, most online shopping sites accept only credit card payments, thus, those applications may want the “submit credit
Modeling Variant User Interfaces for Web-Based Software Product Lines

In another case, corporate purchasing often submits purchase orders, and then pays the bill after receiving the invoice. In this case, “submit purchase order” may be desired. Yet another variant is in the case where a customer wants to receive the purchase and check it first before making a payment, these customers may want the “submit Cash-On-Delivery (COD) order.” Yet some merchants may offer a combination of these payment methods. There are a number of variants in the “submit order” activity, and we need to be able to model the variants. This paper extends UML activity diagram to model the requirements as follows.

Figure 5 shows a graphical symbol for the SPLAction. The symbol exposes the base action and its four variants actions. The shape of the base “submit order” action is filled, while the variants are not. The base Submit Order action defines the common logics that are applicable across all of the variants. Each variant differs from other variants by some features. Our concern is on user interface modeling; it is clear that the user interface to collect information on a credit card order is different from the user interface to collect a COD order in some way.

Sometimes, there are variant logics and behaviors within a variant member product that capture different execution scenarios. Those logics and behaviors can be modeled using standard UML activity diagrams. For example, suppose there is a WUI that provides user interface elements to accept either credit card based order option or purchase order option. If a customer chooses credit card order, the next WUI displayed is to collect the customer’s credit card information. If a customer chooses purchase order based order option, then the next WUI displayed is to collect the customer’s purchase order related information. Thus, the software’s behavior varies due to different execution scenarios. This variant is within a product.

These variant logics and behaviors, due to different execution scenarios, often are easy for one to confuse them with the product line variant logics and behaviors. To identify the product line variants, one must consider the same particular variant logics and behaviors across multiple member products at the same time. If the variant logics and behaviors work the same across the member products, then the variant logics and behaviors are not a product line variant.

Example II: Modeling Variant Interactions

Figure 6a shows an activity diagram for a SPLAction for an online e-retailer SPL. The SPLAction is about “Submit Order.” The SPLAction consists of four variant actions: “Submit Credit Card Order,” “Submit COD Order,” “Submit Check Order,” and “Submit Purchase Order.” A member product of this product line would have the same activity but with only one variant of the submit order action. Figure 6b shows the activity diagram for a member product that allows users to submit Credit Card Orders.

WUIML Elements for Variability Mechanisms

Figure 7 shows the WUIML elements for variability mechanisms that are based on Jacobson, Griss, and Jonsson (1997) and Anastasopoulos and Galek’s (2001) variability mechanisms and the variant notations and rules of the FODA (Cohen
Modeling Variant User Interfaces for Web-Based Software Product Lines

Figure 6a. Exemple SPL variant interactions

Figure 6b. Example of a member product variant interaction

Figure 7. Model elements for variability mechanisms
et al., 1992) technique. Delegation, WUIDerive, WUIExtend, Use, TemplateInstantiation, and RequirePresenceOf are stereotypes extended from Dependency metaclass. WUIAggregation, Configuration, and Parameterization are defined as stereotypes of Class stereotype. WUIGeneralization is a stereotype of the Generalization metaclass. OptionalElement is a constraint to express that an element is optional in the model. XOR and OR are Constraints. A Parameterization element is composed of one or more Property. A Configuration element is composed of one or more Property and zero or more Constraint.

The Use model element is used to specify that the source user interface element (e.g., a user interface fragment to capture the travel date) depends on the target user interface element (e.g., a user interface of a calendar for setting a travel date). The Configuration model element models a set of parameters and rules. These parameters and rules manipulate the composition of the software component of a software system or the setting of software components or software systems, so that variants can be created. The Parameterization model element models a set of parameters that vary the features of a software product. The TemplateInstantiation model element is a special case of the Parameterization model element. In TemplateInstantiation, the parameters are templates. WUIExtend allows small extensions in functionality or “look” to a user interface due to new requirements. WUIDerive extends UML derive stereotype to apply on all basic WUIML elements. Delegation is used to model the situation in which a Web user interface is acting as a representative of another Web user interface in performing certain operations. WUIAggregation allows one to model the situation in which various user interface fragments from various Web user interfaces are used to compose another Web user interface based on a business goal. WUIAggregation differs from UML aggregation in that the aggregated components in WUIAggregation must be an instance of WUIComposite or specific WUI elements. WUIGeneralization models the “is-a-kind-of” relationship between two user interfaces. WUIGeneralization differs from UML generalization in that the generalization in WUIGeneralization applies to WUI elements only. OptionalElement is used to specify that a user interface element is optional in the model. OR models the inclusive or constraint. XOR models the exclusive or constraint. RequirePresenceOf models the situation in which a user interface feature depends on the presence of another user interface feature. For example, to model the style of a column within a table, it requires the presence of a table element.

**Example III: Modeling Variant Web User Interface Features**

To illustrate WUIML for modeling variant WUI features, let us continue the example shown in Figure 3. But this time, we apply the variability mechanisms using the corresponding variability mechanism model elements defined in WUIML. Figure 8 shows a more detailed WUIML model for the online patient registration systems SPL. Figure 3 shows the common user interface features across the product line. Figure 8 shows the variant user interface features among member products within the product line in addition to the common features across the product line.

Applying variability mechanisms and the corresponding WUIML notations, variant WUI features are specified in Figure 8. The variant notations in WUIML are only used in product line WUIML models to show the variant features among member products. Thus, the variant notations in WUIML are not to appear in the WUIML model of a member product. For example, notice that the USAddress and HKAddress WUIComposite elements appear in Figure 3 are now specified with exclusive or constraint. This indicates that if a member product’s WUI uses USAddress format, then it will not use the HKAddress format. TemplateInstantiation vari-
ability mechanism is used to create two variant WUIComposites of PatientInfoReporter. The patient information report can be in graphic format or summary format.

**Modeling Dynamic Aspects of Web User Interfaces**

In addition to interactions as described in the section *Modeling Variant Interactions*, the dynamic aspects of WUIs also include events and actions. In this paper, event literally means “something that takes place; an occurrence” (Pickett et al., 2000). In this paper, an event means an occurrence that takes place in the user interface. Example occurrence may be a mouse click on a button, a selection on a selection box, and so forth. The term action literally means “the state or process of acting or doing” (Pickett et al., 2000). In this paper, an action means doing some user interface related tasks in response to user interface events. An example action may be popping up a message box on the user interface, setting a value for a text input box, and so forth. Moreover, an event is observed by a user interface control, such as a button, and then the user interface control triggers an action. For example, when a button is clicked, a message box is popped up to display a message. In this scenario, the button is the user interface control that is observing the event: clicking the button. The popping up of a message box is the action being triggered by the button click event. The concept of events and actions described in this section are built on the XForms specification.

XForms specification includes a set of events and actions. Many events and actions have to do with XForms processing and are not suitable for use at modeling level. For this reason, only a selected set of events and actions are taken as the bases for building WUIML elements for modeling the dynamic nature of a user interface. In WUIML, events are modeled as operations of a basic WUIML metamodel element. Each basic WUIML metamodel element has a distinct set
of events. Extra events can be added as needed by the modeler at design time as extensions. An action models the resulting behavior of a basic WUIML element in response to events. Actions are represented as operations of a basic WUIML element.

**Example IV: Modeling Product Web User Interface Using WUIML**

Figure 9 shows an even more detailed WUIML model for the online patient registration systems SPL than Figure 8. In Figure 9, more variability mechanisms are applied to create variants. In addition to the variability mechanisms shown in Figure 8, the variability mechanisms applied in Figure 9 include WUIExtend, Use, Configuration, WUIAggregation, Delegation, and WUIDerive. Once we have a SPL WUIML model, we can derive product WUIML model from the SPL WUIML model. A product WUIML model is a WUIML model that reuses all the common features of a SPL WUIML model but reuses only selected variant features from a SPL WUIML model. Figure 10 and Figure 11 show two product WUIML models derived from Figure 9.

The variant patient registration WUIML model shown in Figure 10 is created by taking all the common model elements (i.e., Email, LoginInfo, Address, PhoneNum, NameInfo, OtherContent, PatientInfoReporter, and SubmitRequest) and selected variant user interface features (i.e.,...
USAddress, USPhoneNum, and NameInfo_US-Style) from Figure 9.

Figure 11 shows another variant product WUIML model derived from Figure 9. Compare Figure 11 with Figure 10; Figure 11 shows more variant user interface features. Figure 11 includes the BritishDate WUIComposite that is extended from DateRegistered WUIComposite.

VALIDATION

The goal of this research is to improve UML support in modeling user interfaces for Web-based SPLs. The improvement goal is to have the new WUIML method exhibit decreased effort needed by increasing effectiveness and efficiency. The improvement will reduce the SPL engineers’ efforts needed for developing user interfaces. To exhibit that this improvement goal is met, a case study research validation method is applied to supply supporting evidence for the thesis (research hypothesis).

Case Study Research Method

Using case study (Lynch, 1999; Tellis, 1997a, 1997b; Yin, 2003) as an empirical research validation method has increasingly been adopted in software engineering research (Lee, 2004). This research uses a case study research method to validate the research hypothesis.

The rationale of a case study research method is the notion of “analytical generalization.” Analytical generalization depends on whether the findings of a case study can be replicated. If the findings of a case can be replicated, an analytical generalization may be drawn.

In analytical generalization, the results of a case study should be compared with a proposition. For example, in this case study, the results of a multiple-case study are to compare with proposition 1 and proposition 2 (proposition 1 and proposition 2 will be discussed later). Multiple cases are needed to test a proposition through replications of findings in order to lead to an analytical generalization (Yin, 2003). Many research methods, such as a survey, depend on statistical generalization (Yin, 2003). In statis-
cal generalization, an inference is made about a population (or universe) base on the empirical data collected about a sample (i.e., surveys) (Yin, 2003). Since a case study is not based on statistical generalization, a sampling logic should not be used in a case study research method. As a result, the number of cases in a multiple-case design and the typical criteria regarding sample size are irrelevant (Yin, 2003).

The evidence from multiple-case studies makes the overall study more robust (Yin, 2003). In this empirical study, multiple case studies were conducted. In a multiple-case study, each case must be selected to predict similar results (a literal replication) or to produce contrasting results but for predictable reasons (a theoretical replication) (Yin, 2003). A literal replication explains the conditions under which a particular phenomenon is likely to be found. A theoretical replication explains the conditions when it is not likely to be found. This empirical study relies on literal replications. The two case studies conducted are expected to predict similar results. The study is trying to show that under the condition (i.e., using WUIML in modeling WUIs for a SPL), a particular phenomenon (i.e., increased modelers’ effectiveness and efficiency in modeling) is likely to be found. For each case in the multiple-case study, the study indicates the way a particular proposition was demonstrated (or not demonstrated). Across cases in the multiple-case study, the study indicates the extent of the replication logic and the reasons on the prediction of supporting or contrasting results (Yin, 2003).

**Case Study Design**

The goal of this empirical study is to investigate the effectiveness and efficiency of WUIML. This empirical study uses a case study research method (Lee, 2004; Tellis, 1997a, 1997b; Yin, 2003) as the validation method. The design of a case study is characterized by five important case study components (Yin, 2003): a study’s research
questions, study propositions, units of analysis, the logic linking data (results) to the propositions, and the criteria for interpreting the findings.

Study’s Research Questions

The study’s research questions define the validation goal of a case study. The study’s research questions should be clarified precisely (Yin, 2003). For example, in this empirical study, the study’s research question is “Does Web user interface modeling for a Web-based medical SPL using WUIML increase SMEs’ modeling efficiency and effectiveness (thus decreasing work)?” This study’s research question needs to be clarified further because the notion of efficiency and effectiveness need further clarification. This study’s research question can be decomposed into a set of propositions.

Study Propositions

Study propositions are derived from the study’s research questions (Yin, 2003) but are more specific than the study’s research questions. Study propositions quantify the quality variables (indirect metrics) in a study’s research question into directly measurable quantitative metrics (direct metrics or indicators). For example, in this multiple-case study, the study’s research question is decomposed into two propositions:

1. SMEs are able to correctly model a larger number of required modeling items using WUIML than standard UML in modeling WUIs for a Web-based medical SPL in approximately the same amount of person-hours.

2. SMEs are able to correctly model larger numbers of required modeling items via reuse using WUIML than standard UML in modeling WUIs for a Web-based medical SPL in approximately the same amount of person-hours.

In this multiple-case study, for each WUI, the investigator has identified from the requirements a set of modeling items, called required modeling items that must be modeled by the SMEs. The resulted models produce by SMEs are inspected by the investigator. The investigator first checks the models for required modeling items. Then, based on his modeling experience, the investigator decides the correctness of the required modeling items found in the resulted models.

Units of Analysis

Units of analysis are materials such as documents or other resources that the subject matter experts (SMEs) use as inputs or materials to apply the method or tools being validated. In this study, the method under investigation is WUIML. The units of analysis are the Web user interface requirements for a medical SPL.

In the first case study, the requirements for the Pediatric Medical Profile Login WUI, the Adolescent Medical Profile Login WUI, and the Adult Medical Profile Login WUI are provided. These WUIs are each from a different member product (Pediatric Medical Management System, Adolescent Medical Management System, and Adult Medical Management System) of a medical product line (Medical Management Systems). The WUIs to model are extracted from three Web-based medical products under development in BUSINEX Inc.

The WUIs for the medical Web software products are based on actual medical forms from health-care providers in the United States. For the first case study, three member products of the product line are considered for WUI modeling. In particular, this case study requires the SMEs to model the Medical Profile Login WUI and a related activity across three member products of the product line. This WUI is chosen because it allows one to exercise the modeling of commonality and variability found in product lines.
In the second case study, the requirements for the Pediatric Exercise Record WUI, the Adolescent Exercise Record WUI, and the Adult Exercise Record WUI are provided. These WUIs are each from the same member products in the same product line as in the first case study. These requirements are the units of analysis for the second case study.

Note that within each case study, there are two SMEs. One SME applies WUIML to the requirements to generate results while the other SME applies standard UML to the requirements to generate results. The results generated by applying standard UML are used as the baseline for analyzing the results generated by applying WUIML.

In this research, the SMEs are well trained in software engineering; they are professional software engineers with experience ranging from 7 to 15 years. Their specialties are focused on user interface development. They are representative users for the new WUIML. The investigator provides training on WUIML to the SMEs before they begin conducting the case studies. In each case, all SMEs participate in the case study only once. Not having the same SME to participate in

more than one case is to prevent the introduction of bias due to the familiarity of WUIML by SMEs participating in multiple case studies. The SMEs are to carry out the case study without help from the investigator. The SMEs are also not given information on the expected results of the case study. This is to prevent bias by the SMEs in performing the case studies.

Table 1 shows the required modeling items for the Pediatric Medical Profile Login WUIs. The result of whether these items are correctly modeled by SMEs, the number of correctly modeled items over total number of required modeling items by SMEs with or without product line reuse, and the approximate person-hours spent will be used to support/reject the study propositions 1 and 2. There are specific required modeling items for Adult Medical Profile Login WUI, Pediatric Medical Profile Login WUI, Adult Exercise Record WUI, Adolescent Exercise Record WUI, and Pediatric Exercise Record WUI; for brevity, they are not shown here.

**Linking Data to Propositions**

Data analysis is done in the step of linking data (results) to propositions. In a case study, data are collected using formal case study worksheets. A case study worksheet consists of specific concrete questions associate with each one of the study propositions. The answers to those questions are measured to concrete criteria metrics that can

**SME ID:**

Please answer the following questions:

1. **What tool** did you use to perform the modeling?

2. **What is the filename of the resulted model(s)?**

3. **Please list below the model elements** (e.g. classes and activity nodes, etc.) in your resulted models. For each element, first provide its name and then provide a brief description on its purpose. List as many as you wish in additional pages (if needed).

4. **Among the items listed in 3, which of the model elements are developed via reuse?**

5. **How many person-hours** did you spend in complete the modeling of this WUI?
be analyzed to support (or reject) the propositions. Thus, the most concrete criteria metrics are measured terms found within the questions on the case study worksheets. Figure 12 shows a case study worksheet used in the first case study for modeling the Pediatric Medical Profile Login WUI. In Figure 12, each concrete criteria metrics in questions that link to propositions is identified by a name formed by three sections. For example, “Pediatric_WUIML_personHours” is the metric about person-hours spent in using WUIML to model the Pediatric Medical Profile Login WUI. The same format is used in naming other metrics found in the questions in other case study worksheets in the case studies.

Table 2 summarizes the evidence collected through the case study worksheets in the case study about Medical Profile Login WUIs.

In each case study, WUIML and standard UML are applied to the units of analysis (that is

Modeling Variant User Interfaces for Web-Based Software Product Lines

the Web user interface requirements of a Web-based medical SPL) respectively. The results, that is, the resulting models and the completed use case worksheets, are analyzed to find out the following:

D1. How many of the required modeling items are correctly modeled when the modeling was done in WUIML?

D2. How many of the required modeling items are correctly modeled when the modeling was done in standard UML?

D3. How many of the required modeling items are correctly modeled via reuse when the modeling was done in WUIML? To model via reuse is to create new models by re-using previously created models or model elements. For example, suppose one previously created a model that includes a class representing fruit. Now one can reuse the fruit class to create a class that represents a specific fruit, such as an apple, by extending the fruit class. Both standard UML and WUIML allow SMEs to model via reuse.

D4. How many of the required modeling items are correctly modeled via reuse when the modeling was done in standard UML?

D5. How many person-hours spent to generate the WUIML models?

D6. How many person-hours spent to generate the standard UML models?

D7. The total number of required modeling items. D1, D2, D5, D6, and D7 link to proposition 1. D3, D4, D5, D6, and D7 link to proposition 2.

Criteria for Interpreting a Case Study’s Findings

In this empirical study, the criteria for interpreting a case study’s findings correspond to the metric and measures used in evaluating the results of applying WUIML and standard UML respectively to the units of analysis. “A measure provides a quantitative indication of the extent, amount, dimension, capacity, or size of some attribute of a product or process” (Pressman, 2005). A metric is an important, directly-measurable attribute of a software product, a software service, a software process or a software resource. Direct metrics may be either used as indicators (predictors), or of other more valuable outcomes that are indirect metrics. For example, the indirect metrics in this case study are efficiency and effectiveness. The direct metrics are:

m1. Number of the required modeling items that are correctly modeled when the modeling was done in WUIML;

m2. Number of the required modeling items that are correctly modeled when the modeling was done in standard UML;

m3. Number of the required modeling items that are correctly modeled via reuse when the modeling was done in WUIML;

m4. Number of the required modeling items that are correctly modeled via reuse when the modeling was done in standard UML;

m5. Person-hours spent to generate the WUIML models;

m6. Person-hours spent to generate the standard UML models;

m7. The total number of required modeling items.

The Case Study Procedure for Both Case Studies

0. For those SMEs that need to perform the modeling in WUIML, teach them WUIML.

1. Identify the required modeling items from the software requirements.

2. Provide SMEs who are to conduct the modeling using WUIML with the software requirements.

3. Provide SMEs who are to conduct the modeling using standard UML with the software requirements.
4. Collect the results (WUIML models and the data from the completed case study worksheets) generated from step 2.
5. Collect the results (standard UML models and the data from the completed case study worksheets) generated from step 3.
6. Perform data analysis on the results and data collected from step 4 to find out the following: (a) number of the correctly modeled required modeling items when the modeling was done in WUIML (the measure of m1); (b) number of the correctly modeled required modeling items via reuse when the modeling was done in WUIML (the measure of m3); and (c) person-hours spent to generate the WUIML models (the measure of m5).
7. Perform data analysis on results and data collected from step 5 to find out the following: (a) number of the correctly modeled required modeling items when the modeling was done in standard UML (the measure of m2); (b) number of the correctly modeled required modeling items via reuse when the modeling was done in standard UML (the measure of m4); and (c) person-hours spent to generate the standard UML models (the measure of m6).
8. Evaluate the outcome from step 6 to determine whether or not the proposition 1 is supported or rejected.
9. Evaluate the outcome from step 7 to determine whether or not the proposition 2 is supported or rejected.

RESULTS AND ANALYSIS

WUIML is developed to improve SPL software engineering paradigm in modeling user interfaces for Web-based SPLs. The improvement provided by WUIML should decrease the work needed by the SPL engineers in the WUI modeling perspective.

In the first case study, each SME has to model the WUIs for three product lines: Pediatric Medical Profile Login, Adolescent Medical Profile Login, and Adult Medical Profile Login. One SME is asked to model each WUI using WUIML while the other SME is asked to model the WUIs using standard UML. Each WUI is from a different member product (Pediatric Medical Management System, Adolescent Medical Management System, and Adult Medical Management System) of a medical product line (Medical Management Systems).

Table 3 shows the results for modeling Pediatric Medical Profile Login WUI using standard UML and WUIML, respectively. The last row in Table 3 shows the ratio of the number of correctly modeled required modeling items to the total number of required modeling items in standard UML and WUIML, respectively.

Note that in each case study, there are two SMEs. One SME is asked to model using standard UML while the other SME is asked to model using WUIML. In the following tables (Tables 4, 5, 6, and 7), the numbers shown in the second column from the left were derived from the models created by the SME which was asked to model using standard UML. The numbers shown in the third column from the left were derived from the models created by the SME which was asked to model using WUIML. The sample size is irrelevant in case study research method because case study research method is based on analytical generalization instead of statistical generalization (Yin, 2003). However, the results shown in these tables must replicate (or be replicated by) the results from the second case study in order to lead to an analytical generalization.

Table 4 shows the ratio of the number of correctly modeled required modeling items to the total number of required modeling items in modeling the three WUIs and the person-hours spent on each approach. Notice that the person-hours spent for modeling the Pediatric Medical Profile Login WUI was more than the person-hours spent...
for Adolescent Medical Profile Login WUI and Adult Medical Profile Login WUI respectively in WUIML approach. To model the WUIs for a member product (such as the Pediatric Medical Profile Login WUI), one must first develop the WUI models for the SPL.

Table 5 shows the number of correctly modeled required modeling items per person-hours.

for the models in UML and WUIML for the three member products’ WUIs respectively.

Table 6 shows the ratio of the number of correctly modeled required modeling items via reuse (or product line reuse when WUIML is used) to the total number of reusable required modeling items in modeling the three WUIs and the person-hours spent on each approach.

Table 7 shows the number of correctly modeled required modeling items per person-hours via reuse for the models in UML and WUIML respectively.

The data in Table 3 show that 18 out of 25 required modeling items were correctly modeled for the Pediatric Medical Profile Login WUI using standard UML. On the other hand, the data in Table 3 show that 24 out of 25 required modeling items were modeled for the same Pediatric Medical Profile Login WUI using WUIML. This result in Table 3 indicates that an SME was able to correctly model more required modeling items using WUIML than using standard UML. Table 4 shows the correctly modeled required modeling items and the approximate person-hours for modeling the Pediatric, Adolescent, and Adult Medical Profile Login WUI respectively in standard UML and WUIML. Table 5 shows the calculated value of modeled items per person-hour based on the data from Table 4. The data in Table 5 shows that when using WUIML, an SME was able to correctly model about four times more required modeling items per person-hour (i.e., 9.08) than that in standard UML (i.e., 2.37). Thus, this result indicates WUIML is more efficient than the standard UML in modeling user interfaces for Web-based SPL; therefore, this result supports proposition 1.

Table 6 shows the number of correctly modeled required modeling items via reuse (or product line reuse) and its corresponding person-hours used.
Modeling Variant User Interfaces for Web-Based Software Product Lines

For example, using standard UML to model the Pediatric Medical Profile Login WUI, a SME was not able to reuse any model items out of the ten reusable items in the WUI model. For approximate eight person-hours, the SME has to model without reuse. This is because the Pediatric Medical Profile Login WUI was the first WUI for an SME to model. There is nothing to reuse yet. Notice that the number of reusable required modeling items is only a sub-set of the total number of required modeling items in a WUI model because some items are unique to a particular WUI and cannot be reused.

On the other hand, using WUIML, across all three WUIs (Pediatric Medical Profile Login, Adolescent Medical Profile Login, and Adult Medical Profile Login.), as shown in Table 6, number of correctly modeled required modeling items via reuse are consistent. This is because in WUIML, an SME is to first develop the product line WUI model. The WUI model for the SPL encapsulated all model items for its member product WUI models. Therefore, reusing the items in the product line WUI model creates the WUI model for a member product. As shown in Figure 7, the average number of correctly modeled required modeling items via reuse per person-hours using WUIML (i.e., 2.98) is about four times to that when using standard UML (i.e., 0.65). This result indicates that WUIML enables higher level of reuse than standard UML, thus it indicates increased effectiveness when using WUIML than using standard UML. Therefore, this result supports proposition 2.

The results of the second case study are not shown due to the limitation of the space in the paper. The second case study was conducted by another two SMEs. The units of analysis for the second case study were the software requirements for the Pediatric Exercise Record WUI, the Adolescent Exercise Record WUI, and the Adult Exercise Record WUI. The results from the second case study show that using WUIML to model the Exercise Record WUIs for the three member products of the SPL increases the modeler’s efficiency and effectiveness in modeling. This result is similar to the result from the first case study. The results of the two case studies literally replicate. Based on the results, the analytical generalization that WUIML increases modelers’ efficiency and effectiveness in model WUIs for SPL is drawn in this study.

The generalization thus provides a positive answer to the study’s research question that Web user interface modeling for a Web-based medical SPL using WUIML increases SMEs’ modeling efficiency and effectiveness (thus decreases work).

CONCLUSION AND FUTURE WORK

In standard UML, there is no standard way to model user interface and no standard way to model variant features of user interfaces for a SPL. WUIML defines elements to propose a standard way to model user interfaces as well as
Modeling Variant User Interfaces for Web-Based Software Product Lines

variant user interface features of Web-based SPLs. WUIML improves UML in terms of modeling of user interfaces and use interfaces for SPL.

Case study research method has been applied to investigate whether WUIML method increases modelers’ efficiency and effectiveness on modeling a Web-based medical SPL when compared to standard UML method. The results indicate that modeling WUIs for SPL using WUIML is more effective and efficient than using standard UML.

There are many ways to model software using UML; a human is needed to make the “best” judgment on the correctness of a UML model. In this empirical study, the way to determine whether a required modeling item is modeled correctly or not relies on a human’s modeling experience. Since the same human is using his same modeling experience to make the judgment on all models, the bias due to human judgment should be insignificant.

Since the SMEs are of similar backgrounds and technical experience, the impact on modeling efficiency and effectiveness due to individual SME’s capability should be insignificant. Since the same requirements are given for both approaches (WUIML and standard UML), the reuse opportunity base on application logics (according to the requirements) should be the same for all SMEs.

Future work is to develop a tool to support using WUIML to model WUIs for SPLs and to extend WUIML beyond the Web platform.

Chapter 2.25

A User–Centered Approach to the Retrieval of Information in an Adaptive Web Site

Cristina Gena
Università di Torino, Italy

Liliana Ardissono
Università di Torino, Italy

ABSTRACT

This chapter describes the user-centered design approach we adopted in the development and evaluation of an adaptive Web site. The development of usable Web sites, offering easy and efficient services to heterogeneous users, is a hot topic and a challenging issue for adaptive hypermedia and human-computer interaction. User-centered design promises to facilitate this task by guiding system designers in making decisions, which take the user’s needs in serious account. Within a recent project funded by the Italian Public Administration, we developed a prototype information system supporting the online search of data about water resources. As the system was targeted to different types of users, including generic citizens and specialized technicians, we adopted a user-centered approach to identify their information needs and interaction requirements. Moreover, we applied query analysis techniques to identify further information needs and speed up the data retrieval activity. In this chapter, we describe the requirements analysis, the system design, and its evaluation.

INTRODUCTION

The development of a Web-based information system targeted to different types of users challenges the Web designer because heterogeneous requirements, information needs, and operation modes have to be considered. As pointed out by Nielsen (1999) and Norman and Draper (1986), the user’s mental model and expectations have to be seriously taken into account to prevent her/him from being frustrated and rejecting the
services offered by a Web site. Indeed, this issue is particularly relevant to Web sites offering task-oriented services, because most target users utilize them out of their leisure time, if not at work. Being under pressure, these users demand ease of use as well as efficient support to the execution of activities.

The positive aspect of a technical Web site is, however, the fact that the users can be precisely identified and modeled; moreover, their information needs, representing strong requirements, can be elicited by means of a suitable domain analysis. Therefore, utilities, such as data search and retrieval, can be developed to comply with different goals and backgrounds. Of course, users’ involvement and testing have to be carried out also in this case because they support the development of effective and usable services (see Dumas & Redish, 1999; Keppel, 1991).

In our recent work, we faced these issues in the development of ACQUA, a prototype Web-based information system for the Italian Public Administration presenting information about water resources (a demo is available at http://acqua.di.unito.it). During the system design phase, we put in practice traditional usability principles and adaptive hypermedia best practices and we derived general guidelines for the development of usable Web-based systems for technical users (see Brusilovsky, 1996, 2001; Fink, Kobsa, & Nill, 1999; Maybury & Brusilovsky, 2002). The system described in the rest of this chapter is targeted to two main classes of users:

• Generic users, such as the citizen, who want to be informed about the general health state of rivers, lakes, and underground waters.
• Technical users, such as the public administration employees, who retrieve specific pieces of information for analysis purposes.

In this chapter we describe the requirements analysis, the design, and the evaluation of ACQUA, focusing on the user-centered approach adopted in the prototype design and development phases. We involved domain experts and end users since the beginning of our work in order to assess the usefulness and suitability of the functionality offered by the system, as well as of its user interface. For further information about the system, see Gena and Ardissono (2004).

The rest of this chapter is organized as follows: Section “Background” provides an overview of the relevant user-centered design research. Section “The ACQUA Project” presents our work. Specifically, Section “Application Requirements” describes the interaction and user interface requirements that emerged during the design phase; Section “Adaptive Features” presents the adaptive features we developed for our system; Section “Association Rules” describes the techniques supporting the personalized information search; Section “Evaluation of ACQUA” presents the results of an evaluation we carried out to test the system functionality with real users; and Section “Comparison with Other Solutions” compares our proposal with some related work. Finally, section “Future Trends” discusses some open technical issues and suggests how to address them, and Section “Conclusion” concludes the chapter.

BACKGROUND

Several researchers suggested to address usability issues by developing adaptive systems. For instance, Benyon (1993) proposed adaptivity as a solution, because a single interface cannot be designed to meet the usability requirements of all the groups of users of a system. However, it is possible to prove that adaptivity enhances the usability of a system only if it can be shown that, without the adaptive capability, the system performs less effectively. Benyon identifies five interdependent activities to be considered when designing an adaptive system:
A User-Centered Approach to the Retrieval of Information in an Adaptive Web Site

1. **Functional analysis**, aimed at defining the main functions of the system.
2. **Data analysis**, concerned with understanding and representing the meaning and structure of data in the application domain.
3. **Task knowledge analysis**, focused on the cognitive characteristics required by the system users, such as the user’s mental model, cognitive load, and the required search strategy.
4. **User analysis**, aimed at determining the scope of the user population to which the system is targeted. This analysis concerns the identification of the user attributes that are relevant for the application, such as required intellectual capability, cognitive processing ability, and similar. The target population is analyzed and classified according to the aspects of the application derived from the above-mentioned points.
5. **Environment analysis** is aimed at identifying the characteristics of the environment in which the system is going to operate.

Notice that these phases are similar to the steps followed during the requirements analysis phase of a generic software system (Preece, Rogers, Sharp, & Benyon, 1994). Benyon underlined the fact that adaptive systems should benefit more than other systems from a requirements analysis before starting any kind of evaluation, because the development of these systems has to take a high number of features into account. The recognition that an adaptive capability may be desirable leads to an improved system analysis and design. As a demonstration, he reported an example of an adaptive system development, wherein he prototyped and evaluated the system with a number of users. Several user characteristics were examined to determine their effects on the interaction. Then, further task knowledge and functional analysis were carried out.

Also Oppermann (1994) proposed a user-centered perspective and suggested a design-evaluation-redesign approach. He noticed that the adaptive features can be considered as the main part of a system and thus have to be evaluated during every development phase. The problem is circular:

- A problem solvable by means of the adaptivity has to be identified.
- The user characteristics related to the problem have to be selected.
- Ways of inferring user characteristics from interaction behavior have to be found.
- Adaptation techniques offering the right adaptive behavior have to be designed.

This process requires a bootstrapping method: first some initial adaptive behavior is implemented, then tested with users, revised, and tested again. The reason is that it is hard to decide which particular adaptations should be associated to specific user actions. Furthermore, the adaptations must be potentially useful to the user. The necessity of an iterative process is due to the fact that the real behavior of users in a given situation is hard to foresee; therefore, some evidence can be shown only by monitoring the users’ activity. From the iterative evaluation point of view, the design phases and their evaluation have to be repeated until good results are reached.

Oppermann’s iterative process is very similar to the user-centered system design approach originally phrased by Gould and Lewis (1983) and extended by Norman and Draper (1986).

Dix, Finlay, Abowd, and Beale (1998) pointed out that the iterative design is also a way to overcome the inherent problems of incomplete requirements specification, as only a subset of the requirements for an interactive system can be determined from the start of the project. The iterative evaluation process requires empirical knowledge about the users’ behavior from the first development phases. In the case of an adaptive system, prior knowledge about the real users, the context of use, and domain experts facilitates the
A User-Centered Approach to the Retrieval of Information in an Adaptive Web Site

selection of the relevant data for the user model, such as personal features, goals, plans, domain knowledge, and context. Deep knowledge about users also offers a broad view of the application goals and prevents the system designer from serious mistakes, especially when dealing with innovative applications.

Petrelli, De Angeli, and Convertino (1999) proposed the user-centered approach to user modeling as a way to move from designer questions to guidelines by making the best use of empirical data; they advocated incremental system design as a way to satisfy large sets of users. They reported that at the early stage of development of a mobile device presenting contextual information to museum visitors, they decided to revise some of their initial assumptions about the user model. Indeed, they made this decision after having analyzed the results of a questionnaire distributed to 250 visitors. For instance, they discarded the former user modeling techniques based on stereotypes (because the sociodemographic and personal data taken in consideration did not characterize the users’ behavior in a satisfactory way) in favor of a socially oriented and context-aware perspective. For instance, they noticed that people do not like to visit museums on their own and prefer looking at paintings to interacting with a device.

As discussed by Höök (2000), intelligent user interfaces may violate many usability principles developed for direct manipulation systems. The main problem is that these systems may violate many good principles, such as enabling the user to control the system, making the system predictable (given a certain input, the system always generates the same response), and making the system transparent so that the user understands at least partially how it works. In addition, most adaptive interface developers are more concerned with defining inference strategies than with interface design. For Höök, intelligent user interfaces sometimes require a new way of addressing usability, different from the principles outlined for direct-manipulation systems. Instead of measuring factors such as task completion time, number of errors, or number of revisited nodes, other aspects have to be considered. For instance, “if the system should do information filtering, then we must check whether subjects find the most relevant information with the adaptive system and not necessarily whether they find it fast. This is not to say that the traditional measurements are always wrong—this of course depends upon the task that user and (adaptive) system should solve together” (Höök, 2002, p. 12).

Finally, Palmquist and Kim (2000) investigated the effects of (field independent and field dependent) cognitive style and online database search experience on WWW search performance. They concluded that cognitive style significantly influences the performance of novice searchers. In contrast, experienced searchers display a common behavior: they usually do not get lost in Web pages including many links, but they are able to choose useful navigation strategies. Therefore, Palmquist and Kim suggested that novice users should benefit from Web pages that have a simple design and few links providing information necessary to perform analytic search.

THE ACQUA PROJECT

Application Requirements

In 2003, the Water Resources Division (Direzione Risonse Idriche) of the Piedmont Region and the University of Torino started a project for the development of ACQUA, a Web-based information system presenting data about water resources derived from the monitoring activities on the territory. The goal was to make information available on a Web site that describes the Division and supports a search for data in real time, in order to limit the distribution of information on a one-to-one basis via e-mail messages and paper publications. The technicians of the Division guided us in the system development
by specifying application requirements and by sharing with us a repository of e-mail messages they exchanged with users asking for information throughout the years. The repository provided us with evidence about the users’ interest in water resources data, the inspected information, and the regularities in the search for data. Most questions were posed by the following:

- Employees of other Public Administrations, such as technicians and researchers, who are often interested in environmental impact studies, construction feasibility studies, and historical data.
- Technicians, such as companies working at the construction of bridges and houses.
- Attorneys, who are typically interested in the examination of data concerning specific regions, for example, as a consequence of an environmental disaster.
- Farmers, who wish to monitor the biochemical state of their fields.
- Students attending secondary school, university, and also doctoral programs. These users collect information for the preparation of reports concerning, for example, historical changes in biological and chemical composition of waters, or the evolution of the capacity and hydrometric levels of rivers, and similar.

Following a user-centered approach, we developed the system by involving domain experts and end users since the first design phases. After a requirements analysis phase, we developed a number of mock-ups, which we discussed and redesigned after several focus group sessions with the experts and the users involved in the project. We decided to adopt a cooperative design approach (Greenbaum & Kyng, 1991) in order to utilize the experience of domain experts and technicians in the design of an effective user interface. We based the development of our first prototype on the collected feedback. As the ACQUA system is devoted to the Public Administration, we had to satisfy usability and predictability requirements that imposed the design of a simple user interface. Specifically, our interlocutors suggested the following:

- The interface should be usable and intuitive in order to satisfy user needs and expectations. This first requirement should be followed in every interface design project; however, Public Administrations have the mandatory goal of satisfying all the citizens, thus usability is also intended as a service for the collectivity.
- The system behavior should be highly predictable (Dix et al., 1998) to support first-time visitors in their search task, but also to avoid frustrating professional users who would regularly use it at work. Notice that the predictability requirement has some subtle aspects: for instance, not only the user should foresee what is going to happen next, but also what should not be expected from the service. This is very important to prevent the user from starting the exploration of paths that will not provide her/him with the information, or the functionality (s) he is looking for.
- The system should provide the user with data that can be analyzed without preprocessing. Therefore, search results should be presented in machine-processable formats, in addition to the pictorial ones suitable for a general-purpose presentation in Web pages.
- For the sake of accessibility, the pages of the user interface should be optimized for standard browsers, without the need of special equipments or software environments.

In order to maximize the usefulness of the information that can be retrieved from the Web site, we decided to make the system generate the search results in formats, such as MS Excel® tables and textual (TXT) files, directly supporting the
data analysis and interpretation at the user side. We also tried to address efficiency in the retrieval of information by reconsidering the design of the general Web site to be presented. We wanted to offer the right information the user is looking for; thus, we decided to show the main search functions in the home page of the Web site, and to move textual information, such as the pages describing the Public Administration divisions, in secondary pages, which can be reached by following hypertextual links.

Moreover, having analyzed the data about the users interested in water resources, we identified two main targets to which the system should adapt. For shortness, we denote these categories as novices and experts.

- **Novice users**, such as students and generic citizens, visit the Web site on an occasional basis and are not familiar with the content presented by the information system.
- **Expert users**, such as technicians, farmers, and the personnel of other Public Administrations, frequently visit the site and are familiar with the domain-specific information provided by the system.

In order to take the interaction requirements of these users into account, we defined two search functions:

i. The **simple search** is a geographical search modality and guides the user step by step in the retrieval of information;

ii. The **advanced search** offers forms where the expert user may compose the queries in single step. Figure 1 shows the user interface of the ACQUA prototype supporting

---

**Figure 1.** Searching quantitative data (continuous hydrometric and chemical-physical parameters) about Po River in the Torino-Murazzi observation point
the advanced search; the menus enable the user to specify the river (“Scegli il corso d’acqua”), observation point (“Scegli il punto di monitoraggio”), start date (“Data Inizio”), and end date (“Data Fine”). Moreover, the user interface enables the user to select the hydrometric and chemical-physical parameters to be inspected.

Thus, novice users may search for information in a friendly modality and the eligible choices are restricted and presented along the path, while expert users benefit from a faster search function.

As a matter of fact, the information about water resources exploited by the system is unavoidably incomplete. For instance, some data are collected by automatic stations, which have been set up at different times over the years and sometimes are out of order. Moreover, unfortunately, data collected in manual observation points have been stored in unstructured formats and the historical series has been reconstructed only for the very recent past.

For the sake of predictability, the simple and advanced search functions prevent the user from composing any queries that are incorrect, or are aimed at searching for unavailable data. The idea is that, in both cases, the system should only present the choices leading to available results. For instance, as shown in Figure 1, the labels of the parameters, which are not available for the Po River, are shaded and cannot be selected by the user to define a query.

**Adaptive Features**

The information about water resources concerns rivers, lakes, and underground waters and includes the following:

- Descriptive data about resources and observation points: for example, maps of the points, charts representing environmental changes, pictures, documents, publications, and descriptions of the monitoring stations. For instance, Figure 2 (“Caratteristiche della stazione di monitoraggio TORINO” [“Features of the Torino monitoring station”]) shows the coordinates and other information about the observation point on Po River located in Torino, Parco Michelotti.

- Measurement parameters concerning physical dimensions and other features, which characterize the environmental state of the resources. These parameters are grouped in two main classes:
  - **Qualitative parameters**, which are periodically measured: technicians visit the observation points, collect data, and take samples for laboratory tests.
  - **Quantitative parameters**, which are monitored by automatic stations.

These stations carry out the measurements on a daily basis.

The ACQUA Web site is organized in four main sections, respectively devoted to the presentation of qualitative and quantitative information about rivers, information about lakes, and information about underground waters. The system enables the user to retrieve data about water resources by performing a simple or advanced search in all the sections of the site. Therefore, a large amount of heterogeneous data is accessible, ranging from biological and chemical data to capacity measurement and hydrometric levels (for details, see Gena & Ardissono, 2004).

We noticed that, by performing queries aimed at selecting a large number of data items, belonging to different categories, the results returned by the system were complex and hard to present in an intuitive results table. However, as shown by the repository of user requests we analyzed, users often need to combine heterogeneous data to accomplish their goals. For example, in construction feasibility studies, users are interested in qualitative and quantitative parameters of
A User-Centered Approach to the Retrieval of Information in an Adaptive Web Site

rivers and underground waters, considering the historical series. In order to keep the user interface simple and to guarantee that the presented results are not confusing, we decided to limit the user’s freedom in composing the queries: to retrieve very heterogeneous types of information, the user must define more than one search query. For example, as shown in Figure 1, the ACQUA query interface enables the user to choose from different rivers, observation points, years, and data types. Other categories, such as qualitative and quantitative data about rivers, lakes, and underground waters are treated as separate sections of the Web site and have their own query functions.

Unfortunately, although this approach enforces the clarity of the results, it makes the search for multiple types of information a lengthy task. Therefore, a compromise between clarity and efficiency must be found. In order to address this issue, we extended the system with an intelligent search component, which complements the user’s explicit queries with follow-up queries (Moore & Mittal, 1996) frequently occurring together in navigation paths. When possible, the system anticipates the user’s queries and makes the extended search results available as personalized suggestions that can be downloaded on demand. If the user is interested in the recommended information, (s)he can retrieve it by clicking on the adaptive suggestion links, without performing any further queries. At the same time, the system retrieves the extended results only after
the user clicks on a suggestion link in order to avoid precaching possibly useless data.

For instance, Figure 3 shows the recommendations generated by the system in the lower portion of the page (“Ti consigliamo anche i valori dei parametri chimici e microbiologici” [“We also suggest results about chemical and microbiological parameters”]).

During different interaction sections, the same user may be interested in rather different types of information; therefore, we decided to base the system’s recommendations on the analysis of her/his navigation behavior, leaving the management of a long-term user model apart. One immediate advantage is the fact that the user can interact with the system in an anonymous way, without signing up for the service. The follow-up queries are generated as follows: the search queries performed by the user while (s)he browses the Web site are monitored and association rules which suggest other, strictly related queries are applied.

Each association rule has a condition part specifying constraints on the previous navigation behavior, and an action part defining a relevant follow-up query to be performed in order to retrieve complementary information. The rules we defined in our current prototype are mutually exclusive and they are selected and fired by applying a very tiny and efficient inference engine. This engine would not be suitable to manage a large set of conflicting rules: a general-purpose rule-based engine should be employed to that purpose. However, we prefer to maintain a simple set of adaptation rules, and to avoid embedding complex rule-based engines in order to keep the adaptive features as lightweight as possible. In fact, the management of the interaction is subject to a relevant overload due to the generation of results in multiple formats, which is a main requirement for the information system. In this situation, minimalist but efficient adaptation to the user is strongly preferred to flexible but complex one.

**Association Rules**

In order to define the association rules to be applied for anticipating the user’s information needs, we analyzed a repository of requests, which real

---

**Figure 3. Annotated link for the suggested information and descriptions of the monitoring stations**
A User-Centered Approach to the Retrieval of Information in an Adaptive Web Site

users posed to the Water Resources Division over the years; the requests consisted of e-mail messages and fax documents. As we noticed that different kinds of information frequently occurred together in these requests, we decided to analyze the frequency of co-occurrence in order to identify the regularities. Specifically, we analyzed 97 requests and we selected a set of features describing the requests in a systematic way. These features concerned rather different aspects of the requests; thus, for clarity purposes, we grouped them in subcategories. In the following, we report the subcategories we defined and for each one we list some sample features:

- **Kind of request:** for example, environmental impact study, construction feasibility studies, and lawyers’ studies.
- **Request features:** for example, information about one or more rivers, about lakes or underground waters, about one or more observation points on a river or lake.
- **Kind of data:** for example, qualitative or quantitative parameters, biological and chemical data, hydrometric level, average daily capacity.
- **Data features:** for example, raw data, or elaborated data such as medium, maximum, and minimum values during a time interval.
- **User features:** for example, research center, Public Administration, technicians, farmers, and attorneys.

We computed the frequency with which the features co-occurred in the requests: if the frequency exceeded a given threshold, the set of involved features became a possible candidate for an association rule. Then we compared the extracted associations with their original requests in order to validate our findings with factual knowledge, and finally we asked the technicians of the Water Resources Division if our conclusions were correct. After this last check, we selected the correct associations and we encoded the rules in the system.

For instance, a rule suggests to retrieve qualitative parameters about a water resource if the user has asked for quantitative historical data for more than one observation point on that resource, supposing that (s)he is looking for information for a construction feasibility study. Another rule suggests retrieving the environmental state indexes of a resource if the user has requested biological and chemical data, under the hypothesis that (s)he is involved in an environmental impact study.

**Evaluation of ACQUA**

We first evaluated the ACQUA prototype in a usability test by involving external users who were not cooperating at the project (see Dumas & Redish, 1999, for methodological details). The evaluation highlighted some usability problems concerning the presentation of basic information, such as the choice between simple and advanced search and the background color of the menus. After having solved those problems, we tested the final prototype with real end users representative of the users the Web site is devoted to. In particular, we involved technicians working at the Water Resources Division in different fields (rivers, lakes, underground rivers, etc.) and not collaborating to the design of the project. We carried out both an experimental evaluation and a qualitative session to assess the suitability of the adaptive features offered the system.

**Subjects.** We evaluated 10 potential users of the ACQUA system, four females and six males, aged 30–50. All the users worked in the water resource area and none of them was involved in the project.

**Procedure.** The subjects were split up in two groups (five subjects each) and randomly assigned to one of the two groups. The experimental group had to solve some tasks using the adaptive Web site, which applies the association rules described in Section “Adaptive Features” to compute the
results of follow-up queries related to the users’ explicit queries. Instead, the control group had to solve the tasks without adaptation.

**Experimental tasks.** Every subject had to solve seven tasks, each one representing a real task the user can perform in the Web site. As suggested by our correlation study, the tasks were strictly correlated and could be grouped in three search activities the user often performs together. The first activity conveyed the whole information useful to an environmental impact study. The second one supported construction feasibility studies. The third activity supported lawyers’ studies and activities.

- In the control group, the users had to submit a new query for every task, in order to obtain the requested results. The new queries were submitted by filling in the query specifica-

- In the experimental group, the users could obtain the extra information related to the next task to be performed by clicking on an adaptive suggestion link that supports the immediate retrieval of the suggested information (see, e.g., Figure 3).

**Experimental design.** Single-factor (the adaptivity) between-subjects design.

**Measures.** The subjects’ navigation behavior was recorded by using Camtasia Studio®. We measured the task completion time and then the subjects’ satisfaction, by means of a post-task walk-through.

**Hypothesis.** We hypothesized that the users working in the experimental group could obtain better performance results than those of the control group.

**Results.** The ANOVA (analysis of variance) showed that the subjects of the experimental group achieved the best performance results. In addition, we calculated the effect size (treatment magnitude) and the power (sensitivity) as suggested in Chin (2001). The effect size ($\omega^2$) measures the strength, or the magnitude, of the treatment effects in an experiment. In behavioral sciences, small, medium, and large effects of $\omega^2$ are 0.01, 0.06, and $>0.15$, respectively. The power of an experiment ($n'$) is the ability to recognize treatment effects and the power can be used for estimating the sample size. In social science, the accepted value of the power is equal to 0.80, which means that the 80% of repeated experiments will give the same results. In the following, we show a summary of the results:

**Task 2.**

ANOVA: $F(1.8) = 12.45$  \( p<0.01; \)
$\omega^2=0.53; \ n'=3.49$

**Task 3.**

ANOVA: $F(1.8) = 12.12$  \( p<0.01; \)
$\omega^2=0.53; \ n'=3.60$

**Task 5.**

ANOVA: $F(1.8) = 14.16$  \( p<0.01; \)
$\omega^2=0.57; \ n'=3.04$

**Task 7.**

ANOVA: $F(1.8) = 9.23$  \( p<0.05; \)
$\omega^2=0.45; \ n'=4.86$

It should be noticed that all the results are significant and have a large estimate of the magnitude of the treatment effect. In addition, by exploiting a power of 0.80 and the corresponding $\omega^2$ for each task we could determine the requested sampled size, which fits our sample size ($n=5$) (for details about statistics, see Keppel, 1991).

**Post-task walk-through.** During any post-task walk-through, test subjects are asked to think about the event and comment on their actions. Thus, after each test we talked to the subjects to collect their impression and to discuss their performance and the problems encountered during the test. In this session, we also aimed at retrieving useful feedback for a qualitative evaluation of the site. In fact, although our experimental evaluation
reported significant results supporting our hypothesis, the actual user behavior could be different. As recently pointed out by Nielsen (2004), statistical analyses are often false, misleading, and narrow; in contrast, insights and qualitative studies are not affected by these problems because they strictly rely to the users’ observed behavior and reactions.

In most cases, the interviewed users were satisfied with the site. Most of them encountered some problems in the execution of the starting query of task 2, thus we modified the interface form.

- All the users of the experimental group followed the adaptive suggestion link provided by the system but they did not realize that it represented a personalization feature. When we explained the adaptations, they noticed the particularity of the suggestion (“We also recommend you ...”). Anyway, they were attracted from the suggestions and they appreciated the possibility of skipping the execution of a new query. The adaptive suggestions were considered visible and not intrusive.

- The users of the control group reported similar considerations when we described the adaptive features offered by the Web site. Even if they did not receive any suggestions during the execution of tasks, they explored the result pages in order to find a shortcut to proceed in the task execution. After having followed some links, they went back to the previous query page or to the home page by clicking on the “Back” button of the browser.

Both groups displayed a common behavior pattern: the users explored a results page before starting a new search. Nevertheless, their behavior could be influenced by the test condition, because tested users tend to pay a lot of attention to their own actions and to the page design.

We conclude by admitting that although the test subjects were satisfied with the adaptation features, only the real system usage can demonstrate our hypothesis. However, both quantitative and qualitative test results are encouraging and we think that the adaptations are correctly placed. After this test, we presented the adaptive version of the Web site to the technicians of the Water Resources Division collaborating on the project. They confirmed the correctness of association rules we defined and they decided to replace the non-adaptive version of the prototype system with the adaptive one.

**Comparison with Other Solutions**

The ACQUA system has a plain user interface, designed to meet simplicity, usability, and predictability requirements, but it offers advanced interactive features enabling the user to create a personal view of the information space. Two search features, targeted to novice and expert users, are available, and the search results are presented in both pictorial and machine-readable formats in order to support direct data manipulation at the userside. Moreover, the system analyzes the user’s queries to identify her/his information needs, and it employs association rules to propose follow-up queries complementing the search results with strictly related information. The follow-up queries are applied on demand; thus, the user can ignore them if (s)he is not interested in the additional data, and the system does not need to retrieve any uninteresting information.

The advanced search features we presented differ from the related work in various aspects. On the one hand, the inferences performed by our system are simpler than the probabilistic ones applied in other automated assistants, such as Lumiére (Horvitz, Breese, Heckerman, Hovel, & Rommelse, 1998) and ACE (Bunt & Conati, 2003), which exploit Bayesian networks to capture the dependencies among the user actions.
The point is that the user interacting with the ACQUA system does not carry out a complex task requiring a problem-solving activity. Therefore, lightweight rules associating contextually related search queries are sufficient to predict the implicit information needs and to complement the search for information accordingly. Our approach also differs from the follow-up question answering techniques proposed by Moore and Mittal (1996): in order to efficiently manage the query selection process, our follow-up queries are precompiled in a set of association rules, instead of being generated by a planner.

On the other hand, we apply query analysis techniques to identify regularities in search patterns. This differs from the typical inferences carried out in recommender systems, which reason about the features of the selected items to identify the user’s priorities (see, e.g., Billsus & Pazzani, 1999), or about the regularities in the selection of individual items (see, e.g., the work by Cotter & Smyth, 2000; GroupLens, 2002).

Liu, Yu, and Meng (2002) propose other query analysis strategies for personalized Web search. However, instead of personalizing the proposed results, their system supplies a small set of categories as a context for each query. The system combines the user’s search history with a general user profile automatically extracted from a category hierarchy to offer a personalized context for disambiguating the proposed query results. In ACQUA, we do not manage long-term user preferences because we noticed that, in different interaction sections, the same users are interested in rather different types of information. We thus decided to base the recommendations only on the analysis of the user’s search behavior.

**FUTURE TRENDS**

It is worth mentioning that the manual definition of the first set of association rules supporting the user’s search task was a lengthy work and might not be easily replicated to revise the rules along time. However, if the Water Resources Division employs the ACQUA system as its official Web site, the log files generated by the system will provide structured evidence about user behavior (in addition to e-mails and faxes). Thus, data-mining techniques could be exploited to automatically recognize usage patterns and revise the association rules accordingly.

Indeed, we believe that these techniques can support the analysis of user behavior in an effective way, but they still have to be coupled with human analysis, in order to validate and interpret results: in several cases, these techniques have generated some very interesting results, but also other irrelevant or hardly understandable findings, which have been discarded.

At any rate, Web usage mining techniques, derived from machine learning methods such as knowledge discovery in data (KDD or data mining) can contribute to automate the adaptation of Web-based systems to the users. According to the scheme proposed by Pierrakos, Paliouras, Papatheodorou, and Spyropoulos (2003), ACQUA can be classified as a Web personalization system offering task performance support: this functionality involves the execution of a particular action on behalf of the user. In our case, the system generates queries and makes the results available as links to some files storing them. This functionality is considered as the most advanced personalization function and it is seldom offered by Web-based personalized services.

The most suitable data-mining technique, given the adaptive goals of the ACQUA system, is the **sequential pattern discovery**, which is aimed at identifying navigational patterns (event sequences) in the analyzed data (in our case, Web usage data). This methodology supports the discovery of event sequences that can be summarized as follows: “If event A, B, and C occur in that order, then events D, E, and F always follow.”
Two types of methods are generally applied to discover sequential patterns: deterministic techniques, which record the navigational behavior of the users and extract knowledge from the analyzed data, and stochastic methods, which use the sequence of already-visited Web pages to predict the behavior occurring in the next visits. Once sequential patterns have been discovered, the extracted knowledge can be automatically integrated in the personalization process, and the system behavior adapted accordingly.

CONCLUSION

We presented our experience in the design and development of ACQUA, an interactive prototype Web site for the Public Administration. The system presents information about water resources and supports the user in the search for generic information, as well as technical information about the rivers, lakes, and underground waters.

The usability and functional requirements that emerged during the design of the ACQUA system were very interesting and challenging, as they imposed the development of functions supporting the efficient retrieval of data by means of a simple user interface. We found out that the introduction of basic adaptivity features, aimed at understanding the user's information needs in detail, was very helpful to meet these requirements.

We were asked to develop a system having a simple user interface, designed to meet usability and predictability requirements. This fact limited our freedom to add advanced interaction features, desirable in a Web site visited by heterogeneous users; however, it challenged us to find a compromise between functionality and simplicity. In order to address this issue, we developed two interactive features enabling the user to create a personal view on the information space:

- The system offers a simple and an advanced search functions targeted to novice and expert users, respectively.
- Moreover, the system carries out a query analysis aimed at identifying the user's information needs, and applies association rules to extend the user's queries and complete the search results with data that is usually retrieved together by end users.

Qualitative and quantitative evaluation results showed that the adaptive user interface was more successful than the nonadaptive one. The reason was probably the concrete help offered by the adaptive suggestions, which speed up the execution of time-consuming search tasks. Moreover, the adaptive features were not perceived as intrusive and the user was allowed to skip useless suggestions. Furthermore, the system did not impose a previous annoying and discouraging registration phase.

As discussed in Section “Future trends,” the adaptive features offered by the ACQUA system could be improved by the integration of Web-usage mining techniques aimed at discovering real usage patterns. In that way, the association rules employed to identify the user's implicit information needs could be automatically updated along time. However, we believe that the rules we manually defined provide a knowledge base that cannot be replaced with automatically extracted rules. In principle, both kinds of rules could be integrated in order to enhance the effectiveness of the system adaptations.

INTRODUCTION

This project experiments with the designing of a Web site that has the self-adaptive feature of generating and adapting the site contents dynamically to match visitors’ tastes based on their activities on the site. No explicit inputs are required from visitors. Instead a visitor’s clickstream on the site will be implicitly monitored, logged, and analyzed. Based on the information gathered, the Web site would then generate Web contents that contain items that have certain relatedness to items that were previously browsed by the visitor. The relatedness rules will have multidimensional aspects in order to produce cross-mapping between items.

The Internet has become a place where a vast amount of information can be deposited and also retrieved by hundreds of millions of people scattered around the globe. With such an ability to reach out to this large pool of people, we have seen the expulsion of companies plunging into conducting business over the Internet (e-commerce). This has made the competition for consumers’ dollars fiercely stiff. It is now insufficient to just place information of products onto the Internet and expect customers to browse through the Web pages. Instead, e-commerce Web site designing is undergoing a significant revolution. It has become an important strategy to design Web sites that are able to generate contents that are matched to the customer’s taste or preference. In fact a survey done in 1998 (GVU, 1998) shows that around 23% of online shoppers actually reported a dissatisfying experience with Web sites that are confusing or disorganized. Personalization features on the
Web would likely reverse this dissatisfaction and increase the likelihood of attracting and retaining visitors.

Having personalization or an adaptive site can bring the following benefits:

1. Attract and maintain visitors with adaptive contents that are tailored to their taste.
2. Target Web contents correspondingly to their respective audience, thus reducing information that is of no interest to the audience.
3. Advertise and promote products through marketing campaigns targeting the correct audience.
4. Enable the site to intelligently direct information to a selective or respective audience.

Currently, most Web personalization or adaptive features employ data mining or collaborative filtering techniques (Herlocker, Konstan, Borchers, & Riedl, 1999; Mobasher, Cooley, & Srivastava, 1999; Mobasher, Jain, Han, & Srivastava, 1997; Spiliopoulou, Faulstich, & Winkler, 1999) which often use past historical (static) data (e.g., previous purchases or server logs). The deployment of data mining often involves significant resources (large storage space and computing power) and complicated rules or algorithms. A vast amount of data is required in order to be able to form recommendations that made sense and are meaningful in general (Claypool et al., 1999; Basu, Hirsh, & Cohen, 1998).

While the main idea of Web personalization is to increase the ‘stickiness’ of a portal, with the proven presumption that the number of times a shopper returns to a shop has a direct relationship to the likelihood of resulting in business transactions, the method of achieving the goal varies. The methods range from user clustering and time framed navigation sessions analysis (Kim et al., 2005; Wang & Shao, 2004), analyzing relationship between customers and products (Wang, Chuang, Hsu, & Keh, 2004), performing collaborative filtering and data mining on transaction data (Cho & Kim, 2002, 2004; Uchyigit & Clark, 2002; Jung, Jung, & Lee, 2003), deploying statistical methods for finding relationships (Kim & Yum, 2005), and performing recommendations bases on similarity with known user groups (Yu, Liu, & Li, 2005), to tracking shopping behavior over time as well as over the taxonomy of products. Our implementation works on the premise that each user has his own preferences and needs, and these interests drift over time (Cho, Cho, & Kim, 2005). Therefore, besides identifying users’ needs, the system should also be sensitive to changes in tastes. Finally, a truly useful system should not only be recommending items in which a user had shown interest, but also related items that may be of relevance to the user (e.g., buying a pet => recommend some suitable pet foods for the pet, as well as suggesting some accessories that may be useful, such as fur brush, nail clipper, etc.). In this aspect, we borrow the concept of ‘category management’ use in the retailing industry to perform classification as well as linking the categories using shared characteristics. These linkages provide the bridge for cross-category recommendations.

**DESCRIPTION OF SYSTEM**

In this article, we seek to provide an adaptive feature using a fast and cost-effective means. The aim is to provide adaptiveness in the sense that when a visitor selects the next link or a new page, the contents of the page generated will have relatedness to previous pages’ contents. This adaptive feature will be immediate and will not experience delay or repetitive computational filtering problems, as compared to using mining or collaborative filtering (Claypool et al., 1999; Basu et al., 1998).

The rules-based technique offers an excellent and flexible mechanism to specify rules that map categories that exhibit relatedness among themselves (IBM, 2000). Adding new product
lines is simple, by just adding new sets of rules to map the new products accordingly. For direct item-to-item relatedness mapping, it is not so scalable and feasible to implement through use of the rules-based technique. Instead we will use content-based filtering for generating direct item-to-item mappings. The content-based technique (Claypool et al., 1999; Basu et al., 1998) allows item-to-item mapping to be implemented in a scalable manner by just defining the item’s attribute, and the recommendation engine will automatically generate or match items of same attribute without involving user efforts (Basu et al., 1998).

In order to facilitate the deployment of these recommendation techniques, the Web domain is structured into their respective categories that exhibit relatedness among them. For example, pet dog would have relatedness to books on dogs. Each of the categories is given a unique ID value. The relatedness rules make use of these IDs to generate recommendations. The Web site domain is structured into supernodes (SA, SB...) which branch into child nodes (A1,A2...An;...K1,K2...Kn). These supernodes are a representation of products on the Web site, and the child nodes are used to represent the breakdown of the products into categories. Below each of the child nodes are the sub-child nodes (Aa1,...Axm;...Ka1,Ka2,...Kxm) that represent the items. Each of the child nodes (A1,A2...An;...K1,K2...Kn) is identified with its corresponding ID value. With this structure, rules-based mapping can be easily identified and applied among the child nodes by defining the IDs that will result into a recommended page.

The syntax of a relatedness rule is:

\[ \text{ID}_a:\text{ID}_b:\ldots\Rightarrow \text{Target page} \]

The entries \( \text{ID}_x \) represent the IDs of Web pages that have relatedness and thus can be mapped directly to the Web page (link) identified as target page. A rule is considered matched when any of the Web page IDs in the rule is also found to exist in the selector’s list (visitor’s profile). The selector’s list is compared against all the rules in the rule file. Only one of the rules will be used, and that is the rule that has the most number of \( \text{ID}_x \) elements matching the selector’s list. In the event of tie, the rule which matches with selector entry that carries the higher points will be used, or if they still tie, then precedence of rule entry in the rule file will be used to determine the final rule to use.

Mappings across sub-child nodes are done based on their attributes (content based). A file will be used to define the list of items (or contents) of each Web page (at category level) and also any of attributes for each of the items. The syntax for this item list file is:

\[ \text{Id}_x:\text{Id}_y:\ldots:\text{attr}_a:\text{attr}_b\Rightarrow\text{display.html} \]

The entries \( \text{Id}_x \) are indexes to the html page that contains all the information regarding the item. An example of these indexes could be the type of pet. The information about each type of pet is found in the corresponding html file. An item sorter engine will, at startup, sort out the indexes and their corresponding html files. This will allow the page contents to be arranged or displayed based on any of these indexes. The other set of entries \( \text{attr}_x \) define the attributes of the item. When the visitor selects any of the items for browsing, the corresponding \( \text{attr}_x \) will be tracked. Whenever the visitor browses a new page, the recommendation engine will check for items that have the same \( \text{attr}_x \) and automatically include the corresponding html file for display (see Figure 1).

Our prototype system also incorporates means of generating a dynamic profile that changes as the visitor browses through the Web site. Implicit tracking does not require any explicit inputs or intervention by the visitor. Conventionally this is done either through use of user authorization, hidden form fields, URL rewriting, or cookies (Hunter et al., 2002). Although cookies offer an
elegant solution to the stateless HTTP protocol when compared to the other three, it is also frowned upon by some visitors and as such are disabled (Mobasher et al., 1999; Cooley, Mobasher, & Srivastava, 1999). Instead, the tracking of visitors’ activities is implemented through use of a session object on the server side (Hunter et al., 2002). This object will be used to record all the Web pages (tagged with IDs on the server side) browsed by the visitor during the current session, hence obtaining the profile of the visitor. However, a cookies mechanism is still implemented to provide the “remember” feature, in the sense that if the cookies feature is enabled on the visitor’s browser, the activities on the Web site from the most recent visit will be available (and retrieved) during the next visit. This allows the system to build the visitor’s profile immediately. Hence we are able to combine the static profiling (from cookies) with the dynamic one (tracked by session object) to build a profile that can “remember” a visitor’s previous preferences and dynamically change itself as the visitor continues browsing the Web site.

In order to give priority to activities that occur more often and recent, a point system is used whereby the current session log is given heavier weight than those retrieved from the cookies so that the current activities will be more likely to be nominated into the visitor’s latest profile. The activities log tracked by the session object will be given higher consideration during profiling in order for the system adaptiveness to be reflected accordingly and immediately to the changes in the visitor browsing behavior. In this design, a total of three activities logs are used (two from cookies if available, and the remaining one is from the current session object that tracks the current activities).

In order to demonstrate the adaptiveness feature, the Web site domain should consist items or products that have the following characteristics:

1. Products that can be easily categorized.
2. Selection of items or products should be able to reflect the taste or preference of visitor.
3. Certain form of relatedness between the products.
Auto-Personalization Web Pages

With the above considerations taken into the account, we implemented a Web portal using an online shop named My-Pet that sells the following products:

1. Pets
2. Books on pets
3. Accessories for pets
4. Food for pets

To demonstrate how the system functions, we selected the following list of categories:

Pets: Bird, Dog, Cat, Hamster, Fish
Books: How to care…, Diseases of…, Nutrition for …
Accessories: Pet wears, Toys, Restraints
Foods: Meals, Snacks, Supplements

The My-Pet recommendation engine is based on the relatedness determination among its products. The relatedness determination for My-Pet is defined at three levels:

1. Relatedness between categories across products (e.g., pet dog and dog food and books on dogs);
2. Relatedness between categories in the same product (e.g., books on how to care for dogs and books on diseases of dogs and books on nutrition for healthy dogs); and
3. Relatedness at items level across products (e.g., food and accessory items from the same company/brand).

Items (1) and (2) are achieved based on the rules-base technique, while content-based filtering is used for item (3).

The server software architecture is decomposed into independent modules that have very similar structure. Each product has its own module that is responsible for presenting and generating its dynamic Web page contents. The development platform chosen is Java Server Pages (JSP), which offers object-oriented components deployment. By developing the whole Web program in JSP

Figure 2. Software architecture
and Java, the server program is OS-platform independent.

Each module is made up of the following components:

- JSP Page
- Logs Processor (JavaBean)
- Recommendation Engine (JavaBean)
- Item Sorter (JavaBean)

The JSP page is responsible for delegating the tasks to the respective components, and at the end presenting the results into HTML format for viewing by the visitor.

The Logs Processor component serves to log all the activities by the visitor and process the activities logs before submitting to the Recommendation Engine. It plays the role of profiling the visitor’s activities. The Recommendation Engine is mainly used for determining product-to-product mapping based on the selector’s list (profile) generated by the Logs Processor. The Items Sorter’s main function is to read the list of product items and sort them such that they can be retrieved via means of indexing or key. This component is also used to retrieve an item attribute that is used for Content-Based filtering, based on the input determined by the Logs Processor component (see Figure 2).

IMPACT OF SYSTEM

The prototype system is implemented using a Java Server from JRUN which provides the container for running JSP and JavaBeans classes. The database stores all external data inputs. The Web server PC is installed with JRUN and the Web application. Customers can access the Web site using any Web browser.

To illustrate the effectiveness of this system in providing dynamic content generation, a series of user inputs and the subsequent system responses are tabulated.

From the trial run results obtained, it was observed that the system behaved as expected, providing the adaptive feature of generating Web contents based on users’ activities on the Web site (see Table 1).

</tr>
<tr>
<td>4. ability to generate a recommendation based on cookies retrieved from the visitor’s PC.</td>
<td></td>
</tr>
</tbody>
</table>

CONCLUSION

We have developed a system that can adapt its Web contents based on visitors’ activities on the Web site through combining rule-based with content-based filtering techniques—resulting in an implementation that is both flexible and can rapidly adjust its recommendations. Rule-based structure offers cross-product mapping. Content-based filtering takes the items’ attributes into account when generating recommendations. The system transparently and seamlessly tracks the visitor on the server side and does not require explicit inputs (ratings or purchases or login account) to determine the visitor’s profile dynamically.

My-Pet’s system design utilizes the concept of category management, which is widely practiced in brick-and-mortar shop fronts and maps product

taxonomy into a cyberspace virtual environment. The key to using category management is that it makes system expansion systematic and easy. In our illustration, we included a handful of products and categories. However, the system architecture provides a structure that allows more products or categories to be added easily. Sub-categories can also be added as long as each of them is given a unique ID page. A new set of relatedness rules can then be defined for these newly added elements. This is in fact a strength of rule-based implementation, where new linkages between product categories and subcategories can be added and removed as need arises. Rules may also carry different precedence values.

Such a highly adaptive system does have a weakness—it has taken away some navigation control from the user. It was noted in a 1998 survey (GVU, 1998) that 17% of Web users experience difficulty in returning to pages visited before. A system with an auto-recommendation feature is likely to fair worse in this aspect. Therefore, for
future improvement to the system, a feature could be added to the system whereby a link page is created and this page contains all links to pages that were previously browsed by the user.

In addition, a search option can also be included. This search option indirectly provides a way for the visitor to tell the system his/her taste or preference. This serves as an excellent and accurate input in building a profile that even more closely reflects the visitor’s preferences. Hence the system will be able to use a more accurate visitor’s profile when generating recommendations.

REFERENCES

**KEY TERMS**

**Category Management:** Classify and manage items based on some predetermined categories.

**Clickstream:** A sequence of mouse clicks.

**Collaborative Filtering:** Unveiling general patterns through “sniffing” through user’s past activities.

**Personalization:** Customization to individual user’s preferences and needs.

**Portal:** The entry node/point of navigation semantic unit for a Web site.

**Profiling:** Capturing individual user’s interests and needs.

**Self-Adaptive:** Ability of a Web portal to automatically adjust its presentations to perceived user’s preferences.

**Session Object:** Information items that capture characteristics and activities of a user during a Web session.

Chapter 2.27
A Qualitative Study in User’s Information-Seeking Behaviors on Web Sites: A User-Centered Approach to Web Site Development

Napawan Sawasdichai
King Mongkut’s Institute of Technology, Ladkrabang, Thailand

ABSTRACT
This chapter introduces a qualitative study of user’s information-seeking tasks on Web-based media, by investigating user’s cognitive behaviors when they are searching for particular information on various kinds of Web sites. The experiment, which is a major part of the recently completed doctoral research at the Institute of Design-IIT, particularly studies cognitive factors including user goals and modes of searching in order to investigate if these factors significantly affect users' information-seeking behaviors. The main objective is to identify the corresponding impact of these factors on their needs and behaviors in relation to Web site design. By taking a user-based qualitative approach, the author hopes that this study will open the door to a careful consideration of actual user needs and behaviors in relation to information-seeking tasks on Web-based media. The results may compliment the uses of existing quantitative studies by supplying a deeper user understanding and a new qualitative approach to analyze and improve the design of information on Web sites.

INTRODUCTION
When visiting a Web site, each user has a specific goal that relates to a pattern of needs, expectations, and search behaviors. They also approach with different modes of searching based on varied knowledge, experience, and search sophistication. This leads to differences in information-seeking strategies and searching behaviors. Since information on Web sites is traditionally structured and presented based on Web sites’ goals and contents,
it may or may not match with user goals or search behaviors.

Because of these problems, information structuring is the essence of Web design since these problems cannot be solved by the development of technically sophisticated systems alone. User search behaviors need to be studied and deeply understood in order to design systems that allow them to perform their information-seeking tasks easily, without struggle and frustration. The contents need to be authored, organized, structured, and presented to fit their needs, expectations, and search behaviors, while being able to carry out the goal of the Web site simultaneously. Both the provider and user must benefit at the same time to ensure the Web site success. As a result, user-centered design process is important in Web development to help people succeed within an information context that seeks to achieve business goals (Brinck, Gergle, & Wood, 2002).

In attempts to move toward user-centered design, many studies have been developed to establish design principles that better serve Web-based media. Among these attempts, Web usability, grounded in human-computer interaction (HCI), has currently assumed a significant role underpinning the design of many Web sites in order to maximize efficient use. Web usability studies and practices are primarily concerned with people performing a task accurately, completely, and easily. These may involve making information accessible, retrievable, legible, and readable, ensuring that all Web pages are reachable and practically navigated, or dealing with technical aspects of media interface and Web system by ensuring that all system functionality can be operated correctly and easily.

**User Research in Web Development**

User research in relation to Web site development is mostly conducted by using quantitative methods or automated programs, such as data mining and Logs File Analysis (analyze usage data), GOMS analysis (predict execution and learning time), and Information Scent modeling (mimic Web site navigation) serve different purposes. These automated methods are particularly essential to usability testing (evaluation), especially in cases where numerous users are involved since they can reveal a substantial amount of information with regard to usage patterns by representing the actual usage characteristics. Some also provide in-depth statistical analysis of usage. For example, *logs file analysis* can show overall hits, conversion rates, entrance pages, search terms, peak times, demographics, and system down-time (see Figure 1 and 2). These develop an understanding of how the Web site is being used by the actual users, which helps identify potential problems of the Web site, and may assist in suggesting a change or directing the future design (Brinck et al., 2002).

However, the limitations of these automated methods are that they cannot be employed without an existing Web site; the Web site needs to be prototyped or implemented at some level before these methods can be applied since they are intended as an analytical means rather than a generative one. More importantly, these automated methods cannot capture important qualitative and subjective information such as user preferences and misconceptions (Ivory & Hearst, 2001). They tend to yield a higher level of user data — what they do or what they do not do — but they usually fail to capture and analyze user cognitive behaviors such as their satisfaction, decision-making pattern, or reasons that underpin their needs and behaviors.

Therefore, qualitative study using nonautomated methods such as user observation, focus groups, user interviews and surveys still play an important role in Web development. These nonautomated methods can be used in the design process to capture, analyze, and conceptualize Web structure before usability evaluation takes
A Qualitative Study in User’s Information-Seeking Behaviors on Web Sites

Applying both quantitative and qualitative studies can significantly improve the quality and quantity of user input and feedback that may help suggest a change or direction that better supports user satisfaction. As a result, this study investigates a relatively new area of user research in Web-based media, offering a user-centered perspective with place. They can be employed in the evaluation process as complements to the automated methods as well, in order to help capture and analyze qualitative and subjective user information that is missing from the automated methods alone.

![Visits](image1)

Figure 2. An example page from logs file analysis example: Top entry pages

![Top Entry Pages](image2)
consideration of user goals, user modes of searching, and their search behaviors by taking a user-based qualitative approach. The study expects to expand understanding within the area of user studies, and accordingly investigates how these user cognitive factors contribute to differences in user information needs and their information-seeking behaviors on Web-based media, particularly in view of user search strategies and user search methods. Understanding within this area will contribute to the further development of information architecture and interface design.

SCOPE OF THE RESEARCH

The practices of Web site development are fundamentally concerned with two equally important and interrelated parts: (1) Web functionality and (2) Web information. In the user-centered perspective, usability, accessibility, sustainability, suitability, credibility, and usefulness of both Web functionality and Web information for its intended users are important for the Web to succeed. In most current practices, the user-centered approach is usually taken into design consideration in a general sense; for example, by conducting user studies to establish who are the intended users of the Web site (user profiles), and what do they want to achieve (user goals)? Others may perform user testing with regard to usability evaluation in terms of what is working, and what is not (usability of Web functionality). These current user-centered approaches are concerned with Web functionality rather than Web information. Furthermore, they pay considerably more attention to usability aspects while the Web information content receives less attention. Therefore, this research primarily focuses on the design of Web information, particularly in view of the importance, suitability, and usefulness of information design provided on Web sites (see Figure 3).

The study is particularly concerned with user information needs and user information-seeking behaviors; it also investigates whether the design of information provided on the Web site supports these needs and behaviors. Secondly, the research is also concerned with the suitability and usefulness of Web functionality necessary for users to gain access to the information they need. The research also looks into different types of search methods or search tools provided on Web sites to investigate whether these search methods or tools are useful and suitable to user search strategies.

When searching, each user has a different search plan: For instance, they lightly explore or seriously search and they select search methods and tools in order to easily achieve their goal. This search plan is primarily based on their search strategy, which is the scheme that generally distinguishes user search patterns. Besides search strategies, each user may use a particular search method, which is the procedure for how they actually perform their search. User search method is based on the types of search tools they choose for their search, which may include menu bar, table of contents, index, or search engine. User search strategies can range from general or less-focused search to more specific or purposeful search. Furthermore, it may change from time to time based on the current context or situation that unfolds while they are searching as well as the search results that they find or retrieve. Based on user search strategies and its results, user search methods are changed accordingly.

As a result, this research is aimed to uncover the primary factors governing or influencing these user search strategies and methods.

More importantly, in order to understand and eventually determine what types, characteristics, formats, and presentation methods for information is suitable and useful for users, the research needs to investigate the relatively new areas of user-centered approaches to Web site design: user goals and user modes of searching (see Figure 4).

Information scientists have studied user modes of searching for decades, and these ideas are well categorized by Rosenfeld and Morville (1998) in
A Qualitative Study in User’s Information-Seeking Behaviors on Web Sites

Figure 3. Primary focuses of the research: The design of Web information-based on user-centered approach, particularly with regard to usefulness and suitability

Their book Information Architecture for the World Wide Web. However, since the notion of user modes of searching has never been elaborated in terms of what to expect from their differences, it needs further investigation — this becomes the primary focus of this research to uncover its substantial impact on user needs, expectations, search strategies, or information-seeking behaviors in this medium. In addition, typical user profiles are also categorized in order to determine whether these profiles exert any substantial impact on user needs, expectations, or search patterns. These profiles particularly focus on user demographic and techno-graphic data,
A Qualitative Study in User’s Information-Seeking Behaviors on Web Sites

Figure 4. Primary focus of the research: User goals and user modes of searching

including prior knowledge in the content they are searching, prior experience in the particular or similar Web site interface, and sophistication in general Internet use.

RESEARCH ANALYTIC FRAME

The research begins with defining and categorizing the important elements or factors of the study, including user goals, user modes of searching, as well as Web site goals and contents. Accordingly, the research analytic frame is established to help identify potential cases for the study. User goals and modes of searching were investigated within the context of specific Web site goals to reveal common user search patterns, search strategies, and search methods associated with each case and to identify the primary problems that occur in each pattern.

User Goals

Each user has a specific goal when visiting a Web site. Different goals suggest different kinds of needs, expectations, and search behaviors, which are factors in Web usage and success. Further, users may access the same Web site with different goals at different times; moreover, they often link several goals and explore them sequentially. User goals may be categorized as follows:

- **To seek specific information:** In this category, users may engage a Web site to search for specific information that helps them to stay updated, make decisions, fulfill a specific inquiry, perform tasks, learn, or conduct research.
- **To fulfill personal interests:** Some users may engage a Web site as a resource for pleasure to fulfill a personal interest (e.g., watching a video clip or listening to music on an entertainment Web site).
- **To communicate and/or perform tasks:** Others may use Web sites as a channel for communicating or as a means for performing tasks (e.g., connecting to a community Web site or paying bills on a company Web site).

Among these three categories of user goals, the information-seeking goal is prevalent and poses the greatest problem for users. Consequently this is the primary investigative focus in this research.

User Modes of Searching

Besides user goals, users also approach a Web site with varied levels of specification of their
needs and different levels of search specification and determination, this leads to differences in information-seeking behaviors including search strategies, search methods, and selection of search tools. Some users may know exactly what they are looking for and where to find it, while others are without a clue. Since these search behaviors and user expectations vary widely, it is important to recognize and distinguish among them noting their differences.

A current study (Rosenfeld & Morville, 1998) has delineated users’ different modes of searching as known-item searching, existence searching, exploratory searching, and comprehensive searching (research). Based on Rosenfeld and Morville’s model, user modes of searching are modified and extended in this research to include topical searching which falls between existence and known-item searching. User modes of searching may be categorized as follows:

• **Exploratory searching (browsing):** Users have a vague idea of their information needs. They do not know exactly what they are hoping to find, but some may know how to phrase their question. They want to explore and learn more.

• **Existence searching:** Users have an abstract idea or concept of what they are hoping to find, but do not know how to describe it clearly or whether the answer exists at all. They want to search for what matches their idea or mental image.

• **Topical searching:** Users know what they want in general. Some may want to search for an answer to their specific question. They know what they are hoping to find, but do not know where/which categories they should look for.

• **Known-item searching:** Users know exactly what they want, and usually know where/which categories they should look for. Users’ information needs are clearly defined and have a single, correct answer.

• **Comprehensive searching (research):** Users want to search for specific information, and they want everything available regarding this information. Users’ information needs are clearly defined, but might have various or many answers.

**Users Search Behaviors**

When users are searching for information and trying to accomplish their goals, they move between two cognitive states (thoughts/decisions — with regard to their goal and interest) and physical states (interactions — concern with functions, navigation, and computer performance) with regard to information provided on each Web page.

For instance, some users may want to keep searching because they need detailed information, while others may be satisfied with only a short descriptive text presented on the first page. Some may prefer textual information, but others may feel more satisfied with visual information. These search behaviors may be identified as shown in Table 1. These cognitive and physical behaviors with regard to user search, previously observed from initial user observation, will be further used to establish a coding scheme used in an analytical process of the research.

**Web Site Goals and Contents**

While this research focuses on the relatively new areas of user studies: user goals and user modes of searching, other factors such as site contents, site goals, and site functions nevertheless play a significant role in determining the design of a Web site. Each Web site contains unique contents and goals depending on the nature of the company, institution, or individual that owns that Web site. Based on the book *Web Navigation: Designing the User Experience* (Fleming, 1998), these Web sites can be distinguished and generalized by the similarities of their goals and contents into six categories: (1) commercial Web site, (2) identity

Web site (Web site for company or institution), (3) information Web site, (4) education Web site, (5) entertainment Web site, and (6) community Web site. However, only the first four categories, in which the problems of information-seeking tasks are primarily found, will be investigated in this study. Moreover, entertainment and community Web sites are quite different from other Web sites because of their unique goals, contents, and functions.

By simultaneously considering the three important factors of information design on
Web sites: (1) Web site goals and contents, (2) user goals, and (3) user modes of searching, an analytic frame is constructed. Different aspects of each factor are systematically combined with one another to establish prominent cases or scenarios for the study; each of which presents a unique combination of the three factors: (1) Web site goals and contents, (2) user goals, and (3) user modes of searching.

Nevertheless, these cases are not mutually exclusive; they might overlap or combine since one Web site may consist of two or more combinations (see Figure 5). As shown in Figure 6, case 1 represents the scenario in which users with

Figure 5. The research analytic frame: Generating 10 different study cases for the research
exploratory searching mode visit a commercial Web site in order to find information to make a decision. Case 2 represents a similar scenario to case 1; however, users in case 2 arrive with an existence mode of searching. Cases 3, 4, and 5 represent similar scenarios in which users visit identity (company) Web sites to find information to fulfill a specific inquiry.

However, each case has a distinctive search mode. Users in case 3 approach with an existence mode; case 4 with a topical mode; while case 5 approaches with a known-item mode. Cases 6, 7, 8, and 9 represent the scenarios in which users visit information Web sites to find information to stay updated. Though, they are assigned different modes of searching, which include exploratory, existence, topical, and known-item modes respectively. Case 10 represents a scenario in which users with a comprehensive mode of searching approach an educational Web site to find information for learning or researching a specific content. Each of these 10 cases will be investigated and analyzed to uncover similarities and differences in patterns of user information-seeking behaviors, as well as to identify user information needs, user search strategies, and user search methods associated with different user goals, modes of searching, and Web site characteristics.

**RESEARCH QUESTIONS**

The study is specifically conducted within these selected 10 cases generated from the research analytic frame shown in Figure 5 in order to find the answers to these research questions:

- What are the common patterns of user information-seeking behavior presented in each study case?
- What are the user search strategies, search methods, or selected search tools commonly found or employed in each study case?
What kinds of information do users need in each study case in terms of the types, characteristics, formats, presentation methods, quantity and quality of information?

What are the key factors in each study case that help or obstruct users to accomplish the information-seeking task?

The research findings that answer these questions will be analyzed to identify the relationships existing among user goals and user modes of searching with their information needs, search strategies, and search methods. These results will help establish the classification of cognitive factors, as well as provide an analysis framework for information design on Web sites.

RESEARCH METHODOLOGY

Research Methods

A qualitative research method is used in this study to explore the similarities and differences of user search patterns. Users’ information-seeking behaviors are observed through controlled observation, through video observation combined with protocol analysis. User profiles are also collected through a series of questionnaires. Ten scenarios are designed to create the 10 study cases originating from the research analytic frame to help the participants enter the situation and the tasks they needed to accomplish. Each scenario is embedded with a particular mode of searching, and a different search goal resulting in the performance of a task, ranging from open-ended to very specific purpose and search.

Scenario 1 explores a commercial Web site: Expedia.com. User goal is to make a decision; user search mode is exploratory searching.

Scenario 2 explores a commercial Web site: Toyrus.com. User goal is to make a decision; user search mode is existence searching.

Scenario 3 explores an identity Web site: Paris-ile-de-France.com. User goal is to fulfill a specific inquiry; user search mode is existence searching.

Scenario 4 explores an identity Web site: Apple.com. User goal is to fulfill a specific inquiry; user search mode is topical searching.

Scenario 5 explores an identity Web site: FoodTV.com. User goal is to fulfill a specific inquiry; user mode is known-item searching.

Scenario 6 explores an information Web site: TVGuide.com. User goal is to stay updated on some interesting topics; user search mode is exploratory searching.

Scenario 7 explores an information Web site: ABCNews.com. User goal is to stay updated on a specific topic; user search mode is existence searching.

Scenario 8 explores an information Web site: DiscoveryHealth.com. User goal is to stay updated on a specific topic; user search mode is topical searching.

Scenario 9 explores an information Web site: CNN.com. User goal is to stay updated on a specific topic; user mode is known-item searching.

Scenario 10 explores an information/education Web site: WebMD.com. User goal is to research and learn about a specific topic; user search mode is comprehensive searching.

Fifty participants from different cultures, all of whom were literate in English, are observed regarding how they search for information and try to accomplish the tasks defined by the scenario.
they received. The participants approached the selected Web site with unspecified and various modes of searching and searched for information with goals appropriate to the selected scenario. Ten participants are randomly selected to participate in each scenario, with each participant doing two cases or two different scenarios.

As a result, the research collects in total 100 observation cases, which consist of 10 cases for each of 10 scenarios. The participants’ interactions (physical behaviors) on Web sites are simply captured through a video recorder. Furthermore, by using protocol analysis, the participants express verbally what they think while performing tasks in order to reveal their thoughts (cognitive behaviors) and comments, which are extremely important for the analytical process.

**Analysis Methods**

Since the research data collected from participants is qualitative in nature, several methods of qualitative analysis are used in this research to carefully analyze various aspects of the data, in order to obtain integrated research findings that answer the related but different research questions on which this research focuses. Each analysis method used in the study delivers distinctive analytical results answering a specific research question. The analytical results obtained from these different analysis methods are also cross-examined in order to accumulate further findings. This collective analysis process helps to uncover the pattern of relationship that exists among various user cognitive factors, as well as to identify their substantial impact on user search behaviors and information needs.

*Thematic analysis* (Boyatzis, 1998), the process used for encoding qualitative information, is performed in this study to analyze the overall user search behaviors including user task list and process. In order to uncover the differences and similarities in user search behaviors, a thematic analysis framework with a coding scheme is designed based on an initial observation on user search behaviors. Participants’ search behaviors are captured through video and sound recording, then analyzed and encoded by using the coding scheme (see Table 2).

User search behaviors are analyzed at each Web page the user visited as cognitive behaviors (thoughts/decisions) and physical behaviors (interactions). Each behavior is encoded using the preset coding scheme. The result is the sequence of user tasks performed by each user when searching for specific information on the particular Web site as described in the scenario they received (see Table 3).

The results, displayed as the encoded information of user search behaviors, are then further analyzed and generalized to determine the common patterns of information-seeking tasks that are associated with each study case (scenario) by using a *time-ordered matrix* (Robson, 1993). The time-ordered matrix is used to systematically display the encoded information of user search behaviors in *time-ordered sequences* by presenting various types of user search behaviors, both physical and cognitive behaviors, observed in each Web page from the start to completion of the task (see Figure 7).

Color coding is also added to help identify and group the same or similar tasks together. This enables one to see the overall task list and its sequence visually and practically in order to compare the differences and similarities that occur within and across different scenarios.

In addition, the results gained from thematic analysis are eventually summarized as *procedural analysis*, which presents the common process or pattern of user search behaviors in each study case (scenario) including search methods and task descriptions (see Figure 8).

The encoded information of user search behaviors is also further transformed into Chernoff Faces (Chernoff, 1973; Wainer & Thissen, 1981) in order to further identify and compare the common patterns of search behaviors that are associ-

</table>

different scenarios. For example, in this coding scheme, the face is used to represent the user’s information-collecting state. The bigger the face, the more information has been collected by the user. The eyes represent how much the user searches, while the eyebrows represent a struggling state (see Tables 4.1, 4.2, and Figure 9).

As shown in Figure 9, Chernoff Face Analysis reveals the patterns of user’s prominent tasks performed in each different scenario. For example, users in scenario 2, as shown in the top row, need to perform an extensive decision-making task indicated by the gray and black hair they are all wearing; in contrast to users in scenarios 4 and 9.
A Qualitative Study in User’s Information-Seeking Behaviors on Web Sites

who all appear with no hair signifying that they do not perform any decision-making task at all. The analysis also visually addresses user search struggle or satisfaction clearly. As seen clearly in Figure 9, all users in scenario 9 appear with complete satisfaction while most users in scenario 4 are unsatisfied with their search.

In order to identify the patterns of user search strategies and methods commonly used in each scenario, a checklist with a sequence record (Robson, 1993) is designed to record participants’ frequency and sequence of use of various search tools available on each Web site. The recorded data is then further analyzed to identify the com-

*Participant N/n means scenario ‘N’/participant ‘n’.
mon patterns of user search strategies and search methods primarily used in each scenario, as well as to compare the differences and similarities of user search patterns within and across different scenarios (see Table 5).

Similarly, in order to identify the patterns of user information needs commonly found in each study case, another Checklist Record (Robson, 1993) is designed to record the frequency of use of different kinds of information available on each Web site. Different types, characteristics, formats, and presentation methods of information display that are viewed by users while performing information-seeking tasks are captured by using the Checklist Record. This process is used to analyze and identify the main types, characteristics, formats, and presentation methods of information needed by users to accomplish the given task within and across different scenarios (see Table 6).

The analysis of user profiles is collected and built upon user data acquired through a series of questionnaires provided to the research participants when the observation took place (see Figure 10). The questionnaire was designed to acquire user demographic and techno-graphic data focusing on different aspects of user experience, including users’ prior knowledge and experience in the specific content they are searching, users’ prior experience in the particular or similar Web site interface, and users’ general experience in Internet use for information-seeking purposes.

Furthermore, qualitative comparison is conducted by constructing truth tables (Ragin, 1987, 1994) to help further identify additional insights and various factors that may reveal additional

- **Positive decision**: Users make a positive decision (to proceed) about something according to information they found.

- **Negative decision**: Users make a negative decision (not to proceed) about something according to information they found.

- **Positive decision**: Users go back to the previously selected or recorded (bookmarked) pages or results, and/or compare the selected pages or results side by side in case there are more than one page or result selected.

- **Negative decision**: Users are satisfied. All users’ needs are fulfilled. Users are able to accomplish their goals based on the information they found.

- **Negative decision**: Users are somewhat satisfied, but not completely satisfied. Users’ primary needs are fulfilled, and users are able to accomplish their goals based on the information they found. However, users still need more information to fulfill all their needs completely.

- **Negative decision**: Users are not satisfied. Users’ needs are not fulfilled. Users are unable to accomplish their goal(s).
Validation of Coding System

Reliability and validity of coding schemes specifically designed to use for analysis in this research is fundamentally important and needs to be examined before the study proceeds further. In qualitative research, the observer’s consistency and bias in interpreting user behaviors and using coding schemes to code events are a primary concern. As a result, to measure reliability and validity of the coding scheme and analysis methods, a second observer is invited to independently...

Remarks: Users thoughts, comments on their information needs

Many users would like to see more and bigger pictures, or some interactive displays showing the usage of product.

Some users expect to see the same or similar information to what they would see on the package of the product when they buy in a store.

Most users want to see comparison information or want a comparison tool.
interpret and code the same video data. The scripts encoded by both observers are then compared to identify the degree to which both observers agree in their interpretation and coding. This validation process is called double coding, which is perhaps the most used technique to attain sufficient reliability to proceed with analysis and interpretation (Boyatzis, 1998; Miles & Huberman, 1984).

After the double coding process is completed, the confusion matrix is constructed to show where the two observers are different in their judgment when coding the events. Agreement takes place when both observers use the same code for the same event. On the contrary, disagreement occurs when observers use different codes to code the same event. To read the confusion matrix, the scores on the diagonal from top left to bottom right indicate agreement between the two observers, while the scores off this diagonal indicate their disagreement (Robson, 1993) (see Figure 11).

As shown in Figure 11, the scores on the diagonal from top left to bottom right appear-

Note: Coding ‘A’, ‘B’, ‘C’, ‘D’, and ‘L’ indicate agreement between the two observers. However, for the coding ‘E’, there is also a score appearing off this diagonal which indicates an event of their disagreement. Note that in this particular case, both observers do not assign coding ‘F’, ‘G’, ‘H’, ‘I’, ‘J’, ‘K’, and ‘M’ to any events. Therefore, there is no score for unused coding in the matrix; this will be different from one case to another.

Then, based on the scores on the confusion matrix, the proportion of agreement, the proportion expected by chance, and the Cohen’s Kappa are respectively calculated to measure inter-observer agreement (see Figure 12). “The inter-observer agreement is the extent to which two or more observers obtain the same results when measuring the same behaviors (e.g. when independently coding the same tape).” (Robson, 1993, p. 221).

In order to assess the significance of Kappa scores, Fliess (1981) has suggested the following rules of thumb: the Kappa scores of 0.40 to 0.60 is considered “fair”; the Kappa scores of 0.60 to 0.75 is considered “good”; and the Kappa scores above 0.75 is considered “excellent.” The results obtained from this validation process show that validity of the coding schemes used in this study, in the view of inter-observer agreement, is positively strong. The Kappa scores of seven observation cases acquire “excellent” points (0.75-0.95), and the other three cases also show “good” scores (0.64-0.71).

However, the extent of agreement between two observers who use the coding scheme to code
A Qualitative Study in User’s Information-Seeking Behaviors on Web Sites

The same events independently is also affected by some other factors. One primary factor may be the observer’s learning curve with regard to the coding scheme; one observer is more familiar with the coding scheme while the other observer is new and still learning to use the codes and/or interpret the events. Another important factor may be the observer’s lack of experience or direct contact with the actual participants in the prior observation when the events were recorded. This occurs when one observer attended the observation in person when the events were recorded while the other observer was absent. The observer who had experience or direct contact with the actual participants when the events were recorded will be able to capture the participants’ emotions or thoughts that are hard to detect through watching video data alone. As a result, the two observers may interpret the same user behavior differently since the first observer also makes judgments

Figure 12. An example calculation of the proportion of agreement, the proportion expected by chance, and the Cohen’s Kappa Score to measure the extent of inter-observer agreement

**Proportion of Agreement**

\[
P_0 = \frac{\text{(number of agreements)}}{\text{(number of agreements)} + \text{(number of disagreements)}}
\]

\[
P_0 = \frac{5 + 8 + 4 + 4 + 2 + 1}{25} = 0.96
\]

**Proportion of Expected by Chance**

\[
P_C = \frac{P_{1A} \times P_{2A}}{P_{1A} \times P_{2A}} + \frac{P_{1B} \times P_{2B}}{P_{1B} \times P_{2B}} + \frac{P_{1C} \times P_{2C}}{P_{1C} \times P_{2C}} + \frac{P_{1D} \times P_{2D}}{P_{1D} \times P_{2D}} + \frac{P_{1E} \times P_{2E}}{P_{1E} \times P_{2E}}
\]

\[
P_C = \frac{0.26 \times 0.33}{0.26 \times 0.33} + \frac{0.30 \times 0.30}{0.30 \times 0.30} + \frac{0.15 \times 0.15}{0.15 \times 0.15} + \frac{0.11 \times 0.07}{0.11 \times 0.07} + \frac{0.03 \times 0.03}{0.03 \times 0.03} = 0.1969
\]

**Cohen’s Kappa**

\[
K = \frac{P_0 - P_C}{1 - P_C}
\]

\[
K = \frac{0.96 - 0.1969}{1 - 0.1969} = 0.7631 = 0.95
\]

\[
K = \frac{0.96 - 0.1969}{1 - 0.1969} = 0.8031
\]
A Qualitative Study in User’s Information-Seeking Behaviors on Web Sites

based on experience with the actual participant. These are factors that may play an important role in the inter-observer agreement.

ANALYSIS OF RESEARCH DATA

Patterns of User Search Behaviors

The research provides a new perspective on design considerations for a Web site by incorporating requirements from both Web site (client) intentions and user goals. The results from this study in which user goals and their modes of searching were investigated simultaneously with Web site goals to reveal common search patterns associated with each case and significantly show that the patterns of user search behaviors are uniquely different depending on their goals and current modes of searching. Even though each user performed his/her task in isolation and in his/her own way, similar search patterns appeared based on a shared goal and/or the same mode of searching. Different search patterns were associated with different user goals and modes of searching, as well as Web site intentions.

In this research, user search behaviors are primarily analyzed by using the thematic analysis (Boyatzis, 1998) with time-ordered matrix (Robson, 1993) (see Table 3 and Figure 7), along with procedural analysis (see Figure 8), and Chernoff Faces (Chernoff, 1973, Wainer and Thissen, 1981) (see Figure 9), to uncover the patterns of user tasks in each scenario, while Checklist and Sequence Record (Robson, 1993) (see Table 5) is used to identify the types of user search strategies and methods. The analyses (see an example in Figure 7) show that users who begin with the same goal will perform their search similarly in terms of what tasks are necessary to reach the goal. However, if they use different modes of searching, which depend mainly on how precisely they know what they want, they will have different search strategies and consequently choose different kinds of

Figure 13. User goals and user modes of searching, the main factors regulating user search behaviors and the resulting search patterns
search methods even though they begin their search with the same goal. Therefore, based on these research findings, user goals and modes of searching are the main mechanisms that play an important role in determining user behaviors and the resulting search patterns.

While user goal is the main factor regulating their task description, user mode of searching provides the major impact on search strategies and search methods. User goals determine the different tasks they need to perform to achieve their goal. Simultaneously, user modes of searching influence their search strategies, or the plans of their search, determining how hard or easy the search can be and how much time is spent on their search, which accordingly results in selecting different search methods based on their search strategies (see Figure 13).

The analyses are collectively done on 10 observation cases of each of 10 scenarios which are systematically fabricated according to the research analytic frame previously demonstrated, in order to uncover the patterns of similarities or differences of user search behaviors. Based on research findings, the participants in scenarios 1 and 2 share the same search goal. As a result, even though they have different modes of searching and perform their tasks on different Web sites, the patterns of their task descriptions are very alike. Likewise the participants in scenarios 3, 4, and 5, or the participants in scenarios 6, 7, 8, and 9 have different modes of searching on different Web sites but have very similar tasks. Each group of these participants who share the same search goal, perform their tasks similarly although they do not share the same search modes and they visit different Web sites.

**Patterns of User Search Strategies and Methods**

When performing their search, individuals need a search plan — how to perform their search and which kinds of search tools to use in order to easily achieve their original goal. This plan is different from person-to-person based on user search strategy. However as stated earlier, one’s search strategy is influenced by one’s mode of searching (see Figure 13).

As a result, when visiting a Web site, individuals who arrive with different modes of searching will form different intentions as well as plan different search strategies, and accordingly perform their search in different ways to reach the same goal. Search strategies range from a general or less objective search (browse) to a more specific or purposeful search. These are directly proportional to user modes of searching which range from open-ended to specific search. They may also plan a fast or slow search based on time available and the urgency of their need. Users who plan a slow search usually want to record their search results by using the bookmark function or simply print out the results of retrieval pages for later use. Search strategy may change from time to time in accordance with modes of searching, which are based on the current context or situation that unfolds while they are searching as well as in response to the search results they find or retrieve.

While search strategy is the scheme that generally characterizes user search patterns, search method is the procedure for how they actually perform their search. This concerns the types of search tools chosen for use in their search. These search tools may include a menu bar, table of contents, index, site map, shortcut, search engine, and so forth. Users select from a combination of these search tools to perform their search based on their strategy. For example, users who are in the mode of exploratory searching (open-ended search), will likely plan a slow and general search (search strategy) and explore by browsing the menu bar and table of contents (search method). On the other hand, users who are in the mode of known-item searching (specific search), will
usually plan a fast and purposeful search (search strategy) and comfortably use the index or shortcut (search method) to pursue their search.

The analyses (see an example in Table 5) show that users who begin with the same mode of searching have similar search strategies and choose similar methods. Based on research findings, the participants in scenarios 1 and 6 begin their search with the same mode of searching. As a result, even though they have different search goals and perform their tasks on different Web sites, they choose similar search strategies and methods. Each group of participants who share the same mode of searching chooses similar search strategies and methods although they do not share the same search goals and they visit different Web sites. However, note that even though the participants in scenarios 2, 3, and 7 have different modes of searching from the participants in scenarios 4 and 8, they also share similar search strategies and methods.

Patterns of User Information Needs

In this research, user information needs are primarily analyzed by using the Checklist and Sequence Record (Robson, 1993) (see Table 6) to identify the types, characteristics, formats, as well as quality and quantity of information preferred or needed by users to fulfill their original goals. Besides having different search strategies and methods, users also have different needs for information that can fulfill their goals. The findings demonstrate that user goals, modes of searching, and prior knowledge and experience in the contents they search are collectively the main mechanisms that play an important role in determining their information needs. Consequently, each user who comes to visit a Web site with a different goal, mode of searching, and prior knowledge and experience will need different kinds of information in order to fulfill his/her goal. Information provided on a Web site may be categorized based on various aspects of information including the characteristics of the information; formats and presentation methods of information display; types of information; as well as quality and quantity of given information.

Information characteristics differ widely including quick reference information such as short or brief information organized and presented using bullet points; frequently asked question (FAQ); glossary or explanation; procedural guideline or step-by-step instruction; comparison information; recommendation; sequential story or report; and complete description. Based on the research findings, user need for different characteristics of information is influenced by their different goals.

Types of information can be categorized into three different groups. The first group includes information that comes from personal or expert opinion, critique, review, or recommendation such as an editor’s choice or customer’s review. The second group may include the information that is collected from news or reports such as today’s news or weekly reports, and the last group includes the information that presents the facts or scientific information for any given topic or item. Similar to user need for different information characteristics, the research findings demonstrate that user information needs for different types of information are influenced by different user goals.

Formats of information display range from an abstract level, including keyword; topic or headline; abstract; summary, to the detailed level including brief/short text or information, full/long text or information, reference, and bibliography. Based on the research findings, user needs for different formats of information display are influenced by different modes of searching. Presentation methods for information display range from textual to visual presentation, including textual or descriptive information (text), diagram, matrix,
A Qualitative Study in User’s Information-Seeking Behaviors on Web Sites

table, icon, image, illustration, or combinations of these methods. The research findings show that information needs for different presentation methods of information display are influenced by the type and character of the site contents.

Quality and quantity of information range from shallow information, which is usually not enough to help individuals to take further actions, to a variety of deep and detailed information. Based on the research findings, user information needs for different levels of quality and quantity of given information are influenced by various factors related to both the user and the Web site simultaneously. These factors include user goal; modes of searching; prior knowledge and experience in the contents they search; as well as the characteristics of Web contents — simple, everyday topics, or complicated, hard topics.

Discussion on Relevant Factors for User Search Success

Even though the accuracy of a search engine is one of the most recognized factors determining user search success or failure, qualitative comparison conducted by constructing truth tables and applying Boolean algebra method (Ragin, 1987, 1994) demonstrates that there are other relevant factors that play an important role to influence user search success or struggle. These influencing factors derive from both user profiles and behaviors as well as Web site attributes.

The qualitative comparison method is used in this study to examine among cases the combinations of causal conditions that help produce the positive outcome (users achieve the goal). These causal conditions include user prior experience in the content and Web site interface, their behaviors while searching, and several Web site attributes. Two truth tables (truth table 1 [see Table 7], and truth table 2 [see Table 10]) are constructed from observation data, which is recorded into nominal-scale and represented in binary form, to display different combinations of values on the conditions and outputs.

A presence-absence dichotomy is used in the tables to specify what outcomes and causal conditions are either present or absent in each observation case. Code number 1 indicates the presence of a condition or an output; code number 0 indicates the absence (see Tables 7 and 10). Truth table 1, as demonstrated in Table 7, is constructed to examine the causal conditions of user prior experience and search behavior and identify the combinations that significantly contribute to user search success.

With uppercase letters indicating presence and lowercase letters indicating absence of a particular causal condition shown in the combination, the data on user search success (S) from truth table 1 can be represented in the Boolean equation as follows:

\[
S = ABCD + ABCd + ABcD + AbCD + AbcD + abCD + AbCd + aBcD + Abcd + abcD + abCd
\]

This equation for S (search success) shows 11 primitive combinations of causal conditions that help users to achieve their goal. In order to simplify these primitive expressions, the concept of Boolean minimization is used. The most fundamental of Boolean minimization rules is (Ragin, 1987):

*If two Boolean expressions differ in only one causal condition yet produce the same outcome, then the causal condition that distinguishes the two expressions can be considered irrelevant and can be removed to create a simpler, combined expression (p. 93).*

The Boolean minimization process is conducted in a bottom-up fashion until no further stepwise reduction of Boolean expression is possible. This process is applied to the primitive...

</tr>
</tbody>
</table>
expressions derived from truth table 1 as demonstrated in Table 8. With the Boolean minimization process applied, the reduced expressions (prime implicants) on user search success (S) from truth table 1 can be represented in the simpler equation as follows:

\[ S = AC + AD + Ab + bC + bD + cD + ABD + Abd + Acd \]

Then, the final step of Boolean minimization is conducted by using the prime implicant chart (see Table 9) to map the links between nine prime implicants (see the second equation previously shown) and 11 primitive expressions (see the first equation). This process helps to eliminate redundant prime implicants in order to produce a logically minimal number of prime implicants which cover as many of the primitive Boolean expressions as possible.

Eventually, with the final process of Boolean minimization applied, the final equation (S) from truth table 1 demonstrates six combinations of causal conditions that produce the positive outcome (user search success) as follows:

\[ S = AC + AD + Ab + bC + bD + cD \]

This final equation significantly demonstrates the result showing that causal condition ‘A’ (users have prior knowledge and/or experience in the content), condition ‘C’ (users utilize different kinds of search tools), and condition ‘D’ (users read text or detailed information thoroughly) are the important variables that help users to achieve their goals.

Contrary to the traditional view on user experience with Web site interface (first-time versus return users), the result shows that causal condition ‘B’ (users have visited the Web site before) is not the primary factor contributing to users’ accomplishment in their search.

In addition, the second truth table (truth table 2) is constructed to examine the impact of various causal conditions including user prior knowledge in the contents they search (condition ‘A’) and prior experience in Web interface (condition ‘B’), combined with different causal conditions from various Web site attributes (see Table 10). These variables include condition ‘E’ (Web site provides different approaches to content classification), condition ‘F’ (Web site has well-organized search retrieval results), and condition ‘G’ (Web site provides search tips or examples).

With all processes of Boolean minimization applied, the final Boolean equation (S) from truth table 2 demonstrates six combinations of causal conditions that produce the positive outcome (user search success) as follows:

\[ S = AeF + AEFg + AEfG + BeFg + bEFg + Abefg \]

Significantly, this final equation derived from truth table 2 also confirms that causal condition ‘A’ (users have prior knowledge and/or experience in the content) is the important variable that helps users to achieve their goals. Besides the condition ‘A,’ the Web site variables that have significant impact on user search success include condition ‘E’ (Web sites that provide different approaches to content classification) and condition ‘F’ (Web sites that have well-organized search retrieval results). The result also shows that condition ‘B’ (users have visited the Web site before), and ‘G’ (Web sites provide search tips or examples) have less impact on user search success compared with other variables. These analytical results as well as others are further summarized and synthesized, in order to develop explanatory frameworks of user search behaviors and needs, as well as to establish classifications of substantial user factors and analytical frameworks to evaluate information design on Web sites.

*Number ‘1’ indicates the presence of a causal condition or an output, and ‘0’ indicates its absence. **Code ‘n/a’ indicates that the output code for the particular row is not applicable or it cannot be identified because the instance of the causal combination on that row is absent.
CONCLUSION

This investigation demonstrates that a user-centered approach can improve information design on Web-based media through study of various factors, especially user cognitive factors including user goals and modes of searching, to identify the corresponding impact of these factors on information and functional needs in terms of user behaviors. As an attempt to solve the problems of information-seeking tasks in Web-based media, the research is successful in providing a new perspective on Web site design considerations by strongly taking a user-centered approach to incorporate a careful consideration of actual user needs and behaviors together with requirements from a Web site.

By conducting extensive qualitative research on user study in relation to search needs and behaviors on Web sites as well as employing various analytical methods to uncover different aspects of the research data, the study answers the research questions. The common patterns of user information-seeking behavior, user search strategies and methods, as well as user information needs presented in different cases are revealed. These valuable findings will be further synthesized to develop frameworks and classifications.

Deeper understanding of these various factors, especially user cognitive factors, may complement the use of existing analytical or design methods such as task analysis and scenario-based design, by helping Web developers to recognize the important factors that may be subtle or previously unidentified yet substantially affect user task performances. By recognizing these elements, Web developers can identify the useful and appropriate functions and/or information to include in each particular case, in order to support user needs and task performances and eventually promote their satisfaction.

ABSTRACT
An important theoretical undertaking in personalization research is to identify the structure of the multidimensional construct of personalization and to operationalize them in measurable terms. The purpose of this study was to develop and validate measurement scales for personalization by identifying four distinctive personalization archetypes and hypothesizing their respective relationships with different cognitive and affective outcomes. This effort was successful in several respects. New scales for measuring personalization strategies were developed based on the definitions of personalization archetypes (architectural, instrumental, social and commercial), which were in turn derived from an extensive review of multidisciplinary studies. A lab experiment with 229 student subjects was conducted to explore the structure of the personalization construct and to validate the instrument using four Web site stimuli representing four types of personalization strategies. The new measures were found to have strong psychometric properties and exhibit significant linkages with respective cognitive and affective outcomes as theoretically postulated.

INTRODUCTION
In e-commerce and mobile commerce, personalization has been recognized as an important element in customer relationship and Web strategies. Personalization is commonly treated as an independent variable that influences Web usage outcomes such as customer experience (Novak, Hoffman, & Yung, 2000), Web site usability (Agarwal & Venkatesh, 2002; Palmer, 2002), and
Developing and Validating a Measure of Web Personalization Strategy

customer churning behavior (Chen & Hitt, 2002). However, the extant research on personalization is constrained by the shortage of high-quality measures for the personalization construct (Fan & Poole, 2006). Due to the inadequacy of existing personalization measures to capture all dimensions of personalization consumers actually value (Chen & Hitt, 2002), empirical studies have often failed to support the hypothesized association between personalization and the behavioral outcomes (Chen & Hitt, 2002; Novak et al., 2000).

In responding to the need for better measures of personalization, this study aims to develop and validate measures for four archetypes of personalization.

Personalization can be generally defined as “changing the functionality, interface, information access and content, or distinctiveness of a system to increase its personal relevance to an individual or a category of individuals” (Blom, 2000, p. 313). While there exist a set of narrow, specialized definitions of personalization that are built around varied goals and techniques of personalization in the literature, Blom’s definition of personalization provides an integrated view of personalization that centers on the general goal of increasing personal relevance without limiting the personalization concept to particular motivations, context or techniques (Fan & Poole, 2006).

In developing measures for personalization, we focus on four personalization archetypes: architectural, instrumental, social and commercial personalization, which are theorized to be four distinctive personalization strategies that elicit different cognitive and affective outcomes (Fan & Poole, 2006). While the existing personalization categories, such as Rossi et al.’s three personalization categories pertaining to link, navigation structure, and navigation context, are largely concerned with the system-level personalization mechanisms (Rossi, Schwabe, & Mattos Guimares, 2001; Wu, Im, Tremaine, Instone, & Turoff, 2003), Fan and Poole’s personalization archetypes provide a high-level framework for the design of personalization by delineating different philosophies concerning user-centered motivations behind personalization and their corresponding strategies of personalization. Developing valid measures for those four personalization archetypes will not only facilitate the investigation of cognitive and affective aspects of using the personalization system, but also promote the accumulation of personalization research results on the basis of a common measure of personalization. In addition to the significant theoretical value, developing and validating such measures also has great practical value for both personalization technology vendors and user organizations.

In the rest of this article, first we review prior literature on personalization, followed by a discussion of four personalization archetypes and proposition of hypotheses for their individual influences on cognitive and affective aspects of Web usage. Then, we present the method and procedure of developing the multi-item measurement scales of the four personalization archetypes. Next, we discuss the research design of an empirical study to test and validate the measurement model. After that, the results of data analysis are reported and interpreted. Finally, limitations of the study are addressed along with future directions.

REVIEW OF PRIOR LITERATURE

As an important social phenomenon that brings considerable economic values (Davenport & Beck, 2001; Pine & Gilmore, 1999), personalization has been studied extensively in e-commerce research. Considerable research efforts have been devoted to classifying different mechanisms for implementing personalization. Rossi et al. (2001) made a distinction between base information and behavior, what the user perceives and how the user perceives. Rossi et al.’s framework mainly deals with system-level elements such as personalization for links, navigation structure, and navigation context. Wu et al. (2003) classified personalization
Developing and Validating a Measure of Web Personalization Strategy

on e-commerce Web sites into five categories: control, content, link, customized screen design, and anthropomorphic personalization. Wu et al.’s personalization categories fit a two-by-two framework with implicit vs. explicit personalization on one dimension and Web content vs. Web interface on the other dimension. Terziyan (2001) defined three levels of personalization: service, content, and dynamic personalization. Although these findings have shed light on the practice of “how to do personalization,” there is still a lack of understanding regarding “how personalization can be done well.”

To guide the design of personalized systems, user-centered perspectives of personalization are needed to develop a vision of what personalization could be, which articulates the goals of personalization and criteria for evaluating the goal attainment by personalization. In response to this need, we developed a high level framework for classifying personalization. This framework delineates fundamental assumptions and user-centered motivations underlying personalization in the literature and relates them to design strategies for developing personalized systems. In addition to its significance for personalization design, the high-level framework of personalization is built around the motivations and goals of personalization from a user perspective, and thus provides an effective way to conceptualize and operationalize personalization dimensions that the user values. This has significant implications for studying the effects of Web personalization features on customer-related Web usage outcomes.

Our personalization framework differentiates four general personalization archetypes extracted from the personalization literature of several fields. Representative of four distinct schools of thought on the underlying motivations and goals of personalization, the personalization archetypes not only offer an analysis of possible design choices for personalization, but also provide a structure for defining general personalization strategies and examining their respective influences on user responses. The next section describes the concepts and strategies of four personalization archetypes in the Web site context, as well as the hypothesized relationships between different archetypes of personalization strategy and the cognitive or affective aspects of Web usage outcome.

FOUR ARCHETYPES OF PERSONALIZATION STRATEGY

Different schools of thought can be discerned within the diverse personalization literature. To capture the characteristic features of these logically consistent approaches to thinking about personalization, we conducted a multiparadigm review of the literature on personalization. During the review process, we utilized two metatriangulation techniques discussed by Lewis and Grimes (1999) to uncover paradigmatic disparity and complimentary. Metatriangulation is a theory-building strategy for exploring the assumptions of divergent theoretical views and gaining insights into the multiple paradigms (Lewis & Grimes, 1999). First, we used the paradigm bracketing technique to differentiate and articulate various sets of assumptions of alternative paradigms of personalization. Second, we employed the technique of paradigm bridging to identify “transition zones” (Lewis & Grimes, 1999), where paradigmatic boundaries become fuzzy and new views permeating across paradigms are synthesized.

The sample for the multiparadigm review includes 86 journal articles, 35 books or book sections, 13 conference papers, and 8 Web references, obtained from the electronic library.
Developing and Validating a Measure of Web Personalization Strategy

databases using the keywords “personalization,” variants of the same word stem, and related terms such as “customization,” “adaptation,” “individuation,” “consumer-centric,” and “one-to-one relationship.” The sample spans six general areas in which personalization has been studied: marketing/e-commerce, computer science/cognitive science, architecture/environmental psychology, information science, and social sciences, including sociology, anthropology and communication. Utilizing the paradigm bracketing technique, we distinguished disparate views of personalization by: 1) conducting a detailed analysis of each personalization study in the sample, 2) identifying and categorizing the different viewpoints on the motives or goals of personalization which match the requisite diversity in the sample, and 3) writing a paradigm account for each different viewpoint resulting from step 2.

During step 2 of paradigm bracketing, we relied on Weber’s ideal type theory in defining different views of personalization in the form of personalization archetypes. This conceptual apparatus Weber defined as the ideal type is an abstraction of essential features of a particular social or economic phenomenon in the purest form possible (Ringer, 1997; Rogers, 1969; Weber, 1968). The ideal type theory is useful for studying personalization for two reasons. First, it is important to study each of the distinct schools of thought on personalization in its “pure form” so as to capture their respective central characteristics. According to Weber (1968), an ideal type of personalization is an abstraction constructed from the accentuation of certain features of reality relevant to one theoretical view of personalization. The relevant features are put together into a consistent, logic construct and separated from other features that are only visible through other views of personalization (Weber, 1968). The resulting ideal type of personalization is thus a “pure” type in a logical sense where “the real indistinctness and ambiguity” are set aside and its relevant features are “perfect on logical grounds” with the “merit of clear understandability and lack of ambiguity” (Weber, 1968). Therefore, the ideal type theory provides a methodology for analyzing the typical or “logically consistent” features of different views of personalization. Second, there is a strong need to establish a common frame of reference against which the current practice of personalization can be evaluated. The ideal types describe “objectively possible” courses of action (Rogers, 1969) and can serve as guidelines for conducting and evaluating personalization systems in light of alternative approaches.

As a result, four archetypes of personalization were distilled from the literature: the architectural, social, instrumental and commercial personalization (Fan & Poole, 2006). Each archetype represents a different philosophy concerning the motivation behind personalization and what personalization tries to accomplish. Each archetype also implies a different strategy for personalization, different means for carrying out this strategy, and different user modeling techniques. Finally, each archetype implies different criteria for evaluating personalization systems.

Architectural personalization is defined as the construction of the digital environment to create a pleasant user space and a unique experience for the user through arrangement and design of digital artifacts in a way that meets the user’s needs and reflects his or her style and taste. Because architectural personalization is concerned with building digital environments, it relates particularly to the interface aspect of the system. The goals for personalization in this view are two-fold: (1) to create a functional and delightful Web environment that provides aesthetic value and reflects the user’s personal style; and (2) to help the user cultivate a sense of personal and social identity within the space (Becker, 1977).

Instrumental personalization refers to the utilization of information systems to enhance efficiency and personal productivity by providing, enabling and delivering useful, usable, user-friendly tools in a way that meets the user’s
Developing and Validating a Measure of Web Personalization Strategy

situated needs. Instrumental personalization focuses on the functionality of the system. Its goal is to support users in accomplishing their goals. Unlike architectural personalization, in which function and form balance each other, instrumental personalization emphasizes functionality and usability and treats aesthetics as a secondary consideration to be addressed once instrumental standards are met.

Social personalization can be defined as the personalization via the mediation of interpersonal relationships and utilization of relational resources to facilitate social interactions by providing a convenient platform for people to interact with others in a way that is compatible with the individual’s desired level of communality and privacy. The motivation behind social personalization is to personalize by fulfilling the user’s needs for socialization and a sense of belonging. The goal is two-fold: (1) to enhance the effectiveness of interpersonal interactions, and (2) to help generate “social capital” (Wellman, 2002) by providing new opportunities for strengthening social relationships and maintaining social networks. Applications amenable to relational personalization vary greatly in size and complexity. They can be as simple as providing an “e-mail to a friend” button to notify others of one’s flight schedule after booking tickets online or as complicated as a conglomeration of online information portal and activity center in a “Digital City” that engages residents or visitors (Toru, 2002).

Commercial personalization is the differentiation of product, service, and information to increase sales and to enhance customer loyalty by segmenting customers in a way that efficiently and knowledgeably addresses each user or group of users’ needs and goals in a given context. One of the most important human activities is the consumption of goods and services. The motivation of commercial personalization is to fulfill users’ material needs and thus contribute to their psychic welfare (Douglas & Isherwood, 1979). It primarily focuses on the content of the system and assumes that product, service and information of high relevance to the consumer yield a satisfying shopping experience and loyal adherence to the Web site, as well as the organization behind it. There has been much evidence that commercial personalization, by providing highly relevant products/services/information to the customers, promotes long-term customer relationship building and creates high customer retention called Web site “stickiness” in the context of e-commerce (Liu & Arnett, 2000; Zott, Amit, & Donlevy, 2000). The primary method to realize commercial personalization is segmentation. Commercial personalization is ultimately effective only to the extent that the offerings provide value to the target market segments by differentiating the product, service and information provided.

After the four personalization archetypes were identified through paradigm bracketing, we then conducted paradigm bridging, which involves the identification of paradigmatic connections, similarities, and complementarities among the four perspectives of personalization. A close examination of the four personalization ideal types reveals that the four types can be further classified into a 2x2 grid (see Table 1). First, the perspectives can be differentiated in terms of their associations with extrinsic or intrinsic motivation. The instrumental and commercial personalization archetypes support extrinsic motivation. They emphasize task performance and commercial transactions and hence are employed to enhance the usability and utility of information system for specific goal/task achievement; while architectural and social personalization archetypes attempt to support intrinsic motivation by providing self-fulfilling aesthetic and socio-emotional values for users to obtain pleasure or enjoyment from the activity itself.

The four personalization archetypes can also be differentiated in terms of the basic premise of use, whether the user primarily engages the system as an individual or through an interaction. Both architectural and instrumental personalization are
concerned with individual use of an artifact, be it a building, an information system or a Web site. Design emphasis is on individual's interaction with the artifact. On the contrary, relationships among multiple entities and the management of the relationships are of paramount importance in relational and commercial personalization.

**Effects of Personalization**

The personalization archetype scheme implies that no single standard or approach to personalization is “the best.” Each archetype employs different criteria for evaluating how well the system succeeds in delivering the desired effect. Based on our paradigm bridging of the four personalization archetypes, the effects of different personalization archetypes can be differentiated in terms of the extrinsic or intrinsic motivation they intend to support.

Commercial and instrumental personalization, predominantly used for information retrieval, transaction processing, and content management, belong to the class of productivity/utility applications. They are utilitarian-oriented, the goal of which is to achieve specific objectives or tasks. The idea behind instrumental personalization is that users will find systems that are designed and tailored to realize their particular goals or tasks as more relevant and hence useful. For commercial personalization, customizable or customized products/information/services are more useful because they meet individual needs. Because utilitarian use is goal-driven and emphasizes extrinsic motivation, useful content and functionality, as well as usability are given priority in design. Instrumental personalization that focuses on providing usable, useful and user-friendly tools is also expected to relate to the ease of use aspect of Web site design. Therefore, in conceptualizing the effects of commercial and instrumental personalization, we adopt the constructs of perceived usefulness and perceived ease of use in Davis’ TAM model (Davis, 1989), which is widely used to evaluate user perceptions of utilitarian systems under extrinsic motivation. Although the TAM model was originally developed to predict the adoption of workplace technology, it has also been successfully applied to the context of e-commerce. Studies have demonstrated the importance of TAM model in predicting intentions to adopt or revisit the Web site and online shopping behaviors (Gefen, Karahanna, & Straub, 2003; Gefen & Straub, 2000; Koufaris, 2002; Shang, Chen, & Shen, 2005; van der Heijden, 2000, 2003). Even for the Web site users who are highly computer

Intrinsic Motivation Extrinsic Motivation
literate, the perceived usefulness and ease-of-use of a Web site relative to the competing Web sites may still greatly influence the users’ intention to return to that Web site (van der Heijden, 2000). Therefore, we consider perceived usefulness and ease-of-use as important outcome variables of Web personalization, and formally posit the following hypotheses:

**H1:** The instrumental personalization will positively influence the perceived usefulness of the Web site.

**H2:** The commercial personalization will positively influence the perceived usefulness of the Web site.

**H3:** The instrumental personalization will positively influence the perceived ease of use of the Web site.

While instrumental and commercial personalization archetypes are generally utilitarian-oriented and focus on extrinsic motivation, architectural personalization and social personalization are closely associated with intrinsic motivation. The latter two are used primarily for creating an attractive Web environment, a comfortable, interactive social network, and a sense of psychological and social well-being. The design focus for this category centers on the enjoyment and entertainment aspect of the user experience. Hence, a balance between form and function, as well as the meaning of using the system, is emphasized. Architectural personalization affords an intrinsically pleasant experience of creating a personalized digital space through the arrangement and design of digital artifacts in a way that reflects the user’s individual style and taste and meets the user’s needs for easy navigation, intelligent presentation and aesthetic delight. To investigate the effects of architectural personalization, we employ two intrinsic motivation variables, perceived enjoyment and ease of use (Atkinson & Kydd, 1997). Davis et al. define perceived enjoyment as “the extent to which the activity of using the computer is perceived to be enjoyable in its own right, apart from any performance consequences that may be anticipated” (Davis, Bagozzi, & Warshaw, 1992, p. 1113). Therefore, by definition, perceived enjoyment is largely concerned with fulfillment of intrinsic motivation, which is based on emotionally satisfying experience with the system for its own sake but bears no relation to task objectives external to the user-system interaction (Van der Heijden, 2004). Perceived ease of use has been shown to contribute to both extrinsic and intrinsic motivations (Atkinson & Kydd, 1997; Davis, 1989; Lee, Cheung, & Chen, 2005). On the one hand, perceived ease of use can improve user’s task performance, which is critical for extrinsic motivation (Davis, 1989), and on the other hand, perceived ease of use can enhance user’s self-efficacy, which is an important component of intrinsic motivation (Bandura, 1977, 1982; Lee et al., 2005). Due to the focus of architectural personalization on fulfilling user’s intrinsic motivation by providing aesthetically pleasant, easy-to-navigate Web interface, we suggest the use of architectural personalization strategy will improve user’s perceived enjoyment and ease of use of the Web site. Therefore, formally we have:

**H4:** The architectural personalization strategy will positively influence the perceived enjoyment of the Web site.

**H5:** The architectural personalization strategy will positively influence the perceived ease of use of the Web site.

The social personalization strategy personalizes one’s world by creating a unique Web of social relationships. It seeks to provide a common, convenient platform for interpersonal communication and community building that emphasizes design on the basis of what Preece terms
Developing and Validating a Measure of Web Personalization Strategy

sociability (Preece, 2000). The intrinsic value of sociability is grounded in human motivation of being altruistic, interconnected, and seeking acceptance, attachment and care in interpersonal relationships (Argyle, 1996; Argyle & Lu, 1990). Positive social relationships give individuals a sense of well being and a feeling of comfort by creating support and a sense that they are not alone and are valued. Building a personalized network of social relationships is a self-fulfilling socio-emotional experience of satisfying the desire for social interaction, communication, and affiliation with others having similar interests or goals. There is mounting evidence of strong social ties built on social-emotional communications among participants of online communities (Fischer, Bristor, & Gainer, 1996; Granitz & Ward, 1996). The social personalization strategy enhances feelings of satisfaction and enjoyment by providing the social context important for fulfilling users’ needs for sociability. This suggests the following:

H6: The social personalization strategy will positively influence the perceived enjoyment of the Web site.

RESEARCH METHOD

The goal of this research is to develop and validate measures for different dimensions of personalization corresponding to the four distilled personalization archetypes. We first distilled the four personalization archetypes stated above from an extensive literature review of five general areas in which personalization has been studied: marketing/e-commerce, computer science/cognitive science, architecture/environmental psychology, information science, and social sciences, including sociology, anthropology and communication. Next, we generated and pretested 20 candidate measurement items for all four archetypes of personalization (see Table 2).

We used a lab experiment to test the validity and reliability of the proposed measurement model of personalization. We used the personalization features of actual commercial Web sites as the experimental stimuli. Because most Web sites tend to employ a combination of different personalization strategies, for example, Amazon.com implements both commercial (personalized recommendations) and social personalization (“Your Amazon friends” community strategies, the lab experiment allows us to measure participants’ responses to only one personalization feature of the Web site at a time. This helps to minimize the variations among participants’ responses due to exposure to mixed personalization features.

Experimental Design

A total of 229 undergraduate students (94 male, 135 female) enrolled in an introductory IS course were recruited to participate in the study for the benefit of extra course credit. Because this course is designed for non-IS majors, the sampling frame represents a wider range of disciplinary backgrounds than IS or business courses. Majors of subjects included chemistry, agriculture, liberal arts, and life sciences. This type of heterogeneity is advantageous in testing the reliability and generalizability of the measurement instrument (Shadish, Cook, & Campbell, 2001).

During the experiment, we showed the movie clips of someone using the personalization features of Web sites to the participants rather than having them actually visit the site. We did this for two reasons. First, having the participants view the movie clips ensures that they are only exposed to the personalization features that they are assigned to. Second, this approach reduces or eliminates the differences in participants’ responses resulting from irrelevant factors such as different browsing paths participants traversed.

To approximate actual Web browsing in the movie as closely as possible, we used Camtasia

software to capture the entire course of Web interactions, dubbed with synchronized human voice to explain each mouse movement. To prime participants, we created four scenarios for each Web site describing the typical context and purpose of using the personalization features. It is important to make the usage context and purpose explicit to the subjects, as the conceptualization
and operationalization of the four personalization strategies are based on the user motivations and objectives underlying personalization. To ensure the best audio quality, we tested several volunteers and chose one with the most pleasant voice in speaking standard American English. A total of five AVI files were generated, including instructions for the participants, and one for each site. The resolution of the movie clip on screen is 1080x720.

To optimize the effect of movie viewing, we conducted the experiment in a state-of-the-art instructional lab, in which participants viewed the movie on a personal computer via a 19-inch flat screen LCD monitor using a headphone. For practical purposes, balanced incomplete block design (BIBD) was adopted for the experiment. To reduce judging fatigue and increase reliability of evaluations, each participant was randomly assigned to view only two of the four Web site stimuli, with order counterbalanced across the participants. Among the 458 data points collected from the experiment, 390 were useable after discarding the questionnaires with incomplete responses and inconsistent answers to the same question being asked twice.

**Experimental Web Sites**

In determining the Web personalization stimuli for the experiment, we chose to use actual Web sites rather than creating our own because actual ones are representative of the tradeoffs designers will have in creating them to meet actual business needs and therefore will enhance generalizability of the experimental results to other commercial Web site settings. We identified four prominent Web sites whose personalization strategies have addressed personal needs of a wide base of Web users and been advocated as exemplars of Web personalization in the literature (Amazon’s book recommendation system, Land’s End’s 3-D virtual model tool, MyMSN information portal, and Yahoo!Group). Then, we made an interpretive analysis of those personalization strategies to match them with the four personalization archetypes (see Table 3). The interpretive analysis began with an examination of those personalization strategies in relation to the various personal needs of Web users they are intended to fulfill. Making explicit the relations between personalization strategies and types of user needs allowed us to trace back to the motivations underlying these personalization strategies and identify a match between each personalization strategy and personalization archetype. In this way, the personalization archetypes were respectively operationalized through the selected Web personalization stimuli.

Amazon’s book recommendation system was used to operationalize commercial personalization. The virtual model tool on the Land’s End Web site was used to represent instrumental personalization. Architectural personalization was implemented as the customizable information portal on the MyMSN site, where users can personalize the content and look-and-feel of the Web page by choosing different themes and color palates. Yahoo!Group was used to represent social personalization. It is expected that each representative site’s personalization stimulus will score significantly different from the other three sites’ stimuli and score the highest on the personalization type it represents. In order to verify the sufficiency of manipulation, we followed the recommendation of using manipulation check in the experiment (Shadish et al., 2001). This would suggest the following criteria for checking the manipulation of the personalization stimuli:

**Criterion 1:** MyMSN personalization stimulus will score higher on architectural personalization than the other three sites.

**Criterion 2:** Amazon personalization stimulus will score higher on commercial personalization than the other three sites.

</table>

**Criterion 3:** Land’s end personalization stimulus will score higher on instrumental personalization than the other three sites.

**Criterion 4:** Yahoo! Group personalization stimulus will score higher on social personalization than the other three sites.

**DATA ANALYSIS AND RESULTS**

Factor analyses were conducted to assess the reliability, and the discriminant and convergent validities of the personalization measures. We first performed exploratory factor analysis (EFA) on the pooled response data of all the four person-
alization stimuli, and derived four dimensions of personalization, which were consistent with our measurement model of personalization. Next, confirmatory factor analysis (CFA) was conducted on the response data of each personalization stimulus separately, to show that the measures of four dimensions of personalization and the three outcome constructs held relevant across the four sites, providing strong evidence of external validity for the measurement model. In addition, conducting separate analysis on four sites independently may provide site-specific knowledge on the relative importance of the constructs under investigation, given the different business natures and design features of these sites (Kim, Lee, Han, & Lee, 2002). Next, a series of planned contrast analyses are conducted for manipulation check purpose. Finally, we employed correlation and regression analyses to test the hypothesized relationships between personalization strategies and their cognitive and affective outcomes.

Results: Personalization Strategy Measures

We first computed reliability coefficients of the scales using Cronbach’s alpha on all 20 items. Based on each item’s contribution to reliability, we discarded two items (SOCIA1 and COMM2 and ARCH1) that showed very low corrected item-total correlations (0.44, 0.0004, and 0.29, respectively). Next, we removed two items (Instr5 and Instr3) that exhibited cross loading problems. After removing items with low reliability and cross-loading problems, the instrument consisted of 15 items, shown in the left-most column in Table 4.

Reliability

Table 3 presents the reliability coefficients in the right-most column, which are calculated from the EFA analysis of the data across four sites.

Convergent Validity

As our theory predicted, four components had eigenvalues greater than 1. The four columns in the middle of Table 3 present the factor loadings for the four constructs of personalization from the EFA analysis based on data pooled from all four sites. All 15 items converge well on their corresponding constructs, with high loadings on the constructs they are intended to measure and low loadings on others (factor loadings that are less than 0.5 are not shown in the table).

Independent CFA analysis (see Table 5) on each site showed varied indices of goodness of fit for the measurement model. Among the four sites, Amazon seems to demonstrate the best fit (GFI=0.8582, CFI=0.9454, RMSEA=0.0588, chi-square/DF < 2). Yahoo!Group and MyMSN also obtained acceptable goodness of fit indices (Yahoo!Group: GFI=0.8604, CFI=0.8981, RMSEA=0.0602, chi-square/DF < 2; MyMSN: GFI=0.8272, CFI=0.8281, RMSEA=0.0882, chi-square/DF < 2), which supports the validity of the four measures for these three sites. Land’s End, on the other hand, did not have a good fit. One reason could be that the instrumental personalization features present in the experimental stimulus such as using the avatar and virtual product presence were not included in the measures of instrumental personalization, and thus were not properly measured by the current instrument. This result, however, provided us valuable feedback on how to improve the instrument.

Discriminant Validity

Table 6 presents the factor correlations and average variances extracted (AVE) for the four personalization constructs from the EFA analysis. The

| Table 6. Factor correlation and AVE for personalization strategy constructs |
|-----------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| Instrumental | Social | Architectural | Commercial |
| Instrumental | 0.634 | 0.195 | -0.443 | 0.404 |
| Social | 0.7667 | 0.7615 | -0.141 | -0.207 |
| Architectural | 0.7615 | -0.133 | 0.5625 |
diagonal elements in Table 5 are the square root of AVE, and the off-diagonal elements are factor correlations. The four diagonal values are all larger than 0.5 and also larger than the correlation coefficients of their corresponding factors with other factors, which suggests that the measures have appropriate discriminant validity across all four sites (Gefen & Straub, 2000). The low factor correlations between pair-wise subscales of personalization also indicate the distinctive dimensionality of the four theoretical archetypes within the personalization construct.

**Results: Manipulation Check**

In order to check the representativeness of each personalization stimulus for its respective personalization strategy, a series of priori planned contrast tests were conducted to compare the performance of the four personalization stimuli based on their scores on different personalization strategies. Due to the nonorthogonality of treatment and individual effects in this study (incomplete block design), we performed a combined intra- and inter-block analysis using SAS Proc Mixed procedure to estimate the treatment least-squares means and treatment contrasts. Table 8 shows the contrast coefficients, the personalization type as dependent variable, the t value, and the significance level for each contrast test.

Contrast 1 (testing criteria 1) compared the commercial personalization scores between the Amazon personalization stimulus and the other three Web sites (Land’s End, My MSN, and

**Figure 1. Site comparison chart**

![Figure 1. Site comparison chart](image-url)
Developing and Validating a Measure of Web Personalization Strategy

Yahoo!Group): Contrast 2 (testing criteria 2) tested whether the instrumental personalization score for the Land’s End stimulus is higher than the other three Web sites’ scores (Amazon, My MSN, and Yahoo!Group). In contrast 3 (testing criteria 3), we tested whether the My MSN stimulus scores higher than the other three Web sites (Amazon, Land’s End, and Yahoo!Group) on architectural personalization. Finally, in contrast 4 (testing criteria 4), we compared the social personalization score for the Yahoo!Group stimulus with those scores of the other three Web sites (Amazon, Land’s End, MyMSN).

As expected, the results indicate that the Amazon stimulus scored significantly higher than the other three Web sites on commercial personalization; the architectural personalization score for the My MSN stimulus was significantly higher than those for the other three Web sites; and the Yahoo!Group stimulus had a significantly higher score on social personalization than the other three Web sites. However, the Land’s End stimulus did not differ from the other Web sites on the score of instrumental personalization. Therefore, criteria 1, 3, and 4 were supported by the planned contrast tests, but criteria 2 was not met. An examination of Figure 1, which visualizes the performance of each personalization stimulus on each of the four personalization archetypes, reveals that all personalization stimuli except Land’s End personalization stimulus scored significant higher on two personalization archetypes: the personalization archetype they each represent and instrumental personalization. The reason may be that all personalization strategies are to some extent instrumental in a sense that they all provide a means to fulfill individual’s personal needs or goals, be it creating an aesthetically appealing interface, building a personal social network, or purchasing the products satisfying an individual’s needs. Although Land’s End personalization stimulus did not score higher on instrumental personalization than the other personalization stimuli, it still had a significantly higher score on instrumental personalization than on any of the other three personalization archetypes, as shown by the results of pairwise comparisons between its scores on instrumental personalization and on each of the other three personalization archetypes (all three P values < 0.001 after Bonferroni adjustments). Hence, this confirmed our expectation that Land’s End personalization stimulus would be perceived to be more instrumental than architectural, social, or commercial.

RESULTS: ASSOCIATION BETWEEN PERSONALIZATION STRATEGY AND OUTCOME

In order to test H1 through H6, we conducted three multiple regressions, each using mean personalization score as the independent variables and one of the outcome scores as the dependent variable. Table 7 shows the results of the multiple regressions, in which the scores of perceived usefulness, perceived ease of use, and enjoyment of Web site were respectively regressed on the mean scores of four personalization dimensions. All four multiple regression analyses were significant. We discuss the results related to the hypotheses testing as follows.

Hypotheses 1 and 2 suggest that instrumental and commercial personalization will influence perception of Web site usefulness. The results of multiple regression 1 show that social personalization (Beta = 0.336, t = 5.562, p < 0.001) and instrumental personalization (Beta = 0.396, t = 5.916, p < 0.001) strategies are strong and significant predictors of perceived usefulness of the Web site. However, the effect of commercial personalization was not significant. So, H1 was supported, but H2 was rejected.

Hypotheses 3 and 5 were supported by the results of the second multiple regression, which show that both instrumental personalization (Beta = 0.279, t = 3.696, p < 0.001) and architectural...

personalization (Beta = 0.194, t = 2.727, p = 0.007) strategies have significant, positive effects on the user’s perceived ease of use of the Web site.

Consistent with hypothesis 4, the results of the third multiple regression indicate that implementing the architectural personalization (Beta = 0.425, t = 7.164, p < 0.001) strategy of a Web site has strong, significant effect on users’ feeling of enjoyment when they interact with the Web site. We also found that instrumental (Beta = 0.259, t = 4.109, p < 0.001) and commercial personalization (Beta = 0.168, t = 2.866, p = 0.005) strategies can influence users’ perceived enjoyment of using the Web site. However, hypothesis 6 was rejected because the effect of social personalization on perceived enjoyment of the Web site was not significant.

**DISCUSSION**

The purpose of this study was to develop and validate measurement scales for personalization by identifying four distinctive personalization archetypes and hypothesizing their respective relationships with different cognitive and affective outcomes of usage. This effort yielded promising results in several respects. New scales for measuring personalization strategies were developed based on the definitions of personalization archetypes, which were derived from the review of extensive multidisciplinary studies. A total of 25 items initially generated based on the four archetypes was honed down to 20 items, five for each personalization type. A lab experiment with 229 student subjects was conducted to explore the structure of the personalization construct and to validate the instrument of using four Web site stimuli, respectively representing four types of personalization strategies. According to the results of data analysis, the measurement scales of four dimensions of personalization exhibited sufficient psychometric properties in terms of reliability and validity. Convergent and discriminant validities were supported by both the analysis of pooled data across all four sites and the independent analysis.
Developing and Validating a Measure of Web Personalization Strategy

on each site separately. The study empirically supported our theoretical model of the structure of personalization construct, which consists of four distinct dimensions: architectural, instrumental, social and commercial.

Because of the multidimensional nature of the personalization construct, we should not use only a single yardstick to measure the effectiveness of personalization strategies. We identified two major categories of use outcomes associated with extrinsic motivation and extrinsic motivation, respectively. To test the relationship between personalization and extrinsic motivation, we hypothesized that instrumental and commercial personalization would positively influence two TAM constructs: perceived usefulness and ease of use. To test the relationship between personalization and intrinsic motivation, we hypothesized that social and architectural personalization would positively influence perceived enjoyment and ease of use. Our hypotheses were partially supported by the empirical results which revealed additional interesting findings.

Among significant findings, instrumental personalization was found to have a positive influence not only on perceived usefulness and ease of use but also on perceived enjoyment. Instrumental personalization facilitates perceived ease of use as it is driven by the design philosophy that emphasizes clarity, consistency, freedom from ambiguity and error (Norman, 1988). Perceived ease of use concerns the degree of “free of effort” (Davis, 1989), and low attention allocation to the system interaction, whereas enjoyment relates to the highly aroused emotions and focal attention allocation. With the presence of ease of use, enjoyment can be facilitated by the availability of additional attention resources. The absence of ease of use may hamper enjoyment because focal attention has to be allocated to “cope” with the system. This leads to our speculation that ease of use may be the antecedent to enjoyment. Note that instrumental personalization is the only strategy that lands itself on all three use outcomes. To some degree, the result adheres to the TAM prediction that ease of use mediates usefulness.

Contrary to our hypothesis, we did not find significant linkage between social personalization and enjoyment. Instead, the results suggest that social personalization is associated with perceived usefulness. We offer two explanations for this result. First, viewing the movie clip instead of experiencing the actual social interaction via the personalized communication platform may have mitigated the social-emotional impact of the stimulus on participants. The stimulus may

| Contrast | Personalization Type | Website |  | Land’s End | My MSN | Yahoo!Group | T Value |
|----------|----------------------|---------|  |           |       |             |        |
| 1        | Commercial           | 3       |  | -1        | -1    | -1          | 6.40** |
| 2        | Instrumental         | -1      |  | 3         | -1    | -1          | 0.73   |
| 3        | Architectural        | -1      |  | -1        | 3     | -1          | 11.81**|
| 4        | Social               | -1      |  | -1        | -1    | 3           | 17.53**|

* P value < 0.05
** P value < 0.001
have simply been too weak to elicit the expected response. Although we are confident in the ability of the movie to simulate the visual and audio qualities of browsing, as well as the level of detail of the Web interaction process captured in the movie, viewing interaction taking place may not be a perfect surrogate for actually being in the interaction. Secondly, the result reveals that social personalization serves some useful goals external to the socializing process. People engage in social personalization not just for pure experience only, but for a purpose too. This would be consistent with the view of relationship as social capital (Wellman, 2002).

Finally, contrary to our expectation, we did not find significant association of commercial personalization with perceived usefulness, but rather a small association with enjoyment (0.168). This might be due to the following reasons. On the one hand, commercial personalization usually requires users to set up personal accounts in order to facilitate future transactions, which can be tedious and time-consuming and hence may not lead to perceived usefulness of the system. On the other hand, providing personally relevant products to the customers through commercial personalization can lead to high levels of satisfaction and evoke a feeling of enjoyment in the customers.

**CONCLUSION: THEORETICAL AND PRACTICAL CONTRIBUTIONS**

In sum, the main contribution of this research is two-fold: theoretical and practical. Theoretically, the study answers the call for conceptualizing the multidimensional personalization construct. As previous empirical studies have shown, a one-dimensional scale was not sufficient to tap into the different effects yielded by personalization construct. We have identified four dimensions underlying the personalization construct and developed a measurement scale representing the four dimensions. The instrument exhibited sufficient psychometric properties on the calibrated Web site that are representative of respective dimensions.

In practice, this instrument can be utilized in at least two ways. Firstly, the instrument we developed in this research can be used as a guideline for developing Web personalization strategies because it provided four basic means to personalize Web sites; that is, by providing functionalities and information specifically needed by the user so as to enhance efficiency and productivity, by tailoring the interface to the user’s own taste and style, and by enabling interaction and connectivity specifically for the user’s social network. For productivity-oriented personalization systems, key usability issues to consider would be ease of use, clarity, consistency, free from ambiguity, and error. The aspect of ease of use includes both the use of the application itself and the setup and configuration to make personalized features functional. Consistency helps users better orient themselves to the site and alleviates cognitive effort. The enjoyment or entertainment-oriented personalization applications capitalize on the process and experience of using the systems. They are designed to stimulate thinking and to invoke feelings. The results are not tangible, but the process itself is critical in creating an engaging, fulfilling user experience. The principle of consistency may not be sufficient to invoke feelings or engage users on the site for an extended amount of time. In addition, the instrument can measure users’ perception of different personalization strategies and be used as a criterion for evaluating the effectiveness of the implementation of personalization strategy. For example, at the design and testing stage, Web designers and researchers can evaluate the performance of the site in terms of its ability to cater to users’ personal needs by having the users rate the site using the instrument. Weak scores would indicate potential areas for improvement.
Secondly, we empirically tested the hypothesis that different personalization strategies lead to different cognitive and affective outcomes of usage. As extant literature shows, measuring the effectiveness of Web site personalization using a monolithic method such as Return-On-Investment or click-to-buy ratio is not sufficient to gauge the multidimensional nature of personalization. As Web users come to interact with the site with different motivations, which largely dictates their usage expectation and online behavior (Davis et al., 1992; Venkatesh, 2000), understanding the underlying motivations for using Web personalization features and how different motivations relate to respective cognitive and affective outcome is crucial for realizing the potential of Web personalization. This study is our initial attempt along this line of research. Drawing on the existing literature on the distinction between extrinsic and intrinsic motivations, we empirically tested different usage outcomes by using different Web personalization features. Specifically, we found significant and strong correlations between architectural personalization and perceived enjoyment and ease of use, and between instrumental personalization and perceived usefulness and ease of use. The empirical data also suggested significant, small-sized correlation between social personalization and perceived usefulness, and between commercial personalization and perceived enjoyment. Our initial hypotheses were partially supported and new insights were obtained.

LIMITATIONS

Several limitations should be considered when interpreting the results of this study. First, the data were collected from a convenience sample of students, which may restrict the generalizability of the results. Although college students are representative of many young Web users and online consumers in the real world, the participants of this study are heavier Internet users and more frequent online shoppers than other segments of the general population. Their perceptions of personalization may be different from other segments.

Second, having the participants watch the movie clips instead of letting them interact with the Web sites freely has some drawbacks. Although this method allowed us to have a tighter control over the experiment (e.g., to ensure that the participants are only exposed to the personalization features that they are assigned to, and to reduce or eliminate the differences in participants’ responses resulting from irrelevant factors such as different browsing paths participants traversed), watching other people using the Web personalization features may be different from experiencing the features by oneself. This might introduce error into the data because the environment of the experiment may not be ecologically representative. In addition, because the conceptualization and operationalization of the four personalization strategies are based on the user motivations and objectives underlying personalization, we also provided audio instructions to make the usage context and purpose of the experimental personalization features explicit to the participants. However, priming the participants to a particular personalization regimen could produce bias in the participants’ responses.

Third, the positivist research approach of this study introduced further limitations. Positivist research emphasizes objectivity, which separates the researcher from the respondent. It is practiced through standardized process, control of possible influential variables, and pre-determined structured questions that facilitate measurement. This approach leads respondents to reply in a restricted range of ways rather than let them answer the questions and elaborate on their replies in their own ways. As a result, the positivist research may fail to yield an authentic understanding of the respondents’ opinions, attitudes, feelings, and experiences. Therefore, the results of this study
Developing and Validating a Measure of Web Personalization Strategy

may not represent a full insight into the participants’ view of Web personalization features.

Finally, another limitation of this study is concerned with the four criteria we developed to check how well each stimulus represents its corresponding personalization archetype. Because the focus of this study is to differentiate the four personalization archetypes and their respective cognitive and affective effects, the criteria examine each stimulus’ representativeness of its corresponding personalization archetype relative to the other three stimuli. Therefore, a criterion will be supported if the stimulus of focus is shown to represent its corresponding personalization archetype better than the other three (i.e., the stimulus has a higher score on its corresponding personalization archetype than the other three). However, meeting such a criterion may not be sufficient to establish the stimulus of focus as a successful operationalization of its corresponding personalization archetype, because the criterion evaluates the performance of stimulus using its relative score rather than its absolute score on the corresponding personalization archetype.

Despite the abovementioned limitations of this study, we do believe our results provide valuable insights on different dimensions of personalization and their influences on users’ cognitive and affective responses. This research is the beginning of a rich stream of research investigating the multidimensional nature of personalization. We call for further studies along this line of research using the validated instrument of personalization, and testing it in various settings.

FUTURE DIRECTIONS

There are several possible ways of continuing this research. First, the current study suggested ways of improving the instrument. Revising the items for the instrumental personalization by focusing on the design aspects of instrumental personalization, such as providing, enabling and delivering useful personalization tools, is our next step toward a more valid and stable instrument. The improved instrument can be used for: 1) stimulus scaling, that is, to scale Web sites of different domains (online retailer, sports, information portal, etc.) and industries (finance, travel, entertainment, education, government, etc.). The purpose is to discover patterns of Web personalization strategies within and across domain or industry, which can be used to inform further improvement. 2) Subject scaling, that is, to scale Web users along the dimensions of personalization so that a personal profile based on individual’s response will be created. It would be another tool for business to further understand their users.

In conclusion, the overarching goal in this article was to enrich our understanding of the multidimensionality of the personalization construct, and how different dimensions of personalization elicit different cognitive and affective user responses. Given that personalization is becoming an important offering of IT artifact, such research has value for theory development as well as for practice. Several avenues for further study are suggested in hope of a fruitful buildup of a continuous body of personalization research.

Chapter 2.29
User Interface Formalization in Visual Data Mining

Tiziana Catarci

University of Rome “La Sapienza”, Italy

Stefano Lodi
University of Bologna, Italy

ABSTRACT
Despite the existence of various data mining efforts that deal with user interface aspects, very few provide a formal specification of the syntax of the interface and the corresponding semantics. A formal specification facilitates the description of the system properties without being concerned about implementation details and enables the detection of fundamental design issues before they manifest themselves in the implementation. In visual data mining, a formal specification can enable users to decide which interaction/operation to apply to get a desired result; help users to predict the results of their interactions/operations with the system; and enable the development of a general interaction model that designers/developers can use to understand the relationships between user interactions and their compositions. In this work, we describe an approach for formalizing the visual interface of a core data mining system, which has been employed in the development of a visual data mining system named VidaMine.

INTRODUCTION
In this day and age, data still present formidable challenges to effective and efficient discovery of knowledge. It should be acknowledged that a lot of research work has been and is being done with respect to knowledge discovery (KD). Much of the work has concentrated on the development and the optimization of data mining algorithms using techniques from other fields such as artificial intelligence, statistics, and high performance computing (Fayyad, Piatetsky-Shapiro, & Smyth, 1996b). Besides various glaring issues (such as
the need to have an overall framework that can support the entire discovery process, supporting human involvement in the entire process, etc. Mannila observes that relatively little research work has been published on the theoretical foundations of data mining (Mannila, 2000). On the same note, although there are many data mining efforts that deal with user interface issues, very few efforts provide or give a precise definition of the syntax of the user interface and the corresponding semantics.

Formal specifications enable the description of the system properties without having to be concerned about implementation details. The system properties are often specified using a precise notation. The specification can be used to construct models of the system. Formal methods make the analyst think abstractly about the problem at hand and the corresponding system thereby exposing fundamental design decisions well in advance before they manifest themselves in the implementation of the system. While it is true that the formal specification should not determine the programming aspects (e.g., algorithms and data structures), it should describe the behavior of the system in a precise or rigorous manner. Moreover, with a formal specification it is possible to transform a system model while preserving important properties of the model. In practice, a formal approach in which each and every design decision is proven to be a correct refinement step is rarely performed due to the high costs involved. However, substantial application of refinement does considerably improve the understanding of the design process. A formal specification of the visual interface of a data mining system can facilitate the gathering of information about the most useful usage patterns, which can then be used to guide the design and layout of user interfaces for visual data mining. Moreover, a formal specification of the visual interface can facilitate automated (and/or objective) evaluation of the usability of the user interface of a visual data mining system.

In information visualization, various specifications/models for characterizing visualization aspects have been proposed such as (Baudel, 2004; Chi & Riedl, 1998; Chuah & Roth, 1996). In fact, it does turn out that most of the efforts that are related to our work are mainly found in information visualization and exploration efforts rather than in core data mining. Some of the benefits of specifications/models such as the foregoing do apply to visual data mining as well, where visualization tends to be a key ingredient. Consequently and borrowing from Chi et al. (1998), a similar formal specification in visual data mining can: enable users to decide which user interaction/operation to apply in order to get a desired result; help users to predict the results of their interactions/operations with the visual data mining system; and enable the development of a general interaction model that designers/developers can use to classify and understand the relationships between user interactions and the composition of interactions. In fact, such a model could help eliminate errors caused by other imprecise or incorrect models. In this work, we describe an approach for formalizing the visual interface of a core data mining system. The proposed approach has been employed in the development of a visual data mining system named VidaMine.

**BACKGROUND**

**Knowledge Discovery**

Knowledge discovery (KD) may be defined as the process of identifying valid, novel, potentially useful, and ultimately understandable models and/or patterns in data (Fayyad, Piatetsky-Shapiro, Smyth, & Uthurusamy, 1996a; Fayyad et al., 1996b). On the whole, the knowledge discovery process may be defined as an interactive and iterative non-trivial process that entails various phases as seen in Figure 1.
The KD phases include carrying out some initial planning (understanding the application domain, relevant prior knowledge, and goal/s of the user), data integration, selection of target data, data cleaning and pre-processing, data reduction and transformation, selection of suitable data mining techniques to support the discovery process, and evaluation, presentation, and interpretation of results. Through carrying out the phases, the KD process intends to find a subset of results that may be considered as new “knowledge” (Fayyad et al., 1996a, 1996b). KD is of interest to researchers in many research disciplines such as machine learning, pattern recognition, databases, statistics, artificial intelligence, expert systems, and information visualization.

**Data Mining**

Data mining is a core step in the knowledge discovery process that, under acceptable computational efficiency limitations, enumerates models and patterns over the data (Fayyad et al., 1996a, 1996b). It is worth recalling that the knowledge discovery process is as an interactive and iterative non-trivial process that entails: carrying out some initial planning (understanding the application domain, relevant prior knowledge, and goal/s of the user), data integration, selection of target data, data cleaning and pre-processing, data reduction and transformation, selection of suitable data mining techniques to support the discovery process, and evaluation, presentation, and interpretation of results from which there exists a subset that may be considered as new “knowledge” (Fayyad et al., 1996a, 1996b). Data mining methods include clustering, classification, regression, characterization, dependency modeling change and deviation detection, and pattern-based similarity matching.

The primary goals of data mining are verification and discovery. The verification goal aims at validating some hypotheses based on specific user needs. The user generates a series of hypothetical patterns and relationships (assumptions or claims). The user then formulates and issues
queries to the system (actually to the data itself) to verify (or disprove) the claims. The discovery goal involves finding “new” patterns or discovering new knowledge. Rather than verify hypothetical patterns, the goal here is to use the data itself to uncover or identify such patterns. Such methods of discovery may be initiated based on the guidance of a user to analyze a certain domain through a predetermined perspective or by automated learning. Discovery can be predictive or descriptive. Prediction entails “foretelling” unknown or future values of the same variables or other variables of interest whereas description involves getting an interpretation/understanding of the data. Classification, regression, and time series models are primarily useful for prediction. Clustering, association, and sequence discovery models are primarily useful for description of the behavior that is captured in the data.

Rules

Metaqueries

Metaquerying (Mitbander, Ong, Shen, & Zaniolo, 1996) is a data mining technique that is especially useful in mining relational and deductive databases. Metaqueries (or metapatterns) provide a generic description of a class of patterns that the user may want to discover from the underlying dataset. With metaqueries, it is possible to mine patterns that link several tables in the target dataset. Metaquery specification can be carried out manually (for instance by an expert user). Alternatively, the specification can be automated by exploiting the schema of the underlying dataset.

Let \( U \) be a countable domain of constants. A database \( DB \) is \( (D, R_1, ..., R_n) \) where \( D \subseteq U \) is finite, and each \( R_i \) is a relation of fixed arity \( a(R_i) \) such that \( R_i \subseteq D^{a(R_i)} \).

A metaquery is a second-order template of the form (Angiulli, Ben-Eliyahu-Zohary, Ianni, & Palopoli, 2000):

\[ T \leftarrow L_1, ..., L_m \]

where \( T \) and \( L_i \) are literal schemes. Each literal scheme \( T \) or \( L_i \) is of the form \( Q(Y_1, ..., Y_n) \) where \( Q \) is either a predicate (second-order) variable or a relation symbol, and each \( Y_j (1 \leq j \leq n) \) is an ordinary (first-order) variable. If \( Q \) is a predicate variable, then \( Q(Y_1, ..., Y_n) \) is called a relation pattern of arity \( n \), otherwise it is called an atom of arity \( n \).

The left-hand side \( T \) is called the consequent or the head of the metaquery. The right-hand side \( L_1, ..., L_m \) is called the antecedent or the body of the metaquery. Consider the relations CustCent, ClustOutI and ServCent with the following attributes: CustCent.CustID, CustCent.CentID, ClustOutI.CustID, ClustOutI.ServID, ServCent.ServID and ServCent.CentID. The following is an example of a corresponding metaquery:

\[ CustCent(CustID, CentID) \leftarrow \{ClustOutI (CustID, ServID), ServCent(ServID, CentID)\} \]

Intuitively, given a database instance \( DB \), answering a metaquery \( MQ \) on \( DB \) amounts to finding all substitutions \( \sigma \) of relation patterns appearing in \( MQ \) by atoms having as predicate names relations in \( DB \) such that the Horn rule \( \sigma(MQ) \) (which is obtained by applying \( \sigma \) to \( MQ \)) encodes a dependency between the atoms in its head and body. The Horn rule is supposed to hold in \( DB \) with a certain level of plausibility/relevance. The level of plausibility is based on measures of interestingness such as support and confidence. The measures of support and confidence are described in Section “Support and Confidence.”

Metaqueriers have been applied in the telecommunication industry, in a common-sense knowledge base, and in the chemical industry (Leng & Shen, 1996). Metaqueries have also been applied in analyzing time sequence data for semiconductor...
ASSOCIATION RULES

Association rules were introduced in Agrawal, Imielinski, and Swami (1993). Association rules represent a data mining technique that is used to discover implications between sets of items in the database.

Let \( I = I_1, I_2, ..., I_m \) be a set of data items or literals and \( D \) a set (or database) of transactions, in which each transaction \( T \) is a set of items from \( I \) (i.e. \( T \subseteq I \)). Each transaction \( (T) \) is assigned some unique identifier, \( TID \).

Let \( X \subseteq I \) and \( Y \subseteq I \). A transaction \( T \) is said to contain \( X \) if \( X \subseteq T \). An association rule is an implication of the form:

**Equation 3**

\[
Y \rightarrow X
\]

where \( X \cap Y = \emptyset \). The left-hand side, \( Y \), is the consequent or the head of the association rule whereas the right-hand side, \( X \), is the antecedent or the body of the association rule.

The problem of mining association rules is to generate all association rules with a degree of relevance/interestingness that is greater than a certain minimum (such as user-specified) value. The problem of discovering all association rules can be decomposed into two sub-problems (Agrawal et al., 1993):

1. Finding all sets of items (itemsets) that have support above the minimum support. The measure of support is described in Section “Support and Confidence.” Itemsets with minimum support are called large itemsets and all others small itemsets.
2. Using the large itemsets to generate the desired rules. The desired rules are those whose confidence is greater or equal to the minimum confidence. The measure of confidence is described in Section “Support and Confidence.”

Computing the solution to the first sub-problem naively is very expensive, and efficient techniques to reduce its complexity have been researched extensively (e.g., Agrawal et al., 1993; Agrawal & Srikant, 1994). Solving the second sub-problem is comparatively much easier, since it amounts to computing, for every frequent itemset, the confidence of the association rules obtained by picking one item as the consequent of the rule from the frequent itemset.

Association rules are valuable and readily applicable in many areas, including marketing, catalog design, business management, decision-making, add-on sales, mailing, customer segmentation, and store layout. For instance, a superstore dealing in clothing may find that customers who buy ties also tend to buy shirts at the same time (same “market basket”). Consequently, the following would be an association rule with fairly high measures of interestingness:

**Equation 4**

"shirt" \( \rightarrow \) "tie"

SUPPORT AND CONFIDENCE

The relevance of a rule may be determined by measures of interestingness. In general, measures of interestingness measure the overall value of a rule with respect to utility, novelty, certainty, and simplicity. In the mining of metaqueries and association rules, there are two common measures namely confidence and support.

Let \( D \) be the target dataset. The support of a rule in \( D \) is the fraction or percentage of tuples in \( D \) that contain the union of the antecedent and the consequent. For instance, the association rule

\[
Y \rightarrow X
\]

where \( X \cap Y = \emptyset \), is said to contain \( X \) if \( X \subseteq T \). An association rule is an implication of the form:

**Equation 3**

\[
Y \rightarrow X
\]
in Equation 3 has support $supp$ in $D$ if $supp\%$ of transactions in $D$ contain $X \cup Y$. The confidence of a rule in $D$ is the fraction or percentage of tuples in $D$ containing the antecedent, that also contain the consequent. For instance, the association rule in Equation 3 has confidence $conf$ in $D$ if $conf\%$ of transactions in $D$ that contain $X$ also contain $Y$. Intuitively, support indicates how frequently the items in the rule occur together in the transactions of the database, and therefore represents the utility of the rule, whereas confidence indicates the strength of the implication represented by the rule.

## Clustering

Clustering is a process through which the target dataset is divided into groups of similar objects, such that the objects in a particular group are dissimilar to objects in other groups. Each such group is referred to as a cluster. Clustering is applicable in many arenas such as in analyzing astronomical data, in demographics, in insurance, urban planning, and Web applications.

### Classification of Clustering Methods

Traditionally, clustering methods have been classified into a taxonomy having two broad groups: hierarchical and partitional (Jain, Murty, & Flynn, 1999).

#### Hierarchical Clustering

Hierarchical methods produce a sequence of nested partitions. A compact way to represent nested partitions is by a dendrogram, i.e., a tree having single objects as leaves, showing the hierarchical relationships among the clusters. It is therefore possible to explore the underlying dataset at various levels of granularity. Hierarchical methods are further subdivided into agglomerative and divisive (Jain & Dubes, 1988; Kaufman & Rousseeuw, 1990).

Agglomerative (bottom-up) clustering starts with singletons, i.e., with each cluster containing exactly one point. The clustering then recursively merges two or more most appropriate clusters. The process goes on until a stopping criterion is fulfilled (such as the number of clusters input by the user). Examples of agglomerative algorithms include CURE (clustering using representatives) (Guha, Rastogi, & Shim, 1998), and CHAMELEON (Karypis, Han, & Kumar, 1999).

Divisive (top-down) clustering starts with one single cluster of all objects, and recursively subdivides the most appropriate cluster. The process goes on until some criterion is met. The PDDP (principal direction divisive partitioning) (Boley, 1998) algorithm is an example of divisive algorithms. Also in this category of divisive clustering are approaches based on the k-means algorithm (Hartigan, 1975; Hartigan & Wong, 1979) such as the bisecting k-means algorithm (Steinbach, Karypis, & Kumar, 2000; Wang, Wiederhold, Firschein, & Wei, 1998).

#### Partitional Clustering

Partitional methods attempt to identify clusters directly either by iteratively relocating points between subsets, or by associating clusters with the areas that are densely populated with data. Consequently, partitional methods fall into two categories: relocation methods and density-based methods.

Relocation methods focus on how well points fit into their clusters. Such methods intend to ensure that the built clusters have the proper shapes. Relocation methods are further subdivided into probabilistic, k-medoids, and k-means. The probabilistic clustering model is based on the assumption that data has been independently drawn from a mixture model of several probability distributions. The results of probabilistic clustering are often easy to interpret. Probabilistic clustering algorithms include SNOB (Wallace & Dowe, 1994), AUTOCLASS (Cheeseman &
In clustering methods that adopt the k-medoids approach, a cluster is represented by one of its points. When the medoids are selected, clusters are considered to be subsets of points close to respective medoids. Algorithms based on the k-medoid approach include PAM (partitioning around medoids) and the algorithm CLARA (clustering large applications) (Kaufman et al., 1990), CLARANS (clustering large applications based upon randomized search) (Ng & Han, 1994). In k-means (Hartigan, 1975; Hartigan et al., 1979), a cluster is represented by its centroid, which is a componentwise arithmetic mean of points within a cluster. Although the k-means algorithm does not work well with a dataset that has categorical attributes, the algorithm is an appropriate choice for datasets with numerical attributes.

Density-based methods aim at identifying connected components/areas in the dataset that are dense with data. In this respect, a cluster therefore corresponds to a connected dense component. Density-based methods can be further divided into two main categories: density-based connectivity and density functions. Density-based connectivity approach reduces density to a training data point. Algorithms that use the approach include DBSCAN (Ester, Kriegel, Sander, & Xu, 1996), OPTICS (ordering points to identify the clustering structure) (Ankerst, Breunig, Kriegel, & Sander, 1999), DBCLASD (distribution based clustering of large spatial databases) (Xu, Ester, Kriegel, & Sander, 1998). Density functions approach reduces density to a point in the attribute space. DENCLUE (Hinneburg & Keim, 1998) is an example of an algorithm based on density functions. In fact, DENCLUE is a blend of density-based clustering and grid-based preprocessing.

Miscellaneous

There exist many other clustering techniques that do not fit well in one of the foregoing categories. For instance grid-based techniques, co-occurrence techniques, etc.

Grid-based techniques work indirectly with data by constructing summaries of data over the attribute space subsets. They segment the space and then aggregate appropriate segments. On the one hand, grid-based methods often use hierarchical agglomeration as a phase in their processing. Algorithms that use this approach include BANG (Schikuta & Erhart, 1997), STING (statistical information grid-based method) (Wang, Yang, & Muntz, 1997), and WaveCluster (Sheikholeslami, Chatterjee, & Zhang, 1998). On the other hand, the idea behind grid-based methods is exploited by other types of clustering algorithms (such as CLIQUE (clustering in quest) (Agrawal, Gehrke, Gunopulos, & Raghavan, 1998), MAFIA (merging of adaptive finite intervals) (Goil, Nagesh, & Choudhary, 1999; Nagesh, Goil, & Choudhary, 2001) as an intermediate phase in their processing.

Co-occurrence techniques are meant to handle special requirements when it comes to clustering categorical data. Algorithms ROCK (Guha, Rastogi, & Shim, 1999), SNN (shared nearest neighbors) (Ertöz, Steinbach, & Kumar, 2003), and CACTUS (clustering categorical data using summaries) (Ganti, Gehrke, & Ramakrishnan, 1999).

The Proposed Clustering Taxonomy and Framework

The foregoing traditional categorization of clustering methods into two broad groups—hierarchical and partitional (Jain et al., 1999)—is technically sound and relevant to various application domains. However, such categorization does not highlight similarities and differences between the various definitions of a cluster that are implicit in the methods. For instance, Ward’s minimum-variance method (Ward, 1963) and the PAM method PAM (partitioning around medoids) (Kaufman et al., 1990) are similar. However, the former is hierarchical whereas the latter is partitional.
As an alternative to the foregoing traditional approach of categorizing clustering methods, clustering can be regarded as an optimization problem, in which the function to be optimized is a mathematical measure of homogeneity or separation (Hansen & Jaumard, 1997). Such a perspective enables one to categorize clustering methods according to a taxonomy of homogeneity or separation functions. Therefore, such a perspective provides recourse for categorizing clustering methods.

Moreover, such taxonomy expresses cluster definitions in an implicit manner. Such categorization is most likely more effective in capturing different behaviors in practice. It therefore provides a more natural avenue for the process of selecting a clustering algorithm, which is most suited to a particular application or domain.

In this research work, we therefore adopt this perspective and to the best of the research survey, this is actually the first effort that uses a uniform framework for selecting clustering algorithms. More details about the same and how it has been applied in our design and implementation efforts will be discussed in Section “Formal Specification of the Visual Interface.”

**USER INTERFACE FORMALIZATION IN VISUAL DATA MINING**

**Introduction to VidaMine**

VidaMine is a visual data mining system that exploits various visual strategies thereby offering a consistent, uniform, flexible visual interface that allows or enables the user not only to process data, but also to steer, guide, or direct the entire process of data mining (DM) (Kimani, 2002). We adopted a user-centered user interface design,
equipped with usability studies. As reported in Kimani, Catarci, & Santucci (2003), we employed various usability methods progressively in the development lifecycle. The visual interface of VidaMine offers visual interaction environments across different mining techniques and tasks. At present, the system offers visual environments for mining metaqueries, performing clustering, and mining association rules. Figure 2, which is for the metaquery environment, is an illustration that shows the overall outlook and feel of the visual interface.

Formal Specification of the Visual Interface

In developing a formal specification for the visual interface, we propose the provision of two specifications: an abstract formal specification that is defined for each of the mining methods currently supported by VidaMine and a corresponding operational specification that is defined and exploited for implementation purposes. The place of the two specifications with respect to the system can be seen in Figure 3.

Abstract Formal Specification of the Visual Interface

In this area, we started by considering the definition an abstract syntax and a formal semantics for the visual interface. The abstract syntax is intended to provide a snapshot of the visual environment in terms of static and compact structures. This visual syntax reduces distance to mathematical objects (such as some specific data mining functions). We intend to describe an abstract formal specification of the visual interface for each of the visual interaction environments corresponding to each of the data mining methods currently supported by VidaMine aka metaqueries, clustering, and association rules.

In order to define a semantics for a supported data mining method, it is necessary to first define the visual language supported by the corresponding visual interaction environment (user interface). An abstract syntax for a visual language can be defined in terms of multi-graphs as follows (Erwig, 1998). Let $\alpha, \beta$ be sets representing label types. A directed labeled multi-graph of type $(\alpha, \beta)$ is a quintuple $G(V,E, l, v, e)$ consisting of finite sets of nodes $V$ and edges $E$ where $l : E \rightarrow V \times V$ maps every edge to the pair of nodes it connects, $v : V \rightarrow \alpha$ maps every node to its label, and $e : E \rightarrow \beta$ maps every edge to its label. A visual language of type $(\alpha, \beta)$ is a set of directed labeled multi-graphs of type $(\alpha, \beta)$. Intuitively, visual controls are the nodes of the multi-graph, whereas the spatial relations between visual controls are the edges of the multi-graph. Since many of the visual controls appearing in the user interface are standard (such as check buttons, radio buttons, combo boxes, spin...
boxes, edit boxes, and sliders), their geometric properties will be ignored and simply use an abstract value to represent each visual control. Based on the foregoing notion of abstract syntax, we will define the visual language for each of the three visual interaction environments, and then describe the corresponding semantics.

Clustering

The clustering environment in VidaMine provides various visual widgets for specifying or selecting parameters characterizing a clustering task. The parameters include a fixed number of clusters or a measure (of homogeneity, separation, or density); attributes that will be directly involved in cluster analysis; and supplementary attributes (e.g., for labeling cases in the output). Specifying each such parameter may also involve more specific options/settings. The corresponding environment is seen in Figure 4.

In clustering, it is virtually impossible to apply uniformly a single technique to uncover the variety of structures present in multidimensional data sets (Jain et al., 1999). In most data mining applications, the user has to evaluate a set of techniques and then, based on experience and domain knowledge, select possibly more than one data mining technique to apply on the target dataset. A visual data mining system aimed at supporting the user during the entire mining process might be expected to provide support to the broadest range of clustering techniques possible. While it is true and commendable that VidaMine has an extensible framework, it is worth observing that adding one extension module for every clustering technique would render the system hard to utilize to anyone but the most informed practitioner, due to the variety of parameters and terminology. Therefore, in VidaMine, the approach is to provide and support three generalizations from the commonest types of clustering techniques. The three clustering generalizations are:

![Figure 4. The clustering environment: Input. Reproduced from Kimani et al. (2004) with the permission of Elsevier B. V.](image)

Table 1. Definitions of the main sets and functions

<table>
<thead>
<tr>
<th>Main Sets and Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dataset</strong> $S = {O_i</td>
</tr>
<tr>
<td>Symmetric dissimilarity function $diss : S \times S \rightarrow R^+$</td>
</tr>
<tr>
<td><strong>Classification</strong> $C$ of $S$ is a subset of a partition of $S$</td>

<tr>
<td><strong>Accuracy function</strong> $m$ is a function on the set of all classifications of $S$ to $R^+$</td>
</tr>
</tbody>
</table>
1. Clustering based on homogeneity.
2. Clustering based on separation.
3. Clustering based on density.

Here are some common terms that will be used while describing the foregoing clustering generalizations: Consider a dataset $S = \{O_i \mid \text{for } i = 1, 2, \ldots, N\}$, and a symmetric dissimilarity function $diss : S \times S \rightarrow R^+$. It is worth noting that classification $C$ of $S$ refers to a subset of a partition of $S$. Let an accuracy function $m$ be a function on the set of all classifications of $S$ to $R^+$. The foregoing main sets and functions are summarized in Table 1.

The justification for adopting the three clustering generalizations (or categorization) is highlighted in the descriptions of the generalizations. In the sequel are the descriptions of the clustering generalizations.

**Clustering Based on Homogeneity or Separation**

Traditionally, clustering methods have been classified into a taxonomy having two most general groups: hierarchical and partitional (Jain et al., 1999). Hierarchical methods produce a sequence of nested partitions, whereas partitional methods only produce one partition. Such distinction, although relevant for many application domains, does not highlight similarities and differences between the various definitions of a cluster that are implicit in the methods.

Alternatively, clustering can be regarded as an optimization problem, in which the function to be optimized is a mathematical measure of homogeneity or separation (Hansen et al., 1997). Homogeneity is a global measure of the similarity between points belonging to the same cluster, separation is a global measure of the dissimilarity between points belonging to different clusters. For instance, the maximum cluster diameter over all clusters is a measure of homogeneity, whereas the minimum distance between objects in different clusters is a measure of separation.

In such a perspective, clustering methods are classified according to a taxonomy of homogeneity or separation functions, which expresses implicitly cluster definitions. Such categorization is most likely more effective in capturing different behaviors in practice. It therefore provides a more natural avenue for the process of selecting a clustering algorithm, which is most suited to a particular application or domain.

It is worth noting that the actual implementation of the search for an optimal solution is left entirely unspecified. Therefore, a suitable uniform abstraction can be given for a broad class of methods, ranging from classical hierarchical methods, to approximation algorithms, and a consistent parametric user interface between the clustering engine and the graphical user interface can be designed.

Therefore and following up from Section “The Proposed Clustering Taxonomy and Framework,” clustering can be formally defined as an optimization problem (Hansen et al., 1997) that takes one of the following forms:

**Problem $\Pi_1$:** Given an integer $K > 1$, find the partition $P$ of $S$ of size $K$ such that $m(P)$ is optimal.

**Problem $\Pi_2$:** Given a threshold $\theta \in R^+$, find the partition $P$ of $S$ of minimum (maximum) cardinality such that $m(P) \leq \theta$ ($m(P) \geq \theta$). In other words, sometimes $m(P)$ is optimal when large and at other times it is optimal when small.

In this research work, consideration is made only for functions $m$ ranging over the union of two families $H$ and $S$. The former family represents homogeneity functions and the latter represents separation functions. For a given data set $S$ and dissimilarity $diss$, define $H$ by:
**Equation 5**

\[ H_\omega(P) = \{ Q : O \in C(O) \ diss(O, O) | Q \in \{ \text{max}, \Sigma, \text{avg} \} \} \]

**Equation 6**

\[ H_c(P) = \{ Q : O \in C_h(O) \ diss(O, O) | h \in H_\omega(P), Q \in \{ \text{min}, \text{max}, \Sigma, \text{avg} \} \} \]

**Equation 7**

\[ H = \{ Q_c \in P \ h(C) | h \in H_c(P), Q \in \{ \text{min}, \Sigma, \text{avg} \} \} \]

and \( S \) by

**Equation 8**

\[ S_\omega(P) = \{ Q : O \in C(O) \ diss(O, O) | Q \in \{ \text{min}, \Sigma, \text{avg} \} \} \]

**Equation 9**

\[ S_c(P) = \{ Q : O \in C_s(O) \ s(O) | s \in S_\omega(P), Q \in \{ \text{min}, \text{max}, \Sigma, \text{avg} \} \} \]

**Equation 10**

\[ S = \{ Q_c \in P \ s(C) | s \in S_c(P), Q \in \{ \text{min}, \text{max}, \Sigma, \text{avg} \} \} \]

where \( C(O) \) is the cluster containing object \( O \).

Equation 5 defines a family of pointwise homogeneity functions, expressing that the homogeneity of object \( O \) can be defined as either the maximum (i.e., worst-case) dissimilarity to other objects in the same cluster, or the sum or average of all such dissimilarities. Likewise, Equation 6 defines a family of clusterwise homogeneity functions, expressing that the homogeneity of a cluster can be defined as the maximum, minimum, sum, or average of pointwise homogeneity of all its objects. Finally, Equation 7 defines a family of partitionwise homogeneity functions; the homogeneity of a partition can be defined as either the minimum (i.e., worst-case) clusterwise homogeneity over all its clusters, or the sum or average of all such homogeneities. Equation 8-Equation 10 provide analogous definitions for the separation function. Note, however, that the quantifier expressing worst-case pointwise or partitionwise separation is the minimum instead of the maximum, and that the quantifiers defining the separation of \( O \) extend to every object not in its cluster. Equation 5-Equation 10 induce a simple taxonomy with four levels into which functions \( m \) are classified. At the first level, homogeneity is separated from separation. Then, classes at lower levels in the taxonomy are separated according to the objectwise, clusterwise, or partitionwise quantifier.

**Clustering Based on Density Estimation**

In this section, \( diss \) is assumed to be a distance function and \( S \) to be a subset of a metric space \((X, diss)\). By elementary intuition, clusters can be regarded as regions of the object space where objects are located most frequently. Such simple analogy leads to approaches to clustering based on statistical techniques of non-parametric density estimation (Ankerst et al., 1999; Ester et al., 1996; Hinneburg et al., 1998; Schikuta, 1996; Silverman, 1986). The goal of density estimation is to fit to a data set \( S \) a density function of type \( X \rightarrow R^+ \). The implemented system supports clustering based on an important family of estimates, known as kernel estimators (Silverman, 1986). Functions in such family are defined modulo two parameters, the window width \( h \), and the kernel function \( \psi \). The value of the estimate at \( x \in X \) is obtained by summing, over all data objects, a quantity modeling the influence of the object. Influence is computed by transforming distance, scaled by a factor \( 1/h \), using \( \psi \):
Since the estimated density at $x$ should be large when the number of data objects which are located near $x$ is large, far data objects should have little influence. Thus $\psi$ is usually a probability distribution function, which decreases monotonically with distance from zero. Commonly used kernel functions are the Gaussian kernel, 
\[
\frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}x^2\right),
\]
and the Uniform kernel, 
\[
\frac{1}{2}(\text{sign}(x+1) - \text{sign}(x-1)).
\]
The parameter $h$ controls the amount of smoothing of the estimate, i.e. the sensitivity of the estimate to local structure in the data.

Once a density estimate is computed for a given kernel function, clusters can be defined in the following way. Let $A(O)$ be a neighborhood of $O$, and let $\alpha_{h,\psi}(O)$ be the data object (if it exists) nearest to $O$ in $A(O)$ having density greater than $\hat{\phi}_{h,\psi}(O)$:

\[
diss(\alpha_{h,\psi}(O), O) = \min_{O_j \in A(O)} \{diss(O_j, O) : \hat{\phi}_{h,\psi}(O_j) > \hat{\phi}_{h,\psi}(O)\}
\]
The tree roots in the forest induced by $\alpha$ are objects whose neighborhood does not contain objects having greater density. Therefore, the tree roots may be considered as representatives of the modes of the density estimate, and the descendants of a root are part of a single cluster. Formally, $\alpha$ induces a forest whose connected components are clusters: If $\sim$ is the equivalence relation generated by $\alpha$, then the clustering $P$ is the set of its equivalence classes:

\[
P = \{C : (\exists x_o \in S)C = \{x \in S : x_o \sim x\}\}
\]
The method can be further enhanced by introducing a notion of noise objects (Ester et al., 1996): Density at a noise object is less than a specified threshold parameter $\theta$. Noise objects are not part of any cluster, thus the method generates a classification instead of a partition:

\[
C = \{C : (\exists x_o \in S)C = \{x \in S : x_o \sim x \wedge \hat{\phi}_{h,\psi}(x) \geq \theta\}\}
\]

Abstract Syntax and Semantics of Clustering
The visual language is defined by the following:

\[
\alpha = \mathbb{R}^+ \cup \{\min, \max, \Sigma, \text{avg}\} \cup \{\pi_1, \pi_2\} \cup \{\text{Homogeneity, Separation, Density}\}
\]

\[
\beta = \phi
\]

\[
\]

Finally, let for brevity $hpq = v(\text{HomPartwQCom}), hcq = v(\text{HomCluswQCom})$,
User Interface Formalization in Visual Data Mining

\[ h o q = v(H o m o b j w Q C o m), \quad s p q = v(S e p P a r t w Q C o m), \quad s c q = v(S e p C l u s w Q C o m), \]
\[ s o q = v(S e p O b j w Q C o m). \]

The classification \( C \) of the dataset \( S \) is defined by:

\[ C = P_{h o m}(S) \text{ if } v(accurRad) = \text{Homogeneity}, \]
\[ P_{s e p}(S) \text{ if } v(accurRad) = \text{Separation}, \]
\[ C_{d e n}(S) \text{ if } v(accurRad) = \text{Density} \]

and the following hold

\[ |P_{h o m}(S)| = v(N C l u s S p i n) \]
\[ |P_{s e p}(S)| = v(N C l u s S p i n) \]
\[ |C_{d e n}(S)| = v(N C l u s S p i n) \]

\[ m_{h o m}(P) = \min_{c \subseteq P} \{ v(S m o o t h S l i d)_c \} \]
\[ m_{s e p}(P) = \min_{c \subseteq P} \{ v(S m o o t h S l i d)_c \} \]

\[ m_{d e n}(C) = \min_{c \subseteq C} \{ v(S m o o t h S l i d)_c \} \]

\[ m_{h o m}(P) \leq v(H o m S l i d) \]
\[ m_{s e p}(P) \geq v(S e p S l i d) \]
\[ m_{d e n}(C) \leq v(D e n S l i d) \]

\[ m_{h o m}(P) = \min_{c \subseteq P} \{ v(S m o o t h S l i d)_c \} \]
\[ m_{s e p}(P) = \min_{c \subseteq P} \{ v(S m o o t h S l i d)_c \} \]

\[ m_{d e n}(C) = \min_{c \subseteq C} \{ v(S m o o t h S l i d)_c \} \]

Metaqueries: In the metaquery environment of VidaMine, the user can specify patterns/relationships between or among data tables in an intuitive visual manner. The interface provides “hooks” and “chains” through which users can visually specify the relationships. By simply linking two attributes, the users indicate to the system that they are interested in metarules that have the two attributes related. Therefore, VidaMine enables users to visually construct metaqueries of interest. The left-hand side of Figure 2 shows the part of the metaquery environment that supports the foregoing specification.

Abstract Syntax and Semantics of Metaquerying

Here a simple abstract syntax for the metaquerying visual interaction environment is defined, together with its semantics, that is, the set of rules discovered by the system as instantiations of the metaqueries corresponding to the visual state of the interface when the “torch” icon is clicked (see Figure 2). For consistency with the visual interaction environments for the other mining techniques, the metaquerying visual environment
represents metaqueries using relation schemes instead of literal schemes, that is, using named attributes to denote table columns, instead of the usual logical variables.

The metaqueries, which are added to the pool when the “add pattern” button is clicked, are all constructible metaqueries, given the named and unnamed relations (i.e., named “X”) in the target space. Note that the links between handles which are represented in the target space do not have a counterpart in the “IF . . . THEN” expressions in the pool. In fact, such expressions only show the relation schemes, and not the literal schemes, that compose the head and body of a rule. Therefore, only the content of the target space defines multiple occurrences of variables in a rule. Since a user might click “add pattern” several times with different configurations of the target space, before clicking the “torch” button, for simplicity only one such configuration is considered in the semantics.

In the target space, rectangular frames enclosing attribute or relation names, and lines representing links connecting the frames (ignoring the handles) are nodes of the multi-graph. A node representing a frame is labeled by the relation name or attribute name it represents (i.e., the name appearing inside the frame). Attribute and relation frames may be adjacent, and attribute frames may be connected by lines. Therefore, for relations, attributes and links, two visual relations need to be represented: adjacent and intersecting. Adjacency will be assumed antisymmetric: A frame is adjacent to another if and only if the two frames share a horizontal edge, and the first frame is located above the second in the display.

In the following, let $U$ and $R$ be universes of attribute names and relation names, respectively, in the database. Let $V = \{X_1, \ldots, X_m\}$ be a countably infinite set of variable symbols, and $W = \{P_1, \ldots, P_r\}$ be a countably infinite set of predicate variable symbols. $V$ and $W$ are assumed disjoint and both disjoint from $R$. Let also $\zeta: V \rightarrow V, \lambda: V \rightarrow W$ be injective functions. In the sequel, $\zeta$ and $\lambda$ will be used to construct the literals of the rules from the frames.

The language is defined by the following:

**Equation 26**

$$a = R^* \cup U \cup R \cup \{"X"\}$$

**Equation 27**

$$\beta = \{\text{adjacent, intersecting}\}$$

**Equation 28**

$$V \supset \{\text{ConfSlid}, \text{SuppSlid}\}$$

The set $IRS$ of rules returned by metaquerying is defined as follows.

**Equation 29**

$$IRS = \{r \in RS : \text{conf}(r) \geq v(\text{ConfSlid}) \land \text{supp}(r) \geq v(\text{SuppSlid})\}$$

**Equation 30**

$$RS = \{r : (\exists \sigma)(\exists mq \in MQ) r = \sigma(mq)\}$$

**Equation 31**

$$MQ = \bigcup_{b \in L} \{b \leftarrow b \in L \cup \{b\}\}$$

**Equation 32**

$$L = \{P(X_1, \ldots, X_m) : (\exists n) P = \text{pred}(n) \land \text{isrel}(n) \land (\forall i \leq m)(\exists n') X_i = \zeta(n') \land \text{inschema}(n', n)\}$$

where

**Equation 33**

$$\text{isadj}(n,n') \iff (\exists e)l(e) = (n,n') \land e(e) = \text{adjacent}$$
Equation 34

\[ \text{intersects } (n,n') \Leftrightarrow (\exists e)(e) = (n,n') \land e(e) = \text{intersecting} \]

Equation 35

\[ \text{pred}(n) = \begin{cases} \lambda(n) \text{ if } v(n) = "X", \\ v(n) \text{ otherwise} \end{cases} \]

Equation 36

\[ \text{isconn} = \text{isadj}^e \]

Equation 37

\[ \text{isrel}(n) \Leftrightarrow (\exists n') \text{isadj}(n', n) \]

Equation 38

\[ \text{islink}(n) \Leftrightarrow (\exists n')(\exists n'')(\exists n_1)(\exists n_2) \text{isrel}(n_1) \land \text{isrel}(n_2) \land \text{isconn}(n', n_1) \land \text{isconn}(n'', n_2) \land \text{intersects}(n, n') \land \text{intersects}(n, n'') \]

Equation 39

\[ \text{inschema}(n, n') \Leftrightarrow (\text{islink}(n) \rightarrow (\exists n'') \text{isconn}(n'', n')) \land \text{intersects}(n, n'') \land (\neg \text{islink}(n) \rightarrow \text{isconn}(n'', n)) \]

and \( \text{isadj}^e \) is the equivalence relation generated by \( \text{isadj}^e \), that is, the smallest equivalence relation containing \( \text{isadj} \). Therefore, an equivalence class contains nodes corresponding to frames gathered in one relation scheme in the target space.

\( L \) is the set of literals defined by the visual configuration (Equation 32).

In each literal, \( P \) is the relation name enclosed in a frame, or a distinct predicate variable, if the name is “\( X \)” (Equation 35 and Equation 37). Every variable corresponds to an attribute frame that is connected to the relation frame, which names the literal, or corresponds to a link that intersects such an attribute frame (Equation 39). The set \( MQ \) of metaqueries is obtained from \( L \) by generating one metaquery for each literal, having the literal as head and the remaining literals as body. The rules \( RS \) instantiating \( MQ \) are defined by means of a class of substitutions. In Equation 30, \( \sigma \) is any substitution which, given a metaquery \( mq \), consistently replaces exactly every predicate variable occurring in \( mq \) with a relation name. Finally, the rule set \( IRS \) is defined as the set of all rules in \( RS \) that satisfy the support and confidence specified by the sliders \( \text{SuppSlid} \) and \( \text{ConfSlid} \).

Association Rules: Let \( \Omega \) be a set of items, and \( T \) be a database of transactions, that is, a list of elements of \( 2^\Omega \). Association rules (Agrawal et al., 1993) are implications of the form:

Equation 40

\[ I_{v_1}, \ldots, I_{v_m} \rightarrow I \]

where \( /I, I_{v_1}, \ldots, I_{v_m} \in \Omega \). If \( r \) is the foregoing association rule, and \( t = \{ I_{v_1}, \ldots, I_{v_m} \} \), then \( r \) has confidence \( \text{conf}(r) \) and support \( \text{supp}(r) \) in \( T \) defined by:

Equation 41

\[ \text{conf}(r) = \frac{|\{ t \in T : \{ I_{v_1}, \ldots, I_{v_m} \} \subseteq t \}|}{|T|} \]

Equation 42

\[ \text{supp}(r) = \frac{|\{ t \in T : \{ I_1 \cup I_2 \} \subseteq t \}|}{|T|} \]

In the association rule environment of Vida-Mine, there is the provision of “market baskets.” As seen in Figure 5, the association rule environment offers two baskets, the IF basket and the THEN basket. The IF basket represents items in the antecedent part of an association rule and the THEN basket represents items in the consequent part of the rule. Users may “drag and drop” items from the target dataset into the relevant baskets.
When through with the visual construction of a particular association rule, the users may empty both baskets into a pool of association rules that are of interest to them, and may go ahead and construct another rule.

**Abstract Syntax and Semantics of Association Rules**

The VidaMine system's support for association rules permits the specification of syntactic constraints (Agrawal et al., 1993), that is, listing items, which must appear in the antecedent or the consequent. Such items are dragged from the target space to the “IF” or “THEN” basket, and later combined to form the rule and put into a “pool” (of rules). The reader may refer to the association rule visual environment in Figure 5, and where the “pool” of rules is formed below the baskets.

It is assumed that the abstract graph contains one “item” node for every item occurring in the “IF” . . . “THEN” rule, labeled with the item’s name.

Assuming also nodes representing confidence and support (see Section “Abstract Syntax and Semantics of Metaquerying”), the set of association rules returned by the system is:

**Equation 43**

\[ IAR = \{ r \in AR : \text{conf}(r) \geq v(\text{ConfSlid}) \land \text{supp}(r) \geq v(\text{SuppSlid}) \} \]

**Equation 44**

\[ AR = \{ I_1, \ldots, I_m \to I : V_{THEN} = \{ n \} \to I = v(n) \land (\forall n \in V_{IF})(\exists i \leq m)I_i = v(n) \} \]

where \( V_{IF} \) and \( V_{THEN} \) are the sets of “item” nodes in the rule’s “IF” and “THEN” part, respectively.

**Operational Specification of the Visual Interface**

As part of implementation, our research effort also considers the provision of an operational specification. This specification entails defining a concrete syntax of mining tasks and an XML-based communication protocol. The concrete syntax of mining tasks is a high-level syntax of each of the tasks proposed in our task analysis and usability tests (Kimani et al., 2003). This syntax describes the click-streams that are allowed to occur during the user’s interaction with the interface. The syntax reduces distance to the specification of procedural objects. The XML-based protocol serves as a two-way link for

---

*Figure 5. Association rule environment: Input. Reproduced from Kimani et al. (2004) with the permission of Elsevier B. V.*
exchanging information between any applications that deal with mining aspects. It is interesting to note that the protocol idea can be exploited not only to import and incorporate new components into the system framework, but also to export the system’s components to external systems.

We start by describing the syntax of mining tasks. We then use the clustering subtask to demonstrate how the communication protocol has been defined.

**Concrete Syntax of Tasks**

Specifying a concrete, high-level syntax of mining tasks can serve at least three purposes. First, it highlights the most useful usage patterns, which guided the interface’s layout and design. Second, it permits an objective evaluation of the results of usability tests. Finally, it provides a design specification, which can be refined to yield the complete parsing structure of the interface at the level of information passed to and returned by the mining engines. The abstraction level will be such that terminal symbols represent interactions that can be regarded as elementary in the current

state of technology (e.g., clicking buttons, setting a slider’s position, selecting an item in a combo box, setting the value of a spin box, etc.). The syntax will be defined using standard grammar notation, where terminal symbols are enclosed in double quotes. For brevity, only the first occurrence of every grammar rule, which is shared by two or more tasks has been written.

Figure 6 describes the mining task. Each subtask (clustering, metaquerying, association rules) comprises an input task, clicking the “torch” button to run the discovery algorithms, and an output task.

In the sequel we briefly describe the concrete syntax of clustering input and which can be seen in Figure 7. The task is divided into two consecutive parts, namely specifying target data and parameters, matching the upper and lower sections of the clustering interface. Specifying constraints means performing a sequence of manipulations of the controls in the top part of the specification phase, e.g., setting the number of attributes of a given type, choosing a relation, etc. (see Figure 4). Assigning attributes corresponds to dragging and dropping attributes from the resource relations to the “X” relation, which is subsequently dragged into the target space. Selecting an accuracy measure leads to selecting either homogeneity, separation, or density, by pushing the respective radio buttons (see Figure 4). Subsequently (see Figure 7), the user may select quantifiers, or the kernel function and the amount of smoothing. Selecting the problem type gives access to setting the number of clusters or the threshold for the accuracy function.

An XML-Based Communication Protocol

The large amount of recently proposed mining techniques, and the need to easily select the most effective method for the multivariate data set at hand, calls for the design of extensible data mining systems. Exchanging XML documents allows for the addition of new mining engines or new methods for existing engines as plug-ins. Such a protocol would serve as a two-way link for exchanging information between any applications that deal with mining aspects. It is interesting to realize that this idea can be exploited not only to import and incorporate new components into the system framework, but also to export the system’s components to external systems. In the VidaMine system, communication between the GUI and the mining engines is established by means of XML document streams. The communication protocol is specified by XSchema for the selection of methods and passing parameters, and for passing output results to the GUI. Since PMML, the predictive model markup language (DMG), has already set an XML standard for representing mining results in the data mining community, our specification is based on, and in some parts extends, PMML.

Example of XML-Based Protocol for Clustering Task

Assuming the target dataset in Figure 4, the generated XML document for method selection is listed in Figure 8. Each attribute listed in the “X” relation matches exactly one corresponding “DataField” in “DataDictionary” and one “MiningField” in “MiningSchema.” In this research work, “active” corresponds to the “checked” state whereas “supplementary” corresponds to the “unchecked” state of the attribute’s check box in the target space. It is worth observing that “checked” attributes are those that have been chosen to directly participate in cluster analysis. “Unchecked” attributes are those that will not directly participate in cluster analysis but will be included in the results for other purposes (such as for labeling). “AccuracyFunction” allows for selecting one of “Homogeneity,” “Separation,” and
“Density.” Within each, the problem’s form can be selected by “FixedNumberOfClusters” (problem $\Pi_1$ of Section “Clustering Based on Homogeneity or Separation”) or “FixedThreshold” (problem $\Pi_2$ of Section “Clustering Based on Homogeneity or Separation”). The “Density” element includes the type of density estimate used. Currently, the only allowed type is “Kernel.” Other types can be easily added as alternatives to “Kernel.” Figure 10 is a view of the XSchema, which specifies documents containing the selection of a method and parameters for clustering. It is worth noting that the XSchema in Figure 10 does not allow for specifying the algorithm used to solve the problem.

Thus, for given problem definition and form of the accuracy function, the clustering engine may implement an exact or approximate algorithm. In the current example, the selection of min for objectwise, clusterwise, and partitionwise quantifiers is equivalent to the worst-case split clustering problem (Hansen et al., 1997). For such problem, an exact solution can be obtained applying the well-known single link hierarchical algorithm to the target dataset, halting at the topmost partition whose worst-case split value is less than the value of the split function (0.03 in the example). The
document containing clustering result/output, whose view can be seen in Figure 9, represents the solution to the clustering problem in Figure 4. For brevity, the XSchema for the clustering output is omitted, which is an extension of the corresponding XSchema in PMML. The “Cluster” elements describe five clusters named 1, 2, 3, 4, and 5. Each “Cluster” element contains the clusterwise accuracy function that was selected for clustering, and its value at the cluster. (The split of the cluster, in the example.) The engine may include any other accuracy function in the result document, specifying its value at the cluster, and the clusterwise parameters defining it. (In the example, the engine returned the cluster’s “Homogeneity” computed as its diameter.) Finally, “ClusteringArray” assigns each object in the target dataset to its cluster.

Mapping Between Clustering Task and XML Documents

It is important to define a mapping between the clustering and the XML-based communication protocol that was just defined. When the formal specification of the interface is defined through an abstract syntax and semantics, a mapping between user actions and XML documents describing the actual parameters passed to the engines can be defined by means of a recursive function. In the VidaMine system, a mapping function \( M \) is defined by recursion on the grammar rules describing the clustering task of Figure 7 to XML documents conforming to the XSchema of Figure 10.

Although for brevity we have omitted its formalization, it should however be noted that \( M \) basically is a mapping satisfying a list of equalities of the forms:

**Equation 45**

\[
(term)^M = xml(value_1, \ldots, value_p)
\]

**Equation 46**

\[
(nt_1, nt_2)^M = (EXT(nt_1)^M(nt_2)^M)
\]

In **Equation 45**, \( term \) is a terminal symbol, \( xml \) is a function constructing an appropriate XML element corresponding to \( term \), \( value \) is the value of a visual control. In **Equation 46**, \( nt \) is a nonterminal symbol representing the manipulation of a visual control, \( EXT \) is a function that extends the XML tree in its second parameter using the elements in the first parameter. \( EXT \) also provides appropriate defaults when the user’s actions do not affect some of the controls.
Comparison with Data Mining Systems

SQL Server 2005, developed by Microsoft Corporation, includes several data mining tools: association rules, clustering, decision trees, linear and logistic regression, naive Bayes, and neural networks. Its interface is based on menus, panes, and tabs. Three panes present the user with an explorer tree of folders related to analytical tasks (data sources, multidimensional cubes, mining structures, etc.), a properties visualization tool, and tabs for model settings, visualization, evaluation, and for prediction. Parameters for the mining algorithms can be accessed from pop-up menus. The visualization tab supports all mining models with several types of visualization each, with some active graphical elements. Visual features, such as color, can be associated to quantitative features of models, such as relative frequency. Overall, the interface provides a powerful set of functionalities, but requires training to be used, in particular for structuring the mining task. No formal model is known for the graphical part of the interface.

Clementine was originally developed by Integral Solutions Ltd (ISL) and later distributed as a part of the SPSS system, after SPSS purchased ISL on December 31, 1998. Clementine supports many prominent mining techniques including clustering, association rules, sequential patterns, factor analysis, and neural networks. Users construct a map (a “stream”) of their data mining project/model by selecting icons called “nodes” that represent steps in the data mining process. Clementine allows users to adjust/refine their “streams” and rerun the system on the refined model. Although its visual interface illustrates the flow of control and data, allowing the user to better understand and follow the mining process, no formal syntax and semantics of the interface as a whole is reported.

Enterprise Miner, developed by the SAS Institute, provides a large number of data mining algorithms, including decision trees, neural networks, regression, radial basis functions, self-organizing maps, and clustering. Enterprise Miner has an interesting visual interface, allowing for powerful support of data transformation, visualization tools for multidimensional analysis, and extensive parameter options for the algorithms. The user drags and drops icons from a task bar into a work area where the icons can be connected. Each connection represents the flow of information from one node to its successor, and each icon type represents a type of processing (for example, imputation of missing data, declaration of variable types and target variables, regression, etc.) on the data from the predecessor node. Mining algorithms are viewed as a special type of processing. The visual metaphor of nodes and edges is intuitive; however, most of the complex settings of each node type cannot be operated upon graphically, but must be accessed through a type-specific tab-based interface. The effort does not report any formal description of the graphical interface available.

Intelligent Miner is a data mining software developed by IBM, supporting association rules, clustering, classification trees, and neural networks. There are two versions of Intelligent Miner, Intelligent Miner for Data and Intelligent Miner Modeling/Scoring/Visualization. Intelligent Miner for Data is a standalone program. Its interface is based on explorer-like panes and drop-down menus introducing the various data mining techniques, parameter settings, and visualization windows. Intelligent Miner Modeling/Scoring/Visualization is a suite of three distinct tools, for the extraction mining models, for prediction, and the visualization of models. The product is integrated into the IBM DB2 Universal Database, which provides all metadata support, for example by storing the mining models and their visualizations. The interface of the modeling component is textual and consists of stored procedures for data mining algorithms callable from DB2’s command windows, whereas the visualization component
has a graphical display with active elements and extensive sorting options. The interface of Intelligent Miner for Data has no known formal specification, as the interface of Intelligent Miner Modeling/Scoring/Visualization. (For the latter, a formal specification is relevant only to the visualization component, which is however, the same supplied with the standalone version.)

OPEN ISSUES AND FUTURE TRENDS

Despite the remarkable efforts and developments that have taken place in the field of visual data mining, the field still faces quite a number of challenges and also exhibits various issues as highlighted in the sequel:

• Data mining methods normally can handle or cope with large amounts of data. Since visual data mining systems integrate data mining techniques and visualization techniques, visualization techniques have to face up to the challenge regarding large quantities of data. Bearing in mind the limitations of the display space, visualizations have to seek effective mappings so as to display all relevant data. Moreover, visualizations have to use efficient techniques to load relevant data in the main memory.

• Most of the existing visual data mining systems have not been subjected to thorough usability evaluations. In order to determine the usefulness of visual data mining systems, the importance of usability studies cannot be overemphasized. On the same note, it is worth acknowledging that the lack of precise theory or a universal/standard framework for developing visual data mining systems may not only be partly responsible for the current situation, whereby each visual data mining system seems to be an ad-hoc development, but may also to some extent at least complicate the usability issue as far as the visual data mining field is concerned. In that respect, Grinstein, Hoffman, Laskowski, and Pickett’s work on benchmarking and evaluation in visualizations for data mining (Grinstein et al., 2002) might be instructive.

• It is a challenging activity to find the methods, techniques, and corresponding tools that are suitable for a specific visual mining task, or a particular type of data. One way forward would be to evaluate the disparate frameworks to determine their effectiveness and to verify their applicability in different application domains (Simoff, 2001).

• Visual support often necessitates the usage of graphical elements. The user is expected to interact with these graphics in real time. When the user interacts with the visualization, there should be some kind of immediate feedback from the graphic. Bearing in mind the fact that the memory demands on the computer that are posed by graphics, may decrease the performance of the system. Consequently, changes introduced on the visual environment may not immediately reflect the changes occurring in the information realm in real time and vice versa. It is no trivial task determining a good balance between interactivity and performance.

In terms of our future research activities, we are planning to support the output of descriptive statistics, principally using pie charts and histograms, in the clustering environment. It also is worth noting that a set of the system features are under an engineering process in order to become part of the commercial suite D2I, distributed by Inspiring Software (http://www.cisat-group.com). The D2I (Data to Information) environment will serve as a generic suite for handling the data to be subjected to mining. Even as we consider the foregoing research directions, it is also important to be aware of various trends in data mining. One
of the current trends is distributed data mining, where the target data is located in different places and/or in different physical locations. There is also a growing interest in ubiquitous data mining, where the user may carry out data mining from ubiquitous devices (such as PDAs, cellular phones, etc) rather than from the conventional computer. Another area that has been drawing a lot of attention is hypertext and hypermedia data mining. Efforts in the foregoing type of data mining would normally entail one or more of the following three aspects: content mining, structure mining, and usage mining. It is also interesting to observe a growing interest in audio data mining, where audio signals are used to represent data trends/patterns or other specific data features.

CONCLUSION

Despite the existence of many data mining efforts that deal with user interface aspects, there is relatively little work going on or that has been published on the specification of the syntax of such user interface and the corresponding semantics. In general, a formal specification can bring about many benefits such as facilitating the description of the system properties without having to be concerned about implementation details and enabling the detection of fundamental design issues before they manifest themselves in the implementation. In visual data mining, where visualization is often a key ingredient, a formal specification can be rewarding. For instance, it can enable users to decide which interaction/operation to apply to get a particular output, it can help users to predict the output of their interactions/operations with the system, and it can facilitate the development of interaction models. In this work, we have proposed and described an approach for specifying such a formal specification in the process of developing a visual data mining system, VidaMine.

Chapter 2.30
Understanding the Nature of Task Analysis in Web Design

Rod Farmer
The University of Melbourne, Australia

Paul Gruba
The University of Melbourne, Australia

ABSTRACT
Designing usable Web-based interfaces challenges practitioners to carefully consider end-user behaviour and requirements. Unfortunately, in meeting this challenge, human-computer interaction (HCI), task analysis is often poorly understood and applied during Web design activities. Rather than purely evaluating usability against prescriptive guidelines, we argue that designing for Web-based interaction requires a more holistic and descriptive approach. This chapter provides an overview of cognitive and postcognitive HCI task analysis frameworks, and their respective abilities to capture a systemic view of stakeholder requirements. As such, this chapter provides a valuable resource for researchers and practitioners alike.

INTRODUCTION
Although improved system design results when researchers and developers understand how users use technology (Raeithel & Velichkovsky, 1996), understanding individual user traits, such as motivation and other contextual factors that guide user participation during computer-mediated activities can be deceptively complex. Simply asking users what they want and how they use a system is further complicated by the fact that users are often incapable of vividly and objectively describing their experiences with the system (Sommerville, 2004). Expertise, sociocultural, and organisational policy factors may impact perception of purpose, meaning, and context, and hence influence the quality of user feedback (Gasson, 1999). Therefore, determining whether a
Understanding the Nature of Task Analysis in Web Design

system is fit-for-purpose for a particular end-user population can be extremely challenging.

As developing fit-for-purpose systems is a principal concern of human-computer interaction (HCI), the system design process must ensure that end-user requirements are validated against those who have a vested interest in its use (stakeholders). Therefore, choosing the right HCI framework for eliciting, analysing, and modelling stakeholder requirements is critical for ensuring overall system quality (Farmer, Gruba, & Hughes, 2004). The process of seeking to understand the human nature of these requirements is referred to in HCI as task analysis. There is a wealth of frameworks, models, methodologies, and tools that can be applied to assist in this process. However, choosing the “most appropriate” approach is dependent upon several factors, including: the domain, context of use, and available resources.

Task analysis is arguably the most important aspect of HCI as it provides the analyst, researcher, or developer with insights into the nature of human behaviour. A major benefit of conducting task analysis throughout the software development life cycle (SDLC) is its communicative power and ability to elicit and elucidate requirements throughout each phase of development via a set of formalised attributes and notations. Unfortunately, comparing and choosing the right task analysis approach during system design is frequently hampered by the lack of universal notations and user attributes that can be applied across frameworks (Balbo, Ozkan, & Paris, 2004).

The primary aim of this chapter is to provide a critical overview of task analysis in HCI and its application to Web design. Specifically, the chapter will discuss the cognitivist origins of task analysis, and the recent shift towards more ecologically valid approaches. We discuss several leading approaches within each paradigm and describe their general applicability to Web design. We conclude with an integrative approach to task analysis that attempts to bridge the divide between cognitive and postcognitivist perspectives.

**TASK ANALYSIS IN HCI**

The term task analysis is commonly used to denote a wide range of activities and processes that attempt to either describe, equate, or predict human performance during task-based interaction (Diaper, 2004). A direct corollary of early cognitive psychological research concerning cognition and procedural knowledge (Kirwan & Ainsworth, 1992; Miller, 1953, 1962), task analysis has been applied successfully to numerous fields of research, including:

- Interactive system design (Newman & Lamming, 1998)
- Safety critical systems design and evaluation (Paternò & Santoro, 2002)
- Cognitive engineering (Rasmussen, Pejtersen, & Goodstein, 1994; Vicente, 1999)
- Computer-assisted language learning (Corbel, Gruba, & Enright, 2002; Farmer & Hughes, 2005a, 2005c)
- Multi-modal interaction (Farmer, 2005)
- Intelligent learning object classification (Farmer & Hughes, 2005b)
- Social intimacy (Vetere et al., 2005)
- Web design (Dix, 2005)

It is therefore not surprising to see an increasingly divergent array of theoretical perspectives emerging on the nature of human-machine interaction. Observing that methodologies in HCI have already reached a sufficient level of sophistication and application, Whittaker, Terveen, and Nardi (2000) have argued that it is time to address existing problems, rather than develop additional idiosyncratic models and notations. Indeed, renewed focus has recently been applied to the problem of integrating and grouping task analysis theories and techniques, which at first glance may appear fundamentally incommensurate (Farmer, 2006; Wild, Johnson, & Johnson, 2003).

The primary aim of task analysis is to produce a reliable procedural description of human praxis.

However, unlike mere procedural functions, tasks incorporate the notion of purpose (Preece, Rogers, Sharp, Benyon, Holland, & Carry, 1994, p. 411), hence goals and planning. Many task analysis techniques are built on the belief that systems are reducible to their constituent parts, promoting a systematic, linear decomposition of human praxis (Watts & Monk, 1998). However, systems can never be logically decomposed into subsystems without losing some implicit value, whether operational (knowledge) or functional (capability) (Latour, 1987). This said, linear reductionist descriptions of work may be appropriate for developing highly constrained, well-defined environments, such as interactive voice response (IVR) systems that typically restrict users to inhabiting a single state. Such cognitive environments therefore promote a strong adherence to a narrow view of user behaviour (Robinson, 1993). Table 1 shows a variety of task analysis approaches typically employed within HCI.

Disregarding the actual methods applied within these frameworks, we can further collapse these approaches onto two conceptual axes: descriptive/analytical and cognitive/system. The descriptive/analytical axis reflects whether the purpose of the analytical framework is to describe or to empirically analyse interaction behaviour. The cognitive/system axis reflects whether the framework is cognitively oriented, concerned with modelling mental processes during work activity, or system oriented, concerned with modelling how individuals relate cognitively to their social, organisational, and environmental work contexts. As these axes represent continuums, more fine-grained categories of task analysis now emerge.

Low-level analytic/cognitive approaches such as goals, operators, methods and selection rules (GOMS) and hierarchical task analysis (HTA) tend to treat task interaction as a series of linearly sequenced actions from which we can derive the sense of the activity, and thus effective system design. Higher-level system/descriptive approaches, such as soft systems methodology (Checkland, 1999), tend to take a more holistic perspective, focusing on situated activity rather than actions. The growing importance of modelling situation awareness during HCI is representative of a paradigmatic shift away from individual, information processing accounts of interaction, towards more socially relevant, tool-mediated representations of activity.

Gathering Requirements via Task Analysis

Requirements engineering (elicitation, analysis, and specification) is essential to developing quality Web-based systems as it (1) helps to elicit possible user groups and their level of involve-
Understanding the Nature of Task Analysis in Web Design

ment; (2) provides insight into user and system requirements; and (3) places the development effort within a contextual environment (Balbo et al., 2004; Farmer et al., 2004). Schach (1999) provides a case-based analysis of software development projects, highlighting that the origin of 80% of all software defects can be traced back to earlier requirements engineering and design phases. In addition, the cost of fixing a defect during the maintenance phase, as opposed to these earlier phases, is an order of magnitude. As both requirements engineering and task analysis serve to determine which features of a system will render it fit-for-purpose, it is necessary to ensure they are conducted appropriately throughout the SLDC (see Table 2).

According to Mager (1991), there are four distinct fields of work analysis: (1) performance, (2) critical incident, (3) task, and (4) goal analysis. Performance analysis attempts to describe aspects of human activity that are directly related to understanding and improving human performance. Traditionally, this area of research has focused on two aspects of work: operator awareness and capability modelling; and human-system simulation environments. Operator modelling is for the most part a behavioural activity, using techniques such as time analysis and operator function models (Kirwan & Ainsworth, 1992). Human-system simulation environments, on the other hand, require sophisticated, computational-task simulation tools and theories to evaluate human decision making, including recognition-primed decisions and naturalistic decision making (Zsambok & Klein, 1997).

Critical incident analysis focuses on developing causal models of relationships within complex systems to prevent accidents or error states in safety-critical environments (Shrayne, Westerman, Crawshaw, Hockey, & Sauer, 1998).

Table 2. Purpose of task analysis various stages of the SDLC
As such, this work requires a higher-degree of probabilistic modelling and stochastic analysis than the other fields. More than any other work analysis related field, critical incident analysis attempts to reduce complex activities to discrete, measurable events.

Perhaps the most difficult category to define, however, is task analysis. Researchers and practitioners have failed to agree upon a universal definition of “task,” including an appropriate unit of analysis (Carroll, 2002). As a result, the term task analysis has been used to describe all four categories of work analysis, especially goal analysis. Accordingly, contention has arisen concerning the structure of tasks, and their relationship to goals and planning (Nardi, 1996; Suchman, 1987).

What is a Task?

Figure 1 depicts a traditional structural view of task in HCI where it is seen as a conscious act (Kirwan & Ainsworth, 1992; Watts & Monk, 1998). Task-as-activity is comprised of some goal that must be achieved through mediated interaction via agents and artefacts of the environment (Flor & Hutchins, 1991; Hutchins, 1995). Planning is implied as goals reflect the system state to be achieved through effecting some combination of actions (events). Unfortunately, here we run into trouble. Preece et al. (1994) conceive activities as devoid of control structures and not requiring thought. While this may be true of some activities where procedural knowledge has reached a certain level of automaticity through habituation, it cannot be true of all interactive systems, such as Web environments.

Goals require constant monitoring and evaluation (Suchman, 1987), which implies conscious decision making. Indeed, it is more logical to assume that tasks are constructed and maintained within a frame of reference that includes planning (Filkes, 1982). Planning requires knowledge of when and how to initiate tasks. We therefore question the correctness of this traditional view of Task, and propose Figure 2 as an alternative. Here the term task is substituted for activity. As activities are motivated social constructs (Leont’ev, 1978), it is appropriate that they appear superordinate to goals, individual goals being a subset of collective goals. As activities exist at the social level, they are less temporal than subjective individual acts. Planning is therefore rooted firmly within specific communities of practice, and less open to change and violent fluctuations in behaviour. Given their degree of permanence, we classify conscious decision making conducted at this level, meta-planning. Furthermore, Suchman (1987) argues that individuals plan reflexively rather than deliberatively, responding to immediate changes in environmental conditions. As such, planning at the goal level is likely to be affected by micro changes during an activity. We classify this within-activity planning, micro-planning. Figure 2 suggests that tasks are subordinate to goals, thus inverting the traditional view. Moreover, Figure 2 distinguishes between two types of task: conscious and unconscious.

The mediating variable in task classification is habituation. The more one practices an event, the fewer attentional (cognitive) resources need to be assigned to performing that task. Conversely, when an error or breakdown in information flow occurs, these tasks are raised into consciousness.

Understanding the Nature of Task Analysis in Web Design

Divisions within HCI on Task Analysis

The notion of Task has historically been dependent upon the predominant theoretical models of the time. According to Goguen (1996), there are today two dominant theoretical perspectives within HCI: the cognitive (cognitive science and experimental psychology) and the postcognitive (sociology and anthropology). These perspectives exist along a continuum polarised by the split between the natural and social sciences (Raeithel & Velichkovsky, 1996). Selecting between cognitive and ecological theories of human praxis can have considerable impact upon system development. For instance, the view that participation within an activity is not isolated, yet inexorably bound to external relationships and sociocultural conditions poses serious questions for how we model both functional and nonfunctional requirements during online system design.

Cognitive approaches to task analysis primarily focus on aspects of user performance (Diaper, 2004), often neglecting sociocultural phenomenon essential to meaningful interaction. Postcognitivist, or ecological, approaches underscore the importance of context in evaluating human praxis. Postcognitive approaches hold that meaningful interaction can only be derived from careful consideration of the environmental, sociocultural, and historical contexts in which an activity occurs. Moreover, activity itself is distributed among various cognitive systems within the environment, and not just at the user interface, as interaction requires the accessing of information and/or anticipation of events that may be beyond the user’s experience. Hence, measuring the meaningfulness of interaction is
not merely an empirical measure of performance (human or technological), rather an evaluation of the appropriateness of an activity in relation to a set of established goals. Furthermore, meaning during online activity is negotiated through the user interface, and not at the user interface.

Contrary to the more behaviouristic views of cognitivist approaches, postcognitive perspectives are driven primarily by sociological considerations, including how work is shared, organised, and completed within communities of practice (Wegner, 2003). This shift is also indicative of increased research into how we can better capture the context of interaction; develop greater understanding of user behaviour — in situ —; and how tool mediation impacts knowledge acquisition and management (Kaptelinin, 1996b).

The cognitivist dialogue maintains an assumption that derived task models can be universally applied across different user groups, implying a greater degree of similarity between individuals than should otherwise be accorded (Preece et al., 1994). Carroll (1997) suggests that designing systems upon the notion of universally applicable task models implies certain cognitive equivalences between humans and computers, yet maintains that artefacts lack self-awareness, and should never be thought to possess knowledge of their behaviour. Although some may suggest that artefacts possess certain cognitive affordances, this is often a misinterpretation of the impact of social process, such as cultural conventions, on object use (Norman, 1999).

APPROACHES TO TASK ANALYSIS IN HCI

As previously highlighted, the two primary task analysis movements within the field of HCI are cognitive (behaviourist) and postcognitive (socio-cultural). Methods employed within the cognitivist paradigm promote action-oriented analyses of interaction (Kaptelinin, Nardi, & Macaulay, 1999). Postcognitive frameworks represent not so much an opposing view, but rather an argument for greater emphasis on modelling human activity as it occurs in situ. Postcognitivist methodologies favour goal-oriented or object-oriented analyses. To better understand how these paradigms differ from one another, we now consider related methodologies.

Behavioural Task Analysis

Behavioural, or cognitive task analysis frameworks focus primarily on how human behaviour is determined by the user’s internalisation and transformation of input, and how this information results in output as action. Cognitive approaches to HCI mostly focus on the user-computer interface, as it forms the critical point of coherence between two discrete models of processing — that of the human and the computer. While this is true of most underlying cognitive task models, differing purposes of use have resulted in considerable variation between approaches.

Cognitive Task Models

There are various levels of behavioural task analysis approaches within HCI. These include low-level cognitive methodologies, such as HTA (Annett, 2004; Annett & Duncan, 1967; Shepherd, 2001), and higher-level, meta-cognitive frameworks, such as scenario-based design (Carroll, 1996, 1997, 2000, 2002; Rosson & Carroll, 2002).

Behavioural frameworks are structured upon specific task models, structured descriptions of the interactive task to be performed by the user(s). It encompasses the notion of task and as such represents the specific set of actions that the user may undertake in a goal-directed activity. Task models may also include a task hierarchy, indicating task sequencing and any additional constraints upon usage (Limbourg & Vanderdonckt, 2004). Although most vary substantially in their depth
of analysis, degree of formalism, and purpose, all task models comprise a set of common objectives (Table 3).

According to Table 3, these common objectives imply that task models can be used for a variety of purposes, from requirements engineering through to system evaluation, representing varying levels of abstraction and serving different purposes within the SDLC (Balbo et al., 2004).

The underlying theme within behaviourist frameworks is that users have an overarching system goal they wish to achieve, which through intentionality is transformed into action. Decision making occurs through comparison of intention and perceived system behaviour (feedback) (Norman, 1999). As such, interaction is modelled as a closed information-processing loop — input, transformation, and output. These types of analysis are effective for modelling and evaluating the primitive tasks that determine user behaviour in well-structured activities. Here, we briefly describe a set of highly influential, cognitive task analysis frameworks. With the possible exception of cognitive work analysis (CWA), we argue that these approaches fail to sufficiently support decision making and problem solving in unstructured and dynamic environments.

### Goals, Operators, Methods and Selection Rules

GOMS-based approaches have received considerable attention in the HCI literature (John & Kieras, 1996a, 1996b), as it can be used quantitatively to predict efficient user interaction with a system design (task performance), and qualitatively as a means of modelling low-level tasks (Kieras, 2004). GOMS-based approaches are also effective at predicting future task performance. However, models of interaction derived from a GOMS analysis tend to be abstract, rather than specific. Moreover, GOMS — as initially conceived — does not account for motivational factors involved in computer-mediated activities, nor is it well suited for modelling social and collaborative work practices.

The unit of analysis in GOMS is the task. Like HTA, GOMS describes task-based interaction as a hierarchically ordered sequence of actions, aligned with specific goals (and subgoals) (Card, Moran, & Newell, 1983). Briefly, GOMS views tasks as comprising:

1. **Goals**: Desired outcomes within some computer-mediated activity;

</table>
Understanding the Nature of Task Analysis in Web Design

2. **Operators**: Actions that must be executed in order to achieve some goal;

3. **Methods**: The set of operators that are required to achieve some larger (system) goal; and

4. **Selection rules**: Logic rules used to choose between competing methods given some system feedback.

Within GOMS, input is received from the system, which is processed and associated with internalised representations of the system (mental models). This internal system information is aligned with immediate and overarching goals, and subsequently associated with competing possible actions. Selection rules serve as transformation functions, helping to determine which actions possess the greatest utility, and thus provide the most effective means of interaction. Output is the corollary of some cognitive utility evaluation, representing the most effective path to achieving the desired goal.

For GOMS, generating meaning from interaction occurs at the man-machine interface and is highly determined by subjective internal representations of the activity. Unfortunately, GOMS is highly prescriptive and fails to consider distributed models of interaction, which consider environmental artefacts, organisational behaviour, and social conventions that reflect historical decision-making processes and cultural conventions (Hutchins, 1995).

**Hierarchical Task Analysis**

HTA is an action-oriented, decompositional framework primarily concerned with the training of people in system design and use. Initially developed for analysing nonrepetitive operator tasks (Annett, 2004; Annett & Duncan, 1967), HTA grew out of the need for a more expressive model for describing mental processes during man-machine interaction. HTA's theoretical foundations lie in system theory and information processing, seeing task performance “as the interaction between human and machine, the latter becoming increasingly complex as computers and automation developed” (Annett, 2004, p. 68). With relation to task performance, the term *analysis* in HTA refers to the process of problem identification and structuring. HTA is an effective process for proposing empirical solutions to existing specified problems (Annett, 2004).

In HTA, *goal* refers to an expected outcome, or system state. Goals and subgoals, may be active or latent, arising when the need presents itself to achieve some expected outcome. HTA frequently models this goal-oriented behaviour as tree structures, such as decision trees. Goals are established and acquired through an information processing cycle similar to that in our discussion of GOMS (Annett & Duncan, 1967; Kieras, 2004). As with goals, *actions* in HTA may also be decomposed into nested actions, each maintaining their direct relationship to an established system state. Being nested, actions are available at both the current node of activity, and at their super node (parent task). Therefore, according to HTA, user behaviour can be reduced to a cycle of monitoring for new input, deciding upon available alternatives and controlling subsequent behaviour.

Although an attractive framework, there are a number of problems HTA practitioners typically encounter. Firstly, when a parent goal becomes active, all subgoals (and their related actions) become active as well. However, it is seldom the case that a user is simultaneously aware of current and future goals. Rather, user behaviour is typically more anticipatory and reflexive (Endsley, 2000; Suchman, 1987). According to HTA, subgoals and their actions are maintained as conscious constructs available to the user. Again, this is unlikely to be the case, as many procedural actions essential for effective task completion are habituated or unconscious even when the associated goal is being actioned (Whittaker et al., 2000).
GroupWare Task Analysis

Developed by van der Veer, Lenting, and Bergevoet (1996), GroupWare task analysis (GTA) attempts to incorporate cooperative strategies within cognitive task models. Within GTA, complex tasks are decomposed into low-level unit tasks (Limbourg & Vanderdonckt, 2004). However, by assigning roles to both tasks and agents in the environment, GTA differs from HTA in its ability to model aspects of collaboration and cooperation. As roles change within the organization and across activities, traits that link specific tasks to activity structure, agents, and artefacts can be identified. This process contributes a social dimension to task performance analysis. Unfortunately, GTA currently lacks sufficient formalism, and therefore expressive power, to handle complex environments. Additionally, GTA is presently only effective when evaluating existing systems. It is therefore not appropriate for exploratory modelling activities.

Cognitive Task Analysis

Cognitive task analysis (CTA) refers to a host of techniques that can be applied to investigating expert system usage (Gordon & Gill, 1997). Examples include naturalistic decision making, recognition-primed decisions, and schema theory (Zsambok & Klein, 1997). CTA techniques address many of the weakness inherent to HTA and GOMS by explicitly modelling procedural knowledge and complex information-processing structures (Hollnagel, 2003). Decision ladders capture the central characteristic of information processing, yet incorporate short circuits, or experience-based patterns of action that permit experienced individuals to move between goal structures in response to changing action and planning resources. CTA is therefore highly suited to modelling expert behaviour. However, analysing sociocultural features of an activity is not sufficiently developed or formalised in CTA. Although HTA and GOMS may be cast as derivatives of the CTA approach, CTA is inherently more adaptable, as seen through (1) its advocacy of methodological plurality; (2) promotion of task heterarchies over hierarchies; and (3) its consideration of both cognitive and environmental artefacts within an activity. As CTA models activities in terms of cognitive architectures, it is less applicable to investigating exploratory, descriptive, and ill-structured social activities.

Cognitive Work Analysis

CWA is a work-centred framework that represents a major advancement upon traditional CTA approaches. It is designed specifically for analysing work environments that require significant human behavioural adaptation to new and existing tasks (Rasmussen et al., 1994; Vicente, 1999; 2004). It is built upon a meta-cognitive task model that integrates both cognitive and ecological practices within a holistic framework for work practice analysis.

CWA differs from other cognitive approaches in that it does not merely focus on normative modelling (how HCI should proceed); descriptive modelling (how HCI currently occurs); or formative modelling (how specific actions are sequenced during an activity). Rather, the aim of CWA is three fold:

1. Identify the properties of the work environment
2. Define likely work boundaries
3. Evaluate boundary effects on HCI

In CWA, actor-system interaction is always situated within some activity; hence, it considers not just the tasks actors perform, but also the situation in which they are undertaken. In conducting a work analysis, activity is broken down into five levels of analysis: (1) work domain analysis; (2) control task analysis; (3) strategies analysis; (4) social-organisational analysis; and
(5) work competencies analysis. In practice, these five levels are used to constrain possible human-computer design considerations. Although prescriptive methods are formalised and integrated within CWA, the framework itself advocates a plurality of analysis techniques, so long as they fulfil a practical purpose. As conceptual levels are interdependent (soft boundaries), analysis progresses from one layer to another in an iterative fashion — all layers activated to some lesser or greater extent at any point in time. Moreover, in applying CWA, there is no explicit ordering of analysis activities (Vicente, 1999). This renders the approach extremely flexible and reduces the learning curve required to apply its principles in practice.

Work domain analysis seeks to establish the structural limitations of the work domain. This stage identifies the type of users expected to participate in the activity, the activity problem, and additional logical and physical constraints upon the system. Control task analysis represents the set of abstract tasks that control the general flow of information within an activity. Strategies analysis investigates how individuals or groups overcome a problem when presented with a set of alternatives. This decision-making process is similar to that of selection rules in GOMS. However, unlike GOMS, this process considers prior experiences, spatio-temporal constraints upon operation, motivation, aptitude, and other similar criteria. Social-organisational analysis seeks to establish how tasks are shared between actors and artefacts in a cooperative and collaborative manner. Finally, work competencies analysis examines the degree of training and experience actors bear upon some activity.

Summary of Approaches

To determine which approach may best be used within a particular Web design project, Table 4 provides a brief overview of the cognitive approaches previously mentioned and demonstrates their shared and unique attributes.

Ecological Task Analysis

Until recently, task analysis in HCI has focused almost exclusively upon deriving reductionist cognitive representations of individual tasks (Hollan, Hutchins, & Kirsch, 2001). Although HCI is

currently moving towards more ecologically valid models of human praxis, postcognitivist theorists have yet to agree upon the most promising alternatives (Kaptelinin, 1996a). Resolving this issue depends on two factors:

1. Establishing a common unit of analysis
2. Constructing integrative frameworks that model both cognitive and social phenomena

The need for integrative frameworks is especially relevant to Web designers who must not only support existing social practices through a novel medium, but also the cognitive demands imposed by semiotic constraints when delivering information via the Web (Smart, Rice, & Wood, 2000). Table 5 outlines the required properties of an integrative framework.

At the heart of the postcognitive movement lies the notion of situation awareness. Situated awareness represents an understanding of social norms and rules, or a state of knowledge about the context, situation, and environment in which an activity takes place (Erickson & Kellogg, 2001). Situation awareness does not describe, per se, the process of acquiring knowledge, but rather is the end result of invoking any number of cognitive and meta-cognitive processes during active participation in a practice (Endsley, 2000). Furthermore, situation awareness is distributed among individuals, and hence, actionable and relevant only within specific communities of practice (Gasson, 1999). Situation awareness requires individuals to maintain an awareness of the continuously unfolding characteristics of an activity. Summarising Endsley (2000), situation awareness entails:

1. Perceiving relevant contextual information
2. Understanding how the roles and relationships between actors impacts information presentation and communication
3. An ability to use social cues to assist in planning for future events

Albers (1998) states that the quality of an individual’s situation awareness is governed by their ability to comprehend, integrate, and reconstruct new information. This three-step process involves extracting the relevant basic information from the task/activity, integrating the information into the individual’s conceptual understanding of the problem, subsequently generating new rules and beliefs so as to extrapolate the information into future problem-solving situations. As situations change and new information is presented, so must the individual’s awareness of emerging conditions that are likely to impact upon their effective participation in an activity. The problem of situation awareness is highly relevant to developers of Enterprise Content Management systems where the most critical factor impacting successful deployment and integration is user adoption. Postcognitive task analysis frameworks that maintain the centrality of situation awareness are more likely to succeed at meeting this challenge.

Goals, experiences, expectations, and motivations are interdependent constructs that produce localised expectations about situated action, and as such influence situation awareness (Endsley, 2000). Goals help to orientate an individual across a series of tasks, including error recovery. For example, when a user encounters an error during interaction with a Web-based form, a breakdown in planning occurs. In assessing available feedback, the user must evaluate available actions against their goals and state of knowledge about the activity. In overcoming the breakdown or conflict, emergent behaviour may not only result in a reprioritisation of individual goals, but may also lead to new interaction strategies.

Expectations are influential in the division of attention during HCI, acting as a selection mechanism, reducing demand on cognitive resources to efficiently respond to new information. Experience is also influential in the development of automaticity. For instance, expert system users are expected to demonstrate better skills compared to novices, as they are likely to have developed more efficient strategies and greater responsiveness to overcoming breakdowns. The difficulties novices face may be a result of their lack of habituated actions during HCI, rendering the task more cognitively demanding. Situation awareness among novice users typically increases through gradual exposure to, and experience with, the system. However, increased situation awareness does not imply good task performance. It is a probabilistic construct, making good performance more likely, yet not assured.

The notion of situation awareness is found within several postcognitive HCI frameworks. Here, we present a broad comparison of a few notable frameworks. We examine how each of the competing frameworks conceives of an appropriate unit of analysis, and how this unit of analysis impacts each framework.

**Situated Action Models**

The situated action view of HCI treats knowledge as a subjective construct. Knowledge is inextricably linked to interpersonal communication and contextual activity. Knowledge is not only subjective, but specifically relevant to a particular situation in which some work practice occurs (Gasson, 1999). Nardi (1996) notes that situated action perspectives are more focused on context-sensitive practices than on the cognitive properties of the artefacts with which individuals interact.

The unit of analysis in situated action is the motivated activity within a relevant community
of practice (Lave, 1988), supplanting the largely cognitivist unit of analysis, task. Within each of the ecological perspectives treated in this chapter, the notion of task is redefined or appropriated to mean action. Subjugating the importance of task to activity promotes the influence of actor roles, relationships, and sociocultural cues within a particular setting.

One of the key characteristics of the situated action model is its adherence to reflexivity in system design. Experience, cultural and historic beliefs and anticipatory planning on behalf of the individual are therefore de-emphasised within this perspective. Rather, situated action focuses on the immediacy of interaction, the fluctuating conditions of the situation, and the learning opportunities provided by an individual’s creative response(s) to alternative paths through the activity (Lave, 1988; Nardi, 1996; Suchman, 1987). An activity’s structure is not something that precedes interaction but emerges directly out of the immediacy of the situation. Planning and goals are produced in the course of action, and thus are work products, rather than characteristics that orient the activity (Bardram, 1998). This view implies that people are basically opportunistic. Planning and goals either emerge concurrently out of participation in the activity itself, or by conscious reflection upon previous interaction.

As situated action subscribes to the view that analysts should only be concerned with recording observable behaviour (Endsley, 2000), we believe that it is not appropriate for analysing exploratory domains, where it is crucial to first identify the contextual problem under investigation and subsequently determine the expected outcomes of the activity. Similarly, we feel that the approach is not sufficiently descriptive to examine large collaborative work activities where knowledge and planning are often spread across actors. In large organisations, activity is seldom seen as a knee-jerk reaction to current events.

Distributed Cognition

Distributed cognition is concerned with how knowledge is propagated and transformed by agents within activity. An agent is any cognitive artefact of the system, be it human, machine, or other work product. The unit of analysis is the cognitive system. Distributed cognition relaxes the assumption that the individual is the best or only useful unit of analysis and thus extends the reach of what is considered cognitive to both systems that are smaller and larger than the individual (Hollan et al., 2001; Hutchins, 1995). The cognitive system in distributed cognition is thus more akin to the term complex cognitive system.

Goals, according to distributed cognition, are not merely maintained within the mind of the subject (individual or group), but rather embedded within the cognitive system. Distributed cognition posits that artefacts may themselves possess goals. The cognitive system can only be understood when we know the contributions of individual agents, their shared contributions and collaboration strategies, and the nature agent behaviour in the environment. In contrast to situated action, distributed cognition incorporates culture, context and history, but from within an embedded perspective (Hollan et al., 2001).

There are striking similarities between the distributed cognition and activity theory (Nardi, 1996). Both are activity-centric: they recognise activity as a hierarchical, goal-oriented structure; align physical, verbal, and nonverbal actions with specific goals; and they distinguish between conscious and unconscious actions. Additionally, neither framework prescribes a particular set of methodological practices. Nevertheless, there are two notable differences between the approaches:

- Activity theory is essentially human-centric, individuals motivating activity.
• In activity theory, artefacts are not seen as goal-oriented, cogent entities.

In contrast to activity theory, distributed cognition holds that in cooperative environments, individuals maintain only partial models of the problem. Hence, for distributed cognition, complex systems rather than individuals are the appropriate unit of analysis.

Latour (1987) provides theoretical support for this last argument, stating that part of what is technological is social, and what is social is technological. As relationships in actor-networks constitute human-human and human-artefact interaction, a change in content structure, user interface, pedagogy, or number of participants in an activity has the potential to change the nature of an activity. While not implying that an artefact is cogent, actor-network theory suggests how a work product may impact social and cognitive processes (Tatnall, 2002).

Activity Theory

Activity theory is a descriptive conceptual framework that has emerged primarily from contributions by Vygotsky (1986), Leont’ev (1978), and Engeström (1987). Activity theory serves to describe the different forms of human praxis and developmental processes involved in HCI. Activity theory represents a truly ecological approach to task analysis, providing a broad theoretical framework for examining collaborative activities (Stanton, 2004). As the name suggests, the unit of analysis in activity theory is the activity itself. Individual and social processes are interwoven in the generation of contextualised meaning. Similar to distributed cognition, individual knowledge and meaning cannot be separated from the context of an activity.

Activity theory (depicted in Figure 3) is an object-oriented, task analysis framework. The importance of goals is present, however they are subordinate to motivated outcomes, or objective purpose (object) (Whittaker et al., 2000). Unlike situated action, interaction is not opportunistic, but purposeful. Purpose is context specific as activities define context, and context defines an activity. Therefore, the act of doing in one context cannot be considered congruous with the act of doing in another (Lave & Wegner, 1991). This is in direct contrast to cognitive task models such as GOMS.

One of the principal tenets of activity theory is tool mediation. Activities are mediated by individuals carrying out their tasks through the use of available artefacts in the environment. When an artefact is used to mediate interaction, it is said to become a tool. A tool can be any material or mental process used to transform or convey

Figure 3. Activity theory framework
Understanding the Nature of Task Analysis in Web Design

information (Kaptelinin, 1996b). As tools exist only through purposeful activity, they contain cultural and historical residue. They are therefore capable of imparting external sociocultural beliefs and historic conventions upon an activity.

Activity theory posits a hierarchical structure of activity, consisting of three primary elements: activity, object-oriented actions, and operations (Leont’ev, 1978). As shown in Figure 3, activity is motivated by the subject (individual or group). An activity is comprised of mediated, object-oriented actions. Each action is associated with one or more parent and subgoals. This implies that actions are polymotivated; each action (task) may be applied to accomplish several goals. This is important as it provides a way of supporting alternative paths or strategies within an activity for obtaining the purposeful outcome. Accordingly, we cannot focus purely on the action itself, as its purpose or role is ambiguous. Lastly, operations are habitual behaviours or unconscious actions.

According to activity theory, there is constant interaction between these three elements of human praxis. This dynamicism is critical to our understanding of human behaviour in interactive environments. However, despite the advantages of applying an activity theoretic approach to interactive system design, there is as yet no systematic way of interfacing the approach with rigorous software engineering methodologies (Turner, Turner, & Horton, 1999).

Scenario-Based Design

Scenario-based design (SBD) promotes the use of scenarios (or structured narratives) in HCI as a way of understanding human activity and creating computer systems (Carroll, 2000). Today, they are widely used across disciplines. In an attempt to render software development more social, Carroll (1996, 1997) argues that activity theory can be applied effectively to SBD. While Carroll does not describe how this can be accomplished, suggestions are found elsewhere (Carroll, 2000; Go & Carroll, 2004; Kazman et al., 1996; Rosson & Carroll, 2002). Admittedly, natural language narratives are not the most scientific notation used within HCI or software engineering; however, it is often by these means that technical information is conveyed throughout the development effort (Carroll, 1996). Moreover, scenarios provide a flexible mechanism for integrating “real life” accounts of activity with the more empirically discrete views employed within software engineering.

During discovery and definition (see Table 1), scenarios can be used speculatively at the start of the SDLC to document expected user behaviour or to describe hypothetical activities. In the absence of an existing system, this process improves ecological validity during requirements engineering (Stanton, 2004). To assist with requirements engineering, Kaptelinin et al. (1999) suggest that Activity Checklists can assist practitioners to focus on salient aspects of an activity, thereby constraining the process of requirements engineering during SBD.

Scenarios represent purposeful interaction within a system, and are inherently goal-oriented. Scenarios are always particular to a specific situation, and thus situated within a particular frame of research. Because scenarios are actor-driven, describing interaction from the perspective of at least one individual, they can be effectively integrated with an activity theory framework. Finally, as scenarios use a common notation, natural language, all stakeholders in the development process can easily communicate requirements, experiences, and other opinions/beliefs without requiring extensive training. Consequently, scenarios serve as an excellent lingua franca for communication between all project stakeholders; a primary goal of any good task analysis framework (Balbo et al., 2004).

Summary of Approaches

Table 6 provides a brief overview of the postcognitive approaches described previously and demonstrates their shared and unique attributes.

TOWARDS SITUATED TASK ANALYSIS IN WEB DESIGN

In this chapter we have outlined the limitations associated with both cognitive and postcognitive approaches to task analysis. Cognitive approaches suffer from their inability to model dynamic social processes; to consider aspects of interaction which are not reducible to discrete cognitive events; and to elicit and describe user goals and their limited extensibility and transferability to new domains. Postcognitive approaches on the other hand suffer from a lack of tools and techniques that bridge theoretical frameworks and practical design and evaluation methods. Although promoting increased reuse of HCI knowledge, postcognitive frameworks are less computationally powered, thus possessing a significant barrier to their integration into standard Web design practices as described in Vora (1998). The challenge therefore is to promote integrative, task analysis frameworks that support both cognitive and ecological perspectives (Czerwinski & Larson, 2002). This new breed of task analysis frameworks is referred to as situated task analysis (Farmer & Hughes, 2005b).

Situated task analysis incorporates the view that in natural settings, problems are frequently ill defined, requiring communication, collaboration, negotiation, and prioritisation. This broadens the field of regard from the individual to include organisational and social contexts. This situated view can be seen as an example of macrocognitive architecture, describing cognitive functions as they are performed in natural settings (Klein,
Understanding the Nature of Task Analysis in Web Design

Ross, Moon, Klein, Hoffman, & Hollnagel, 2003). This is in opposition to the traditional microcognitive view of task analysis that focuses on the building blocks of cognition. A detailed account of a situated task analysis framework: cognition, activity, social organisation, environment (CASE) is provided in Farmer (2006).

A Simple Approach to Situated Task Analysis in Web Design

A major obstacle in developing Web sites that are both usable and fit-for-purpose is capturing stakeholder requirements and communicating them to other project team members, especially designers. User requirements are often qualitatively produced, resulting in rich descriptions of functional and operational requirements. While this assists with understanding the nature of activity, it does not always suit developers who are required to describe the system in terms of discrete, verifiable behaviour. In the following, we describe an iterative five-step process that facilitates communication and integration of both static and dynamic views within the requirements engineering and design phases of Web site development.

Step One: Requirements Engineering and Goal Generation

The first step in our process is requirements engineering. Scenarios are ideal in this situation as they are written in natural language and are therefore highly accessible and require little practitioner training (Go & Carroll, 2004).

Figure 4 describes the iterative process of eliciting user requirements using activity checklists (Kaptelinin et al., 1999) and scenarios. Scenario descriptions are iteratively refined until they are stable, the outcome being a set of scenarios reflecting multiple viewpoints of interaction. Using an initial Activity Checklist, containing likely questions and statements related to the purpose of the activity, and a minimal-use scenario, we initiate the requirements elicitation process. As shown in Figure 4, our first aim is to elicit initial traits or themes that emerge out of the user’s perception of the activity. Users may be additionally asked to develop their own use scenario to increase participation and contextuality during the development process. This process continues, redefining the scenarios and checklists, until we are able to group these traits into sets of themes or categories. At each stage, the new scenarios are...
validated against the users themselves in order to maintain internal consistency.

In a similar manner, once no further traits emerge from our analysis, we proceed by reducing these initial categories to a core set of salient concepts. These concepts can be considered high-level objectives within the activity or goals. These concept-goals can be considered fairly stable and transferable between users, as they will have been derived from multiple perspectives. Finally, we arrive at a set of scenarios that represent the key concept-goals of our activity. These scenarios can be linked together to provide a chain or hierarchical view of the scenarios relative to a particular requirement. The corollary of this process becomes increasingly important as we move towards the initial design phase.

In Figure 5 we see more clearly this process of scenario refinement and linkage. Our initial minimal use scenario (R1.1) is iteratively refined to reveal particular traits of the activity (R1.2). As this ultimately is an exploratory process, each stage can be seen as a form of goal refinement. We notice in Figure 5 that within this process of refinement, conflicts between scenario views (i.e., between users or between users and developers) result in an update of the Activity Checklist. In this way, we are able to capture the context of use and apply this knowledge to subsequent elicitation cycles. As we move towards concept-based scenarios in our analysis, we move away from action-oriented perspectives towards more holistic, goal-oriented views of activity.

**Step Two: Determine Salient Features of Interaction**

Having constructed a core set of requirements containing both low and high-level views of interaction, the next step is to determine which concepts are most critical to the success of the Web application. Although we already possess relatively stable concept-goals with which to initiate our design process, some concepts may be more salient than others. Techniques for determining salient cognitive and social features during interaction are described in Farmer (2006).

*Figure 5. Iterative goal-driven scenario development*
Step Three: From Scenarios to UML Use Cases

Upon establishing the most salient concept-goals with the system, the next step is to transform these rich textual descriptions into static, structural views, amenable to inclusion in the design process. This can be achieved using unified modeling language (UML), use case diagram notation (Rumbaugh, Jacobson, & Booch, 1999). We start by modelling the high-level use cases. These typically correspond to the concept-goal scenarios previously elicited, and hence provide a goal-oriented system view. Subsequently, we drill down into each of these use cases, decomposing them into their subsystems and determining their structural constraints.

Use case decomposition, as shown in Figure 6, is the process of iteratively decomposing an activity into its constituent parts. This process has already been achieved via the bottom-up process of concept-goal generation. Therefore, use case decomposition may easily be achieved by associating each concept-goal with its related categories and traits. This information is present within the previously constructed scenario chains. Designers are therefore able to isolate requirements at particular levels of granularity as well as investigate the structural relationships between use cases (implements, depends, generalises) via the rich descriptions provided in the scenarios.

Figure 6 provides an example of a use case decomposition for an online shopping activity. In this instance, the user has only four concept-goals. These are search catalogue, view shopping cart, buy book, and change profile. Common concepts that are shared among requirements, such as login, can be modelled via a dependency relationship. Modelling the relationship between a concept and a category (see Figure 4) can be achieved through inheritance, or implementation. In addition to modelling relationships, designers may choose to isolate particular concept areas, such as social organisation, to further narrow the design perspective.
**Step Four: From Use Cases to Design**

After constructing the UML use cases at various levels of granularity (from goals to actions), the next step involves transforming these formal decompositions into design elements. One way to manage this complex process is to establish distinct viewpoints, modelling the system from various perspectives (Rumbaugh et al., 1999). Here, we only consider the structural and behavioural system views. The major distinction between these views is that the former emphasises object-oriented interaction, whereas the latter describes event-driven interaction.

The structural view provides a physical description of how the Web site will be made up of various components, including relationships between those components. This is primarily achieved using UML class diagrams that provide an object-oriented view of the system. While primarily promoting a static view of the system, object methods and attributes can also be shown. Using the use cases generated previously from the concept scenarios, it is possible to rapidly construct a high-level representation of the site structure, objects acting as placeholders for each concept goals.

Having modelled at a conceptual level the key user requirements as UML classes or objects, we use the link structure provided during the initial requirements engineering phase to determine additional objects, methods, and attributes of the system. For instance, we can model category-based scenarios in UML class notation via aggregate relations (“is-part-of”) to our concept-based objects (Figure 7). Additional techniques, such as noun extraction (noun=object, verb=method, adjective/adverb=attribute), may be used to extract structural information from the scenarios themselves (Schach, 1999).

Figure 7 provides a simple demonstration of this process. In this instance, the class objects **Login** and **Search** represent complex objects associated with login management and searching a Web site. We note these relationships could have been modelled alternatively as methods (login and search are verbs) within other classes, or as interfaces that could be implemented by other objects, as shown in Figure 6.

This process can be extended to the trait-based scenarios to establish additional object attributes.

---

*Figure 7. UML Class diagram representation of concepts*
This process has several benefits: it provides a rapid means of determining initial site structure within a goal-oriented framework; it permits designers to link design decisions back to initial requirements, as well as examining requirements from various stakeholder points of view and at various levels of granularity; and designers may link additional design-centric scenarios to each requirement, providing details such as event sequencing and information flow, therefore improving traceability between the SDLC phases.

In examining methods and attributes more closely using our scenarios, we are likely to become more focused on event-driven behaviour. In developing a behavioural system view, we are interested in modelling the flow of system information through event or function-driven interaction. We typically see functional flows (Appendix A) and sequence diagrams used at this point in the initial design phase. These techniques constrain interaction to a finite-state representation, limiting users to predetermined paths through the system. Where multiple paths may exist, functional flow analysis and task models may be used to determine optimal paths through the system in order to reduce variability and improve site effectiveness and efficiency. At this point, our design analysis has moved away from modelling goals to modelling actions and evaluating task performance.

Finally, these event-driven views may be abstracted to form UML dialog models or activity diagrams, providing a means of aggregating task models or flow analyses. These dialog models may then be linked into our initial scenario/requirement chain to provide additional system information. This process ensures a multi-view representation of requirements that are linked forwards and backwards to design. Moreover, it ensures that both goal-oriented and action-oriented perspectives of interaction are conveyed during development.

**Step Five: Start Over**

We recall that task analysis is not a once-off process (Balbo et al., 2004). This is especially true of interactive systems and environments, such as the Web. It is important to note that most people actually learn by doing (Lave & Wegner, 1991). Rather than thinking of a site’s design as merely being usable, we should consider how the site or application, as a tool, facilitates participation in an activity.

Developing effective Web sites requires consideration of both novice and expert users. Most users, however, do not arrive at a site as experts. They reason, use past experiences, and explore through interaction. Their ability to gain expertise in these virtual environments is partially governed by how well the design supports and extends the user’s current capabilities. This can only be achieved when there is sufficient coherence between the context of use and the virtual environment’s design. Taking a user-centred approach to Web design, including an appropriate task analysis framework and set of methodological practices, ensures that developers will never be too far away from their users. Ultimately, it is they who will judge the relative merits of your site/application.

**CONCLUSION**

Web design is a complex activity at the best of times. Not only do designers frequently encounter technological limitations imposed by a novel communication medium, but also they are highly isolated from their users. Moreover, arguably more than with any other technological medium, the Web application target audience is extremely heterogeneous. Therefore, the ambiguous and diverse nature of Web application use imposes critical limitations on Web design practices. Shadowed by the importance of developing
quality, fit-for-purpose systems, this chapter has highlighted the considerable benefits to be gained by incorporating task analysis in Web design. Specifically, this chapter has described how task analysis is not a single process that can be applied indiscriminately of context and use. It is a highly stylised and domain-dependent activity that occasionally suffers from conflicting theoretical and methodological approaches.

We have argued that task analysis is not a silver bullet, rather a means of “getting to know” your users and communicating this information through product development and evaluation. Rather than describing a core set of prescriptive guidelines for conducting task analysis in Web design, this chapter has set out to inform the reader via a critical examination and principled discussion of various approaches to task analysis. Consequently, our hope is that the reader as practitioner will be both more aware and appreciative of the role task analysis can and should play in Web design.

**ACKNOWLEDGMENTS**

We would like to thank Baden Hughes and Sandrine Balbo for their collaboration and comments on related work. Special thanks go to Sandrine Balbo for her presentation on task models in HCI, which spawned an insightful and lively afternoon of discussions that stimulated aspects of our discussion here.

ABSTRACT

The traditional desktop computing paradigm has had major successes. It also should be noted that we are in a day and age where many good computer and device users are increasingly finding themselves being required to perform their activities not in offices/desktops but in real-world settings. Ubiquitous computing can make possible in the real-world setting what would have otherwise been impossible through desktop computing. However, there is a world of difference between the real-world and the desktop settings. The move from the desktop to the real-world settings raises various issues when we consider the nature of tasks that the ubiquitous devices/applications would be expected to support and the real-world context in which they will be used. A careful study of the nature of tasks in ubiquitous computing can make some design requirements in the development of ubiquitous applications more evident. This chapter proposes ubiquitous application design and evaluation considerations emerging from a deeper understanding of the nature of tasks in ubiquitous computing.
INTRODUCTION

It is worth acknowledging that the traditional desktop computing paradigm has had major successes. On the same note, it should be observed that we are in a day and age where many people have become good computer and device users. However, these users are increasingly finding themselves performing or being required to (or having to) perform their activities not in offices and desktops but in the real world settings. In describing the situation, Kristoffersen and Ljungberg indicate that the hands of such users “are often used to manipulate physical objects, as opposed to users in the traditional office setting, whose hands are safely and ergonomically placed on the keyboard.” (Kristoffersen & Ljungberg, 1999). It is interesting to observe how ubiquitous computing can come in handy toward making possible in the natural setting what would have otherwise been impossible through the desktop computing paradigm. It is therefore not uncommon to encounter a user who “carries out one or many parallel activities from virtually anywhere at anytime while at the same time interacting with other user(s) and/or device(s).” (Bertini et al., 2003).

However, it is worth noting that there is a world of difference between the real world setting and the desktop setting. As we consider the move from desktop computing (fixed user interfaces) to the real world settings, various issues and demands arise when we consider the nature of tasks the ubiquitous devices/applications (and thus ubiquitous user interfaces) would be expected to support and the real world context in which they will be used.

Consequently, it does turn out that a careful study of the nature of tasks in ubiquitous computing can make some requirements in the design and evaluation of ubiquitous applications become more evident, which forms the basis of this chapter. In particular, we will describe the nature of tasks in ubiquitous computing, and then propose and describe ubiquitous application user interface design and evaluation considerations emerging from a deeper understanding of the nature of tasks in ubiquitous computing.

The rest of the chapter is organized as follows; it first provides some background knowledge. It then gives an overview of the nature of tasks in ubiquitous computing. After that we propose and describe ubiquitous application design and evaluation considerations respectively based on the foregoing. We then highlight some open issues and conclude the chapter.

BACKGROUND KNOWLEDGE

In this section, we describe some of the key concepts relevant to the chapter. In particular, we describe ubiquitous computing. It should be noted that in the history of computing, the requirement to take into consideration the real world context has arguably never been more critical and pressing than in this day and age of ubiquitous computing. After describing ubiquitous computing, we then focus the description on the concept of context.

Ubiquitous Computing

Weiser coined the term ubiquitous computing (ubicomp) and gave a vision of people and environments augmented with computational resources that provide information and services when and where desired (Weiser, 1991). Dix et al. define ubicomp as: “Any computing activity that permits human interaction away from a single workstation” (Dix et al., 2004). Since then, there have been tremendous advances in mobile and wireless technologies toward supporting the envisioned ubiquitous and continuous computation and, consequently, ubiquitous applications that are intended to exploit the foregoing technologies have emerged and are constantly pervading our life. Abowd et al. in (Abowd et al., 2000) observe
that ubicomp applications are characterized by the following:

- **Natural interfaces**: Supporting interaction techniques that permit humans to interact with computing machines through the use of more natural interaction paradigms (e.g., speech, gesture, pen writing).
- **Context-awareness**: Ubicomp applications are expected to exploit the whole set of computing and telecommunication technologies that operate taking into account the context.
- **Automatic capture of live experiences**: Ubicomp applications often adopt or provide techniques that enable the user to record elements of their live experiences (e.g., photos, video, audio) and the management of the same.

**Context**

Context has been defined as “any information that can be used to characterize the situation of an entity.” (Dey, 2000), where an entity refers to “a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves.” (Dey, 2000). Context entails aspects such as location, infrastructure, user, environment, entities, and time. The infrastructure could include technical resources such as server and network capabilities and connections, applications, and so forth. User includes user data/profile, usage patterns, and so forth. The environment refers to the physical condition of the setting an could include light, temperature, and so on. Entities refer to people, devices and objects. Time could include date, time of the day, season, and so on. Abowd et al. provide in (Abowd et al., 2000) a review of ubicomp research and summarize context in the form of “five W’s”:

- **Who**: As human beings, we tailor our activities and recall events from the past based on the presence of other people.
- **What**: Perceiving and interpreting human activity is a difficult problem. Nevertheless, interaction with continuously worn, context-driven devices will likely need to incorporate interpretations of human activity to be able to provide useful information.
- **Where**: In many ways, the “where” component of context has been explored more than the others. Of particular interest is coupling notions of “where” with other contextual information, such as “when.”
- **When**: With the exception of using time as an index into a captured record or summarizing how long a person has been at a particular location, most context-driven applications are unaware of the passage of time. Of particular interest is the understanding of relative changes in time as an aid for interpreting human activity. Additionally, when a baseline of behavior can be established, action that violates a perceived pattern would be of particular interest.
- **Why**: Even more challenging than perceiving “what” a person is doing is understanding “why” that person is doing it.

**NATURE OF TASKS**

The interaction of the user with the ubiquitous device/application can be viewed in at least two dimensions:

- user-ubiquitous application interaction dimension and
- user-ubiquitous device dimension.

User-ubiquitous application interaction dimension entails tasks in which the user is primarily interacting with the ubiquitous application and
the device I/O modalities in order to access services such as support services (e.g., emergencies, help/service), information services (e.g., gathering/recording information, accessing/retrieving information, sharing information, communicating) and entertainment services (e.g., games, music, videos). User-ubiquitous device dimension categorizes tasks that entail the actual handling of the device (such as holding the device, wearing the device, attending to the device).

There are situations whereby interaction with the ubiquitous application, though important, is not the primary task but rather a secondary/supplementary task. In such a case, such ubiquitous devices/applications would be used to provide support/assistance and gather/make available some resources (such as information) on behalf of a user who is engaged in another primary task in the real environment/setting. In fact, the tension between the primary tasks of a ubiquitous user and the user’s interaction with the ubiquitous device/application can be seen in the literature (e.g., Pascoe et al., 2000). Notwithstanding the foregoing, there also are situations in which interaction with the ubiquitous application is the primary contributor to the user’s accomplishment of the primary task; interacting with the ubiquitous device/application can be viewed as directly carrying out the primary task. In this case, the use of the ubiquitous device/application tends to be more intimately connected with what the user is really doing (or intends to achieve) in his/her embodied/physical self. For instance, where the user is using the ubiquitous application to inform him/her about the location he/she is in. However, it is also worth pointing out that at different time granularities, the primary task and secondary task may swap in ubiquitous computing. The foregoing situations raise challenges and that would need to be taken into consideration when designing and evaluating (developing) ubiquitous application user interfaces.

Some ubiquitous interactions are low-intention or incidental interactions—that is one where the user is not focused on the interaction being supported by the ubiquitous system and may not even be directly aware of the support (Dix et al., 2004, Dix, 2002). In such cases, the primary task or purposeful task needs to be understood in order to interpret sensor data. However, the supported task also needs to be understood in order to be able to administer appropriate support. This distinction is likely to be useful in other context sensitive situations. For example, if a user has recently consulted an online diary related to a coming birthday and a short while later starts to initiate a phone call, then it may be appropriate for the number of the person whose birthday is coming to be at the top of the list of suggested numbers. The former task, looking up the diary entry, is the initial purposeful task and needs to be interpreted in order to determine which people are important or relevant. The latter task, phoning, is the supported task and the knowledge of which people are currently significant is used to support this task.

While simpler task models assume a level of pre-planning or training, it is expected that most ubiquitous interactions are worked out at the moment (see situated action below) or maybe triggered from things in the environment (Dix et al., 2004b). Furthermore, being in a particular place or meeting a particular person may prompt tasks or activities that were not particularly waiting to be done, but were either very low priority but suggested by having the right resources available. Whilst more goal-oriented models of tasks assume one gathers resources to perform a task, in many real-world situations this gathering of resources is the hard or expensive thing, and it is worth doing activities using the resources and location available, even preparatory ‘just in case’ activities.
DESIGN CONSIDERATIONS

It is worth noting that the user of a ubiquitous device often has to focus on more than one task because s/he might have to interact with the device itself (which is itself a task) while probably performing another task in the real world setting (where this could be the primary task or the secondary task). On one hand, interaction with the ubiquitous device/application to some extent requires user’s innate resources (such as attention). On the other hand, the latter task often too does require the user’s physical, visual, and cognitive involvement/resources (such as hands, visual attention, mental focus). The user’s physical, visual, and cognitive involvement/resources are therefore likely to get constrained. Ideally, the ubiquitous application (including interactions with the device) should support the user in carrying out that which is the primary task without ‘supporting’ the user in tampering with the primary task. We should minimize distracting the user from the primary task or disrupting the user’s primary task, unless the disruption/distraction is of genuine (and great) value or of critical importance. In the words of Holland and Morse: “It is important that the critical focus of the user’s attention be directed towards the primary task at hand” (Holland & Morse, 2001). In adopting ways to meet the requirement, it is also critical to consider the status of a user’s attention in the timing of the tasks on the ubiquitous device. Borrowing from a research effort on guidelines for using agents and direct manipulation (Horvitz, 1999), it is important to “consider the costs and benefits of deferring action to a time when action will be less distracting.” Where necessary, the ubiquitous application should enable/allow the user to temporarily halt a task on the device and to resume the interrupted task.

One of the challenges with a new or innovative technology/application is that its users may try to use it in situations or ways the designers and developers had never thought of. This is true in mobile computing (Gorlenko & Merrick, 2003). There is therefore a sense in which the user may perform tasks on the device (and otherwise) in unpredictable and opportunistic ways. Taking into account all possible scenarios of use for a product is a non-trivial challenge to the ubiquitous application analysts and designers. It is also worth observing that the variability of the environment/natural setting may affect the course of a task. Therefore, analysts and designers may also need to account for such variability in the task analysis (Gorlenko et al., 2003).

The model human processor model (Card et al., 1983) has been a benchmark for a lot of work in HCI. The model is a simplified view of the human processing while interacting with computers. It focuses on the internal cognition driven by the cooperation of the perceptual system, the motor system, and the cognitive system. Each of the systems maintains its own processing and memory. However, as the role and domain of the computers (and devices) have widened, researchers and designers have been considering theories and approaches that take into account the relationship between the internal cognition and the outside world (Dix et al., 2004). Among these, researchers are exploring the following three main understandings of cognition for possible application in ubiquitous computing; they are activity theory model, situated action model, distributed cognition model (Abowd et al., 2002), and even their variants.

Activity Theory

The activity theory model provides a broad conceptual framework for describing the structure, development, and context of computer-supported activities. It was developed by the Russian psychologists Vygotsky, Rubinshtein, Leont’ev and others (Kaptelinin et al., 1995; Leont’ev, 1978). Activity theory is comprised of a set of basic
principles that constitute a general conceptual system, rather than a highly predictive theory. The principles include the hierarchical structure of activity, object-orientedness, internalization/externalization, tool mediation, and development. It should be noted that the principles should be considered as an integrated system, because they are associated with various aspects of the whole activity. In activity theory, the unit of analysis is an activity. The activity is directed at an object which motivates the activity, giving it a specific direction. An activity is made up of goal-directed actions that must be undertaken to fulfill the object. Different actions may be undertaken to meet the same goal. Actions are conscious and they are implemented through automatic operations. Operations do not have their own goals, but rather they provide an adjustment of actions to suit current situations. Therefore, the constituents of activity are not fixed, but can dynamically change (or adjust) as situations/conditions change. This principle is of great interest in ubiquitous computing, since it is desired that the ubiquitous application appropriately adapt to the changing conditions/context. In the context of activity theory, the principle of object-orientedness states that human beings live in a reality that is objective in a broad sense; the things that constitute this reality have not only the properties that are considered objective according to natural sciences, but also socially/culturally defined properties as well. The principle of object-orientedness is very relevant to ubiquitous computing since the ubicomp to a great extent leads to situations where the user directly interacts with other people while (at the same time) using the ubicomp device or application. Therefore the social and cultural issues become even more crucial. An example is society’s perspective regarding a person’s speaking on a cellphone while directly interacting with another person. Internalization is the transformation of external activities into internal ones. Externalization transforms internal activities into external ones. Activity theory emphasizes that internal activities cannot be understood if they are analyzed separately from external activities, because they transform into each other. The external activities in this case can be closely associated with the contextual aspects in ubiquitous computing. For instance, the way the activity of speaking on the cellphone is designed could be better informed by considering the contextual aspects such as the simultaneous but direct interaction with another person, the noise level in the locality, and so forth. Activity theory emphasizes that human activity is generally mediated by tools. Tools are created and transformed during the development of the activity itself. Tools carry with them a particular culture, and therefore the use of tools is an accumulation and transmission of social knowledge. In ubiquitous computing, such tools could in a way be viewed as the ubicomp devices and applications. As far as activity theory is concerned, development is not only an object of study, but also a general research methodology. Gay and Hembrooke have noted a weakness in the original formulation of the activity theory model by pointing out that the model “has traditionally been understood as asynchronic, point-in-time depiction of an activity” (Gay & Hembrooke, 2003).

They go on to note that the model “does not depict the transformational and developmental processes that provide the focus of much recent activity theory research” (Gay & Hembrooke, 2003). In (Boer et al., 2002), Boer et al. do propose an extension of activity theory across time and the levels of an organization to explain connections between different activities as well as the influence that an activity may have on itself. Moreover, Boer et al. also consider the role that an activity may play in other activities at different levels of analysis. Those extensions to the activity theory can serve at least two purposes; they can help to explain tensions present in real-world systems and yield a model with a greater degree of agility in representing complex, distributed cognition. Other work (Uden, 2007) describes how activity theory was used to develop a framework for the
Designing for Tasks in Ubiquitous Computing

Activity theory has also been used in the arena of peripheral displays.

In (Matthews et al., 2007), activity theory was used to perform an analysis of peripheral displays. In the same effort, the authors also used activity theory to develop an approach for designing and evaluating peripheral displays.

Situated Action

The situated action model emphasizes the emergent, contingent nature of human activity, that is, the way activity grows directly out of the particularities of a given situation. The focus is situated activity or practice. The situated action model does not underestimate the importance of artifacts or social relations or knowledge or values, but rather its true locus of inquiry is the “everyday activity of persons acting in [a] setting” (Lave, 1988). The world of computing has always faced contextual issues. However, the current wide adoption and usage of ubiquitous computing (e.g., cellphones, personal digital assistants, etc.) have made contextual issues arguably more prominent than during any other time in history of computing. The main reason is that the ubiquitous devices and applications primarily are used in real settings and therefore, there is a need for the ubiquitous devices and applications to support situated activities. The basic unit of analysis in situated action models is “the activity of persons-acting in setting.” (Lave, 1988). The unit of analysis is thus neither the individual, nor the environment, but rather a relation between the two. The situated action model stresses responsiveness to the environment and the improvisatory nature of human activity. Users under the influence of the environment, may use or attempt to use ubiquitous technologies/applications in “new” ways that even the designers had not anticipated. The situated action model, therefore, can be suitable for capturing and accommodating such user improvisations. On the same note, the situated
action model deemphasizes the study of more durable, stable phenomena that persist across situations (Nardi, 1996). A central tenet of the situated action approach is that the structuring of activity is not something that precedes it, but can only grow directly out of the immediacy of the situation (Nardi, 1996; Lave, 1988). The authors of the effort (Fithian et al., 2003) report that they mainly used the situated action model during the design and evaluation of an integrated location-aware event and meeting planner built to work in a PDA form factor. Their justification for adopting the situated action model was that they “wished to examine the behavior and performance of users in real-world situations, where environmental and social factors are a source of both distraction and motivation” (Fithian et al., 2003; Taylor & Harper, 2002). Fithian et al. actually attribute their meaningful evaluation results to their choice of the situated action model.

Distributed Cognition

Flor et al. in (Flor et al., 1991) describe distributed cognition as “a new branch of cognitive science devoted to the study of: the representation of knowledge both inside the heads of individuals and in the world ...; the propagation of knowledge between different individuals and artifacts ...; and the transformations which external structures undergo when operated on by individuals and artifacts.... By studying cognitive phenomena in this fashion it is hoped that an understanding of how intelligence is manifested at the systems level, as opposed to the individual cognitive level, will be obtained.” It should be observed that ubiquitous devices and applications are primarily used within real settings/context (the world). Therefore, it is important that knowledge pertaining to the real settings be modeled. As has been the case with the desktop computing applications, knowledge about the target user too is important in the arena of ubiquitous computing. On the same note, it is worth noting that the users of ubiquitous technolo-

gies tend to operate in real settings and, therefore, often have to simultaneously interact with other people/individuals and artifacts. Knowledge pertaining to such artifacts and such other individuals is, therefore, important to the design and development of the ubiquitous applications and devices being used. In distributed cognition, the unit of analysis is a cognitive system composed of individuals and the artifacts they use (Flor et al., 1991). Distributed cognition moves the unit of analysis to the system and finds its center of gravity in the functioning of the system (Nardi, 1996). In a manner similar to traditional cognitive science (Newell et al., 1972), distributed cognition is concerned with structure (representations inside and outside the head) and the transformations these structures undergo. However, the difference is that cooperating people and artifacts are the focus of interest, not just individual cognition “in the head” (Nardi, 1996). Another aspect that distributed cognition emphasizes is the understanding of the coordination among individuals and artifacts. The work reported in (Spinelli et al., 2002) is an investigation of users involved in carrying out collaborative activities, locally distributed and mobile. The investigation utilizes the distributed cognition framework and contextual design for representing and analyzing the work observed. By using distributed cognition to model cognition across users and artifacts, the study could look at collaboration from an innovative point of view that highlights how context and external resources impact collaboration. In (Laru & Järvelä, 2003), the authors address an effort that has used distributed cognition and collaborative learning in order to develop a pedagogical model of mobile learning. UbiLearn is a ubiquitous and mobile learning project (Laroussi, 2004). Its work is based on two mobile learning viewpoints; the first is the technical oriented perspective which focuses on a traditional behaviouristic educational paradigm as given and tries to represent or to support it with mobile technologies. The second is the pedagogical socio-cognitive and
distributed cognition paradigms, where we face traditional designs of teaching and learning to push community oriented learning (e.g., collaborative learning, problem based learning; informal and ad-hoc learning, etc.). The work (Fischer et al., 2004) explores the concept of distributed cognition in ubiquitous computing from two directions. On the one hand, it explores the unique possibilities that computational media can have on distributed cognition (how ubicomp technologies can be used to support the users’ distributed cognition). On the other hand, it describes a set of interrelated socio-technical developments that support distributed cognition among communities in ubicomp environments, such as a mobile architecture that links mobile travelers with caregiver communities and transportation systems. The architecture embodies “a distributed cognition framework that avoids common cognitive barriers found in current transportation systems (i.e., generic maps, schedules, labels, landmarks and signs) while synthesizing personalized multimodal attention and memory prompts from the transportation environment to provide travelers with the right information, at the right time, and in a form best suited for the individual traveler” (Fischer et al., 2004).

**Situated Interaction**

It may be resourceful to highlight an interaction paradigm, namely situated interaction that has been defined based on and motivated by some of the above models. Situated interaction refers to the integration of human-computer interaction and the user’s situation in a particular working context in a mobile environment (Hewagamage & Hirakawa, 2000). This combination perceives that the interaction is not only a function of device, but also strongly dependent on the user’s activities and context in which the device is used. The concept of situated interaction can be discerned in, and may be said to have been inspired by, both the situation action model and the activity theory model. Situated interaction actually introduces a new paradigm of computing by extending the conventional applications and also by creating a new set of applications. It is worth noting that mobile computing has become popular in enhancing the shopping experience as discussed in (Newcomb et al., 2003) where they utilized ideas from situated computing. They go on to say that understanding situated interactions, where the customer utilizes the user interface while shopping, became the greatest challenge for designing the ubiquitous user interface.

It is worth noting that the acknowledgement of such challenges could also be supported by the adoption of design approaches and methodologies inspired by participatory design, which is based on the observation of users’ activities in authentic everyday settings where mobile computing takes place (Rogers et al., 2002; Strömberg et al., 2004); as an example, micro-learning is an emergent area of investigation that could find useful resources in these methods while addressing its objective of designing and distributing series of very small units of knowledge to be experienced by learners (for lifelong learning purposes) as intertwined in their everyday working practices and ubiquitous computing activities (Gabrielli et al., 2005).

**EVALUATION CONSIDERATIONS**

Conventional user-centered methods could be appropriately exploited in the development process of ubiquitous applications. On the same note, some of the traditional usability evaluation techniques might become useful when adapted for ubiquitous computing. For instance, there are several efforts toward realizing usability principles and heuristics for the design and evaluation of ubiquitous environments/systems, such as ambient heuristics (Mankoff et al., 2003) and groupware heuristics (Baker et al., 2001). On the same note, we actually already have proposed a review of usability principles for mobile computing (Bertini et al.,
Designing for Tasks in Ubiquitous Computing

2005). We have also developed usability heuristics that are appropriate for evaluation in mobile computing (Bertini et al., 2006).

Much traditional understanding of work organizations has its roots in Fordist and Taylorist models of human activity, which assume that human behavior can be reduced into structured tasks. HCI has not been spared from this either. In particular, evaluation methods in HCI have often relied on measures of task performance and task efficiency as a means of evaluating the underlying application. However, it is not clear whether such measures can be universally applicable when we consider the current move from rather structured tasks (such as desktop activities) and relatively stable settings to the often unpredictable ubiquitous settings. Such primarily task-centric evaluation may, therefore, not be directly applicable to the ubiquitous computing domain. It would be interesting to consider investigating methods that go beyond the traditional task-centric approaches (Abowd & Mynatt, 2000). It is also worth keeping in mind that tasks on the ubiquitous device (and elsewhere) tend to be unpredictable and opportunistic.

In this era of ubiquitous computing, the real need to take into account the real-world context has become more crucial than at any other time in the history of computing. Although the concept of context is not new to the field of usability (e.g., ISO 9241 guidelines propose a “model” consideration of context), evaluation methods have, however, found it challenging, in practice to adequately/completely integrate the entire context during the evaluation process. There are various ways to address this challenge.

One option is the employment of observational techniques (originally developed by different disciplines) to gain a richer understanding of context (Abowd et al., 2002; Dix et al., 2004). Main candidates are ethnography, cultural probes, and contextual design. Another option is to use the “Wizard-of-Oz” technique, other simulation techniques, or even techniques that support the participant’s imagination. Prototyping too presents an avenue for evaluating ubiquitous computing applications.

Ethnography

Ethnography is an observational technique that uses a naturalistic perspective; that is, it seeks to understand settings as they naturally occur, rather than in artificial or experimental conditions, from the point of view of the people who inhabit those settings, and usually involves quite lengthy periods of time at the study site (Hughes et al., 1995). Ethnography involves immersing an individual researcher or research team in the everyday activities of an organization or society, usually for a prolonged period of time. Ethnography is a well-established technique in sociology and anthropology. The principle virtue of ethnography is its ability to make visible the ‘real world’ aspects of a social setting. It is a naturalistic method relying upon material drawn from the first-hand experience of a fieldworker in some setting. Since ubiquitous devices and applications are mainly used in ‘real world’ settings, then ethnography has some relevance to ubiquitous computing. The aim of ethnography is to see activities as social actions embedded within a socially organized domain and accomplished in and through the day-to-day activities of participants (Hughes et al., 1995). Data collected/gathered from an ethnographic study allows developers to design systems that take into account the sociality of interactions that occur in the “real world.” The work by Crabtree et al. (Crabtree et al., 2006), shows how ethnography is relevant to and can be applied in the design of ubiquitous computing applications. The ultimate aim of the effort is to “foster a program of research and development that incorporates ethnography into ubiquitous computing by design, exploiting the inherent features of ubiquitous computing applications to complement existing techniques of observation, data production, and analysis.” While describing
how mobile computing has been used in the fashion retail industry, Supawanich et al. highlight challenges such as those pertaining to usability, system tailoring, and the manager-client user experience (Supawanich et al., 2005). It is worth noting that they applied ethnography toward addressing the foregoing challenges. In the work (Newcomb et al., 2003), which we have mentioned before, the authors also have applied ethnography in their effort to examine how grocery shopping could be aided by a mobile shopping application for the consumers. In particular, the authors shopped with customers and followed them throughout the task of shopping, observing their shopping habits. In (Berry & Hamilton, 2006), the authors report that they used ethnography in order to understand multimedia students and how they use Tablet PCs in their everyday design studies.

**Cultural Probes**

Cultural probes (Gaver et al., 1999a) represent a design-led approach to understanding users that stresses empathy and engagement. They were initially deployed in the Presence Project (Gaver et al., 1999b), which was dedicated to exploring the design space for the elderly. Gaver has subsequently argued that in moving out into everyday life more generally, design needs to move away from such concepts as production and efficiency and instead focus and develop support for “ludic pursuits.” This concept is intended to draw attention to the “playful” character of human life, which might best be understood in a post-modern sense. Accordingly, the notion of “playfulness” is not restricted to whatever passes as entertainment, but is far more subtle and comprehensive, directing attention to the highly personal and diverse ways in which people “explore, wonder, love, worship, and waste time” together and in other ways engage in activities that are “meaningful and valuable” to them (Gaver, 2001). This emphasis on the ludic derives from the conceptual arts, particularly the influence of Situationist and Surrealist schools of thought (Gaver et al., 1999a). Cultural probes draw on the conceptual arts to provoke or call forth the ludic and so illuminate the “local culture” in which people are located and play out their lives. During their course of use, ubiquitous devices and applications typically get embedded in the users’ lives and cultures. For instance, people often get personally attached to their cellphones. Cultural probes offer fragmentary glimpses into the rich texture of people’s lives (Gaver, 2002). Cultural probes are not analytic devices but “reflect” the local culture of participants and are drawn upon to inspire design. In the Presence Project, cultural probes inspire design by providing a rich and varied set of materials that help to ground designs in the detailed textures of the local cultures (Gaver et al., 1999a). These materials are products of the probe packs, each consisting of a variety of artifacts relevant to the study. Such artifacts provide a range of materials reflecting important aspects of the participant’s local cultures and, on being returned to the investigators, these reflections inspire design. For instance, in the Presence Project, the artifacts include: postcards with questions concerning participants’ attitudes to their lives, cultural environment, and technology; maps asking participants to highlight important areas in their cultural environment; cameras with instructions asking participants to photograph things of interest to them and things that bored them; photo albums asking participants to assemble a small montage telling a story about participant’s lives; and media diaries asking participants to record the various media they use, when, where, and in whose company. The original idea of culture probes has been extended to include technology and thus the concept, technology probes (Hutchinson et al., 2003; Paulos & Goodman, 2004; Paulos & Jenkins, 2005). According to (Hutchinson et al., 2003), technology probes can assist in achieving “three interdisciplinary goals: the social science goal of understanding the needs and desires of users in a real-world setting; the engineering goal of field testing the technology; and the design goal of in-
Designing for Tasks in Ubiquitous Computing

spiring users and researchers to think about new technologies.” It is also possible to consider a probe that is entirely simulated, such as with paratypes (Abowd et al., 2005). In a research effort aimed at exploring issues of dependability in ubiquitous computing in domestic settings (Crabtree et al., 2002), cultural probes are one of the qualitative methods that was used. In this case, some participants agreed to keep personal diaries of their daily activities. However, all participants were supplied with polaroid cameras, voice activated dictaphones, disposable cameras, photo albums, visitors books, scrapbooks, post-it notes, pens, pencils and crayons, postcards, and maps. In an attempt to elicit the methods and guidelines for designing and developing applications for domestic ubiquitous computing, Schmidt and Terrenghi in (Schmidt & Terrenghi, 2007) adopted various methods including cultural probes. In a study of the possible applications of mobile technology for industrial designers and architects for their daily work, Muñoz Bravo et al. in (Muñoz Bravo et al., 2007) conducted user studies in which one of the studies consisted of using cultural probes.

Contextual Inquiry

Contextual inquiry (Holtzblatt et al., 1993) is a method that aims at grounding design in the context of the work being performed. Contextual inquiry recommends the observation of work as it occurs in its authentic setting, and the usage of a graphical modeling language to describe the work process and to discover places where technology could overcome an observed difficulty. It is worth noting that in its application, contextual inquiry does combine various methods such as field research and participatory design methods (Muller et al., 1993) in order to provide designers with grounded and rich/detailed knowledge of user work. Contextual inquiry is one of the parts of what is referred to as contextual design. Contextual design is a design approach that was developed by Holtzblatt and Beyer (Beyer et al., 1998). It is an approach for designing customer-centered products based on an understanding of the existing work contexts and practices. It is worth noting that ubiquitous devices and applications are often intended to be used and get used in the real world where real work (or primary tasks) take(s) place. Therefore, the design of such devices and applications should be informed by an understanding of the way customers work (or would like to work) in the real world. Contextual design starts with the premise that any product embodies a way of working. The product’s function and structure introduce particular strategies, language, and work flow on its users. A successful design should therefore offer a way of working that customers would like to adopt. Contextual design has seven parts: contextual inquiry; work modeling; consolidation; work redesign; user environment design; testing with customers; and putting it into practice. One of the proponents of contextual design, Holtzblatt, has actually reported on how contextual design can be appropriated to produce a mobile application (Holtzblatt, 2005). It is interesting to observe that the work by Newcomb et al. (Newcomb et al., 2003), did come up with a contextual design which was meant to serve two purposes; these are in the shopper’s home to aid him/her in creating a shopping list, and in the store for the actual shopping. In the effort by Schmidt and Terrenghi (Schmidt & Terrenghi, 2007), which we came across before, contextual inquiry too was used for understanding and proposing methods and guidelines for designing and developing domestic ubiquitous computing applications. The previously mentioned work by Spinelli et al. (2002) on locally distributed and mobile collaborative activities, which we came across before, did use contextual design. The authors defend their choice of contextual design by stating that “the representation of work activities, utilising the methods of contextual design, aid researchers in conceptualising technologies that truly meet the informational and communicative needs of dynamic and fragmented users
and their communities. ... This has allowed us to develop an understanding of, and to design for, users and their communities-in-context, by applying techniques such as affinity diagramming (for theme building) and work models to capture such essential elements as cultural and social models of technology use; ‘breakdowns’ ... in working practices and artefact models ... that allows us to represent users resources and their relationship with these resources. In the process, it also promotes an effective coupling of well-designed technologies with the fast changing physical environments that their users may inhabit” (Spinelli et al., 2002).

‘Wizard-of-Oz’ Simulation and Supporting Immersion

Another possibility is to use the “Wizard-of-Oz” technique or even other simulation techniques such as virtual reality. The “Wizard-of-Oz” technique is an evaluation method where the user of the system is made to believe or perceive that he or she is interacting with a fully implemented system though the whole or a part of the interaction of the system is controlled by a human being, the “wizard,” or several of them. Such techniques are especially appropriate where the ubiquitous application is not fully complete. However, the simulation should closely reflect the real context as much as possible (realistic simulation). There exist various ubiquitous computing applications that have at some point been evaluated using the “Wizard-of-Oz” technique, for example, (Carter et al., 2007; Mäkelä et al., 2001; Rudström et al., 2003), and so on. Another alternative is to adapt more traditional inspection methods to the analysis of ubicomp settings by enriching the range and quality of discovery resources provided to usability experts to support their imagination and immersion about the real world usage settings. We have recently conducted a study in this direction where video data about user interaction with an e-learning course delivered on PDAs were used as additional resources supporting a more effective performance of cognitive walkthrough evaluation by usability experts involved in the study (Gabrielli et al., 2005).

Prototypes

In the formative stages of the design process, low fidelity prototypes can be used. However, as the design progresses, user tests need to be introduced. In the context of ubiquitous computing, user tests will not only require the inclusion of real users, real settings, and device interaction tasks, but also real or primary tasks (or realistic simulations of the real tasks and of the real settings). As mentioned previously, realistic simulations of the real tasks and of the real settings could be adopted as an alternative. Therefore, there would be the need to provide a prototype that supports the real tasks and real settings or their simulations. This does imply some cost in the design process because the prototype at this level would need to be robust and reliable enough in order to support primary tasks in real settings or the simulations. In fact, the technology required to develop ubiquitous computing systems is often on the cutting edge. Finding people with corresponding skills is difficult. As a result, developing a reliable and robust ubiquitous computing prototype or application is not easy (Abowd & Mynatt, 2000; Abowd et al., 2002).

OPEN ISSUES AND CONCLUSION

We have attempted to describe the nature of tasks in ubiquitous computing. We have then proposed and discussed various models and methods appropriate for supporting the development process of ubiquitous computing applications based on the deeper understanding of the nature of tasks. However, still there are many other pertinent aspects which too would need to be addressed and which we consider worthy of our further
Investigation. These include: the choice of the methods; the choice of the models; the classification/categorization and characterization of tasks for mobile and ubiquitous computing; formal specification of social and collaborative aspects; and so forth.

**Choice of Methods**

We have described several methods appropriate for evaluating in ubiquitous computing. One of the major issues is deciding which of the methods to choose. Of such evaluation methods, one may want to know which one(s) will be most suitable for a certain ubicomp application. Considering evaluation methods in general (not just evaluation methods for ubicomp), Dix et al. indicate that: “there are no hard and fast rules in this – each method has its particular strengths and weakness and each is useful if applied appropriately.” (Dix et al., 2004). They, however, point out that there are various factors worth taking into consideration when choosing evaluation method(s), namely:

- the stage in the lifecycle at which the evaluation is carried out;
- the style of evaluation (field or laboratory);
- the level of subjectivity or objectivity of the method;
- the type of measures provided by the method;
- the level of information provided by the method;
- the immediacy of the response provided by the method;
- the level of interference or intrusiveness of the method;
- the resources required by the method.

The foregoing factors may be appropriately borrowed from when we consider the evaluation of ubicomp applications. According to Carter et al. (Carter et al., 2007), in determining which methods for ubiquitous computing to use, (among paper prototypes, interactive prototypes, “Wizard-of-Oz,” and probes,) the designer must make trade-offs between realism, unobtrusiveness, data sparsity, ambiguity, and cost/time. They go on to say that paper prototypes and “Wizard-of-Oz” can be used to explore ambiguity. Probes that can be employed in real-world situations over a period of time can support both realism and sparsity. Moreover, paper and interactive prototypes may be the least costly methods, but they may also be the least flexible methods. It therefore comes as no surprise that some researchers have begun carrying out corresponding comparative studies (Liu & Khooshabeh, 2003; Mankoff & Schilit, 1997).

Many of the methods considered in this chapter are very “open” compared to more traditional task analysis techniques. This reflects the often spontaneously planned and re-planned nature of many tasks “in the wild” compared to (relatively) more constrained office tasks. Methods that embody a fixed or pre-understood idea of human behaviour are likely to miss some of the nuanced activity that is the focus of more open observational techniques such as ethnography. However, without models it is hard to move from what is observed to potential, especially as this potential often involves users appropriating technology for themselves. For this prompting to see what could happen, as well as what does happen, more interventionist methods in particular forms of technology probes or at least rich prototypes seem more appropriate. That is, the more open methods seem best suited for early and late stages in design for understanding the initial situation and later for assessing the impact of a deployment. However in mid-stages, when establishing potential is more important, more structured models and more interventionist methods seem more appropriate.
Choice of Models

Fithian et al. in (Fithian et al., 2003) observe that mobile and ubiquitous computing applications lend themselves well to the models: situated action; activity theory; and distributed cognition. As for which of these models are most suitable for a certain mobile or ubiquitous application, the foregoing authors say that the choice depends largely on the kind of application and of which aspects of design are in the limelight. They recommend that the choice be based on a critical analysis of the users and their knowledge, the tasks, and the application domain.

In (Fithian et al., 2003), Fithian et al. also note that basing entire evaluation on just time measurements can be very limiting, especially if the tasks are benchmarked in a situated action setting. Although time measurements are important, other performance measures that may be much more useful for evaluating such ubicomp applications include interruption resiliency, interaction suspensions, interaction resumptions, and so forth.

Interestingly, these richer metrics require a far richer model of what is going on than simpler end-to-end timing. This reinforces the message on other areas of evaluation that understanding mechanism is critical for appropriate and reliable generalization (Ellis & Dix, 2006).

Classification of Tasks

In a study found in (Carter et al., 2007), Carter et al. report that respondents felt that the current mobile tools are poorly matched to the user tasks of meeting and “keeping up with” friends and acquaintances. The study observed that location-based technology might assist users in such tasks. Moreover, the study found that users would prefer to have cumbersome and repetitive tasks carried out by their mobile technology artifacts (e.g., the device, the application, etc.). Carter et al. also found that planning tasks vary in nature and detail depending on the formal or informal nature of the event. It might be interesting to consider how level of formality could be used as one of the means of classifying tasks in mobile and ubiquitous computing. Carter et al. observe that events with differing levels of formality require different tasks and, therefore, different support. They note that users showed most interest in the systems that supported informal gathering, rather than formal gatherings. Another possible criterion for classifying or categorizing user tasks could be by borrowing from the activity theory’s framework for describing human behavior (e.g., activities, operations, actions, etc.) or more specialized frameworks such as (Bardram, 2005; Bardram & Christensen, 2004). The work (Matthews et al., 2007), proposes the following classification for the types of activities peripheral displays are likely to support: dormant, primary, secondary, and pending.

Characterization of Tasks

In a work which primarily describes the challenges for representing and supporting user’s activity in the desktop and ubiquitous interactions, Voida et al. in (Voida et al., to appear) characterize activities as follows:

- activities are dynamic, emphasizing the continuation and evolution of work artifacts in contrast to closure and archiving;
- activities are collaborative, in the creation, communication, and dissemination of work artifacts;
- activities exist at different levels of granularity, due to varying durations, complexity and ownership; and
- activities exist across places, including physical boundaries, virtual boundaries of information security and access, and fixed and mobile settings.

In (Abowd & Mynatt, 2000), Abowd and Mynatt describe everyday computing as an area
Designing for Tasks in Ubiquitous Computing

of interaction research which results from considering the consequences of scaling ubiquitous computing with respect to time. They indicate that designing for everyday computing requires focus on the following features of informal, daily activities:

- they rarely have a clear beginning or end;
- interruption is expected;
- multiple activities operate concurrently;
- time is an important discriminator;
- associative models of information are needed.

Like Fithian et al.’s metrics described above (Fithian et al., 2003), these properties all emphasize the fact that activities in a ubiquitous interaction are more fragmented and require more divided attention than “architypal” office applications, although arguably these were never as simple as the more simplistic models suggested. However, the first point also suggests that at a high-level there may be more continuity, and this certainly echoes Carter et al.’s study (Carter et al., 2007) with the importance of informal gathering and communication a life-long goal.

Formal Specification of Social and Collaborative Aspects

With a formal specification, it is possible to “analyze” a system long before it gets designed or implemented. Although this benefit applies to virtually all types of systems, it is interesting to the world of ubiquitous computing where, as we have noted, at the end of the previous section, developing a reliable and robust prototype or application is not an easy undertaking. Formal specifications, therefore, can be useful in supporting the development of ubiquitous applications. On the same note, in ubiquitous computing users perform their activities in the real world settings, where there are other people. In other words, ubiquitous computing involves context, which includes other people besides the user. Therefore, collaborative and social aspects have a lot of weight in ubiquitous computing. It has been rightly noted in (Abowd & Mynatt, 2000) that human beings tailor their activities and recall events from the past based on the presence (or even the help) of other people. Therefore, it is important to consider how we can realize formal specifications that can represent collaborative and social aspects for ubiquitous applications. It is worth observing that much of the research in ubiquitous computing has focused on mobility (and other contextual aspects) with regard to an individual user, with little being done regarding social and collaborative aspects.

One of the possible approaches to the formal modeling of social aspects is through the use of agents. It might be worth investigating to what degree such agent-based models can be applied in ubiquitous computing. One such model is OperA (Dignum et al., 2002a; Dignum et al., 2002b; Dignum, 2004). The authors indicate that the concept of agents is useful for representing organizational interaction for two main reasons. The first is that it enables the reference to any autonomous entity participating in an interaction, including people. The second is that it provides theoretical models for entities and interaction. OperA “abstracts from the specific internal representations of the individual agents, and separates the modeling of organizational requirements and aims. Contracts are used to link the different models and create specific instances that reflect the needs and structure of the current environment and participants” (Dignum, 2004).

It might also be appropriate to borrow a leaf from Grid Computing where the need for models for addressing collaborative and social aspects has been identified (Liu & Harrison, 2002). According to Liu (Liu, 2003), in Grid Computing the development of such models has been based on the early work on information systems (Liu, 2000; Stamper, 1973; Stamper, 1996) and computer-supported collaborative work (CSCW),
Designing for Tasks in Ubiquitous Computing

(Liu et al., 2001). One particular model that has been proposed is the SPS model, which entails the integrated modeling of semantic, pragmatic and social aspects (Liu, 2003). Regarding formal specifications for CSCW in general (and not just under Grid Computing), one interesting effort is the work by Johnson (Johnson, 1999), which describes how formal methods can be used creatively to solve a vast range of design problems within CSCW interfaces. It is worth noting that the work does show how mathematical specification techniques can be enhanced to capture physical properties of working environments, thereby providing a link between the physiological studies from ergonomics and the HCI user interface design techniques.

A related and interesting work is found in (Musolesi et al., 2004), in which there is a proposal of a two-level mobility model that is based on artificially generated social relationships among individuals carrying mobile devices. The generation process respects the mathematical basis of social networks theory and, thus, is grounded in empirical experience of actual social relationships. The second level/stage maps the social organization onto topographical space such that the actual generated topography is biased by the strength of social ties.

At a very low level, more traditional formal models become applicable as we are “below” the level of the more complex considerations of ubiquitous computing. In particular, variations of Fitts’ law have been used extensively to understand and to design interfaces for pointing tasks on tiny devices (Guiard & Beaudouin-Lafon, 2004).

**SUMMARY**

As a way of emphasizing the relevance of the theme of this chapter, it is worth observing that there is a growing interest within the research community regarding tasks in ubiquitous computing. Therefore, it comes as no surprise that we are now seeing the emergence of fields such as activity-centered design (Gay & Hembrooke, 2003), activity-based computing (Bardram, 2005; Bardram & Christensen, 2004), and activity-based ubiquitous computing (Li & Landay, 2006).

As we consider the move from the conventional desktop setting to the real world setting, various design issues and demands arise when we consider the nature of tasks the ubiquitous devices/applications would be expected to support and the real world context in which they will be used. A close study of the nature of tasks in ubiquitous computing has the potential to bring to light some of the requirements in the development of ubiquitous applications.

In particular, we have seen how tasks in ubiquitous environments tend to be more dynamic, less pre-planned, and more situated than those commonly assumed to be the case for more traditional desktop applications. In addition, users are likely to be involved in multiple activities, and the task involving a ubiquitous device may not be the primary task for the user either because there is a real world task(s) such as driving that takes precedence, or because the device interaction is merely supporting an ongoing activity such as social coordination. Interruptions and resumptions of activity become the norm (although there is plenty of evidence that this is also the case in the office) and so the need, as advocated in distributed cognition, to offload memory into the device becomes important.

Because of the dynamic nature of tasks we have discussed, various methods and theories that emphasise the richer nature of human activity, and any methods used to study tasks for ubiquitous interaction have to be open to seeing unexpected patterns of activity. However, there are clearly also generic meta-tasks and common issues found in many ubiquitous interactions including offloading of memory, interruption management, location sensitivity, and so forth. It is essential to understand the former, situation specific issues, in order to avoid designs that
are not fit for that purpose; however, the latter, generic issues, offer the potential for lessons to be learnt across systems and for ongoing fruitful research directions.

INTRODUCTION

In ontological engineering research field, the concept of “task ontology” is well-known as a useful technology to systemize and accumulate the knowledge to perform problem-solving tasks (e.g., diagnosis, design, scheduling, and so on). A task ontology refers to a system of a vocabulary/concepts used as building blocks to perform a problem-solving task in a machine readable manner, so that the system and humans can collaboratively solve a problem based on it.

The concept of task ontology was proposed by Mizoguchi (Mizoguchi, Tijerino, & Ikeda, 1992, 1995) and its validity is substantiated by development of many practical knowledge-based systems (Hori & Yoshida, 1998; Ikeda, Seta, & Mizoguchi, 1997; Izumi &Yamaguchi, 2002; Schreiber et al., 2000; Seta, Ikeda, Kakusho, & Mizoguchi, 1997). He stated:

...task ontology characterizes the computational architecture of a knowledge-based system which performs a task. The idea of task ontology which serves as a system of the vocabulary/concepts used as building blocks for knowledge-based systems might provide an effective methodology and vocabulary for both analyzing and synthesizing knowledge-based systems. It is useful for describing inherent problem-solving structure of the existing tasks domain-independently. It is obtained by analyzing task structures of real world problem.

... The ultimate goal of task ontology research is to provide a theory of all the vocabulary/concepts necessary for building a model of human problem solving processes. (Mizoguchi, 2003)

We can also recognize task ontology as a static user model (Seta et al., 1997), which captures the meaning of problem-solving processes, that is, the input/output relation of each activity in a
problem-solving task and its effects on the real world as well as on the humans’ mind.

BACKGROUND

Necessity of Building Task Ontologies as a Basis of HCI

It is extremely difficult to develop an automatic problem-solving system that can cope with a variety of problems. The main reason is that the knowledge for solving a problem varies considerably depending on the nature of the problems. This engenders a fact that is sometimes ignored: Users have more knowledge than computers. From this point of view, the importance of a user-centric system (DeBells, 1995) is now widely recognized by many researchers. Such framework follows a collaborative, problem-solving-based approach between human and computer by establishing harmonious interaction between human and computer.

Many researchers implement such a framework with a human-friendly interface using multimedia network technologies. Needless to say, it is important not only to apply the design principles of the human interface but also principle knowledge for exchanging meaningful information between humans and computers.

Systems have been developed to employ research results of the cognitive science field in order to design usable interfaces that are acceptable to humans. However, regarding the content-oriented view, it is required that the system can understand the meaning of human’s cognitive activities in order to capture a human’s mind.

We, therefore, need to define a cognitive model, that is, to define the cognitive activities humans perform in a problem-solving/decision-making process and the information they infer, and then systemize them as task ontologies in a machine understandable manner in order to develop an effective human-computer interaction.

Problem-Solving Oriented Learning

A task with complicated decision making is referred to as “Problem-Solving Oriented Learning (PSOL) task” (Seta, Tachibana, Umano, & Ikeda, 2003; Seta & Umano, 2002). Specifically, this refers to a task that does not only require learning to build up sufficient understanding for planning and performing problem-solving processes but also to gain the ability/skill of making efficient problem-solving decisions based on sophisticated strategies.

Consider for example, a learner who is not very familiar with Java and XML programming and tries to develop an XML-based document retrieval system. A novice learner in a problem-solving domain tries to gather information from Web resources, investigates and builds up his/her own understanding of the target area, and makes plans to solve the problem at hand and then perform problem-solving and learning processes. Needless to say, a complete plan cannot be made at once, but is detailed gradually by iterating, spirally, those processes while applying a “trial and error” approach. Thus, it is important for a learner to control his/her own cognitive activities.

Facilitating Learners’ Meta Cognition through HCI

In general, most learners in PSOL tend to work in an ad hoc manner without explicit awareness of meaning, goals and roles of their activities. Therefore, it is important to prompt construction of a rational spiral towards making and performing efficient problem-solving processes by giving significant direction using HCI.

Many researchers in the cognitive science field proposed a concept whereby metacognition plays an important role to acquire and transfer expertise (Brown, Bransford, Ferrara, & Campione, 1983; Flavell, 1976; Okamoto, 1999). Furthermore, repeated interaction loops between metacognition activities and cognition activities play an
important role in forming an efficient plan for problem-solving and learning processes.

Figure 1 shows the plan being gradually detailed and refined along the time axis. Figure 1(a) is a planning process when a learner has explicit awareness of interactions and iterate metacognition activities and cognition activities spirally, while Figure 1(b) is a planning process with implicit awareness of them. In PSOL, monitor and control of problem-solving/learning processes are typical activities of metacognition while their performances are ones of cognition. It is natural that the former case allows efficient plans for problem-solving workflow more rapidly than the latter. Without explicit awareness of interaction loops, a learner tends to get confused and lose his/her way because nested structures of his/her work and new information of the target world impose heavy loads.

Therefore, it is important to implement an HCI framework that enables effective PSOL by positioning a learner at the center of the system as a subject of problem solving or learning, and providing appropriate information to prompt the learner’s metacognition effectively.

**MAIN ISSUES IN TASK ONTOLOGY-BASED HCI**

In this section, we introduce our approach to supporting PSOL to understand task ontology based HCI framework.

Rasmussen’s (1986) cognitive model is adopted as a reference model in the construction of the task ontology for supporting PSOL. It simulates the process of human cognition in problem-solving based on cognitive psychology. Cognitive activity in PSOL is related to this model based on which PSOL task ontology is constructed. This provides a learner with useful information for effective performance of cognitive activity at each state, according to the theoretical framework that was revealed in the cognitive psychology.
Rasmussen’s (1986) Cognitive Model

Figure 2 represents an outline of Rasmussen’s cognitive model known as the ladder model.

Activities in PSOL broadly comprise activities in connection with a problem-solving act and activities in connection with a learning act (see Figure 3 in the next section).

An Activation activity in Rasmussen’s cognitive model corresponds to the situation in which a problem is given in problem-solving activities, or one in which a learner detects change in the real world. An Observe activity corresponds to observing the details of the change or a gap from the problem-solving goal. An Identify activity corresponds to identifying its possible cause. An Interpret activity corresponds to interpreting the influence of the change on problem solving and deciding the problem-solving goal. A Define Task activity corresponds to determine a problem-solving task for implementing it based on the problem-solving goal. A Formulate Procedure activity corresponds to setting up a problem-solving plan to solve the problem-solving task.

Although basically the same correspondence applies in learning activities as the case of problem-solving activities, the object of learning activities, mainly focuses on the state of one’s own knowledge or understanding, that is, metacognition activities. Namely, the Activation activity in Rasmussen’s cognitive model corresponds to detecting the change of one’s own knowledge state. The Observe activity corresponds to observing details or a gap from its own understanding state (goal state) decided as a goal of learning. The Identify activity corresponds to identifying its possible cause. The Interpret activity corresponds to interpreting the influence of its own understanding state, especially the influence on problem solving in PSOL, and deciding the goal of learning. The Define Task activity corresponds to setting up a learning task for implementing it based on the problem-solving goal. The Formulate Procedure activity corresponds to setting up a learning plan to solve the problem-solving task.

Clarifying a correspondence relationship between the cognitive activity by a learner in PSOL and the cognitive activity in Rasmussen’s cognitive model permits construction of a problem-solving-oriented learning task ontology as a basis of human-computer interaction comprehending the properties of PSOL appropriately. Implementing an interaction between a system and a learner based on this allows the system to show effective information to encourage the learner’s appropriate decision-making.

Cognitive Model in Problem-Solving Oriented Learning

Figure 3 shows a cognitive model that captures detailed working processes of a learner. This model is PSOL task specific while Rasmussen’s model is a task independent one. By making the correspondence between these models, we can define an HCI framework based on Rasmussen’s theory.
Figures 3(i) and 3(iii) represent the planning process of the problem-solving plan and learning plan, respectively, and 3(viii) and 3(x) represent problem-solving and learning processes in Figure 1, respectively. Figures 3(v) and 3(vi) represent the monitoring process.

We have presented a problem, say, “developing an XML based document retrieval system” in the upper left corner. Two virtual persons, a problem-solving planner and learning process planner in the learner, play roles of planning, monitoring, and controlling problem-solving, and learning processes, respectively.

With PSOL, a learner first defines a problem-solving goal and refines it to sub-goals which contribute to achieving goal G (Figure 3(i)). They are refined to feasible problem-solving plans (Figure 3(ii)); thereafter, the learner performs them to solve the problem (Figure 3(viii)).

If the learner recognizes a lack of knowledge in the sub goals and performs problem-solving plans, we can generate an adequate learning goal (LG) to get knowledge (Figure 3(iii)) and refine it to learning process plans (Figure 3(iv)). In learning processes (Figure 3(x)), s/he constructs knowledge (Figure 3(iv)) to be required to plan and perform the problem-solving process. Based on constructed knowledge, s/he or he specifies and performs the problem-solving processes (Figure 3(viii)), to change the real world (Figure 3(vii)). The learner assesses gaps among goal states (GS), current goal states (CGS) of problem-solving process plans, and current state (c-state) of the real-world (Figure 3(v)) and ones among learning goal states.
(LGS), current learning goal states (CLGS) of learning process plans and understanding state (Figure 3(vi)). She or he continuously iterates these processes until the c-state of the real world satisfies the GS of problem solving.

It is notable that learners in PSOL have to make and perform not only problem-solving plans, but also learning plans in the process of problem solving. Furthermore, it is important for the learner to monitor real-world changes by performing problem-solving processes and to monitor his/her own understanding states by performing learning processes and checking and analyzing whether states of the real world and understanding states satisfy defined goal states (Figures 3(v) and 3(vi)). The gap between current states and goal states causes the definition of new goals to be dissolved.

Consequently, PSOL impels a learner to perform complicated tasks with heavy cognitive loads. A learner needs to manage and allocate the attentional capacity adequately because of limited human attentional capacity. This explains why a novice learner tends to get confused and lose his/her way.

**Task Ontology for Problem-Solving-Oriented Learning**

Figure 4 presents an outline of the PSOL Task Ontology (Problem-Solving-Oriented Learning Task Ontology). Ovals in the figure express a cognitive activity performed by a learner in which a link represents an “is-a” relationship.

The PSOL task ontology defines eight cognitive processes modeled in Rasmussen’s cognitive model as lower concepts (portions in rectangular box (a) in the figure). They are refined through an is-a hierarchy to cognitive activities on the meta-level (meta activity), and cognitive activities on the object level (base activity). Moreover, they are further refined in detail as their lower concepts: a cognitive activity in connection with learning activities and a cognitive activity in connection with problem-solving activities. Thereby, a conceptual system is constructed that reflects the task structure of PSOL. For example, typical metacognition activities that a learner performs in PSOL, such as “Monitor knowledge state” and “Monitor learning plan,” are systematized as lower concepts of metacognition activities in the Observe activity.

Figure 5 shows a conceptual definition of an act that identifies a possible cause of why a plan is infeasible. All the concepts in Figure 5 have a conceptual definition in a machine readable manner like this, thus, the system can understand what the learner tries to do and what information he/she needs.

Cause identification activities defined include: the actor of the activity is a learner; a learner’s awareness of infeasibility becomes an input (in%symptom in Figure 5); the lower plan of an target plan that the learner tries to make it feasible now is made into a reference information (in%reference in Figure 5). Moreover, this cognitive activity stipulates that a learner’s awareness of causes of infeasibility is output (out%cause in Figure 5). The definition also specifies that the causes of the infeasibility include (axioms in Figure 5): that the sufficiency of that target plan is not confirmed (cause1 in Figure 5); that the feasibility of a lower plan, small grained plan that contributes to realize the target plan, is not confirmed (cause2 in Figure 5); and that the target plan is not specified (cause3 in Figure 5). Based on this machine understandable definition, the system can suggest the candidate causes of infeasibility of the object plan, and the information the learner should focus on.

Making this PSOL task ontology into the basis of a system offers useful information in the situation that encourages appropriate decision-making. This is one of the strong advantages using PSOL task ontology.
Figure 4. A hierarchy of problem-solving-oriented learning task ontology

Figure 5. A definition of “identify c-state of NT in executable plan”
An Application: Planning Navigation as an Example

The screen image of Kassist, a system based on the PSOL Task Ontology, is shown in Figure 6. Kassist is an interactive open learner-modeling environment. The system consists of six panels. A learner describes a problem-solving plan, own knowledge state about the object domain, and a learning process in each panels of (a), (b), and (c), respectively. Furthermore, a learner can describe the correspondence relationship between the problem-solving process placed at (a) and the concept of (b), that is, the correspondence relationship with the knowledge of the object domain required for carrying out the process of (a); and the correspondence relationship between the learning process placed at (c), and the concept of (b), that is, the correspondence relationship with the learning process of (c) which constructs an understanding on the concept of (b). Each shaded node in (b) represents either “knowing” or “not knowing” the concept. A learner can describe the correspondence of the concepts and processes in the object world placed on (a), (b), and (c) with resource (f), used as those reference information, so that appropriate information can be referred to when required.

This provides a learner with an environment in which she or he can externalize and express her own knowledge; it then encourages his or her spontaneous metacognition activities such as the Activation activity and Observation activity in Rasmussen’s model. Moreover, we can implement a more positive navigation function that encourages a learner’s metacognition activity.

Figure 6. Interactive navigation based on problem solving oriented learning task ontology
in the subsequent cognitive process by making ontology the basis of a system.

Consider, for example, this task “Investigate how to develop XML-based document retrieval system”. Assume a situation where a learner does not know how to tackle this task:

i. In this situation, a learner clicks the “Investigate how to develop XML-based document retrieval system” node on (e); among the lower learning plans connected by the “part-of” links, a plan “Learn how to design module structure”, whose feasibility is not secured is highlighted based on the ontology; and a learner is shown the causes of infeasibility with a message “connected lower plan is not feasible”.

ii. Then, it shows the cause as a learner has lack of knowledge to specify the plan.

iii. Moreover, plans influenced by the infeasibility of this learning plan are displayed in the interpretation process.

iv. Here, a problem-solving plan “Design module structure” is highlighted. Such navigation allows a learner to comprehend knowledge required to carry out problem-solving and to understand at what stage in a problem-solving process such knowledge is needed and their influence.

Thus, a learner can conduct appropriate decision-making by acquiring detailed knowledge based on this modular design method.

A series of cognitive activities are typical metacognition activities in PSOL. They include: a learner’s awareness of feasibility of a learning process as a start; monitoring one’s own knowledge state; comprehending its influence on a problem-solving plan; and building a learning plan for mastering knowledge required for problem solving. Reference to the appropriate information offered by a system to a learner encourages his or her appropriate metacognition activities, which help implement effective PSOL.

FUTURE TRENDS

Ontology-Aware System

The systems which support users to perform intelligent tasks based on the understanding of ontologies are called “ontology aware systems” (Hayashi, Tsumoto, Ikeda, & Mizoguchi, 2003). Systemizing ontologies contributes to providing theories and models, which are human-orientated to enhance systems’ abilities of explanation and reasoning. Furthermore, from the viewpoint of system development, building systems with explicit ontologies would enhance their maintainability and extendability. Therefore, future work in this field should continue developing systems that integrate ontology and HCI more effectively.

CONCLUSION

This article introduced a task ontology based human computer interaction framework and discussed various related issues. However, it is still difficult and time consuming to build high quality sharable ontologies that are based on the analysis of users’ task activities. Thus, it is important to continue building new methodologies for analyzing users’ tasks. This issue should be carefully addressed in the future, and we hope more progress can be achieved through collaboration between researchers in the fields of ontology engineering and human computer interaction.

Chapter 2.33
Social Networking Theories and Tools to Support Connectivist Learning Activities

M. C. Pettenati
University of Florence (IT), Italy

M. E. Cigognini
University of Florence (IT), Italy

ABSTRACT
This article considers the affordances of social networking theories and tools to build new and effective e-learning practices. We argue that “connectivism” (social networking applied to learning and knowledge contexts) can lead to a reconceptualization of learning in which formal, nonformal, and informal learning can be integrated as to build potentially lifelong learning activities to be experienced in personal learning environments.” In order to provide a guide in the design, development, and improvement both of personal learning environments and in the related learning activities, we provide a knowledge flow model highlighting the stages of learning and the related enabling conditions. The derived model is applied in a possible scenario of formal learning in order to show how the learning process can be designed according to the presented theory.

TOWARDS AN E-LIFELONG LEARNING EXPERIENCE
Formal, nonformal, and informal learning have become subjects of study and experimentation as for their potentialities to be carried on through the network. The pervasiveness of telematic technologies in current learning and knowledge processes justifies the hopes of success and emerging approaches become always more open, destructured, and nonformalised. According to this vision, formal, informal, and nonformal learning can be seen, such as integration of actions and situations, that can be developed both in the network and in
physical contexts. New reflections can therefore be made on the practice known as e-learning, starting from a revision of these dimensions. **Formal learning** has been defined as a type of learning that occurs within an organized and structured context (formal education, in-company training) and is intentional from the learner’s perspective. Normally it leads to a formal recognition (diploma, certificate) (Cedefop, 2000; European Commission, 2000). As regards adults e-learning, formal education in the last decade has encountered and experimented a sort of paradox that often witnessed low returns in terms of knowledge acquisition, compared to cost investment, which is often significantly high. **Nonformal learning** has been defined as learning embedded in planned activities that are not explicitly designated as learning, but that contain an important learning element. Nonformal learning is intentional from the learner’s point of view (Cedefop, 2000). **Informal learning** is learning resulting from daily life activities related to work, family, or leisure. It is often referred to as experiential learning, and can, to a certain degree, be understood as “accidental” learning. It is not structured in terms of learning objectives, learning time, and/or learning support. Typically, it does not lead to certification. Informal learning may be intentional but in most cases, it is nonintentional (or incidental/random) (Cedefop, 2000). Informal learning is an adaptive process determined by the exploration need, which is realised in specific experiential contexts (Calvani, 2005). People acquire their competence in everyday life, talking, observing others, trying and making mistakes, working together with colleagues more or less expert. Informal learning can therefore be intended as the natural corollary of daily life (Bonaiuti, 2006). **Intentionality** of learning is a discriminating factor shifting “nonformal” learning in “nonintentional” or “incidental” learning; contrary to what happens in formal learning, informal learning is not necessarily intentional and can be nonrecognized sometimes from the subject himself/herself as knowledge and competence acquisition (Cross, 2006). According to this perspective, aimed at retrieving and valuing the potentialities embedded in spontaneous contexts, in this case the network, the emerging domain of study of **informal e-learning** is receiving greater attention because of the widespread of social networking practices and technologies. The online transposition of the social network is nowadays referred to as “social networking” phenomena, and it is related to a set of available technologies and services allowing individuals to take part in network-based virtual communities. Social networking is emerging as a highly natural practice because it is deeply rooted in our daily practice; spontaneous relations, interactions, and conversations support informal learning practices, contributing to the creation and transmission of knowledge. In informal learning practices, the social behaviour and the support of technologies converge toward the “network”; a network made by people and resources, a social network, unified by personal needs or common goals, interaction policies, protocol and rules, and telematic systems all together favouring the growth of a sense of belonging to the “net” community.

At the same time, the culture of **lifelong learning** is gaining importance as one of the most effective answers to face the challenges brought by the information and knowledge society (Siemens, 2006): the rapid obsolescence of professional knowledge and skills requires updating and continuous training as well as recurring and personalised learning. Under these premises, the domain of e-lifelong learning is being configured as a sociotechnical system in which knowledge and learning are both the form and the content as for their social and relational meaning. The subject undergoing an e-lifelong-learning experience crosses this territory doing practices and strategies of continuous interconnection and com-
In this work the informal e-learning area constitutes a modularization of the educational sociotechnical system towards the full enactment of a lifelong-learning experience that could value the subject as for his personal and professional characteristics.

In 2004 the paper “Connectivism: A learning theory for the digital age” (Siemens, 2004) launched the theory of connectivism based on a critique of previous main learning theories synthetically labelled as behaviourism, cognitivism, and constructivism. According to Siemens, even the latter theory, which appeared to be the possible theoretical framework for e-learning practices (more specifically in its variant named “social constructivism”) could not provide an adequate theoretical support to the instances brought by the new learning approaches. To fill this gap, Siemens introduced the connectivism theory. According to this author, “The pipe is more important than the content within the pipe,” meaning that it is the network itself that is the basis of the learning processes. If the knowledge society requires the individual to continuously update his/her knowledge, this cannot happen as a process of progressive “knowledge accumulation”; instead, this can occur through the preservation of our connections. Learning, as it is also intended in Wenger’s community of practice vision (Wenger, McDermott, & Snyder, 2002) and in Lévy’s collective intelligence work (Lévy, 1996) is seen as a mainly social activity. In this perspective, the true competence for a lifelong learner of the knowledge society would be the capability to “stay connected” and “belong” to digital communities with which interests are and can be continuously shared. Owning a given piece of information is less important than knowing where and how to retrieve it.

Hereafter we will refer to e-lifelong learning as a possibility that each knowledge society citizen has to build: an individual and personalised lifelong-learning experience that will come across formal, nonformal, and informal learning stages with various degrees of uses of technology. In this domain, theoretical reflection and applied research is still at the beginning.

In this paper we try to provide a reference knowledge flow model to support the design of learning experiences in a networked environment accounting for new practices and technologies of social networking currently widespread in the Internet. The model aims also at giving suggestions to designers of personal learning and personal knowledge management environments in order to maximize the advantages deriving from the effective networking to enhance and improve learning and knowledge management functions.

To this extent, in paragraph 2, we analyse the affordances brought by the connectivist learning environment. In paragraph 3 we discuss the new buzz word of the domain e-learning 2.0 as a pretext to highlight methodology’s and technology’s role in learning. In paragraph 4 we introduce the conceptual view of a personal learning environment as a place where lifelong learning experience can occur. Then, in paragraph 5 we revise the social network technological applications that can serve the scope of the personal learning environment features. In paragraph 6 we discuss how learning can take place in such a context, introducing a knowledge flow model highlighting the learning stages and related enabling conditions in a connectivist environment. Eventually, in paragraph 7, we illustrate how the model of paragraph 6 can be applied in a formal learning situation of a possible higher education scenario.

AFFORDANCES OF LEARNING IN A CONNECTIVIST ENVIRONMENT

Scenarios, which become always more common, highlight that through informal channels, new learning and knowledge management spaces are more easily enabled, thanks to people and their
ability to “network” and reciprocally learn in a natural and spontaneous way. To synthetically analyse the strengths emerging in the context of learning in social network, we refer to Table 1. From this perspective, the main characteristics of social networks are schematized as for their sharing/cooperation/collaboration features.

The concept of social networks and their characteristics have been studied by Siemens (2006) as for their potential in knowledge management. This author first introduced the term of connectivism in order to make up for the lack of theoretical framework to learning in the digital age: “Research in traditional learning theories comes from an era when networking technologies were not yet prominent. How does learning change when knowledge growth is overwhelming and technology replaces many basic tasks we have previously performed?” (Siemens, 2006). “Knowing and learning are today defined by connections... Connectivism is a theory describing how learning happens in a digital age. Connectivism is the assertion that learning is primarily a network forming process” (2006). Siemens’ statement adds social characteristics to the territory in which learning (lifelong learning) can occur.

Connectivism is characterised by nine principles (2006):

1. Learning and knowledge require diversity of opinions to present the whole… and to permit selection of best approach.
2. Learning is a network formation process of connecting specialized nodes or information sources.
4. Knowledge may reside in nonhuman appliances, and learning is enabled/facilitated by technology.
5. Capacity to know more is more critical than what is currently known.
6. Learning and knowing are constant, on-going processes (not end states or products).
7. Ability to see connections and recognize patterns and make sense between fields, ideas, and concepts is the core skill for individuals today.

Table 1. Social network characteristics (Adapted from Pettenati & Ranieri, 2006b)
8. Currency (accurate, up-to-date knowledge) is the intent of all connectivist learning activities.
9. Decision making is learning. Choosing what to learn and the meaning of incoming information is seen through the lens of a shifting reality. While there is a right answer now, it may be wrong tomorrow due to alterations in the information climate affecting the decision.

According to these principles, learning, as it was already conceptualised in Wenger et al.’s (2002) community of practice vision and in Lévy’s (1996) collective intelligence theory, is seen as a prevalently social activity. “Connectivism is the integration of principles explored by chaos, network, complexity, and self-organization theories. Knowledge and learning are processes that occur within nebulous environments of shifting core elements—not entirely under the control of the individual. Learning, defined as knowledge patterns on which we can act, can reside outside of ourselves (within an organization or a database), is focused on connecting specialized information sets” (Siemens, 2006). Connectivism is therefore social networking applied to learning and knowledge.

A New Role for the Learner: Continuously Change and Be Creative

If from one side we value connectivism as a context in which learning can more favourably occur, thanks to available technological solutions (Fallows, 2006), on the other side we acknowledge that connectivism is also enabled and allowed by an always stronger user participation to the creation, sharing, use, and management of resources (contents, relations, applications, etc.) through social software. Users have certainly become more aware consumers and producers of resources; they have become prosumers.

This radical change of the users’ role is under our eyes; between 2000 and 2004, relevant literature reported about research investigating the possible use of blog tools in education without being capable of bringing credible answers. The use of the tool at that time had not yet entered in the praxis and communicative modality of the people and the potentialities related to the aspects of metareflection and self-evaluation of the blog had not yet clearly emerged (Barrett, 2004; Barret 2006; Banzato, 2006). More recently, the exponential growth of blog use, coupled with the syndication technologies, which added the “relational” dimension to these tools, made the blog one of the most important social networking assets used at the moment. This is just an example that serves to highlight that the determinant variable of the shift in the use of the tool was not due entirely to technology, but also to the spontaneous change in the practice of use together with the overcoming of the diffusion critical threshold that could make the tool an important instrument in learning (formal, informal, nonformal) processes. Another relevant mark of this change in the users’ role is related to recent news; in December 2006, all the blogosphere rumoured about TIME magazine’s cover title: “TIME’s Person of the Year for 2006 is you.” According to Lev Grossman (2006), author of this news, the explosive growth and the enormous influence of the user-generated content (such as blogs, video sharing sites, etc.) should be read in a new way: “But look at 2006 through a different lens and you’ll see another story, one that isn’t about conflict or great men. It’s a story about community and collaboration on a scale never seen before. It’s about the cosmic compendium of knowledge Wikipedia and the million-channel people’s network YouTube and the online metropolis MySpace. It’s about the many wrestling power from the few and helping one another for nothing and how that will not only change the world, but also change the way the world changes.”
“E-LEARNING 2.0” OR JUST “LEARNING”?

Innovation in technology has brought new (or revisited) processes and practices, expressed through new (or revisited) criteria and terms: the possible educational universe of e-learning, formal, informal, nonformal, lifelong coupled with connectivism features has been named (or tagged) e-learning 2.0 or learning 2.0, analogous to what happened for the Web 2.0 phenomena (O’Reilly, 2005). E-learning 2.0 is therefore a tag identifying an open, destructured, immersive, and relational learning process amplifying the learning curve towards the social, relational side of knowledge coconstruction over the net. Stephen Downes (2005) illustrated the main concepts of e-learning 2.0:

1. it is a type of learning that is tied to the interests of the learners,
2. it is an immersive learning that is acquired by doing, realised not only in the class, but also in appropriate environments (for instance museums...),
3. it is a type of learning in which Web 2.0 technologies connect the learners to the rest of the world.

However stated, the focus stays on the attention risen by the affordances that the social-technical connectivist learning environment can engender, in light of a background that remains primarily and unavoidably methodological: the design and development of educational environment is, beyond any revisiting, a learner/learning-centred process.

When knowledge technologies change so radically, they change not only “what” we know, but also “how” we come to know (Laurillard, 2003). Knowledge is the result of a fluid combination of experience values, contextual information, and specialist competences, all together providing a reference framework for the evaluation and assimilation of new experiences and knowledge (Pettenati & Ranieri, 2006b). Norris, Mason, and Lefrere (2003) highlights the recursive, dynamic, and networked character of learning in digital contexts: “Knowledge can be understood as interpreted content, available to a member of a community and always shaped by a particular context. Digital representations of content and context become e-knowledge through the dynamics of human engagement with them. The digital elements of e-knowledge can be codified, combined, repurposed, and exchanged.” The relational aspect of learning and knowledge processes that is proposed in this work is supported by Wilson’s (2002) essay “The nonsense of knowledge management,” in which the author states that: “‘Knowledge’ is defined as what we know: knowledge involves the mental processes of comprehension, understanding and learning that go on in the mind and only in the mind, however much they involve interaction with the world outside the mind, and interaction with others. Whenever we wish to express what we know, we can only do so by uttering messages of one kind or another oral, written, graphic, gestural or even through ‘body language.’ Such messages do not carry ‘knowledge,’ they constitute ‘information,’ which a knowing mind may assimilate, understand, comprehend and incorporate into its own knowledge.” Analogously, we attribute to e-learning a social connotation, for us, e-learning is a type of learning that is somewhat supported by technologies, but it is not necessarily conducted at a distance; it allows interaction between people and contents, and among people but (most important) is a type of learning valuing the social dimension of the underlying knowledge processes (based on Calvani, 2005) definition, freely translated and adapted by the authors). The presence of the “e-” before all learning and knowledge concepts is therefore now being abandoned by many researches to underline that pervasiveness of technologies do not differentiate any more “traditional” contexts from “virtual”
Social Networking Theories and Tools to Support Connectivist Learning Activities

ones. The “traditional” concepts of learning and knowledge, newly restated and deprived by the Internet-ic “e-,” globally revolutionize the education and knowledge systems, both in the practices and in the social processes they imply. As the learner in an early stage of the knowledge society had to change and shift identities and practice to access the same processes over the network (Liguorio & Hermas, 2005), so the learning and knowledge practices regain possession of their integrity to come back to their original complexity, now completed and evolved by technologies but not distorted by the same technologies.

**Personal Learning Environments as New Learning Landscapes**

In this scenario, many of the innovative technolo-
gies of the so-called “social software” (see next paragraph) are now playing a crucial role as a support to learning and knowledge processes. This does not mean that the scaffold provided up to now by a formalised online educational envi-
ronment is to be entirely rebuilt, but the current “extended cognitive context” (environmental, situational, cultural characteristics) in which the learning dynamics occur must reshape the learning environment itself (Bonaiunti, 2006). Metaphorically getting out from the often narrow space of the learning/course/content management systems is equivalent to the reasoning conducted up to now: learning does not take place only in classes, for a limited period of time, and under specific certification conditions but (in light of the sociotechnical context now available) can easily take place in nonformal, informal, lifelong settings, prospecting new, challenging and interesting development perspectives. Most evidently, according to this perspective, new coordination and integration needs emerge, as for the experiences conducted in heterogeneous systems, from the functional and from the pedagogical and methodological viewpoints. A new technological solution is never a didactic solution, Quite the opposite, it urges to be considered after the methodological design has been carried out, in order to properly balance the use of the tools with respect to learning objectives, learners, available resources, and infrastructures (Ranieri, 2005). Stating that the “social software” (or Web 2.0) technological apparatus has great educational potentials would be reductive and misleading; which type of learning can occur and under which conditions and ways this learning can oc-
cur should always be methodological priorities to be accounted for during instructional design. The shift required at this stage of the reasoning can be conducted with the avail of a specific environment, personalised on the needs and the competences of the learner, which could always be a “door” to enter learning experiences and a “glue” to support the learner in mastering the heterogeneity of his learning experiences, easily jumping across formal, informal, unexpected, and intentional learning activities (Conner, 2004). This “door-glue-environment” is represented in the hopes of the practitioners of this domain, and in concrete available solutions, by personal learning environments (PLE) that are a “concretization of operational spaces in the network where the subject is at the centre of his network of learning resources” (Bonaiuti, 2006).

PLEs represent the temporal horizon through which we look at the potential lifelong learning of a subject (Tosh, 2005; Tosh & Werdmuller, 2004); they are an open, transversal, and personal environment intercepting and capitalizing learners competences and skills by aggregating, publishing, combining, and integrating diverse and distributed resources and contents. E-portfolios are another way to name PLEs (e-Portfolio, 2006); “an e-portfolio can be seen as a type of learning record that provides actual evidence of achievement. Learning records are closely related to the Learning Plan, an emerging tool that is being used to manage learning by individuals, teams, communities of interest and organizations.” The attention given recently
to this topic at the eStrategy conference on e-Portfolio (Baker, 2006) is but another evidence of the rising importance of studying this field. “In the context of a knowledge society, where being information literate is critical, the portfolio can provide an opportunity to demonstrate one’s ability to collect, organise, interpret and reflect on documents and sources of information. It is also a tool for continuing professional development, encouraging individuals to take responsibility for and demonstrate the results of their own learning. Furthermore, a portfolio can serve as a tool for knowledge management, and is used as such by some institutions.”

Technology to Support the Learning Experience

The further step in the analysis leads us to the problem of evaluating and devising which tools and technologies exist or can be developed in order to match the requirements and purposes of the personal learning environment. Technologies and tools now referred to as Web 2.0 software (Fallows, 2006; Hinchcliffe, 2006; O’Reilly, 2005) certainly provide both the origin of this reasoning as well as the goal at which to aim. Sharing Paul McFedries (McFedries, 2006) tentative definition according to which Web 2.0 is “a second phase of the evolution of the World Wide Web in which developers create Web sites that act like desktop programs and encourage collaboration and communication between users,” we focus on the characteristics of the Web 2.0 applications, highlighting the social perspective of relation, collaboration, and user-participated architecture (McFedries, 2006):

1. content is user-created and maintained (peer production, user-content ecosystem),
2. user-created and maintained content require radical trust,
3. application usability allows rich user experience,
4. combining data from different sources leads to creation of new services,
5. services get better as the number of users increase in an architecture of participation.

WEB 2.0 TOOLS

Folksonomies, cobrowsing, tagging, and social networking are “2.0” practices. The fil rouge they share is that they all are expressions of a shared, diffused cognitive strategy for information retrieval in a spontaneous way, as support to social sharing tools (such as social bookmarking tools, image sharing tools, blog search engines, etc.). Through social tagging, the member of the community defines a link among resources (sites, images, videos, audios, etc.) and the terms used to describe them (Bonaiuti, 2006). This is a bottom-up process, starting from a single user adding a link to a Web site and tagging it at his complete discretion, using keywords that are meaningful to himself/herself. Social sharing tools can display these tags through using a visual approach (which increases the font size of most popular tags), thus realising tag clouds that immediately provide users with a perception of the popularity of the tags. This “folksonomic” classification method, which relies on the spontaneous users’ contributions (be he/she an author or a sporadic resource user), leads to results capable of reflecting the information according to the conceptual model of the population that creates it (Bonaiuti, 2006). Representing information in classificatory structure is information in itself: classification incorporates information and provides the interpretation context that (in its globality) appears transparent, objective, and neutral (Surowiecki, 2004).

Practices and applications described as an example implement ideas derived from “social network theory,” which sees social relations expressed through nodes and links in which nodes represent the subjects in the network and
the links represent relations between subjects. Under this theoretical basis, these applications explicitly represent relations favouring the interconnection among subjects based on interest, competence, hobby, research goals, study, work, and so forth (Fini, 2006). Social networking is

*continued on following page*
the connective tissue in which new applications emerge daily, allowing us to creatively use them for learning purposes. The following table reports a synthetic view of some of the currently available applications matching this philosophy; however, the list is neither complete nor exhaustive, and is intended just to be a memorandum for personal learning environment designers.

**A MODEL FOR EFFECTIVE LEARNING EXPERIENCE**

To comply with the objectives detailed in the previous paragraphs, we hereafter propose a schema to illustrate a (simplified) knowledge flow in a connectivist environment. This model is the result of a re-elaboration of four models:

- the online collaboration model presented in Calvani (2005), which was the starting point of our analysis; this model accounts for effectiveness conditions and principles that are considered to be fundamental for collaboration, as highlighted in reference literature (Dillenbourg, Baker, Blaye, & O’Malley, 1996). However, while in Calvani (2005) the model is conceived to provide useful steps to support an online collaborative group, the model is rooted in a formal educational context;
- the second model studied is the one presented in Ranieri (2006); this model accounts for individual and collaborative knowledge construction processes, but it is not specifically conceived focused on telematic environments, and does not account at all for collaboration enabling conditions;
- the third and fourth models are those presented in Pettenati and Ranieri (2006a, 2006b) in which the authors tried to focus on framing the reasoning in a social networking context in order to account for the benefits of informal learning and online collaboration, as described in the previous paragraphs of this paper. Nonetheless, that model did not account for the knowledge flow (or learning stages) occurring in an online learning experience, thus being only partially helpful in the design of a learning experience.
After having confronted the previous three models with the knowledge flow presented in Siemens (2006), the idea of the model was repurposed in light of the “connectivist” idea of the author’s work, thus leading to a new design of the model now focused on highlighting the possible stages on an effective connectivist learning experience. In this new version, the schema can provide more concrete help in the design of online learning activities, as will be detailed in section 7, using an example. In Figure 1, the transformation processes that involve personal comprehension and knowledge as well as social knowledge creation are illustrated in order to highlight some important processes that should occur during an effective learning experience. Rectangles in Fig. 1 represent the knowledge processes whose results can be concretized in various forms of knowledge (not illustrated in Figure 1) such as enunciations, argumentations, justification, shared meanings, collaborative knowledge, cultural artefacts, and so forth (Ranieri, 2006).

The schema in Figure 1 has no claims to be exhaustive neither perfectly accurate, as knowledge processes are complex, fluid, iterative, and certainly not univocally directed, thus leading to various relations among the composing elements (represented by rectangles in Figure 1). However this schema will be used in section 7 to drive the choice of methodologies and available technologies and their combination in order to serve the educational needs in a possible higher education scenario.

**Enabling Conditions**

The model in Fig. 1 envisages five subsequent stages (or knowledge processes) that are at the heart of the schema. The processes are framed by an external layer, where the enabling conditions that are relevant for the knowledge processes development are highlighted:

*Figure 1. Knowledge process in a connectivist environment: stages of the learning experience and enabling conditions*
1. **Basic skills:** The acquisition of basic technological as well as online-comunicational skills is fundamental (Ranieri, 2006) to allow the subject to positively enter and live the informal and potentially lifelong educational experience; the lack of these conditions can compromise the success of the entire learning initiative;

2. **Generation and support to motivation:** In informal e-learning contexts the motivation is spontaneous; it is often induced by fun and pleasure that individuals have in their network activity; it is also rooted in the positive interaction among people (a subject can more effectively and efficiently pursue his objective if the other subjects pursue theirs);

3. **Meaning perception:** The subject must perceive as really meaningful (useful to himself/herself) the objectives attainable in the learning activities and acknowledge that collaboration can derive real advantage; during the collaboration phases, supporting the individual self-perception of usefulness allows the subject to perceive the significance of its contribution to group activities in order to consider himself a useful contributor to other’s goals;

4. **Group culture:** The awareness of being useful to other community members increases the self-esteem and self-perception of usefulness of the individual and fosters the motivation for a wider visibility (for instance being linked, have positive reputation, produce and/or propose new contents). These factors increase the sense of positive group membership;

5. **Social climate:** In an informal environment, the sense of belonging (membership) to a group is spontaneously supported by the intensity of sharing interests on a topic; regardless of the expertise (which can be widely nonhomogeneous among members) it is still the awareness of the positive interaction with others that sustains mutual understanding and social grounding; in this context the (often tacit) agreement of respect, use of reputation feedback, and respect of a common socioquette, contribute to build a positive social climate, making the online relational environment a “trusted” environment.

### Stages of the Learning Experience

In the centre of Figure 1, a simplified schema of the stages of a connectivist learning experience are schematized:

1. **Awareness and receptivity:** Siemens (2006) points out, in this stage, individuals get used to “handling knowledge abundance,” and are first confronted with resources and tools of the new learning habitat. If this stage is not sustained by a proper motivational context as well as the acquisition of basic skills, as detailed in paragraph 5.1, this phase can become a frustrating experience and often cause the learner to drop out from the learning environment.

2. **Connection forming and selection filtering:** In this stage, individuals begin to use tools and understanding acquired during the previous stage to create and form a “personal network” of resources (people and contents). At this point the learners start to be active in the learning space in terms of “consuming or acquiring new resources and tools” (Siemens, 2006). Affective and emotive factors such as fun, pleasure, positive interaction, and increasing sense of meaning are crucial to building the roots of an effective “personal learning network” (ibidem).

3. **Contribution and involvement:** “In this stage the learner begins to actively contribute to the learning network, essentially,
Social Networking Theories and Tools to Support Connectivist Learning Activities

becoming a ‘visible node.’ The learner’s active contribution and involvement allows other nodes on the network to acknowledge his/her resources, contributions, and ideas, creating reciprocal relationships and shared understandings (or, if social technology is used, collaboratively-created understandings)” (ibidem). In this stage group culture and social climate are key factors enabling the individual participation and involvement.

4. **Reflection and Metacognition:** Reflection on the knowledge processes and products, self-reflexivity, and self-evaluation as well as metacognition (thinking about thinking) play a prominent role in this stage. Individuals are actively involved in modifying and rebuilding their own learning network, acting as “network aware and competent” subjects (ibidem). The experience acquired at this stage within the learning network has resulted in an understanding of the nuances of the space and the knowledge inputs, allowing the subject to act both as a provider of valuable support and to help other networked learners as well as being capable of accessing just in time and personalized knowledge to himself/herself.

The learning process depicted can be used as a model to support design of learning activities and environments in different educational sets. An example of this approach will be shown in paragraph 7 to build a “connectivist learning experience” in a possible higher education scenario.

**Building a Connectivist Learning Experience: A Possible Scenario**

This scenario subject is taken by Bonaiuti (2006), but is significantly detailed, revised, and newly implemented according to what is presented in this paper. More specifically, the focus is on building and exploiting a connectivist online environment according to the model in Figure 1, to match the educational purposes.

**Scenario:** Higher education, course in “Urban Sociology,” class topic: “Juvenile behaviour in urban suburbs” (Bonaiuti, 2006). Scenario details: this course envisages 2 hours face-to-face class time and a total of 10 hours to be devoted to autonomous and group work. The teacher wants to structure the face-to-face meeting as a “role playing” activity. The scenario for the role play is the following: participants: a math teacher, a chancellor, two parents, a young boy. The young boy has been caught by the math teacher outside of the school while cutting the teacher’s car wheels. The teacher has reported the happening to the chancellor and the student is now risking expulsion from the school. Debate with arguments in favour of expulsion, neutral, in defence of the student, and reflective, will be played in 1 hour during the face-to-face class meeting.

The model of Figure 1 can be used to help the teacher settle his/her teaching activities. To this extent, the model is exploited during the three phases of class activities: preclass activities, in class activities, postclass activities. Instrumental background: the university in which this scenario is set has installed a learning environment at the disposal of teachers and students who want to avail of it. This environment is a combination of a “traditional” e-learning environment and a “personal learning environment” conceived according to the e-learning 2.0 philosophy, as detailed in the previous part of this work, and opened to students and alumni who want to keep alive their online lifelong learning landscape. Such a combined environment offers both the course and content management system offered by traditional e-learning systems coupled with social-networking creation, sharing, and management tools.
1. Preclass Activities: Focus on Content Management and Sharing

a. **Awareness and receptivity**: teacher gives starting tasks to the student using the blog of the learning environment in the area reserved for the Urban Sociology course. In this post, he/she proposes a selected reference reading (full text of the reading could be stored in the Course Material area) and suggests a vision of three short videos distributed through a video-sharing social network. The assignment for this phase is to prepare the debate that will take place during the face-to-face class: students are divided in five groups; each group is charged to represent one role in the scenario: math teacher, chancellor, two parents, young boy. Each group, in order to get prepared to sustain the arguments and debate, can find external documentation to get closer to the discussed reality of juvenile behaviour in urban suburbs (multimedia resources are allowed, such as podcast, video, text, etc.).

b. **Connection forming, selection, filtering**: in this phase students prepare themselves to work in a group; each group decides how to carry on its task (for instance attribute roles to the group members, share tasks, provide complementary resources, etc.). This work is done in spontaneous modes for each group: some can use the course forum; teacher can open related threads, or can work in synchronous mode using voiceIP tool and sharing ideas and outline, or to dos using the class wiki or a conceptual map tool; teacher can provide a tool area for each group of the course.

c. **Contribution and involvement**: in this phase students actively work using tools and combining resources to come to a shared strategy of discussion for the class meeting. Students post the outline of their argumentations in the course blog or forum (and can tag it with the group name). Students can use the social bookmarking feature of the course environment to organize and share their resources.

2. In-Class Activity: Focus on Content Production

a. **Contribution and involvement**: during the first hour of the class the role-playing game is set. The teacher listens to the debate and uses a mental map tool to synthesize the emerging discourse pattern.

b. **Reflection and metacognition**: after the end of the play, the teacher restates what happened and comments on group contributions. He/she provides ideas and questions for further insights and refrares all the play in the context of the topic of the class, with reference to the selected reading assigned before the class. At the end of the class, both the conceptual maps drawn and the audiorecord of the play are shared on the course environment.

Students are then given the evaluation assignment to be carried in a post-class phase within 15 days. The assignment is a journalist-style individual writing of a possible local newspaper reporting the case of the role play in light of the analysis of the juvenile behaviour in the urban suburbs. Students are asked to post the assignment in their personal blog, tagging it with the course name and class topic.

3. Post-Class Activities: Focus on Knowledge Acquisition

a. **Contribution and involvement**: students will work individually to study and analyze both the material produced by the whole class and the material provided by the teacher. Students can work at the writing using either an online (to have easy backup and document
portability) or desktop word processor, or a wiki (to keep trace of the evolving versions). Eventually they will post the assignment in their personal blog, tagging it as required. The teacher will easily follow the assignment submissions using a syndication system.

b. Reflection and metacognition: to support the production phase the teacher (or a tutor acting on his/her behalf), in the meanwhile, will use the course blog to more deeply comment on the topic or provide further resources, as well as posting comments on students’ posts (both on the blog, or forum or wiki). After the evaluation phase (marks have been given to student’s assignment in a privacy-respectful way), the teacher could invite students to “digg” their preferred writing to highlight them in the school journal.

CONCLUSION

In this article we tried to provide our interpretation of the current sociotechnical educational system shaped by technologies and practices of the “knowledge society” to locate the role of learning and learners in a lifelong perspective. We believe that both users’ attitudes and available technologies are mature enough to let us envisage that each network user could easily engage in a lifelong learning personal experience if properly lead by appropriate methodologies, and sustained by accordingly designed and developed personal learning environments.

To this extent we provided a model to schematize the knowledge flow occurring during an effective learning experience in a connectivist environment. The purpose of this model is two-fold: from one side it can be used by personal learning-environment designers as a guideline for checking if all phases and enabling conditions are supported by the integrated tools; on the other side it can be used by instructors or designers to set up learning activities. The provided model has some common points with other models at the state of the art; for instance in Salmon (2002), the author provided a staged model for online collaboration activities oriented to knowledge construction; however, that model, and the related implementations and example presented in the essay, was developed in the “1.0” age, where neither technology nor people practice was mature enough in the sense of social networking perspective. We believe that a connectivist revision of this theory is now necessary, and this work intended to be a contribution in this sense. As a conclusion of the paper, we provided a sample application of the model using the scenario. The scenario setting chosen for this purpose is a formal learning higher education context; this choice should not be read as contrasting with the lifelong perspective of learning claimed throughout this work. Instead, it should be read as a preparatory activity that could enter in people’s practice diffused by a formal context but (once mastered as skill) potentially applied in all other nonformal and informal learning contexts.

Applying the knowledge processes flow model in other scenarios such as professional training in enterprises, as well as refining and detailing the model to these purposes, could be an object of future study. Many other issues are still open for further investigation and experimentation: how could a personal learning environment be used to develop pedagogical thinking? How can they be used in professional contexts such as workers for placements/reintegration?, How can the formal educational system be changed as to support self-directed learners?, What arguments can convince politicians (educational and labour ministries) to support individual institutions? These questions, as many others, were not addressed in this work, but can and will be object of future studies. Whether we call it e-learning, e-learning 2.0, lifelong learning, knowledge management or not, the interesting question is to see if and how these approaches can lead us to a true actualization
of a lifelong learning practice for all knowledge society members.

ACKNOWLEDGMENT

We want to thank Prof. Dino Giuli for giving us the possibility to carry on our research in this domain. We are also very grateful to Prof. Antonio Calvani for keeping on asking us stimulating scientific research questions, pushing us to work in order to find possible answers. Moreover, we want to thank the colleagues of the Educational Technology Laboratory and Telematics Technologies Laboratory for the fruitful discussions occurring both in formal and nonformal settings.

ABSTRACT

This chapter examines current research on online learning communities (OLCs), with the aim of identifying user-centered design (UCD) principles critical to the emergence and sustainability of distributed communities of practice (DCoPs), a kind of OLC. This research synthesis is motivated by the authors’ involvement in constructing a DCoP dedicated to improving awareness, research, and sharing data and knowledge in the field of governance and international development. It argues that the sociotechnical research program offers useable insights on questions of constructability. Its attention in particular to participatory design and human-computer interaction are germane to designing user-centered online learning communities. Aside from these insights, research has yet to probe in any systematic fashion the factors affecting the performance and sustainability of DCoP. The chapter concludes with a discussion of UCD principles for online learning community to support the construction and deployment of online learning communities.
INTRODUCTION

Increasingly, distributed communities of practice (DCoPs) are attracting attention for their potential to enhance learning, to facilitate information exchange, and to stimulate knowledge creation across cultural, geographical, and organizational boundaries. Research shows the utility of DCoP on their members is positive (Daniel, Sarkar, & O’Brien, 2004a; Daniel, Poon, & Sarkar, 2005; Schwier & Daniel, Chapter II, this volume). Their allure aside, experience indicates that they may not emerge or flourish even in the presence of demand from users. In fact the process of constructing DCoP is not well understood, and factors influencing sustainability merit further research attention.

This chapter introduces the authors’ involvement in the development of a DCoP. The DCoP in question is the Governance Knowledge Network (GKN). This project began in 2001 with the aim of assessing the interest of academics and practitioners in Canada to develop an online learning community (OLC) for systematizing the exchange of information at the intersection of governance and international development (Daniel et al., 2004a). The surveys of key Canadian stakeholders in the project indicated considerable data existed, and recommended the proposed GKN to: actively engage in dissemination and archiving of data not widely accessible in the public sphere, profile community members, promote social network building and collaboration, and inform members of current events and opportunities.

Following the identification of the demand and interest, the second stage of our research involved the development of a GKN prototype. In this unchartered course, we were guided by enabling technology and other DCoP models (World Bank, UNDP). We also turned to research to inform our efforts on how to effectively sustain the project. Our synthesis of research in the area identified promising insights from studies we refer to as the sociotechnical approach. As applied to DCoP, the sociotechnical approach aims at understanding people’s interaction with technology and the ensuing communication, feedback, and control mechanisms necessary for people to take ownership of the design and implementation process.

This chapter focuses on this interaction, as it is germane to the development and sustainability of the GKN, in particular, and DCoP more generally. The chapter is divided into the following sections. The next section outlines relevant research on DCoPs and the sociotechnical approach. We next provide an overview of the GKN OLC project and present key results from the research that informed the design of the GKN. A discussion of various human and technology elements we consider critical to the initiation, development, growth, and sustainability of the GKN follows, and in the next section, we revisit the key human and technology design issues. Finally, we conclude the chapter and present UCD principles for OLCs drawn from the sociotechnical approach.

RELATED WORK

Daniel, Schwier, and McCalla (2003b) observe that online learning communities have attracted diverse disciplinary interest, but that it is possible to identify two dominant perspectives—technological determinism and social constructivism. The basic tenet of the technology determinism research is that technology shapes cultural values, social structure, and knowledge. Social constructivism theories have inspired research on knowledge construction within communities of practice. Lave and Wenger (1991) assert that a society’s practical knowledge is situated in
relations among practitioners, their practice, and the social organization and political economy of communities of practice. For this reason, learning should involve such knowledge and practice (Lave & Wenger, 1991). Between these heuristic poles there are cross-disciplinary perspectives, of which it is possible to further discern them into four subcategories:

1. **Applied Technology Perspective:** Much of the work on OLC by computer scientists and information systems researchers is driven by a desire to understand and improve computational approaches. Studies in computer science, information systems, and educational technologies are mainly aimed at understanding technology to develop tools and systems that support learning environments (Daniel, Zapata-Rivera, & McCalla, 2003a; Preece, 2002; Schwier, 2001). Findings have been utilized for building technologies that support OLC. For instance, a growing number of developers and researchers in industry and universities are investigating ways to create software packages that add new functionality to systems supporting interaction, collaboration, and leaning in online learning communities (Kim, 2000; McCalla, 2000; Preece, 2000; Resnick, 2002; Schraefel, Ho, Milton, & Chignell, 2000).

2. **Ethno-Narrative Perspective:** Ethno-narrative research is devoted to revealing personal experiences of being a member of an OLC. Most studies adopt a narrative approach, similar to participant observation inquiry used in anthropology. Researchers in this tradition have undertaken comparative analysis of both online learning and temporal communities (Schwier, 2001). Critics have disparaged ethno-narrative studies on the grounds that findings tend to be anecdotal and lack external validity; their conclusions are tentative and limited to the groups under study (cf. Downes, 2001; Rhiengold, 1993, 1999, 2002). Stolterman, Croon, and Argren (2000) argue that although the generalization and validity of such studies is limited, understanding personal perceptions of learning in OLC is essential. It is difficult to imagine how one can improve the learning environment of OLC without the subjective feedback of the learners.

3. **Cultural Studies Perspective:** Cultural studies have contributed enormously to understanding online learning communities. For instance, research by Brook and Boal (1995), Dery (1994), and Hershman and Leason (1996) investigate the relationship between the virtual and the physical, and they fall within the context of cultural interpretation research. Approaches employed in this category include experimental studies, with an emphasis on cultural events in online environments. The background disciplines of this group are diverse, including social psychology, philosophy, psychology, and fine arts.

4. **Sociotechnical Perspective:** The sociotechnical research tradition argues for a balanced approach to integrating cognitive and technical dimensions of OLC. This approach emerged from the extension of sociology, anthropology, and psychology to the study of HCI. Subsequently this research informed disciplines, including computer science and information systems (Heylighten, 1999). Research in sociotechnical areas addresses issues such as:
   - **User-Centered Design:** Moving the focus of interest to learners and away from technology in the design of online learning (Norman, 1996).
   - **Contextual Enquiry:** Understanding the user’s context and its potential influence on the use of technology (Preece, 2000).
   - **Sociability:** Appreciating the importance of community policies for
interactions, governance, and social protocols in OLC (Preece, 2000).

- **Participatory Design**: Involving user participation in the design of OLC and the effects on learning outcomes (Mumford, 1987; Nguyen-Ngoc, Rekik, & Gillet, Chapter XIII, this volume).

- **Direct-Manipulation**: Creating tools for users to create their online learning environment and exploring the effects of functional options such as menu-driven and graphical interfaces (Shneiderman, 1998).

Common to this growing body of research issues is the need for the interplay of human and technology factors to guide the design, development, deployment, and evaluation of online learning communities.

**Formal and Informal Online Learning Communities**

There are numerous computational tools that support social learning across time and place (Laghos & Zaphiris, Chapter XI, this volume). New tools and patterns of communication have enabled social engagement, information, and knowledge sharing within social systems now referred to as OLC. Unlike a temporal community that resides in a fixed locale and whose members often know each other well enough to carry effective interactions, OLCs exist in cyberspace and may or may not be aware of each other (Daniel, Schwier, & McCalla, 2003). The character of an OLC is influenced by structural features, which may include: community size, duration of interaction and anticipated lifespan, location or distribution of the community, the homogeneity/heterogeneity of members, and breadth or narrowness of subject area. Variation of these features gives rise to diverse OLCs.

In Table 1, we simplify this diversity by distinguishing between formal and informal online learning communities. Formal online learning communities have explicit learning goals and evaluation criteria. Examples would include courses/programs offered by education institutions or companies (McCalla, 2000; Schwier, 2001). In contrast, informal OLCs achieve learning outcomes through social learning. Examples would include distributed communities of practice (Daniel, O’Brien, & Sarkar 2004b). A unique feature of DCoPs is the absence of a teacher or instructor; rather, in a DCoP, the learners are also teachers, as members collectively determine the content and support each other throughout the learning process. Further differences are contrasted in Table 1.

A growing body of research identifies the contribution of DCoPs to facilitating information exchange and knowledge creation, thereby enriching the work of the collective (Brown & Duguid, 1991; Hildreth, Kimble, & Wright, 1998; Lesser & Prusak, 2000). These positive outcomes have caught the interest of scholars and knowledge managers. And yet, there is little comparative research on the correlates of DCoP performance or sustainability. We find this surprising, given the fact that OLCs emerged and proliferated with the advent of the Internet and then World Wide Web over a decade ago. The case-study foundations for comparative research are certainly present, however (Kalaitzakis, Dafoulas, & Macaulay, 2003; Hartnell-Young, McGuinness, & Cuttance, Chapter XII, this volume).

Germane to the topic of DCoP emergence and sustainability is the question of “constructability”. Can the DCoP features listed in Table 1 be built, or have DCoPs simply migrated from the temporal to the online world? If we return to the literature review briefly touched on earlier, perhaps not surprisingly we would find a different answer to this question depending on the literature consulted. For example, the sociology
and cultural studies literature tends to be skeptical of the view that DCoPs can be constructed (Kollock & Smith, 1996). By contrast, the computer science and information systems research, on the whole, seem more optimistic that robust DCoPs can be constructed (Preece, 2000; Daniel et al., 2003b; McCalla, 2000).

Further, informed by user-centered design principles, Preece formulated the community-centered development (CCD) framework to guide practitioners in the field (Preece, 2000). CCD provides a blueprint for building a DCoP. The framework encourages designers to: (1) assess members’ interests, (2) identify community norms and appropriate technology, (3) involve stakeholders in prototype design and testing, (4) correct for poor usability, and (5) foster community network building and identity. Literature informed by this approach draws attention to the interaction between human and technology dimensions in setting the context for the development and sustainability of DCoPs.

CCD integrates a sociotechnical perspective and pays attention to HCI. On the human dimension side, attention has been drawn to understanding participants’ goals, motivations, and perceptions of the learning environment (Daniel et al., 2003b); trust (Preece, 2002); and culture and learning needs (Daniel et al., 2004a). On the technology side, issues include privacy and security, usability, scalability, and authenticity (Daniel et al., 2003a; Preece, 2000).

The attention paid by a sociotechnical approach to HCI makes this framework particularly well

</table>
suited to understanding the development and sustainability of DCoPs. In particular, the relevance of a sociotechnical approach to the evolution of the GKN project results from the attention to, and monitoring of, feedback loops to inform design and subsequent operation. For example, a sociotechnical approach cautions against a “build it and wait till they come” approach, and favors a co-design process that enables potential users to define their goals and areas of concerns. Joint construction can be regarded as fostering a shared identity and building networks necessary for the development of trust and effective ICT-mediated interaction.

**OUR CURRENT RESEARCH**

The GKN project was launched to address a perceived need to span geography and cross-organizational boundaries to enhance the scholarship on, and the practice of, governance and its role in advancing international development. The underlying challenge of praxis is not unique to this particular subject area. A consultation document issued by the Social Science and Humanities Research Council of Canada, for example, re-stated the networking challenge for advancing collaboration and innovation in the humanities and the social sciences in the following terms:

“Canada is a will against geography. It has a relatively small population, mostly scattered across more than 5,000 kilometres. It has no centres equivalent to Paris or London that naturally draw the best minds and greatest talents…to meet and interact on a regular basis. It does not have the numerous institutions…the Americans have to move people and ideas around. The net result…is that it is hard for people to know each other well, to trust each other and to work together over time and distance.” (SSHRC, 2004)

With the emergence of ICTs, these obstacles to the exchange of information and collaboration were no longer permanent fixtures, though they have tended to endure.

**Research Approach to the Design of User-Centered Online Learning Communities**

We began our effort to overcome these obstacles through a participatory design approach (PDA). Key to PDA is an iterative process that seeks to address users’ needs and promotes their involvement in project development (Schuler & Namioka, 1993). A PDA, also known as a cooperative design approach, shares numerous similarities with Preece’s (2000) community-centered approach.

The first step identified potential technologies capable of spanning geography and nurturing collaboration in a DCoP. Working on the human dimension, the project team created a profile of key stakeholders of 200 individuals from academia, government, and the non- and for-profit sectors. This list represented our target population for the survey of potential users’ views on knowledge sharing in the field and interest in participating in the development of a DCoP.

The users’ assessment was divided into three sections:

- an assessment of existing communication/networking mechanisms among potential community users,
- an assessment of the level of awareness of work undertaken by users and their affiliated organizations, and
- users’ perceived value of a DCoP and what services would contribute to its potential value.

The goal of the users’ assessment was to identify a target group’s interests, perceived
knowledge gaps, thematic content, and potential design models for the proposed GKN portal.

Following the analysis of the assessment, we identified design features that matched identified services together with appropriate technological requirements. We further contacted those who had completed the survey by telephone for a follow-up interview. The goal of the interview was to elicit further information regarding individuals' preferences for content and portal design. These steps also served the equally important objective of engaging potential community participants. In addition, we were able to gauge the reaction to the objectives of the GKN project and method of development and implementation. In addition, the telephone follow-up was an opportunity to initiate informal connections among various individuals working in the same area of research.

RESULTS AND DISCUSSION

The target population for the survey was close to 200 organizations identified as working in the field of international development and governance. The response rate to the survey was 25%. Of those responding, 38% were university based, 23% were from provincial and federal government institutions, 30% were from non-governmental and research organizations, and 9% were from private consulting firms. The respondents were distributed across Canada: 45% from western Canada, 53% from central Canada, and only 2% from the eastern part of the country. These figures reflect the geographical and sectoral diversity of our sample. Four out of five respondents were interested in applied research and technical assistance in this area, and a similar proportion were interested in influencing, contributing, or participating in the policy-making process. In addition, over 80% of respondents revealed that it is important for them to keep current on new developments in research and practice. Depending on their organizational affiliation, 50% to 80% of the respondents were interested in building collaborative partnerships for research and technical assistance

We also asked respondents what kind of research (applied vs. basic research) they were interested in, and if they were willing to share a range of potential outputs with potential GKN members. The majority (90%) responded that they were interested in applied research. They were also willing to contribute to, and participate in, policymaking processes. Participants identified the potential for the GKN to support their interest in keeping abreast of current research and practice in their fields. In terms of collaboration, a large number of the respondents viewed the GKN as a potential mechanism to facilitate information exchange and knowledge sharing among members. These findings were encouraging for, as Lave and Wenger (1991) suggest, CoP development when individuals realize the potential to benefit by sharing knowledge, insights, and experiences with each other, and enhance their practices and performances.

Survey data and follow-up interviews revealed low levels of awareness of contemporary research and practice in the field. At the same time informants commented on the specialized nature of their work and the limited number of organizations active in the field, they also reported that they were largely unaware of contemporary contributions to knowledge and action that their counterparts have made. Though establishing a benchmark of awareness is problematic, our results indicated a considerable lack of awareness among researchers and practitioners working on governance and international development in Canada. The majority of the participants described current knowledge on governance and development as fragmented, and said that there was a serious lack of awareness among people working on similar issues across provinces and between organizations. Similarly, it was observed that a considerable amount of publicly funded research, reports, and policy
documents are not exchanged in a systematic manner. Respondents identified the potential of a GKN initiative to facilitate relations among public, private, non-governmental organizations and academia.

Though overall results revealed that information sharing and knowledge awareness were fragmented, there was a pattern to the responses. First, organizations within a sector were more knowledgeable of current work undertaken by their counterparts within the same sector than organizations in different sectors. Second, there were marked differences in the level of awareness among counterparts within provinces compared to those operating outside their provinces. Although there was a high utilization of information and communication technologies as means to exchange information and data, they were not used systematically to break down the information barriers across organizations and across geographic jurisdictions.

Consistent with previous findings (Wenger, McDermott, & Snyder, 2000), geographic distance is considered an obstacle to knowledge sharing and utilization, even by those who are active users of ICTs. Moving from geographic to language barriers, several respondents underscored the importance of Canada’s two official languages as a potential barrier. Language is critical to any community, since it is deemed as a part of a community identity: identity fosters collaboration and shared understanding within a community (McCalla, 2000).

Turning to services, the following list identifies the top four stakeholder recommendations:

- Design a DCoP to facilitate information exchange and knowledge sharing.
- Provide a platform for sharing lessons, experiences, and best practices.
- Identify and nurture collaboration among government, research community, academia, NGOs, and development practitioners.
- Build linkages and partnerships with other international research communities to advance policy and practice.

Following the analysis of the data and feedback to respondents, we identified and profiled different technologies capable of supporting a DCoP that would perform to stakeholder expectations. Once the technological elements were identified, feedback was sought again from participants on the relevance of these models. This feedback was integrated in the prototype development of the GKN portal, which is currently in its formative stages. As the GKN project moved from a needs assessment to co-development with interested partners, human and technology interaction issues are gaining more importance.

At present, the GKN team has implemented a beta version of the system, while at the same time pursuing research into social and technical means to nurture and support an evolving community. Currently, we are experimenting with the use of blended strategies of face-to-face workshops and videoconferencing as additional avenues to encourage integration of human and technology factors. We are also developing an evaluation plan to assess the importance of the factors identified earlier to developing and sustaining the GKN project. In the following section, we describe the dimensions of HCI that have the potential to affect the viability and robustness of the GKN project.

**EMERGENT HUMAN AND TECHNOLOGY ISSUES**

There are multiple factors affecting the emergence and sustainability of a DCoP. Drawing from the GKN experience and insights from the sociotechnical approach outlined previously, we maintain that the following set of factors are important to HCI. Their influence and relative importance to
the emergence and sustainability of a DCoP is introduced briefly in the following:

- **Didactics:** Learning is a shared experience, and by extension DCoPs are learning communities. Some OLCs have explicit learning goals (e.g., formal OLCs created around WebCT courses), while others have more implicit goals of sharing ideas, practices, and knowledge (e.g., DCoPs among corporate-oriented/professional communities). The technology must therefore enable learning, and perceptions of learning feedback would likely affect participation.

- **Trust:** Stakeholder surveys revealed that a key attraction of the proposed GKN online community would be the ability to share and retrieve archived data that was not widely available. The creation of this shared resource would depend on the willingness of these stakeholders to contribute their data. Their decision to share data would likely be influenced by their trust in others in the community as well as the environment in which they interact, for instance, questions such as: How would community members treat my data? Would my research be reproduced without my permission or quoted out of context? Creating generalized trust within a DCoP is difficult to “engineer”, but likely a pre-requisite condition for the sharing and accumulation of data.

- **Privacy and Security:** Privacy and security tools address individual perceptions of safety in the community. In an environment where a person feels their privacy threatened, declining participation is anticipated. In this regard, computational tools that protect the privacy and security of individuals must be provided.

- **Scalability and Authenticity:** Scalability expresses the ability of a system to accommodate multiple users, and authenticity refers to the ability of a system to protect individuals in a community from outsiders. A DCoP must encourage entrants and their participation. This dimension is critical to the growth of the DCoP, whereas authenticity appears more important to sustainability. For example, an open system that does not protect users (e.g., from hackers) is susceptible to negative feedback and eventual decline of member participation.

- **Sociability:** Sociability relates to the protocols in use for communication and interaction in the community (Preece, 2000). These protocols may be imposed in the first instance, but will likely shift in response to community dynamics. Sociability is of particular importance to “constructed” online communities that do not inherit protocols in use, as would temporal communities that have migrated to an ICT-mediated environment. This dimension is likely critical to the sustainability of a DCoP, as protocols in use will need to reflect members’ preferences and practices. As new protocols emerge, technology must accommodate such changes.

- **Usability:** Our research indicated that interest in the GKN initiative centered on the promise of instrumental outcomes (e.g., access to information, new insights, and expanded contacts). Here, technology and human interaction are clearly linked, as relevant content is dependent on member input and its ease of retrieval is dependent on technology. User-centered interface design and continuous involvement of users are critical to both the emergence and sustainability of the GKN project.

- **Culture:** An explicit objective of the GKN project was to bridge organizational and linguistic boundaries. As organizational theory suggests that organizations inculcate and perpetuate cultures that may promote or discourage inter-organizational infor-
information sharing and/or collaboration. Once organizational or individual participation is present (a human, not a technical issue), we are uncertain of how technology may shape or accommodate different culture(s). Though others suggest that the viability of DCoPs depends on the development of a shared culture, our project is not sufficiently far advanced to comment on this hypothesis.

**Awareness:** The ability of ICT tools to provide awareness among its members is predicted to have a powerful impact on members’ interactions in the community. More specifically, awareness (e.g., awareness about who is who, and who does and knows what) can have a significant positive feedback that would in turn promote participation and contribute to sustainability.

These elements highlighted exert different forces on technology and human interaction. For reasons stated, we anticipate that each will have a bearing on the emergence and sustainability of the GKN initiative and DCoP more generally.

**DISCUSSION**

The sociotechnical approach to the development of a DCoP suggests that human and technical factors are interlinked and they co-determine the emergence, evolution, growth, and sustainability of DCoPs. For practitioners involved in designing or developing a DCoP, the variables outlined previously will likely provide a useful starting point for guiding implementation and identifying key relationships. For researchers, our preliminary exploration of these relationships creates a number of hypotheses for future investigation. As these relationships have a bearing on both practice and research, we intend to track these relationships through user evaluations and internal monitoring. We anticipate that these findings will work toward a framework for comparative research on factors affecting the emergence and sustainability of a DCoP.

By way of conclusion, we offer the following general UCD principles for designing and sustaining online learning communities based on the sociotechnical approach.

**Design Principles**

- Assessing needs of actual or potential users/learners.
- Identifying the gap between what is and what needs to be.
- Understanding users and usage contexts.
- Profiling learning styles.
- Benchmarking existing community models.
- Identifying existing technological tools.
- Maintaining an iterative design and development processes that keep users/learners informed.
- Providing appropriate tools to support and mediate learning, social interaction and facilitate a sense of togetherness.
- Exploring navigation tools to enable members to gather information about others and have access to community interactions traces of activities.

**Didactic Principles**

- Nurturing open and informal discourse as members interact to satisfy their own personal and community learning needs.
- Encouraging learners to become active users and contributors of content.
- Supporting different learning styles.
- Encouraging participation and discourse around central themes, ideas, or purposes.
- Guiding participants throughout the interaction process, and providing them with clear directions to attainment of learning goals.
- Understanding unique individual learning needs differences, and encouraging partici-
User-Centered Design Principles for Online Learning Communities

pants to construct their own meaning based on unique individual experiences.

Sociability Principles

- Establishing a clear set of social protocols for interactions.
- Encouraging informal interaction and an environment conducive to learner/user interaction so that members have opportunities to test the trustworthiness of others.
- Supporting shared objectives—which creates a rationale for belonging to the community.
- Maintaining relevant content and context for interaction throughout the lifespan of the community.
- Encouraging ongoing active dialogue among members.
- Maintaining different forms of awareness (who is who, who knows what, who knows who knows what, etc.) in the community to lubricate effective interaction.

ACKNOWLEDGMENTS

The research reported in this chapter has been supported financially by the Policy Branch of the Canadian International Development Agency (CIDA), the Social Sciences and Humanities Research Council of Canada (SSHRC), and the International Center for Governance and Development at the University of Saskatchewan.

INTRODUCTION

The contribution of context information to content management is of great importance. The increase of storage capacity in mobile devices gives users the possibility to maintain large amounts of content to their phones. As a result, this amount of content is increasing at a high rate. Users are able to store a huge variety of content such as contacts, text messages, ring tones, logos, calendar events, and textual notes. Furthermore, the development of novel applications has created new types of content, which include images, videos, MMS (multi-media messaging), e-mail, music, play lists, audio clips, bookmarks, news and weather, chat, niche information services, travel and entertainment information, driving instructions, banking, and shopping (Schilit & Theimer, 1994; Schilit, Adams, & Want, 1994; Brown, 1996; Brown, Bovey, & Chen, 1997).

The fact that users should be able to store the content on their mobile phone and find the content they need without much effort results in the requirement of managing the content by organizing and annotating it. The purpose of information management is to aid users by offering a safe and easy way of retrieving the relevant content automatically, to minimize their effort and maximize their benefit (Sorvari et al., 2004).

The increasing amount of stored content in mobile devices and the limitations of physical mobile phone user interfaces introduce a usability challenge in content management. The physical mobile
phone user interface will not change considerably. The physical display sizes will not increase since in the mobile devices the display already covers a large part of the surface area. Text input speed will not change much, as keyboard-based text input methods have been the most efficient way to reduce slowness. While information is necessary for many applications, the human brain is limited in terms of how much information it can process at one time. The problem of information management is more complex in mobile environments (Campbell & Tarasewich, 2004).

One way to reduce information overload and enhance content management is through the use of context metadata. Context metadata is information that describes the context in which a content item was created or received and can be used to aid users in searching, retrieving, and organizing the relevant content automatically. Context is any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and the applications themselves (Dey, 2001). Some types of context are the physical context, such as time, location, and date; the social context, such as social group, friends, work, and home; and the mental context, which includes users’ activities and feelings (Ryan, Pascoe, & Morse, 1997; Dey, Abowd, & Wood, 1998; Lucas, 2001).

By organizing and annotating the content, we develop a new way of managing it, while content management features are created to face efficiently the usability challenge. Context metadata helps the user find the content he needs by enabling single and multi-criteria searches (e.g., find photos taken in Paris last year), example-based searches (e.g., find all the video clips recorded in the same location as the selected video clip), and automatic content organization for efficient browsing (e.g., location-based content view, where the content is arranged hierarchically based on the content capture location and information about the hierarchical relationships of different locations).

**DATE, TIME, LOCATION, AND PROXIMITY**

While context can be characterized by a large number of different types of attributes, the contribution of context attributes to content management is of great importance. We focus on a small number of attributes, which are considered the most important in supporting content management and also have the most practical implementations in real products, such as date, time, location, and proximity (nearby Bluetooth devices). Bluetooth is a short-range wireless technology used to create personal area networks among user mobile devices and with other nearby devices.

The first two attributes, date and time, are the most common in use in a wide range of applications. They are used to organize both digital and analog content, and offer an easy way of searching and retrieving the relevant content automatically. For example, many cameras automatically add the date and time to photographs. Furthermore, the location where content is created is another useful attribute for searching the content (e.g., home, workplace, summer cottage). Mobile devices give users the possibility to create content in many different locations. Users can associate the location with the equivalent content in order to add an attribute to it that will enable them to find it easier. Finally, proximity also plays an important role in content management, as nearby Bluetooth devices can provide information both in social and physical context. While each Bluetooth device can be uniquely identified, information can be provided on nearby people by identifying their mobile phones. An example for physical context is the case of a Bluetooth-based hands-free car kit that can be used to identify that the user is in a car.
USABILITY ISSUES AND PROBLEMS

The expansion of the dimension of context information in order to include location, as well as proximity context, can be of benefit to users while they are able to store, access, and share with others their own location-based information such as videos and photos, and feel the sense of community growing among them (Kasinen, 2003; Cheverist, Smith, Mitchell, Friday, & Davies, 2001). But when it comes to proximity to be included in context information, the problem of privacy emerges. It appears that users are willing to accept a loss of privacy when they take into account the benefits of receiving useful information, but they would like to control the release of private information (Ljungstrand, 2001; Ackerman, Darrel, & Weitzner, 2001).

While context metadata is attached to content, when users share content, they have to decide if they share all the metadata with the content or they filter out all or some part of them. The cost for memory and transmission of metadata, as it is textual information, is not an important factor to influence this decision. When the user receives location and proximity information attached to content, he or she may also find out where and with whom the creator of the content was when the content was created. As a result, both the location of the content creator and the location of nearby people are shared along with the content information. If this information is private, the sharing of it could be considered as a privacy violation. This violation may be ’multiplied’ if the first recipient forwards the content and the metadata to other users.

However, users seem to be willing to share context metadata attached to content, as it would be convenient if context metadata were automatically available with the content (so that users do not have to add this information manually). Furthermore, it would be very helpful for the recipient if the received content was annotated with context metadata so that the recipient does not have to annotate it manually and be able to manage the content more easily. For example, in the case of image and video content, the filtering of context metadata such as location and people could be useless, since these same items appearing in the image or video can be identified visually from the image content itself.

But what is meaningful information to the end user? It seems that users want meaningful information, but they are not willing to put too much effort in creating it, unless this information is expected to be very useful. In the case of location, it would be difficult for users to type the name of the place and other attributes manually, since it would require their time and effort. Thus it would be important if meaningful context metadata, which include the required information, are automatically generated.

Proximity information also needs to be meaningful. In this way, meaningfulness is important when attaching information on nearby devices in the form of metadata. If the globally unique Bluetooth device address and the real name of the owner of the device could be connected, this functionality would give meaningful information to the user.

It is hard to determine which information is useful, while what is useful information in one situation might be totally useless in another. For example, when looking at photo albums, what is thought to be useful information varies a lot. When one is looking at family pictures taken recently, it is needless to write down the names of the people, since they were well known and discernable. But it is different looking at family pictures taken many years ago: the same people may not be that easily recognizable.

It appears that useful information depends on a user’s location, what the information is used for, and in which time span. In order to create meaningful information, users need to put much
Content Personalization for Mobile Interfaces

effort into getting the data, organizing it, and annotating it with context metadata. Ways to minimize their effort and maximize their benefit should be developed.

CONCLUSION

The increasing amount of stored content in mobile devices and the limitations of physical mobile phone user interfaces introduce a usability challenge in content management. The efficient management of large amounts of data requires developing new ways of managing content. Stored data are used by applications which should express information in a sensible way, and offer users a simple and intuitive way of organizing, searching, and grouping this information. Inadequate design of user interface results in poor usability and makes an otherwise good application useless. Therefore, it is necessary to design and build context-aware applications.

Issues of usefulness and meaningfulness in utilizing context metadata need to be further investigated. Usefulness depends on the type of metadata. As far as location and proximity are concerned, it appears that the more time has passed since the recording of the data, the more accurate the information needs to be. Furthermore, in the case of location information, the closer to one’s home or familiar places the data refers to, the more detailed the information needs to be. A main usability challenge is the creation of meaningful context metadata automatically, without users having to add this information manually. There exist many ways for automatic recording of information about a user’s context, but the generated information is not always meaningful.

Another field that requires further research is privacy. It seems that users are willing to accept a loss of privacy, provided that the information they receive is useful and they have control over the release of private information. Content management provides users with a safe, easy-to-use, and automated way of organizing and managing their mobile content, as well as retrieving useful information efficiently.

REFERENCES

**KEY TERMS**

**Bluetooth:** A short-range wireless technology used to create personal area networks among user devices and with other nearby devices.

**Content Management:** Ways of organizing and annotating content in order to retrieve and search it more efficiently.

**Content:** Any information that can be used to characterize the situation of an entity.

**Context Metadata:** Information that describes the context in which a content item was created or received.

**Entity:** A person, place, or object that is considered relevant to the interaction between a user and an application, including the user and the applications themselves.

**Location:** The place where content is created by the user.

**Usability:** The effectiveness, efficiency, and satisfaction with which users can achieve tasks in the environment of mobile devices.
Chapter 2.36
Speech–Centric Multimodal User Interface Design in Mobile Technology

Dong Yu

Microsoft Research, USA

ABSTRACT
Multimodal user interface (MUI) allows users to interact with a computer system through multiple human-computer communication channels or modalities. Users have the freedom to choose one or more modalities at the same time. MUI is especially important in mobile devices due to the limited display and keyboard size. In this chapter, we provide a survey of the MUI design in mobile technology with a speech-centric view based on our research and experience in this area (e.g., MapPointS and MiPad). In the context of several carefully chosen case studies, we discuss the main issues related to the speech-centric MUI in mobile devices, current solutions, and future directions.

INRODUCTION
In recent years, we have seen steady growth in the adoption of mobile devices in people’s daily lives as these devices become smaller, cheaper, more powerful, and more energy-efficient. However, mobile devices inevitably have a small display area, a tiny keyboard, a stylus, a low speed (usually less than 400 million instructions per second) central processing unit (CPU), and a small amount (usually less than 64MB) of dynamic random-access memory. Added to these limitations is the fact that mobile devices are often used in many different environments, such as dark and/or noisy surroundings, private offices, and meeting rooms. On these devices, the traditional graphical user interface (GUI)-centric design becomes far less effective than desired. More efficient and easy-
to-use user interfaces are in urgent need. The **multimodal user interface** (MUI), which allows users to interact with a computer system through multiple channels such as speech, pen, display, and keyboard, is a promising user interface in mobile devices.

Multimodal interaction is widely observed in human-human communications where senses such as sight, sound, touch, smell, and taste are used. The research on multimodal human-computer interaction, however, became active only after Bolt (1980) proposed his original concept of “Put That There.” Since then, a great amount of research has been carried out in this area (Bregler, Manke, Hild, & Waibel 1993; Codella, Jalili, Koved, Lewis, Ling, Lipscomb, et al., 1992; Cohen, Dalrymple, Moran, Pereira, Sullivan, Gargan, et al., 1989; Cohen, Johnston, McGee, Oviatt, Pittman, Smith, et al., 1997; Deng & Yu, 2005; Fukumoto, Suenga, & Mase, 1994; Hsu, Mahajan, & Acero, 2005; Huang, Acero, Chelba, Deng, Droppo, Duchene, et al., 2001; Neal & Shapiro, 1991; Pavlovic, Berry, & Huang, 1997; Pavlovic & Huang, 1998; Vo, Houghton, Yang, Bub, Meier, Waibel, et al., 1995; Vo & Wood, 1996; Wang, 1995). Importantly, the body of this research work pointed out that MUIs can support flexible, efficient, and powerful human-computer interaction.

With an MUI, users can communicate with a system through many different input devices such as keyboard, stylus, and microphone, and output devices such as graphical display and speakers. MUI is superior to any single modality where users can communicate with a system through only one channel. Note that using an MUI does not mean users need to communicate with the system always through multiple communication channels simultaneously. Instead, it means that users have freedom to choose one or several modalities when communicating with the system, and they can switch modalities at any time without interrupting the interaction. These characteristics make the MUI easier to learn and use, and is preferred by users in many applications that we will describe later in this chapter.

MUI is especially effective and important in mobile devices for several reasons. First, each modality has its strengths and weaknesses. For this reason, single modality does not permit the user to interact with the system effectively across all tasks and environments. For example, speech UI provides a hands-free, eyes-free, and efficient way for users to input descriptive information or to issue commands. This is very valuable when in motion or in natural field settings. Nevertheless, the performance of speech UI decreases dramatically under noisy conditions. In addition, speech UI is not suitable when privacy and social condition (e.g., in a meeting) is a concern. Pen input, on the other hand, allows users to interact with the system silently, and is acceptable in public settings and under extreme noise (Gong, 1995; Holzman, 1999). Pen input is also the preferred way for entering digits, gestures, abbreviations, symbols, signatures, and graphic content (Oviatt & Olsen, 1994; Suhm, 1998). However, it is impossible for the user to use pen input if he/she is handicapped or under “temporary disability” (e.g., when driving). MUI, on the other hand, allows users to shift between modalities as environmental conditions change (Holzman, 1999), and hence, can cover a wider range of changing environments than single-modal user interfaces.

Second, different modalities can compensate for each other’s limitations and thus provide users with more desirable experience (Deng & Yu, 2005; Oviatt, Bernard, & Levow, 1999; Oviatt & vanGent, 1996; Suhm, 1998). For example, the accuracy of a resource-constrained, midsized vocabulary speech recognizer is low given the current speech technology. However, if the speech recognizer is used together with a predictive T9 (text on 9 keys) keyboard, users can greatly increase the text input throughput compared with using the speech modality or T9 keyboard alone (Hsu et al., 2005). The gain is obtained from the mutual disambiguation effect, where each error-
prone modality provides partial information to aid in the interpretation of other modalities. Another reason for the improved user experience is users’ active error avoidance, where users tend to select the input modality that they judge to be less error prone for a particular task and environment (Oviatt & vanGent, 1996), and tend to switch modalities to recover from system errors (Oviatt et al., 1999). Mutual compensation is very important for mobile devices because the ability of every single modality in the devices is extremely limited (e.g., a limited display and keyboard size, and limited speech recognition accuracy).

Despite the importance of MUI in mobile devices, designing effective MUIs is far from trivial. Many MUIs in mobile devices are speech centric, where speech is the central and main modality. In this chapter, we will focus on main issues on the design of effective speech centric MUIs in mobile devices based on our research and experience in developing MapPointS (Deng & Yu, 2005) and MiPad (Deng, Wang, Acero, Hon, Droppo, Boulis, et al., 2002; Huang, Acero, Chelba, Deng, Droppo, Duchene, et al., 2001). In Section 2, we describe a generic MUI architecture in mobile setting that consists of various recognizers for different input modalities, semantic parsers, a discourse manager, and a response manager. In Section 3, we discuss special considerations related to speech modality. In particular, we discuss the approaches to overcoming resource limitations on mobile devices, noise robust speech front-ends, noise robust modality switching interfaces, and context-aware language model. In section 4, we introduce the issues related to robust natural language understanding including construction of robust grammars. We discuss the problem of modality fusion, including modality-neutral semantic representation, unification approach, and modality integration, in Section 5. We discuss possible future directions and conclude this chapter in Section 6.

A GENERIC MUI ARCHITECTURE

The ultimate goal of an MUI is to fulfill the needs and requirements of the users. This principle is one of many emphasized in user-centered design (Gould & Lewis, 1985, Norman & Draper, 1986). According to the user-centered design principle, the acceptability of an MUI can be judged using three main attributes (Dybkjaer & Bernsen, 2001; Hone & Graham, 2001; Nielsen, 1993): effectiveness, efficiency, and learnability. The effectiveness assesses whether users can complete the tasks and achieve the goals with the predefined degree of perceived accuracy. It is usually measured on the targeted user population, over a specified range of tasks and environments. The efficiency judges how much effort (cognitive demand, fatigue, stress, frustration, discomfort, and so on) and resources (time) are needed for users to perform specific tasks. It is usually measured with the total time (including time for error corrections) taken to complete a task. The learnability measures whether users can easily discover the system’s functionality and quickly learn to use the system.

Figure 1 depicts a typical speech-centric MUI architecture that is aimed to achieve a high level of effectiveness, efficiency, and learnability. As shown in the figure, users can communicate with the system through speech, keyboard, and other modalities such as pen and camera. Modality fusion usually is the center of an MUI system. There are two typical ways of fusing information from different input modalities, namely, early fusion and late fusion. With the early fusion, signals are integrated at the feature level and hence, the recognition process in one modality would affect that in another modality (Bregler et al., 1993, Pavlovic et al., 1997; Pavlovic & Huang, 1998; Vo et al., 1995). Early fusion is suitable for highly coupled modalities such as speech and lip movements (Rubin, Vatikiotis-Bateson, & Benoit, 1998; Stork & Hennecke, 1995). However, early fusion
can greatly increase the modeling complexity and computational intensity due to its nature of intermodality influence in the recognition phase. With the late fusion, information is integrated at the semantic level. The benefit of late fusion is its isolation of input modalities from the rest of the system. In other words, individual recognizers trained using unimodal data can be directly plugged into the system without affecting the rest of the system. This feature makes the late fusion easier to scale up to more modalities in the future than the early fusion. The architecture shown in Figure 1 utilizes the late fusion approach that has been widely adopted, for example, by a variety of systems including Put-That-There (Bolt, 1980), MapPointS (Deng & Yu, 2005), MiPad (Huang et al., 2001), ShopTalk (Cohen, et al., 1989), QuickSet (Cohen, Johnston, McGee, Oviatt, Pittman, Smith, et al., 1997), CUBRICON (Neal & Shapiro, 1991), Virtual World (Codella, Jalili, Koved, Lewis, Ling, Lipscomb, et al., 1992), Finger-Pointer (Fukumoto et al., 1994), VisualMan (Wang, 1995), and Jeanie (Vo & Wood, 1996).

In the late-fusion approach depicted in Figure 1, the input signals received by the system are first processed by semantic parsers associated with the corresponding modality into the surface semantics representation. Note that although each modality has its own semantic parser, the resulting surface semantics are represented in a common semantic representation and is thus independent of the modality. The surface semantics from all the input modalities are then fused by the discourse manager component into the discourse semantics representation (more discussions on this issue in Section 4). In order to generate discourse semantics, the discourse manager uses the semantic modal and interacts with the context manager to utilize and update such information as dialog context, domain knowledge, user’s information, and user’s usage history. The updated context information can be used to adapt the language model, which can improve speech recognition accuracy and enhance the quality of semantic parsers for the next user-computer interaction.

The discourse semantics, which is the output of the discourse manager, is then fed into the response manager to communicate back to the user. The response manager synthesizes the proper responses, based on the discourse semantics and the capabilities of the user interface, and plays the response back to the user. In this process, behavior model provides rules to carry out the required actions. The combination of discourse manager and response manager is usually referred to as the dialog manager.

Note that the components shown in Figure 1 may reside on the mobile devices, or distributed on other servers in real implementations. In addition, many MUI systems use an agent-based software solution in which a facility or hub is

Figure 1. A typical speech-centric MUI architecture and its components
used to pass information to and from different components (or agents) (Kumar & Cohen, 2000; Schwartz, 1993).

Many best practices and design principles have been developed for the speech-centric MUI design in the past decades (Becker, 2001; Dybkjaer & Bernsen, 2001; Ravden & Johnson, 1989; Reeves, Lai, J., Larson, J.A., Oviatt, S., Balaji, T.S., Buisine, et al. 2004), which we summarize next.

First, the system should explicitly inform the user about its state through appropriate feedback within a reasonable amount of time, so as to avoid state errors, that is, the user’s perceived state is different from the system’s perceived state. The feedback can be in different modalities, but must be clear and accurate. If speech feedback is used, recorded speech is usually preferred over the synthesized speech, due to its higher degree of naturalness. Note that the recorded speech usually takes a larger amount of resources than the synthesized speech. Since the memory and storage available in mobile devices is very limited, designers should strike a balance between the use of synthesized speech and of recorded speech. The system should follow real-world conventions, and use the words, phrases, and concepts that are familiar to the users. The system should also ensure that the output modalities be well synchronized temporally. For example, the spoken directions should be synchronized with the map display.

Second, the system should provide sufficient flexibility so that users can select the modalities that are best for the task under the specific environments. For example, the user should be able to switch to a nonspeech modality when inputting sensitive information such as personal identification numbers and passwords. A good MUI design should also allow users to exit from an unwanted state via commands that are global to the system, instead of having to go through an extended dialog. The system should provide enough information (e.g., through prompts) to guide novice users to use the system, yet at the same time allow barge-ins and accelerators for the expert users to reduce the overall task completion time.

Third, the system should be designed to allow easy correction of errors. For example, the system should provide context sensitive, concise, and effective help. Other approaches include integrating complementary modalities to improve overall robustness during multimodal fusion; allowing users to select a less error-prone modality for a given lexical content, permitting users to switch to a different modality when error happens; and incorporating modalities capable of conveying rich semantic information.

Fourth, the system’s behavior should be consistent internally and with users’ previous experiences. For example, a similar dialog flow should be followed and the same terms should be used to fulfill the same task. Users should not have to wonder whether the same words and actions have different meaning under different context.

Fifth, the system should not present more information than necessary. For example, dialogues should not contain irrelevant or rarely needed information, and the prompts should be concise.

While the best practices summarized are common to all speech-centric MUIs, some special attention needs to be paid to speech modality and multimodality fusion due to the great variations of mobile device usage environments. We address these special considerations next.

SPECIAL CONSIDERATIONS FOR SPEECH MODALITY

There are two main challenges for the use of speech modality on mobile devices. First, the resources on mobile devices, in particular, CPU speed, memory, and communication bandwidth, are very limited. Second, speech recognition accuracy degrades substantially in realistic noisy environments, where there are abrupt changes in
noise, or variable phase-in phase-out sources of noise as the user moves. For example, the recognition accuracy may drop 30-50% inside a vehicle and cafeteria from that in a quiet environment (Das, Bakis, Nadas, Nahamoo, & Picheny, 1993; Lockwood & Boudy, 1992). Since the mobile devices will be used in these real-field settings without a close-talk microphone, robustness to acoustic environment, that is, immunity to noise and channel distortion, is one of the most important aspects to consider when designing speech-centric MUIs on mobile devices. Speech recognition accuracy and robustness can usually be improved with a noise-robust speech front-end, a noise-robust modality-switching interface, and a context aware language model.

Resource Constrained Speech Recognition

Speech recognition on mobile devices is typically carried out with two options: the distributed recognition (Deng et al., 2002) where the recognition happens at a remote server (Figure 2) and the local recognition (Deligne, Dharanipragada, Gopinath, Maison, Olsen, & Printz, 2002; Varga, Aalburg, Andrassy, Astrov, Bauer, Beaugeant, et al., 2002) where the recognition is carried out completely on the mobile device. The distributed recognition can take advantage of the power of the remote server to achieve a fast and accurate recognition, while the local recognition can eliminate the requirement of the device to have a fast data connection.

In the distributed architecture, the main consideration is the latency required to send data to and from the server. The latency is typically determined by the communication bandwidth and the amount of data sent. To reduce the latency, a typical approach is to use a standard codec on the device to transmit the speech to the server where the coded speech is subsequently decompressed and recognized (as depicted in Figure 3). However, since speech recognizers only need some features of the speech signal (e.g., Mel-cepstrum), an alternative approach is to put the speech front end on the mobile device and transmit only speech features to the server (Deng et al. 2002), as shown in Figure 4. Transmitting speech features can further save bandwidth because the size of the features is typically much less than that of the compressed audio signals.

Besides the advantage of using the computing power at the server to improve speech recognition accuracy, there are other benefits of using server-side recognition. One such benefit is its better maintainability compared to the local recognition approach because updating software on the server is much easier and more cost effective than updating software on millions of mobile devices. It, however, does require the recognizer on the server to be front end or codecagnostic in order to materialize this benefit. In other words, the recognizer should make no assumptions on the structure and processing of the front end (Deng et al., 2002). Another benefit of using distributed recognition is the possibility for the server to personalize the acoustic model, language model, and understanding model all at the server, saving the precious CPU and memory on mobile devices.
In the past, distributed recognition is unquestionably the dominant approach due to the low CPU speed and small amount of memory available on the mobile devices. Nowadays, although the CPU speed and memory size are increasing dramatically, distributed recognition is still the prevailing approach over local recognition due to the advantages discussed previously.

The major issue of the local recognition architecture is the low recognition speed and accuracy due to the slow CPU speed and low memory available on mobile devices. Speech recognizers running on mobile devices need to be specially designed (Deligne et al., 2002, Li, Malkin, & Bilmes, 2006; Varga, Aalburg, Andrassy, Astrov, Bauer, Beaugeant, 2002) to fit the
requirement since speech recognizers designed for the desktop or telephony systems cannot be directly deployed to mobile devices. The greatest benefit of using the local recognition approach is its independency of the network connection and the server and hence, can be used everywhere under any conditions. Given the consistent improvement of the CPU speed and memory on the mobile device hardware, in the future, the local recognition approach is expected to become more and more popular for simple tasks such as name dialing and media playing.

**Noise Robust Speech Front End**

Noise robustness is one of the most important requirements for speech-centric MUI on mobile devices. It has attracted substantial attention in the past several years. Many algorithms have been proposed to deal with nonstationary noises. A popular one is an advanced feature extraction algorithm (jointly developed by Motorola Labs, France Telecom and Alcatel) that was selected in February of 2002 as a standard in distributed speech recognition by the European telecommunications standards institute. The algorithm defines the extraction and compression of the features from speech that is performed on a local, terminal device, for example, a mobile phone. These features are then sent over a data link to a remote “back-end processor” that recognizes the words spoken. The major components of this algorithm are noise reduction, waveform processing, cepstrum calculation, blind equalization, and voice-activity detection. The noise reduction component makes use of two-stage Wiener filtering (Macho, Mauuary, Noé, Cheng, Ealey, Jouvet, et al., 2002).

The stereo-based piecewise linear compensation for environments (SPLICE), which has been used in the MiPad system (Deng et al., 2002), is another effective algorithm for noise robust speech feature extraction. SPLICE is a cepstrum enhancement algorithm dealing with additive noise, channel distortion, or a combination of the two. It is a dynamic, frame-based, bias-removal algorithm with no explicit assumptions made on the nature of the noise model. In SPLICE, the noise characteristics are embedded in the piecewise linear mapping between the “stereo” clean and distorted speech cepstral vectors. SPLICE has a potential to handle a wide range of distortions, including nonstationary distortion, joint additive and convolutional distortion, and nonlinear distortion (in time-domain), because SPLICE can accurately estimate the correction vectors without the need for an explicit noise model.

**Modality Switching**

One of the problems in speech recognition under noisy environment is modality switching. If the speech recognition engine is always on, noises and by-talks may be misrecognized as a legitimate user input and hence, can erroneously trigger commands.

A widely used modality switching approach is called “push to talk,” where the user presses a button to turn on the speech recognizer, and releases the button to turn off the recognizer. Another approach is called “tap & talk” (Deng et al., 2002; Huang, Acero, A., Chelba, C., Deng, L., Duchene, D., Goodman, et al., 2000, Huang et al., 2001), where the user provides inputs by tapping the “tap & talk” field and then talking to it. Alternatively, the user can select the tap & talk field by using the roller to navigate and holding it down while speaking. Tap & talk can be considered as a combination of push-to-talk control and indication of where the recognized text should go. Both the push-to-talk and tap & talk avoid the speech detection problem that is critical to the noisy environment under which the mobile devices are typically deployed.

Figure 5 shows an example of the tap & talk interface used in the MiPad (Deng et al., 2002). If the user wants to provide the attendee information for a meeting scheduling task, he/she taps
the “attendees” field in the calendar card. When that happens, the MUI will constrain both the language model and the semantic model based on the information on the potential attendees. This can significantly improve the accuracy and the throughput. Note that tap & talk functions as a user-initiative dialog-state specification. With tap & talk, there is no need for the mobile devices to include any special mechanism to handle spoken dialog focus and digression.

**Context-Aware Language Model**

Here, *context* refers to any information that can be used to characterize the situation related to human-computer interaction. It typically includes the surrounding environment (e.g., location and noise condition), the user (e.g., age and gender, preferences, past interaction experiences, and the interaction history in the current session), and the devices (e.g., remaining battery life, available memory, screen-size, screen-contrast, and speaker volume). Although context-awareness can be beneficial to all components in an MUI, it is especially important for improving speech recognition accuracy under noisy environments.

Context information can be utilized in many different ways in speech modality. One particular approach is to construct the language model based on the context. For example, the tap & talk approach (Deng et al., 2002) customizes the language model depending on the field the user is pointing to, as mentioned in section 3.3. Language model can also be customized, based on the user information and the dialog state. For example, if the system is expecting the recipient information, the language model can include only the names in the global address book. If the user information is also used, the language model can also include user’s contact list and people who have exchanged e-mails with the user in the past. An even more effective language model would weight different names differently, depending on the frequencies the user exchanged e-mail with the person, and the recentness of the interaction (Yu, Wang, Mahajan, Mau, & Acero, 2003). Another example of constructing the language model based on the context and user informa-

---

*Figure 5. An example of the Tap & Talk interface (Deng et al., 2002, © 2002 IEEE)*
tion is described in the speech enabled MapPoint (Deng & Yu, 2005). Without context information, the speech recognizer needs to load all location names and business names in the North America. This is definitely beyond the ability of most state-of-the-art speech recognizers. However, if the user’s location information and/or the interaction history are known, the system can load only the location names and business names around the user’s current location, and weight all the names based on the popularity of the names as well as the user’s interaction history.

A more advanced context-aware language model construction technique is discussed by Wang (2004). This detection-based technique is used in the second generation of the MiPad (Wang, 2004). The basic idea of this approach is to detect the context cues from the user’s partial utterances sequentially, and adjust the language model dynamically for the next part of the utterances. This approach has achieved excellent user experience.

**LANGUAGE UNDERSTANDING**

Good speech recognition accuracy does not always translate to good understanding of users’ intents, as indicated by Wang, Acero, and Chelba (2003). A robust language-understanding model is needed to obtain good user experience for speech-centric MUI applications, especially since speech recognition errors will affect the understanding.

The first issue to address in language understanding is constructing the semantic grammar. Since the importance of each word to the understanding is different, the words need to be treated differently. A typical approach is to introduce a specific type of nonterminals called semantic classes to describe the schema of an application (Wang, 2001; Yu, Ju, Wang, & Acero, 2006). The semantic classes define the concepts embedded in the linguistic structures, which are usually modeled with probabilistic context-free grammars. The advantage of introducing the semantic classes is to make the linguistic realization of semantic concepts independent of the semantic concepts themselves. Once the semantic classes are defined, a robust linguistic grammar can be built using the approaches similar to the one described by Yu, et al. (2006).

The transformation from the recognized text to the semantic representation is usually done using a semantic parser. For example, in MiPad, this transformation is done using a robust chart parser (Wang, 2001). In this parser, “the robustness to ungrammaticality and noise can be attributed to its ability of skipping minimum unparsable segments in the input. The algorithm uses dotted rules, which are standard context free grammar rules in Backus Naur form plus a dot in front of a right-hand-side symbol. The dot separates the symbols that already have matched with the input words from the symbols that are yet to be matched.” (Wang, 2001, pp. 1556) Since the language models used in MiPad are dynamically generated based on the current user information and the tap & talk field, the parser used in MiPad supports dynamic grammars. Given that some part of the user’s utterances is in the free-style form (e.g., the topic of a meeting to be scheduled), they are modeled as dictation grammar rules. Since speech recognition is not perfect, the MiPad robust parser takes into account the N-best list, together with the associated confidence scores returned from the speech recognition engine, and combines the speech recognition score with the parsing score to obtain the best parsing result. More recent progress includes using maximum entropy models to classify the tasks and to disambiguate the meaning of the slots in the recognition result.

**MODALITY FUSION**

One strong advantage of using MUIs is the improved accuracy and throughput through modality integration. There are typically two fusion ap-
proaches: early fusion and late fusion. Given that late fusion has many superior properties over the early one, as discussed in Section 2, it will be the focus of our discussion in this section. There are two tasks in the late fusion: Process and convert the input signals into a common surface semantic representation using the semantic parsers (one specific to each modality), and fuse the surface semantics into discourse semantics using the discourse manager.

**Semantic Representation and Unification**

The semantic fusion operation requires a meaning representation framework that is common among modalities, and a well-defined operation for combining partial meanings.

Many semantic representation formats have been proposed in the past. For example, in Bolt’s (1980) pioneering paper, only very limited modality fusion is required and hence, a simple semantic representation was used. In the past decade, researchers (Cheyer & Julia, 1995; Pavlovic & Huang, 1998; Shaikh, Juth, Medl, Marsic, Kulikowski, & Flanagan, 1997; Vo & Wood, 1996) have converged to using a data structure called typed feature structures (Kay, 1979) to represent meanings. Typed feature structure can be considered as an extended, recursive version of attribute-value-type data structures, where a value can, in turn, be a feature structure. It extends frames (Minsky, 1975) that represent objects and relations as nested sets of attribute/value pairs, by using shared variables to indicate common substructures. A typed feature structure indicates the kind of entity it represents with a type, and the values with an associated collection of feature-value or attribute-value pairs. In the typed feature structure, a value may be nil, a variable, an atom, or another typed-feature structure.

The primary operation on typed feature structure is *unification*. "Typed-feature-structure *unification* is an operation that determines the consistency of two representational structures and, if they are consistent, combines them into a single result." (Oviatt, Cohen, Wu, Vergo, Duncan, Suhm, et al., 2000, online version pp. 21) Unification can combine complementary input from different modalities and rule out contradictory input (Johnston, 1998).

Note that users’ multimodal inputs may involve sequentially integrated or simultaneously delivered signal fragments. In other words, temporal relationships between different input channels are very important. To fuse modalities, we need to first determine whether two input fragments are related. In most of the systems reported, this is achieved by considering all input contents that lie within a predefined time window. To do this, all input fragments need to be time stamped as soon as they are generated to remove the errors due to transit delays.

For example, the speech input “Show me the restaurants around here.” might have a gesture-input accompanying it either “before,” “during,” or “after” the actual utterance, and all these three possibilities should provide the same result. Usually the term “before” represents a timeframe of up to several minutes, “during” represents a timeframe of 4 to 5 seconds, and “after” represents a timeframe of 500ms to 750ms. If these values are too small, many multimodal inputs will be considered as unimodal inputs and will not be integrated. If the values are too large the chances of an old or invalid user input are likely being accepted as part of a valid multimodal input.

To determine whether two input fragments should be treated as parts of a multimodal construction or separate unimodal commands, knowledge gained from a user study is very helpful. For example, it has been shown in Oviatt, DeAngeli, and Kuhn (1997) that users’ written input precedes speech during a sequentially integrated multimodal command. They have also clarified the distribution of typical intermodal lags.
Semantic Fusion with Uncertain Inputs

The challenge of semantic fusion with uncertain inputs is to determine the unified meaning based on multimodal input fragments associated with probabilities. This is especially important for speech-centric MUI because the output of a speech recognizer is never certain. Note that the unification operation on the typed feature structure assumes that all input modalities are certain, and so they cannot be directly applied here. To fuse modalities with uncertainties, a hybrid symbolic/statistical architecture that combines statistical processing techniques with a symbolic unification-based approach is in need. This combined approach involves many factors when fusing the semantics. These factors include recognition accuracy of the individual modalities, the way of combining posterior probabilities, and the prior distribution of multimodal commands.

Note that a multimodal input gives rise to three different types of information overlay: nonoverlayed, overlayed and nonconflicting, and overlayed and conflicting. Nonoverlayed information indicates that the input (unimodal or multimodal) does not have any of the same information represented multiple times. This is the simplest condition. Overlayed and nonconflicting information refers to information segments that may have been represented multiple times without a conflict. The overlayed and conflicting information refers to the case that the information has been provided multiple times and conflicts. There are many approaches to resolving conflicting information in typed feature structure if no uncertainty is involved. The “unification” approach simply returns the value null when a conflict is detected. The “overlay” method returns the first argument when conflicting information is present. However, given that the semantic information from different modalities should not be equally trusted, a better conflicting information resolving approach can be found to handle input signals that may or may not be overlapped in their temporal delivery (Oviatt et al., 1997). Note that overlayed information may arise when inputs are from different modalities (e.g., speech and gesture), or when the same-type modality information occurs multiple times over an extended time frame. Both these two conditions need to be handled.

Conventionally, the probability of the merged feature structures is the cross product of the probabilities of individual feature structures based on the assumption that inputs are statistically independent with each other. In this section, we describe an alternative statistical approach that has been used in QuickSet (Wu, Oviatt, & Cohen, 1999). This approach uses the associative map to reduce the unification pairs and members-teams-committee (MTC) model to refine the multimodal integration process so that different weights are assigned to different modes and different constituents.

**Associative map** defines all semantically meaningful mapping relations that exist between different sets of constituents for each multimodal command. In its simplest form, it can be considered as a simple process of table lookup. For example, if an MUI consists of only the speech modality and the pen modality, we can build a two-dimensional table. If two inputs from different modalities can be fused, the value at the corresponding cell is 1; otherwise, the value is 0. The purpose of the associative map is to rule out considerations of those feature structures that cannot possibly be unified semantically.

**Members-teams-committee** weighs the contributions derived from different modality recognizers based on their empirically-derived relative reliabilities. MTC consists of multiple members, multiple teams, and a committee. “members” are the individual recognizers that provide a diverse spectrum of recognition results (local posterior probabilities). Member recognizers can be on more than one team. Members report their results to their recognizer team leader, which then applies various weighting parameters to their reported
scores. Furthermore, each team can apply a different weighting scheme, and can examine different subsets of data. Finally, the committee weights the results of the various teams, and reports the final recognition results. The parameters at each level of the hierarchy are trained from a labeled corpus.” (Oviatt, et al., 2000, online version, p. 24).

**CONCLUSION AND FUTURE DIRECTIONS**

In this chapter, we discussed the importance of using the MUI in mobile devices, and described the state-of-the-art technologies in designing speech-centric MUI in mobile devices. Specifically, we discussed the noise robustness technologies, the reliable modality switching methods, the context-aware language model, and the robust language-understanding technologies that contribute to the usability of the speech modality. We also described the modality integration technologies that are important to improving the accuracy and throughput of the MUI. Although these technologies have greatly advanced the speech centric MUI design and development in the mobile devices, future research is needed in the following areas.

**Microphone Array Processing**

Noise robustness is still a challenging research area for speech-centric MUIs. Although many single-microphone noise robustness technologies (e.g., Deng, et al., 2002; Macho, et al. 2002) have been proposed to improve speech recognition accuracy under noisy environments, the progress so far is still limited. Given the continuous decrease in the hardware price, using microphone array on mobile devices is a trend to combat noisy acoustic conditions and to further decrease speech recognition errors. Microphone array algorithms, which take advantage of the received signal differences between microphones, can achieve noise suppression of 10-15 db effectively (Tashev & Malvar, 2005). Future research is needed for more efficient and effective algorithms using low-cost, low-quality microphone arrays that may be equipped in speech-centric mobile devices.

**Error Handling Techniques**

Fragile error handling continues to be a top interface problem for speech-centric MUI (Karat, Halverson, Horn, & Karat, 1999; Rhyne & Wolf, 1993; Roe & Wilpon, 1994). A great amount of research work needs to be done in developing graceful error-handling strategies in speech-centric MUI. First, new statistical methods need to be developed to reduce errors through mutual disambiguation between modalities. Second, new dialog strategies (e.g., mixed initiative) need to be developed to allow easy correction of the errors. Third, the system needs to be able to adapt to different environments and challenging contexts to reduce errors. Fourth, better robust speech recognition technologies need to be developed to increase the speech recognition accuracy under a wide range of environments.

**Adaptive Multimodal Architectures**

In most current MUI systems, their behaviors are predesigned by the developers. The system does not automatically learn to improve the performance as users use the system. Given that mobile devices are usually used by a single user, it is very important to develop adaptive MUI architectures.

For example, Oviatt (1999) showed that any given user’s habitual integration pattern (simultaneous vs. sequential) is apparent at the beginning of their system interaction. When the user uses the system, the interaction pattern remains the same. An adaptive MUI system that can distinguish and utilize these patterns to improve the modality fusion could potentially achieve greater recognition accuracy and interactive speed. Another
example is for the system to gradually change the behavior (e.g., automatically predict the user’s next action) when the user changes from a novice to an experienced user.

Future research in this area would include what and when to adapt, as well as how (e.g., through reinforcement learning) to adapt MUI systems so that their robustness can be enhanced.

**Mixed Initiative Multimodal Dialog**

Most current speech-centric MUI systems are user initiative, where the user controls the dialog flow (for example, through push to talk). A user-initiative system can be modeled as a set of asynchronous event handlers. In a more advanced system, the system should also actively interact with the user to ask for missing information (which is called mixed initiative). For example, if the user wants to search for the phone number of a business using a mobile device and he/she forgets to mention the city and state information, the dialog system should automatically ask the user for that information through the multimodal output devices.

Future research should address the design and development of consistent and efficient conversational interaction strategies that can be used by different multimodal systems. Multimodal dialogue systems should be developed within a statistical framework (Horvitz, 1999) that permits probabilistic reasoning about the task, the context, and typical user intentions.

speech processing in MiPad’s multimodal user interface. *IEEE Transactions on Speech and Audio Processing*, 10(8), 605-619.

KEY TERMS

Modality: A communication channel between human and computer, such as vision, speech, keyboard, pen, and touch.

Modality Fusion: A process of combining information from different input modalities in a principled way. Typical fusion approaches include early fusion, in which signals are integrated at the feature level, and late fusion, in which information is integrated at the semantic level.

Multimodal User Interface: A user interface with which users can choose to interact with a system through one of the supported modalities, or multiple modalities simultaneously, based on the usage environment or preference. Multimodal user interface can increase the usability because the strength of one modality often compensates for the weaknesses of another.

Push to Talk: A method of modality switching where a momentary button is used to activate and deactivate the speech recognition engine.

Speech-Centric Multimodal User Interface: A multimodal user interface where speech is the central and primary interaction modality.

Typed feature Structure: An extended, recursive version of attribute-value type data structures, where a value can, in turn, be a feature structure. It indicates the kind of entity it represents with a type, and the values with an associated collection of feature-value or attribute-value pairs. In the typed feature structure, a value may be nil, a variable, an atom, or another typed feature structure.

User-Centered Design: A design philosophy and process in which great attention is given to the needs, expectations, and limitations of the end user of a human-computer interface at each stage of the design process. In the user-centered design process, designers not only analyze and foresee how users are likely to use an interface, but also test their assumptions with actual users under real usage scenario.

Kinetic User Interfaces:
Physical Embodied Interaction with Mobile Ubiquitous Computing Systems

ABSTRACT

This chapter presents a conceptual framework for an emerging type of user interfaces for mobile ubiquitous computing systems, and focuses in particular on the interaction through motion of people and objects in physical space. We introduce the notion of Kinetic User Interface as a unifying framework and a middleware for the design of pervasive interfaces, in which motion is considered as the primary input modality.

INTRODUCTION

Internet and mobile computing technology is changing the way users access information and interact with computers and media. Personal Computing in its original form is fading and shifting towards the ubiquitous (or pervasive) computing paradigm (Want et al., 2002). Ubiquitous Computing systems are made up of several interconnected heterogeneous computational devices with different degrees of mobility and computing power. All of these devices and appliances are embedded in everyday objects, scattered in space, capable of sensing the environment and of communicating with each other, and carried or exchanged by people. Therefore, we are facing a new ecology of computing systems that poses new issues in their integration and usability. Human-computer interfaces that were designed for desktop personal computers must be re-conceived for this new scenario. Due to the different capabilities...
of mobile and embedded devices, the pervasive computing infrastructure, and the nature of their expected usage, it is apparent that new types of user interfaces are needed in order to unleash the usability of new generation distributed computing applications (see (Rukzio, 2006) for a classification of mobile devices interfaces). Additionally, the concept of user interface itself seems to be no longer adequate to cope with ubiquitous computing systems. Rather, it is the concept of interaction and user experience that will take over (Beaudouin-Lafon, 2004).

**Ubiquitous Computing**

Ubiquitous Computing (henceforth Ubicomp) is an emerging research sub-area of Distributed Systems whose main focus is studying how heterogeneous, networked computing devices can be embedded in objects of daily use in order to enable new applicative scenarios and user experiences. Mark Weiser (1991; 1993; 1994) introduced the term Ubiquitous Computing in the ‘90s as a new way to understand computer technology and to lay the foundations of an expected and necessary computing paradigm revolution. Weiser’s vision has been adopted and interpreted by a great number of researchers, among whom we consider relevant for our goals the works of (Abowd & Mynatt, 2000; Abowd et al., 2002; Banavar & Bernstein, 2004; Bellotti et al., 2002; Greenfield, 2006; Norman, 1999; Want et al., 2002). We summarize the Ubicomp vision in four fundamental points that motivate our effort of providing a new conceptual framework for Ubicomp user interfaces:

1. Today’s computer (e.g., the personal computer) will disappear, and the computing power will fade inside the network infrastructure, as it is already the case to some extent with existing web-services.
2. Computing will be extremely distributed and heterogeneous. This will result from the interconnection of several computing devices, each specialized in specific tasks and scattered in the physical environment (ranging from embedded devices to high-performance servers).
3. Computer interfaces will no longer capture the full attention of users. Rather, computer applications will run in “background” most of the time, accomplishing “routinized” operations, and they will try to gain user’s attention only when strictly required.
4. Computer interfaces will be unobtrusive and based on new emerging interaction models obtained by direct interaction with physical objects and with the whole environment.

Ubiquitous Computing is often equated to (or better, confused with) nomadic computing (Kleinrock, 1997). Nomadic computing is a form of computing environment that offers its users access to data or information from any device and network while they are in state of motion. In nomadic computing, the use of portable devices (such as laptops and handheld computers) in conjunction with mobile communications technologies enables users to access the Internet and data on their home or work computers from anywhere in the world. Mobile connectivity certainly does play an important role in Ubicomp, but it is not the only one. We consider of central importance the user’s mobility intended as the user’s ability of moving objects and themselves in the physical space. In fact, in using Ubicomp systems, users are no longer forced to sit in front of a desktop computer and to operate it with mice, keyboards and local input/output devices. Users will interact through actions performed on everyday objects that surround them. As pointed again by Weiser:

> [ubiquitous computing] is different from PDAs, dynabooks, or information at your fingertips. It is invisible, everywhere computing that does not live on a personal device of any sort, but is in the woodwork everywhere.
Kinetic User Interfaces

User Interfaces for Ubicomp Systems

Human-computer interaction (HCI) is a very large domain of research, which includes all related aspects of interaction with digital appliances. Although HCI has been mostly focused on graphical user interfaces (GUIs), we consider here those aspects that pertain to how users will interact with computers in the 21st century (Winograd, 2000), that is, by direct manipulation of objects in their physical environment. Paul Dourish (2001) defined this paradigm as embodied interaction. According to his definition, meaningful embodied interaction with a digital system can be obtained only if an alignment is maintained between the physical and the digital world. In other terms, “bits” and “atoms” must live together in peace (Negroponte, 1995). As recently pointed out in (Sparacino, 2005, p. 2):

[…] computation and sensing are moving from computers and devices into the environment itself. The space around us is instrumented with sensors and displays, and this tends to reflect a widespread need to blend together the information space with our physical space.

Embodied interaction is thus aimed at exploring new interaction patterns where people are exploring how to move the interface “off the screen” and into the real world (Shafer et al., 2001). For instance, in Tangible User Interfaces (TUIs) (Ulmer and Ishii, 2000; Holmquist et al., 2004), tangible interaction is intended to replace desktop GUI’s interaction and elements with operations on physical objects. The motion of objects in the physical space determines the execution of actions, such as item selection (by means of what in TUI are called “phicons” i.e., physical icons), service requests, database updates, and so forth. Rekimoto (1997) proposed the Pick&Drop pattern, an extension of the Drag&Drop pattern, to move items across computers. In his work on graspable user interfaces, Fitzmaurice (2000) proposed to extend the interaction with classical GUI by means of physical objects (such as LEGO bricks) over an augmented desktop surface. Tangible and graspable user interfaces are undoubtedly a great achievement in HCI. However, they are strongly biased by GUIs interfaces; nearly no new types of interaction induced by the nature of the physical space and objects have been proposed other than replications of those available on ordinary desktop GUIs.

The development of the ideas introduced by TUIs, combined with the ubiquity of information over the Internet, has led to a new concept of what counts as an Ubicomp system. Moving from the assumption that only information appliances could constitute a ubiquitous system, the whole material world of things and people now can be made computational and connected. The movement of the “Internet of Things” (ITU, 2005; Bleeker, 2006) is aimed at promoting the idea that any object can have a virtual identity in the Internet realm, as long as the object can embed a unique identifier, which corresponds to an IP address. This is now possible because of the larger 128 bits IP address space offered by the new IPv6 protocol (i.e., \(3.4 \times 10^{38}\) addresses). According to (Greenfield, 2006), the type of infrastructure that enables Ubiquitous Computing is already technically feasible and it will soon scale up to a level that will make it possible to safely connect a huge number of small heterogeneous devices, possibly embedded in everyday objects.

Augmented Reality (AR) (Mackay, 1998) and Wearable Interfaces (Barfield & Caudell, 2001) are emerging technologies that support embodied interaction for Ubicomp systems. We believe that Augmented Reality focuses more on how feedback is provided, whereas Wearable Interfaces focuses on the types of devices that can support embodied interaction.
**Unobtrusive Interfaces**

When HCI intersects Ubicomp, many assumptions that were made when designing interaction for ordinary computing devices are no longer valid. In Ubicomp, computers exist in different forms and only in a minimal portion as ordinary desktop computers (i.e., where interaction is performed through screens, keyboards, mice). As pointed out by Weiser and other promoters of Ubicomp, interacting with a ubiquitous system should be realized through an *unobtrusive interface*, more precisely, an interface that does not capture the full attention of the user, who can still use the system to perform the foreground tasks (Nardi, 1996). In contrast, an *obtrusive interface* is one that requires an unjustified cognitive effort to be operated, thus interfering with the normal usage of the system. Weiser & Seely Brown (1996) call this setting “Calm Technology” in order to stress the importance of adapting the computers and their interfaces to human pace, rather that the other way around. In this vision, computers should follow users in their daily activity and be ready to provide information or assistance on demand. Moreover, they should not require much attention from the user by asking information that can be autonomously obtained from the actual usage context. They must be “aware” of the context and be able to adapt their behaviour and interfaces to different usage situations. In other words, ubiquitous computers must be *smart* and *adaptive*.

**Kinetic-Awareness**

Context-awareness is considered as the most important issue in Ubicomp (Baldauf et al., 2006; Dourish, 2004; Hong et al., 2005). Specifically, location-awareness is considered a key component of context in designing user interfaces for mobile systems. Location-awareness has been always treated as a sub-case of context-awareness, and motion as a form of context change. Location change is taken as a context change for adapting the application’s behaviour, rather than as an explicit intentional act within the application’s interface.

We believe that location changes occurring over time can represent more than just context-change. It can be considered as input modality. This does not mean that location or motion context has to be neglected. Motion input and location context can be used together in the same way as in handheld GUIs, where interaction with the mobile devices can be contextualized through location or motion. For instance, it does make sense to consider a different interpretation for an object’s motion that occurs in a different location, or to interpret the GUI input differently when the mobile device is moving with different kinetic properties. To clarify this aspect let us consider two examples.

The first example is about two possible situations where a paraglide is flying i) over a lake, or ii) over the ground. Motion input is treated accordingly to the actual situation; when flying over the lake some manoeuvres are considered risky, while they are considered safe if flying over the ground (landing is possible everywhere).

The second example is a situation where implicit interaction with GUI is enabled if the handheld device is detected moving with a certain speed. For instance, suppose that a dialogue box asking for a confirmation pops up on the handheld’s GUI. If the user is moving, at a speed of more than 5 Km/h, then after a timeout, the interface assumes that the default choice has been (implicitly) selected. If the user is moving at lower speed or is still, the interface will wait for input without the timeout.

According to Dix et al. (2000), *space* and *location* define a new design space for interactive mobile systems. Mobile devices have increasing capacity in providing location and motion information as part of their usage context. They also acknowledged that accounting for motion as an input modality for location-aware mobile Ubicomp systems opens potential research op-
portunities. In fact, they propose and instantiate a taxonomy of the degrees of mobility with available technologies and applications. They categorize degrees of mobility along three dimensions level of mobility (i.e., the physical bound of the device to the environment), level of independence (i.e., the relation of the used location-aware device with other devices or to the environment), level of co-operativeness (i.e., the extent to which the device is bound to a particular individual or group). Some existing mobile devices and applications are then categorized according to this three-dimensional taxonomy. Some difficult or even impossible cases, such as a fixed-pervasive-personal, that might be instantiated by a fully isolated active cell (e.g., a prison cell with motion sensors). The combination that is relevant for us is that of pervasive-mobile-personal/group devices. Such devices might be location/motion-aware objects that can be used to interact with Ubicomp systems.

Systems combining location and motion awareness, henceforth, will be referred to as kinetic-aware systems. Our analysis of how kinetic information is taken into account in existing Ubicomp systems revealed that there are two main views on the role of kinetic information in user interfaces:

1. In the first view, location and motion are used as a component of the usage context that is exploited by applications running on the mobile information computing devices for adapting their behaviour. In this view, there is no physical interaction with the place (and its contained artefacts) where the users are using their own devices. The environment is not “sensing” the presence and the physical action of the user. Moreover, neither the system nor the environment is supposed to handle spatio-temporally located events.

2. In the second view, location change and motion are considered as primary input modalities reflecting the user’s goals and intentions while using Ubicomp applications. That is, users can intentionally perform explicit and implicit actions through physical motion. These actions are recognized and contextualized in the place where they occur, by possibly affecting the state of co-located devices and remote systems. Interaction through motion with physical space becomes the main focus, rather than simply contextualizing applications based on ordinary user interfaces running on mobile devices.

While the majority of research on location-aware Ubicomp systems focuses on the first view on kinetic awareness, we focus instead on the second view, which can be achieved by recognizing users’ goals and intentions from various properties of motion of objects in the physical space through what we call the Kinetic User Interface (KUI).

Kinetic awareness can be seen as part of a more general paradigm, defined in (Dix et al., 2004) as context-aware computing. This emerging paradigm poses several challenges. One of the biggest recognized difficulties for this type of system is interpreting human activity. We do not propose algorithms for automatic recognition of human activities (which is a machine learning task). Instead, we propose a framework in which activities can be decomposed into smaller and easier-to-detect patterns. These patterns are instantiated by acquiring input from sensors that are linked to software components representing physical objects. We believe that providing a level of abstraction for activities will make easier the design and the implementation of Kinetic User Interfaces for Ubicomp systems.

**Related Works and Technologies**

Location-aware services are nowadays available to mobile Internet users. With the advent of Web2.0, a great deal of applied research and development recently has been devoted to embedding Internet
technology into everyday life mobile devices, ranging from pure entertainment to critical applications such as healthcare, national security, military (Cáceres et al., 2006). The rationale behind these efforts is to provide the mobile Internet users with great flexibility in authoring, publishing, and retrieving information, as well as in accessing services that are relevant in a given situation and place. A remarkable example of Web2.0 mobile application for multimedia information retrieval is SocialLight3, which allows the tagging of geographical location with multimedia tags (e.g., shadow-tags). The roaming users can “geo-tag” a place either by using a mobile phone when they are physically present there, or by attaching the tag on the SocialLight Web page with a GoogleMap mash-up. Information can further be retrieved from the Web site through the mashed-up map or by querying the system by using a mobile, GPS-enabled Internet device. Geo-tagging is also the focus of the Mobile Multimedia Metadata project of the Garage Cinema Lab (Davis et al., 2004), whose main purpose is to cooperatively annotate geo-located pictures. (Ashbrook et al., 2006) push this concept further and propose a roadmap for future research with a new type of scenario based on location-awareness and motion tracking, in which users can capture media while moving, and share their experience by making the captured media stream available to Internet users in real-time.

Location-awareness in Ubicomp has been the main focus of several projects since 1990. Among the projects that heavily rely on location context are the Aware Home (Kidd et al., 1999) at GeorgiaTech, the GUIDE project at Lancaster University (Chervest et al., 2000), the AURA project at Carnegie Mellon University (Sousa & Garlan, 2002), the GAIA’s Active Space project at University of Illinois Urbana Champaign (Román et al., 2002), the Interactive Maps at ETHZ (Norrie, 2005), and the Global Smart Places project (Meyer et al., 2006). It might seem that this is a widely explored research area, but a closer analysis reveals that all of these projects deal with a very basic form of motion-awareness. Location change is taken as a user’s context change, which is used for dynamically adapting the application’s behaviour. They all consider a user’s location as an additional parameter of an explicit service request. Then, the service’s output is delivered on the handheld device carried by the user or on a nearby display.

The Cyberguide project (Abowd et al., 1996) is one among the first attempts in taking a user’s motion into account (see also (Schilit, 1995)). A tourist equipped with indoor (IR beacons) and outdoor (GPS) localization devices can automatically receive contextual relevant information on a PDA while moving, and feed a trip journal.

In the EasyLiving project at Microsoft (Brumitt et al., 2000), a geometric model of the physical space is used in order to enable physical embodied interaction by representing the physical relationships between entities in the world. Unfortunately, this model has a limited scope since it is adapted to room scale, and it only considers current spatial relationships between objects, while ignoring their motion within the tracked space.

The Intelligent Workspace project at MIT (Koile et al., 2003) is a system that records the user’s location history and learns the so-called activity zones. Activity zones are portions of the physical space where the user is doing specific activities and which are repeatedly observed by the system. Once an activity zone is learned, the settlement of user in it will automatically trigger a number of pre-defined services that support the observed activity. In other words, the system reacts to context change and, in particular, to the user’s location change.

However, none of the above-mentioned systems explicitly recognize motion as the primary input modality and as a mean of performing a purposeful (explicit or implicit) action within the application’s interaction space. The following systems make a further step towards a more explicit notion of kinetic-awareness.
In the Sentient Computing project at AT&T Cambridge Research labs (Addlesee et al., 2001), motion tracking is an essential feature for interacting with the system. The system is built around the ActiveBat infrastructure for tracking location and motion using ultrawide-band sensors (now commercialized by Ubisense®). A few applications for the ActiveBat have been proposed, such as “FollowMe” that allows users to move their input-output environments over several devices scattered in the environment (e.g., phone call forwarding, virtual desktop displacement), or the “Virtual Mouse” that allows users carrying the ActiveBat device to use it as a mouse over a wall display. A relevant aspect of this project for us is the adopted context modelling techniques. The application-level and the user-level (mental) model of the environment are kept aligned by the system (Harter et al., 2002). In other words, when users perform actions, they update their mental representation of the resulting state of the environment by directly observing it. This representation might not be consistent with the information that applications have gathered through sensors. The system must take care of checking and possibly restabilising the lost alignment.

The Sonic City project (Gaye et al., 2003) exploits motion in the urban landscape as a way for interactively creating a musical experience. The user motion is tracked, as well as the current position over the city map. Motion and location contexts are combined with other contexts obtained through wearable sensors in order to influence the composition of music content in real-time. Users of the Sonic City interface can hear the result of musical composition during their walking activity.

Other applications of the motion context are pervasive games and races. Games that involve location tracking (like trails in (Spence et al., 2005)) are suited for exploiting the motion context. For instance, in CatchBob (Nova et al., 2006), a multi-player game developed at EPFL, the players’ motion is tracked and their paths are made visible to other team members on a digital map. The goal of the game is to cooperatively perform a task by looking at the motion of the other team members on a handheld display and by communicating direction suggestions in real-time.

Overview of the Chapter

In this chapter, we propose a unifying framework for the design and implementation of Kinetic User Interfaces for Ubicomp systems by (i) defining a set of fundamental concepts and (ii) by presenting a middleware that enables the use of motion in physical spaces as the primary interaction modality.

The remainder of this chapter is structured as follows. In Section 2, we provide some backgrounds and intuitions about the distinguishing features of KUIs compared to other types of user interfaces. We also present a few motivating applicative KUI-based scenarios. In Section 3, we detail the main concepts of KUI and we present the structure of its middleware architecture. Conclusions are finally discussed in Section 4.

Kinetic User Interfaces

The term “Kinetic” is derived from the Greek *kinetikos*, which means “moving of, relating to or resulting from motion (the action or process of moving).” In physics, kinetic theory explains the physical properties of matter in terms of the movement of its constituent parts; kinetic energy refers to energy, which a body possesses by virtue of being in motion. Kinetic abilities of humans are of no question. People move and change their current spatial location all the time and in a mostly unconscious way. Humans are also capable of “modulating” motion in several ways, by keeping or varying their speed, by following different trajectories or patterns (e.g., dancing), or by executing various types of motion in parallel (e.g., gesturing while walking).
At different scales and contexts, motion (or absence of motion) can be recognized as a purposeful action. For instance, if a tourist stops long enough in front of a statue, it might be reasonable to assume that he or she is observing the monument. What if the statue (or the environment) would be smart enough to provide the tourist with relevant information about its author or style, or, even smarter, to figure out that the tourist has already stopped at the statue, to avoid repeating the old information unless the tourist explicitly requests it?

A familiar everyday situation occurs when items are passed through a bar code reader in a grocery store counter. Their motion (the passage in a given place) is recognized as a purchase transaction. Another typical KUI situation takes place when somebody, possibly unconsciously, performs dangerous actions such as moving into dangerous areas. In these cases, a monitoring system could alert the user by signalling the potential danger.

**KUI vs. GUI**

Motion in the physical space is such a common and pervasive phenomenon that we hardly recognize its status as an interaction modality with a computer. While it is apparent that motion plays an essential role in WIMP\(^5\) Graphical User Interfaces (GUI), the virtual and limited nature of GUI's space, the “desktop,” seems not to afford the full bodily motion interaction (Beaudoin-Lafo, 2000). For instance, it does make little or no sense to talk about speed or acceleration of the pointer. Sometimes, however, these properties are taken into account by specific types of PC applications like games or flight simulators.

We introduce the concept of *Kinetic User Interface* (KUI) as a way of endorsing Weiser’s Ubiquitous Computing vision (Weiser, 1993) and the Dourish’s Embodied Interaction vision (Dourish, 2001) discussed in the previous section. Accordingly, KUIs are intended to enable a new interaction model for pervasive computing systems in which the motion of objects and users in the physical space are recognized as events and processes to which the system reacts. To make a parallel with ordinary, pointer-controlled Graphical User Interfaces (GUIs), moving the pointer on the display and clicking on a graphical item is recognized by the system as an intentional act, which usually triggers a system’s reaction on the software representation of the domain object associated to the selected graphical item and, possibly, the execution of an action on the domain object specified in the application currently running on the computer. Similar to “hovering” the pointer over a desktop in GUIs, in KUIs users can trigger input events for the computing environment by moving themselves and by displacing tracked objects. Users can exploit the physical space by executing actions/operations on physical objects, such as moving, grabbing, touching, juxtaposing, whose effects are reflected in the application objects. For instance, following a path or executing a pre-defined motion pattern can be viewed as similar to “mouse gestures” in ordinary desktop GUIs and can consequently trigger reactions by the gesture-enabled application.

KUIs are not limited to single-user interfaces and do not impose a unique locus of interaction. Hence, it enables richer interactions than GUIs and it is better suited to ubiquitous and mobile computing environments. Motion as an input modality can be used alone or in combination with other input modalities available to the user for interaction with the system, which are directly afforded by other mobile devices carried by the users and by fixed input devices located in the interaction space (e.g., ordinary point and click, or speech recognition).

**Feedback Management**

As in GUIs, an important issue in KUIs is feedback management. Due to the different nature of physical space with respect to GUI’s synthetic
Kinetic User Interfaces

In the physical space, feedback cannot be provided in the same way as for GUIs. Since one of the goals of KUI is to help build unobtrusive interfaces, we give back to users only the minimal amount of information required to inform them that their interaction with the physical space has been successfully recognized. In turn, the system should avoid interfering with the user’s current activity if the effects of the recognized action have only a peripheral importance to the current foreground task (i.e., if the effects impact only objects that are not in the current focus of attention of the user). Moreover, since the physical space already allows for the direct manipulation of real objects, feedback should only inform users about those effects produced in the computing space to (virtual) domain objects.

Although users might not always be aware of what effects are caused by their motion and the motion of tracked objects, they will be unobtrusively notified when their motion has been detected and interpreted by the system. Different than GUIs or even in Augmented Reality systems, there will be no need to display a synthetic image of the moving object. The only graphical components of the interface will be those corresponding to additional modalities. For example, we can imagine a scenario where a dialog box is prompted on a mobile device or on an embedded display when the user is detected to walk by or stop at a specific point of interest.

A feedback mechanism of control is also necessary for other reasons, such as privacy; to grant a certain level of protection, users must be somehow aware when their presence and motion is being currently tracked. Consequently, they must always be given the possibility to stop the tracking of the mobile device and to be allowed to use an alternative interaction modality.

KUI Interaction Patterns

Although KUI interaction patterns can be radically different from GUI patterns, some of the most effective GUI patterns, such as Drag&Drop, can be transferred and adapted to KUI interaction with physical space. For instance, in a KUI-enabled SmartHome, the user can “drag” the media being currently played in the living room and “drop” it to the bedroom just by moving a representative localizable object such as the remote controller. It is worth noting that the “Drag&Drop” pattern is provided as an interaction pattern by the KUI middleware and can be activated (and recognized) for specific applications such as the SmartHome control system.

Another useful pattern we include in KUI is continuous tracking. Continuous physical motion is comparable to mouse-gestures in GUIs. KUI-enabled applications are supposed to recognize certain kinetic patterns that might be naturally performed by users during other activities or specific situations.

As an example of the continuous tracking pattern, consider the scenario where the user is driving a car and some of the car’s motion parameters are obtained by embedded sensors such as a GPS tracking system and an accelerometer. The sensors reveal that the car is decelerating in the proximity of a gas station (i.e., a geo-located point of interest already known by the application). This kinetic pattern (deceleration) is detected by the KUI and interpreted by the application as the user’s intention of refuelling at the gas station. This hypothesis might be corroborated by other contextual information from the current car’s sensors (e.g., the fuel level being almost zero). As a result of this behaviour, the system will pro-actively prompt the driver with the current gas prices at the approaching gas station. The application might also perform further contextual inferences and inform the user that keeping the current speed and considering the current fuel level he/she can reach the next gas station that has better gas prices. However, if the system detects that the fuel level is high or the fuel tank is even full, it will not react because it can infer that the
driver stops for other (unknown) reasons (e.g., to take a pause).

This is a clear example of how KUI interaction differs from ordinary location-aware user interfaces. In this scenario, the driver passing by a gas station does not need to explicitly inquire about the gas prices. Current location information is only used to contextualize the query that is triggered as a result of the speed change occurring in the proximity of a given point of interest.

With regard to enabling technologies, continuous motion tracking is already available with current GPS-based car navigation systems, and easily can be integrated with personal mobile devices (e.g., SmartPhones, PDAs) connected to mobile Internet infrastructures (such as UMTS, GPRS, WiMax). With ordinary GPS navigation systems, the user can always check the current location on a graphical map and the proximity to point of interests. With KUI, we extend the possibilities of these systems with an additional level of interactivity and integration with networked services (Pallotta et al., 2006).

KUI-Enabled Scenarios

KUI-enabled applications have a different purpose compared to ordinary location-aware ones. Since motion is used as an input modality, KUI-based applications are expected to provide a higher level of fluidity in interaction and user experience. In those situations in which the interface should not interfere with the foreground user’s activity (which in turn might or might not be a computer-based one), KUI will allow unobtrusive interaction with a computer. We consider here three case studies that have been developed so far and that exemplify the benefits of KUI interaction patterns.

Safety in Air Sports

Jane is flying with her paraglide over the Alps and is trying to reach the other side of a lake she is currently over. Can she do it without any risks?

The UbiGlide flight navigator detects the motion of the paraglide. By interpreting her current activity UbiGlide infers Jane’s intention to cross the lake. UbiGlide then senses the environment, namely, the wind’s force and direction, the lake altitude, the distance between the paraglide and the opposite shore, and finally concludes that the crossing is not possible. Jane is informed immediately about the risk of danger. Later, she is so focused on the flight that she finds herself approaching a no-fly zone (e.g., an airplane landing strip). UbiGlide detects this possibility and alerts her about the danger.

In this scenario the current paraglide motion is not only tracked but also interpreted. An activity report is obtained by composing a number of basic flight movements in order to recognize more complex behaviour patterns. For instance, spiral ascension is made of several turns and altitude changes. Moreover, activities are filtered by other contextual information such as wind speed and direction, air humidity, and so forth.

SmartHome and SmartCity

Julia, Steve, and their daughter Monica live in Geneva. Julia is a busy businesswoman and Steve is a researcher at the university. Monica is in her last year of college. They live in a flat equipped with latest IT technology. They own a networked SmartFridge, which detects when food items go in and out, and automatically generates a list of missing items. The UbiShop system looks at the list generated by the SmartFridge and sends requests to buy the missing items to any family members who pass by a grocery store. Monica is on her way back home after school and passes by a grocery store. A reminder to buy milk is sent on her mobile phone by the UbiShop system. She decides to ignore the reminder since she knows that another grocery store is on her way home. Meanwhile, Steve is also on his way home and near a grocery store. He also receives the reminder and
decides to buy the milk. This purchase causes the deletion of the milk from the shopping list, so that Monica will no longer be bothered. When back home, Steve does not put the milk in the fridge. After a while, the SmartFridge “wonders” why the milk has not yet been put inside, so a request about this item is sent to Steve who had simply forgot the milk in the car.

This illustrates how KUI can contribute to context-aware collaboration in a mixed urban/home environment. Family members’ activities are coordinated according to actual members’ mobility. The system decides to adapt a workflow by interpreting team members’ behaviors in context. Here, the role of the KUI interface is twofold. First, it allows triggering the task assignment when the user is moving into a zone where the task could be accomplished. Second, it detects from the user’s speed whether he/she is likely to be willing to perform the assigned task. For instance, if the user is running, the application could interpret this motion pattern as “being in a hurry” and might decide not to bother the user. Another interesting aspect where KUI plays a role is when the user is expected to perform an action and this action does not occur. This is the case when, in our scenario, Steve forgot to put the milk in the fridge. The application subscribed to a motion event that does not occur within a time interval.

Safe-Critical Work Environments

Bill is a specialized worker in a chemical plant. He typically operates an industrial chemical reactor. He wears a head-mounted display and he is connected to the main control desk through wireless radio communication gears. While normally operating the reactor, suddenly Bill starts running (accelerates) toward the emergency exit. He is not able to alert the control desk about what is happening. The KUI interface detects this motion pattern as abnormal and figures out that the operator is trying to escape from a dangerous situation. The system then opens the doors on the pathway toward the exit of the reactor building and then immediately closes them after the operator is sensed to have passed through them.

In certain industrial settings such as chemical plants, it is important that the operator keeps his hands free in order to be able to do his usual manual work, while at the same time he accesses the automated commands and looks at the supervision information needed to complete the task. The role of KUI is apparent because it provides an additional implicit input modality that might serve to detect sudden instinctive reactions to dangerous situations.

THE KUI MODEL

In this section, we present the main concepts of Kinetic User Interfaces that are implemented as software components in the KUI middleware architecture.

The KUI Conceptual Taxonomy

In KUI, motion is a main (or primary) interaction modality afforded by the physical space to users through the motion of tracked entities. Tracked entities are any objects or autonomous (possibly living) things for which we can provide location and motion information. Tracked entities are represented by KUI components called Kuidgets. Interaction with Kuidgets happens when users affect their motion properties or change spatio-temporal relationships among them (e.g., an object is entering into an area). For instance, when the user is driving a car, the motion properties of its corresponding Kuidget will be continuously updated with its current position, speed, acceleration, and direction.

The term “Kuidget” has been chosen to make the parallel with a GUI’s widgets, that is, soft-
ware components that provide public interfaces for a hardware sensor and whose interaction is implemented in terms of messages and call-backs (Winograd, 2001). Kuidgets are the software counterpart of some real world entities that can be used for interaction in KUIs. A KUI-enabled system is thus able to recognize the current location of Kuidgets, and makes sense of their motion parameters such as path, speed, acceleration, and direction. Location and motion sensors (e.g., GPS or other tracking devices, accelerometers, compasses, altimeters) typically provide three-dimensional location and motion information to Kuidgets. Kuidgets are classified according to four main dimensions: geometry; kinetic properties; degree of autonomy; and type of motion.

From the geometric point of view, Kuidgets can be arbitrary three-dimensional objects. However, it makes sense to distinguish between those objects whose size is not relevant and those for which it matters. Entities of the first type are considered as points while others are considered as geometric shapes. This distinction is application-dependent, because one entity can be considered a point in one application and a shape in others. For instance, a vehicle (a car, a train, a ship, a plane) is a point when considered as a moving object in the space, and it is a space when considered as a container of objects and people. In the KUI model, the same entity plays two roles at the same time and is linked to two distinct Kuidgets.

Kuidgets can be fixed or mobile. Fixed Kuidgets are typically places or landmarks in the physical space, while mobile Kuidgets are physical entities whose location and motion can be observed by tracking the entity or can be provided by their embedded location and motion sensors.

In modelling KUI’s dynamics we adopt the status-event semantics, which means that KUI-based applications should be able to effectively deal both with the status of objects and with the events they generate. Thus, as an underlying model for dealing with Status-Event semantics in KUI, we adopt the Environment and Artefacts theory for multi-agent systems as proposed by (Ricci et al., 2006). Accordingly, we further classify Kuidgets along their degree of autonomy as artefact Kuidgets and agent Kuidgets. Artefact Kuidgets correspond to mobile physical objects that cannot move autonomously (e.g., a mobile phone, a car). The motion properties of an artefact Kuidget can be directly determined and communicated by the artefact itself (e.g., a GPS sensor + a mobile network connection) or observed by another entity (e.g., the infrastructure of the containing object, a nearby artefact, or an agent). The events of moving, grabbing, dragging, and dropping artefact Kuidgets are triggered by the detection of their current kinetic properties in the physical space and by the actions performed through their interfaces for direct manipulation (e.g., pressing a button on the object while moving it). Agent Kuidgets correspond to autonomous moving entities (people, animals, robots). Agent Kuidgets have a higher degree of autonomy, and they can induce motion to other artefact Kuidgets.

At the physical level, there is not much difference between artefacts and agent Kuidgets; they are essentially KUI’s components, and as long as their corresponding physical objects are providing their location and motion information, they are treated equally in KUIs. At a conceptual level, however, they differ because agents can control and operate artefacts and have a higher degree of autonomy. This distinction is particularly useful when KUI-enabled applications need to determine the location and motion of Kuidgets in the absence of up-to-date information. Motion of artefact Kuidgets typically has to be somehow causally linked to agent Kuidgets; sometimes artefacts cause the motion of agents, and sometimes it is the other way around.

Artefact Kuidget typically keeps its last observed (communicated) location if they are not linked to any moving entity (i.e., the law of inertia). Even in cases where no information can be obtained for an artefact Kuidget, its current location can be inferred by default just by knowing that
Kinetic User Interfaces

it is unlinked from a moving Kuidget. Different from artefact Kuidgets, agent Kuidgets have more freedom. When unlinked from any moving artefact Kuidgets, their current location and motion status cannot be safely inferred; they can move without being tracked. Of course, there also might be the case that an artefact is no longer tracked, but this case is considered as an error condition rather than a choice selected by the user. In other words, in KUI agent Kuidgets can decide when they can be tracked, while artefacts cannot.

Two Kuidgets can be logically linked and they can provide location and motion information to each other. For instance, a car equipped with a GPS sensor (an artefact Kuidget) can provide location and motion information to its driver (an agent Kuidget). Conversely, a user carrying a GPS sensor can provide location and motion information to the car Kuidget by setting a logical link between the car and the user who is driving the car. It is important to notice that when the user leaves the car, even if the link is destroyed, the car Kuidget keeps its last location.

It is also our goal to make KUI as general as possible in order to uniformly cope with different geographical scales (e.g., tabletop, room, building, cities) and with different types of location-aware devices (e.g., GPS, RFID, Wireless cell triangulation, ultrasonic, ultra-wideband, infrared). For this purpose, we also distinguish between different types of physical space. Following (Dix et al., 2000), we consider topological and symbolic spaces. In topological spaces, objects are localized by their exact position by means of an absolute coordinate system and through a notion of distance. In symbolic spaces, locations are considered as symbolic elements (e.g., rooms, buildings, cities), and object are localized through spatial relations with other objects (e.g., in the bedroom, near the red table). For topological spaces, the two basic types of references are points and zones, while for symbolic spaces, entities are explicitly connected through symbolic spatial relations such as containment, accessibility, and so forth. Different from (Dix et al., 2000), we do not make any distinction between real and virtual spaces. In our approach, virtual spaces are managed by applications and they do not need to be represented at the KUI level. However, KUI allows the geo-localization of virtual objects; these are entities of the computing space mapped to the geographical space (e.g., a geo-tag or a zone).

The detection of particular spatio-temporal relations between Kuidgets can trigger application-specific KUI events. There are several spatio-temporal relations that can be modelled. We propose here that a basic KUI should provide at least two types of spatio-temporal relations: proximity and containment. For these relations it is important to consider their temporal dimension, namely the start and end time, and the duration of the relation. For instance, if two mobile Kuidgets (e.g., two agents) are observed while moving together along the same path or into the same location, the application will be notified with a “joint motion” event by the KUI manager. Then, the application might make inferences, and as a result, establish an application-dependent relation between the two Kuidgets. For instance, when the two agent Kuidgets are moving together, the application can infer (with the help of other contextual information) that they might be friends. Similarly, when two Kuidgets that are supposed to jointly move cease to do so, an event could be triggered that in certain circumstances could denote an unusual situation. For instance, a car moving somewhere while its owner moves elsewhere else might denote that the car has been stolen.

The last dimension for our classification is the type of motion of mobile Kuidgets. In order to cope with most possible situations, we consider both endogenous and exogenous motion. Endogenous motion occurs when objects move without any change of location. For instance, a rotating object that remains in the same place counts as endogenous motion; another example is the sudden motion sensors embedded in Apple Macintosh laptops that can be exploited as an input modal-
ity in games. Exogenous motion represents the familiar case in which objects are displaced in the space. However, even if an entity is affected by exogenous motion, this does not necessarily mean that the exact change of location is tracked. For instance, if motion is detected by an accelerometer, the interface can use this information to trigger an event. This is the case of a Nintendo Wii™ controller WiiMote that is used to interact with games without detecting the exact change of location of players. More precisely, endogenous motion pertains to the fact that the spatial coordinate system is centred on the moving object, while exogenous motion is referenced to an external coordinate system.

The KUI Middleware

The software architecture we propose for KUI is supposed to be integrated within a larger context-aware middleware for Ubicomp. As in GUI, KUI should be independent from the underlying OS, and should enable rich interaction for context-aware Ubicomp systems. For this reason, we do not commit ourselves to a specific middleware. Rather, we focus on a general “pluggable” software component, which would allow us to make KUI available in an arbitrary context-aware middleware (see Baldauf et al., 2006) for a review). However, KUI can be used as a standalone system if the interface between the KUI manager and motion-aware mobile devices is made through ad-hoc drivers.

The KUI middleware is made of three layers of abstraction (as shown in Figure 1). Below, we provide details about each layer:

- The Observation Layer is the lower level. Its role is to collect kinetic contexts from location and motion aware devices and from other hardware sensors.
- The KUI-Space Layer is an object-oriented environment that contains and manages Kuidgets state and their semantic relationships. Information flow coming from the observation layer is used to update the state of Kuidgets. Location information pertaining to Kuidgets is stored in a suitable data

Figure 1. KUI middleware
Kinetic User Interfaces

structure, the GeoDB (e.g. a GIS\(^1\)), that is also used to store and manage physical space references of fixed and mobile Kuidgets for both topological and symbolic spaces.

- The Activity Layer manages the context history, and aggregates KUI events into higher-level semantic events (i.e., for the detection of specific interaction patterns) that are sent to the applications. In this layer, representations of situations will be constructed by aggregating kinetic information from Kuidgets and other contextual information. Moreover, models of activities will be matched with the spotted situations in order to determine the occurrence of anomalous behaviours.

More specifically, in the KUI software components location and motion information are linked to either fixed Kuidgets or mobile Kuidgets that are localizable by means of tracking hardware.

The KUI Components

The KUI Middleware can be seen as a user interface server that connects client applications to motion-aware input devices. In that sense, our model is similar to the X-Windows toolkit model. KUI provides an API to applications for subscribing aggregated events from the Activity Layer and encapsulates motion-aware devices through the Observation Layer. The main components of the KUI middleware are detailed in Figure 2.

A number of location and motion-aware devices can be connected to any Kuidget for which they cooperate in providing its kinetic information. Kuidgets are identified by universally unique identifiers (UUID), and are linked to entries in

Figure 2. Sketch of the KUI toolkit
the GeoDB that provides both direct localization and indirect localization through explicit relationships with other Kuidgets not linked to directly localizable elements. When the Observation Layer produces fresh kinetic information for a given Kuidget, a callback is sent to KUI-Space manager component, which updates the corresponding geographical information in the GeoDB and manages the relations between active Kuidgets.

The KUI-Space Manager is responsible for the aggregation and filtering of low-level events produced by the Observation Layer. Observations also can be obtained from the hosting context-aware middleware through context widgets (Dey et al., 2001). Context widgets are abstractions for different types of context sensors. They hide the complexity of the sensor communication protocols and offer a hot-plugging mechanism for dynamically adding and removing sensors to the system. As for GUIs, the application does not have to be modified when the pointing system changes, for instance, from mouse to pen. In our case, Kuidgets connected to location and motion Widgets do not know what kind of sensor is actually in use when they get kinetic information.

The Relation Manager receives location updates from the KUI-space and processes them according to the (programmable) relation rules. Relations between Kuidgets are created, deleted or updated and dispatched to the KUI-space manager, which then sends them to the upper Activity Layer through a notification mechanism. When some pre-defined geographical relationship change occurs (e.g., an object enters an active zone), the Relation Manager is responsible of notifying these events to the Activity Layer or directly to the subscribing Kuidgets. These events can be programmed as triggers that check conditions matched against the GeoDB, while aggregate events can be subscribed by objects in the upper Activity Layer. Relations between Kuidgets can be created either by the Kuidget’s internal logic in response to Kuidget events triggered when retrieving information from the GeoDB, or explicitly by applications. The latter case is useful when we logically link agent and artefact Kuidgets together, allowing one of them to inherit motion properties from the other one.

The Activity Layer is responsible of aggregating motion information from one or several Kuidget, as well as dynamic information generated by the Relation Manager. Relations and Kuidgets status are used as the building blocks for the recognition of the previously described kinetic interaction patterns.

Enabling Technology

The KUI middleware can be implemented on top of a context-aware middleware such as the Context Toolkit (Dey et al., 2001) and it can be integrated within any enterprise architecture like J2EE or .NET. Kinetic-aware devices typically will be connected through wireless Internet so that client-server software architecture is apparently justified. Applications exploit localization infrastructures for indoor and outdoor tracking. Indoor localization technologies include RFID antennas, ultrasonic, ultrawide-band, and IR sensors. For outdoor localization and motion tracking, GPS offers the most available tracking solution, which, combined with wireless Internet communication (e.g., GPRS, EDGE or UMTS) is nowadays available on commercial mobile phone and handheld devices. Additionally, we expect to detect others (more local) motion parameters (such as acceleration and direction) by using wearable sensors like accelerometers and digital compasses. For this point, it is crucial for the Observation Layer to be capable of dealing with several location and motion tracking technologies at the same time and of easily associating them with Kuidgets. The accuracy of different localization devices and motion sensors is not considered to be an issue in this discussion that pertains to the conceptual framework for the development of user
Kinetic User Interfaces

interfaces based on kinetic input. We expect, in any case, that motion tracking and wearable sensor technology will rapidly improve, as already has been the case for other enabling technology like, for instance, the diffusion of broadband Internet connection for the Web.

CONCLUSION

In this chapter, we explored the notion of kinetic-awareness in Ubicomp user interfaces by means of the seamless and transparent integration of objects motion detection in the physical space as a primary input modality. Kinetic User Interfaces enable the users of Ubicomp systems to establish an interaction through continuous tracking of kinetic-aware mobile devices at different spatial scales and by the acquisition of kinetic input through motion-aware embedded sensors. KUI interfaces allow the seamless integration of contextual (implicit) and intentional (explicit) interaction through motion. We presented a conceptual framework for KUI interfaces and a middleware as the basis for implementing the KUI component in standard Ubicomp architectures.

Kinetic-awareness in Ubicomp seems to take over simple location-awareness. Motion-based interaction is a complementary notion to context-awareness. It is not just a matter of acting while moving, but acting by moving. Motion is a great source of information that leverages new dimensions of user experience in Ubicomp systems. As noted in (Beaudouin-Lafon, 2004), in post-WIMP user interfaces, it will be necessary to shift towards a more holistic view of user interaction. Users are expected to interact through activities rather than single actions. Moreover, they will try to achieve higher-level goals through activities, rather than to accomplish tasks through planned actions. KUI provides a framework for designing Ubicomp applications with embodied interaction with a special focus on unobtrusiveness and fluidity.

WIMP stands for “Windows, Icons, Menus, Popups”.

The motion detection can be obtained either by the mobile device itself (e.g. a GPS-enabled handheld) or by external device or infrastructure (e.g. a badge tracked by a sensing space).

This interaction pattern is similar to the Teleport application (Addlesee et al., 2001), which allows users wearing ActiveBadges to move their desktop environments from a PC to another.

See (Salkham et al., 2006) for an overview.

We changed the names attributed to these types of space by (Dix et al., 2000). Our “topological” corresponds to their “cartesian” and our “symbolic” corresponds to their “topological”.

Geographical Information Systems

This work was previously published in Advances in Ubiquitous Computing: Future Paradigms and Directions, edited by S. Mostefaoui, Z. Maamar, and G. Giaglis, pp. 201-228, copyright 2008 by IGI Publishing, formerly known as Idea Group Publishing (an imprint of IGI Global).
This section presents extensive coverage of specific tools and technologies that humans interact with and react to in their daily lives. These chapters provide an in-depth analysis of devices and tools such as portable music players, mobile phones, and even blogs. Within these rigorously researched chapters, readers are presented with countless examples of the technologies that support and encourage societal development and their resulting impact.
INTRODUCTION

Bluetooth (Bluetooth SIG, 2004) and ZigBee (ZigBee Alliance, 2004) are short-range radio technologies designed for wireless personal area networks (WPANs), where the devices must have low power consumption and require little infrastructure to operate, or none at all. These devices will enable many applications of mobile and pervasive computing. Bluetooth is the IEEE 802.15.1 (2002) standard and focuses on cable replacement for consumer devices and voice applications for medium data rate networks. ZigBee is the IEEE 802.15.4 (2003) standard for low data rate networks for sensors and control devices. The IEEE defines only the physical (PHY) and medium access control (MAC) layers of the standards (Baker, 2005). Both standards have alliances formed by different companies that develop the specifications for the other layers, such as network, link, security, and application. Although designed for different applications, there exists some overlap among these technologies, which are both competitive and complementary. This article makes a comparison of the two standards, addressing the differences, similarities, and coexistence issues. Some research challenges are described, such as quality of service, security, energy-saving methods and protocols for network formation, routing, and scheduling.

BLUETOOTH

Bluetooth originated in 1994 when Ericsson started to develop a technology for cable replacement between mobile phones and accessories. Some years later Ericsson and other companies joined together to form the Bluetooth Special Interest Group (SIG), and in 1998 the specification 1.0 was released. The IEEE published the 802.15.1 standard in 2002, adopting the lower
Enabling Technologies for Pervasive Computing

layers of Bluetooth. The specification Bluetooth 2.0+EDR (Enhanced Data Rate) was released in 2004 (Bluetooth SIG, 2004).

Bluetooth is a low-cost wireless radio technology designed to eliminate wires and cables between mobile and fixed devices over short distances, allowing the formation of ad hoc networks. The core protocols of Bluetooth are the radio, baseband, link manager protocol (LMP), logical link control and adaptation protocol (L2CAP), and service discovery protocol (SDP). The radio specifies details of the air interface, including frequency, modulation scheme, and transmit power. The baseband is responsible for connection establishment, addressing, packet format, timing, and power control. The LMP is used for link setup between devices and link management, while the L2CAP adapts upper-layer protocols to the baseband layer. The SDP is concerned with device information and services offered by Bluetooth devices.

Bluetooth operates on the 2.4 GHz ISM (Industrial, Scientific, and Medical) band employing a frequency-hopping spread spectrum (FHSS) technique. There are 79 hopping frequencies, each having a bandwidth of 1MHz. The transmission rate is up to 1 Mbps in version 1.2 (Bluetooth SIG, 2003) using GFSK (Gaussian frequency shift keying) modulation. In version 2.0+EDR new modes of 2 Mbps and 3 Mbps were introduced. These modes use GFSK modulation for the header and access code of the packets, but employ different modulation for data. The $\pi/4$ differential quadrature phase-shift keying (DQPSK) modulation and 8 differential phase-shift keying (DPSK) modulation are employed in 2 Mbps and 3 Mbps mode, respectively.

The communication channel can support both data (asynchronous) and voice (synchronous) communications. The synchronous voice channels are provided using circuit switching with a slot reservation at fixed intervals. The asynchronous data channels are provided using packet switching utilizing a polling access scheme. The channel is divided in time slots of 625 $\mu$s. A time-division duplex (TDD) scheme is used for full-duplex operation.

Each Bluetooth data packet has three fields: the access code (72 bits), header (54 bits), and payload. The access code is used for synchronization and the header has information such as packet type, flow control, and acknowledgement. Three error correction schemes are defined for Bluetooth. A 1/3 rate FEC (forward error correction) is used for packet header; for data, 2/3 rate FEC and ARQ (automatic retransmission request). The ARQ scheme asks for a retransmission of the packet any time the CRC (cyclic redundancy check) code detects errors. The 2/3 rate FEC is a (15,10) Hamming code used in some packets. The ARQ scheme is not used for synchronous packets such as voice.

Figure 1. Piconet and scatternet
The devices can communicate with each other forming a network, called piconet, with up to eight nodes. Within a piconet, one device is assigned as a master node and the others act as slave nodes. In the case of multiple slaves, the channel (and bandwidth) is shared among all the devices in the piconet. Devices in different piconets can communicate using a structure called scatternet, as shown in Figure 1. A slave in one piconet can participate in another piconet as either a master or slave. In a scatternet, two or more piconets are not synchronized in either time or frequency. Each of the them operates in its own frequency-hopping channel while the bridge nodes in multiple piconets participate at the appropriate time via TDD. The range of Bluetooth devices depends on the class power, ranging from 10 to 100 meters.

ZIGBEE

ZigBee has its origins in 1998, when Motorola started to develop a wireless technology for low-power mesh networking (Baker, 2005). The IEEE 802.15.4 standard was ratified in May 2003 based on Motorola’s proposal. Other companies joined together and formed the ZigBee Alliance in 2002. The ZigBee specification was ratified in December 2004, covering the network, security, and application layers (Baker, 2005).

ZigBee has been designed for low power consumption, low cost, and low data rates for monitoring, control, and sensor applications (Akyildiz, Su, Sankarasubramaniam, & Cayirci, 2002). The lifetime of the networks are expected to be of many months to years with non-rechargeable batteries. The devices operate in unlicensed bands: 2.4 GHz (global), 902-928 MHz (Americas), and 868 MHz (Europe). At 2.4 GHz (16 channels), the raw data rates can achieve up to 250 Kbps, with offset-quadrature phase-shift keying (OQPSK) modulation and direct sequence spread spectrum (DSSS). The 868 MHz (1 channel) and 915 MHz (10 channels) bands also use DSSS, but with binary-phase-shift keying (BPSK) modulation, achieving data rates up to 20 Kbps and 40 Kbps, respectively. The expected range is from 10-100m, depending on environment characteristics.

Each packet, called PHY protocol data unit (PPDU), contains a preamble sequence, a start of frame delimiter, the frame length, and a payload field, the PHY service data unit (PSDU). The 32-bit preamble is designed for acquisition of symbol and chip timing. The payload length can vary from 2 to 127 bytes. A frame check sequence improves the reliability of a packet in difficult conditions. There are four basic frame types: data, acknowledgement (ACK), MAC command, and beacon. The ACK frame confirms to the transmitter that the packet was received without error. The MAC command frame can be used for remote control and nodes configuration.

In 802.15.4 two channel-access mechanisms are implemented, for non-beacon and beacon network. A non-beacon network uses carrier-sense medium access with collision avoidance (CSMA-CA) with positive acknowledgements for successfully received packets. For a beacon-enabled network, a structure called superframe controls the channel access to guarantee dedicated bandwidth and low latency. The network coordinator is responsible for set up of the superframe to transmit beacons at predetermined intervals and to provide 16 equal-width time slots between beacons for contention-free channel access in each time slot (IEEE Std. 802.15.4, 2003; Gutierrez, Callaway, & Barret, 2003).

A ZigBee network can support up to 65,535 nodes, which can be a network coordinator, a full function device (FFD), or a reduced function device (RFD). The network coordinator has general network information and requires the most memory and computing capabilities of the three types. An FFD supports all 802.15.4 functions, and an RFD has limited functionalities to reduce cost and complexity. Two topologies are supported by the standard: star and peer-to-peer, as shown in Figure 2. In the star topology, the
communication is performed between network devices and a single central controller, called the PAN coordinator, responsible for managing all the star functionality. In the peer-to-peer topology, every network device can communicate with any other within its range. This topology also contains a PAN coordinator, which acts as the root of the network. Peer-to-peer topology allows more complex network formations to be implemented, such as the cluster-tree. The cluster-tree network is a special case of a peer-to-peer network in which most devices are FFDs.

**COMPARING ZIGBEE AND BLUE-TOOTH**

Bluetooth and ZigBee have been designed for different applications, and this section makes a comparison between some features of both technologies, such as data rate, power consumption, network latency, complexity, topology, and scalability (Baker, 2005).

In applications where higher data rates are required, Bluetooth always has advantages, especially the 2.0+EDR version (Bluetooth SIG, 2004). While ZigBee mainly supports applications as periodic or intermittent data, achieving rates up to 250 Kbps, Bluetooth can support different traffic types, including not only periodical data, but also multimedia and voice traffic.

ZigBee devices are able to sleep frequently for extended periods to conserve power. This feature works well for energy savings, but increases the network latency because the node will have to awake in order to transmit or receive data. In Bluetooth, the devices do not sleep very often because the nodes are frequently waiting for new nodes or to join other networks. Consequently, data transmission and networks access is fast. Bluetooth devices in sleep mode have to synchronize with the network for communication, while in ZigBee this is not necessary.

The Bluetooth protocol stack is relatively complex when compared to ZigBee. The protocol stack size for ZigBee is about 28 Kbytes and for Bluetooth approximately 100 Kbytes (Geer, 2005). Bluetooth is also more complex if we consider the number of devices. A piconet can have only eight nodes, and a scatternet structure has to be formed to accommodate more nodes (Persson, Manivannan, & Singhal, 2005; Whitaker, Hodge, & Chlamtac, 2005). The Bluetooth SIG does not specify the protocols for scatternet formation. This task is easier in ZigBee networks, since no additional protocols have to be used. In terms of scalability the ZigBee also has some advantages, because network growth is easier to be implemented with flexible topologies. A Bluetooth network growth requires a flexible scatternet formation and routing protocol.

The applications have to consider these characteristics of both protocols when deciding which is the most advantageous for that specific implementation. Bluetooth will fit better in short-range cable replacement, extending LANs to Bluetooth devices and in industries for communication between fixed equipment and mobile devices or machine-to-machine communication (Baker, 2005). ZigBee is most likely to be applied in wireless sensor networks and industries wireless networks, or any other application where battery replacement is difficult and the networks have to live for months to years without human intervention. Many networks may also implement
both protocols in complementary roles using the more suitable characteristic of each for that application. Table 1 shows some features of both technologies.

### RESEARCH CHALLENGES

In the Bluetooth specification there is no information on how a scatternet topology should be formed, maintained, or operated (Persson et al., 2005; Whitaker et al., 2005). Two scatternet topologies that are created from separate approaches can have different characteristics. The complexity of these tasks significantly increases when moving from single piconets to multiple connected piconets.

Some research challenges in Bluetooth scatternets are formation, device status, routing, and intra and inter-piconet scheduling schemes. Each device needs to determine its role with respect to (possibly) multiple piconets, whether master and/or slave. Whitaker et al. (2005) state:

*There is a large degree of freedom in the number of feasible alternative scatternets, which defines a significant combinatorial optimization problem. This is made more difficult by the decentralized nature of the problem, characterized by a lack of a centralized entity with global knowledge.*

The task of packet routing in a scatternet also is not so easy because the packet may have to be transmitted in multiple piconets until it reaches its destination. In a Bluetooth piconet, the master controls the channel access. A slave can send a packet only if it receives a polling packet from the master. Some slaves may participate in multiple piconets, so they become more important than others and the scheduling scheme may give

priority for these slaves. The nodes involved in many piconets can only be active one at a time, and the scheduling strategy has to consider this characteristic. As stated in Whitaker et al. (2005), many factors influence the design of scatternet protocols, such as distribution of devices, scalability, device differentiation, environmental dynamism, integration between coordination issues, and level of centralization. The design of efficient protocols could make Bluetooth fit for a wider range of applications.

Although in ZigBee the formation of networks with many nodes is not a great problem, the management of a network with thousands of nodes has not been addressed and may be very difficult (Geer, 2005; Zheng & Lee, 2004). Since ZigBee specification was released after Bluetooth, many important issues have not been addressed, and some distributed protocols will have to be designed for these networks. Both standards have security features, including algorithms for authentication, key exchange, and encryption, but its efficiency still has to be analyzed in networks with many nodes.

Other important issue concerning ZigBee and Bluetooth is the coexistence of both devices, as they use the same 2.4 GHz band, and channel allocation conflicts are inevitable between these WPAN technologies (Chen, Sun, & Gerla, 2006; Howitt & Gutierrez, 2003). This band is also used by wireless LANs based on IEEE 802.11 standard cordless phones and microwave ovens. Interference between near devices may be very common, so coexistence strategies have to be implemented. It is important to study the characteristics of each channel allocation scheme and how each channel allocation scheme interacts with the others. The discussion on the coexistence issue between IEEE 802.11 and the IEEE 802.15-based WPAN technologies has been included in the IEEE 802.15.2 standard.

CONCLUSION

Bluetooth and ZigBee are wireless technologies that may enable many applications of ubiquitous and pervasive computing envisioned by Weiser (1991). Millions of devices are expected to be equipped with one or both technologies in the next few years. This work addressed some of the main features and made some comparisons between them. Some research challenges were described. These issues must be properly studied for the widespread use of ZigBee and Bluetooth technologies.

**KEY TERMS**

**Carrier-Sense Medium Access with Collision Avoidance (CSMA-CA):** A network contention protocol that listens to a network in order to avoid collisions.

**Direct Sequence Spread Spectrum (DSSS):** A technique that spreads the data into a large coded stream that takes the full bandwidth of the channel.

**Frequency Hopping Spread Spectrum (FHSS):** A method of transmitting signals by rapidly switching a carrier among many frequency channels using a pseudorandom sequence known to both transmitter and receiver.

**Medium Access Control (MAC):** A network layer that determines who is allowed to access the physical media at any one time.

**Modulation:** The process in which information signals are impressed on an radio frequency carrier wave by varying the amplitude, frequency, or phase.

**Pervasive Computing:** An environment where devices are always available and communicate with each other over wireless networks without any interaction required by the user.

**Scatternet:** A group of independent and non-synchronized piconets that share at least one common Bluetooth device.

**Sensor Network:** A network of spatially distributed devices using sensors to monitor conditions at different locations, such as temperature, sound, pressure, and so forth.

**Wireless Personal Area Network (WPAN):** A logical grouping of wireless devices that is typically limited to a small cell radius.

ABSTRACT
Collaboration is considered as an essential element for effective learning since it enables learners to better develop their points of view and refine their knowledge. Our aim being to facilitate communities of practice members as learners, we argue that collaboration tools should provide personalization features and functionalities in order to fit the specific individual and community learning requirements. More specifically, we propose a framework of services supporting personalization that being embedded in collaboration tools, can act as catalysts for individual and community learning. The proposed set of services has derived after the careful consideration of a generic learner profile, developed to formalize human actors in settings where learning takes place.

INTRODUCTION
As organizations start to acknowledge the significance of communities of practice (CoPs) in helping them meet their business needs and objectives, new efforts to better facilitate the process of learning in these communities are constantly emerging.
Augmenting Collaboration with Personalization Services

(Quan-Haase, 2005). CoPs, also referred to as “knowledge networks,” is a term commonly used to identify institutionalized, informal networks of professionals managing domains of knowledge (Gongla & Rizzuto, 2001). Such communities are formed by groups of people who share an interest in a domain of human endeavour and engage in a process of collective learning (Wenger, 1998). It is this very process of collective learning that creates bonds between them since such communities are formed by groups of people who are willing to share and elaborate further on their knowledge, insights, and experiences (Wenger & Snyder, 2000). Being tied to and performed through practice, learning is considered of premium value by practitioners for improving their real working practices (Steeples & Goodyear, 1999).

Situated learning in particular, that is learning that normally occurs as the function of an activity, context, and culture, is closely related to the social interactions in the community context. Above and beyond learning situated in explicitly defined contexts such as the school classroom, seminars, or even e-learning approaches, modern learning theories strongly support the value of communities and collaborative work as effective settings for learning (Hoadley & Kilner, 2005). More specifically, they emphasize on collaborative learning work that refers to processes, methodologies, and environments, where professionals engage in a common task and where individuals depend on and are accountable to each other. When speaking about collaborative learning, we espouse the Wenger’s perspective of learning as a social phenomenon in the context of our lived experience of participation in the world (Wenger, 1998). As regards to it, an especially valued activity involves information exchanges in which information is constructed through addition, explanation, evaluation, transformation, or summarising (Gray, 2004; Maudet & Moore, 1999). Discoursing, in particular, is considered as an essential element for effective learning, since it enables learners to better develop their points of view and refine their knowledge. This is because, in discoursing, participants focus on the same issues, share their knowledge, and learn to negotiate conflicting opinions in order to reach a commonly accepted solution (Veerman, Andriessen, & Kanselaar, 1998).

Still, it is generally acknowledged that traditional software approaches supporting collaboration are no longer sufficient to support contemporary communication and collaboration needs (Moor & Aakhus, 2006). Research findings on the usage of collaboration tools show that learners are not sufficiently supported in expressing personal ideas and opinions, nor are provided with adequate means for the articulation and sharing of their knowledge. Taking this into account, our work concerns the design of tools that enable discoursing to support collaborative work, emphasis given to aspects, such as the sharing of knowledge and the building of trust. We envisage collaboration tools that can promote learning and encourage creative, parallel, and lateral thinking during collaboration. Towards this, we argue that personalized services can be of great value, as they as they enable the provision of services tailored according to an individual’s (or community’s when applicable) skills, needs, and preferences. In this paper, we present a set of personalization services that has been developed to address the requirements for efficient and effective collaboration between CoP members who can act as catalysts for individual and community learning. Thus, we first performed a comprehensive literature and practice survey of related issues regarding communities of practice, collaboration, and learning. Then, we developed a generic Learner Profile model to formalize CoP members as human actors in settings where learning takes place. The Learner Profile proposed in this paper contributes to the proper user modelling required for the development of virtual environments for collaboration.

The remainder of this paper is structured as follows. The following section discusses
user modelling issues and presents the Learner Profile model of our approach. Next to that, we provide information about the acquisition of the data required for the population of the proposed Learner Profile. Then we present the proposed set of personalized collaboration services towards learning and their relation to the proposed Learner Profile. In the following we discuss implementation issues regarding the embedment of the proposed set of services to collaboration tools. We conclude this paper with final remarks and future work directions.

USER MODELLING

User models are an essential part of every adaptive system. In the following, we discuss design issues, and we present the proposed learner profile model of our approach. The specification of this model is oriented to the development of the personalized services appropriate for learners and/or CoPs.

Design Issues

The primary design aims of our approach in modelling users as learners was to achieve extensibility and adaptability of the user profile as well as the ability to exchange user information between the proposed personalized collaboration services and third-party services. In this context, the proposed learner profile comprises both computational and noncomputational information. Computational information comprises information such as the name, contact details, education, training, and so forth, of users, as well as information about the community they belong to. The noncomputational information is calculated after the processing of the users’ individual behaviour during their participation in system activities. This type of information comprises fields that can be defined during run-time, whenever a new requirement for a new kind of user information is raised. As regards the source of the information stored in the user model, this may derive from the user, the tool, and third-party applications. More specifically, fields that can be filled up by users constitute the user-derived information (e.g., login name, password, address, etc.). In contrast, fields that are calculated and filled up by the tool are machine-derived information (e.g., level of participation, average response time, etc.). Furthermore, some fields can be filled up both from the user and machine (preferences, resources, etc.). In addition, there can be fields that are calculated by external or third-party tools (or applications). Although user and machine-derived information can be easily gathered, third-party tools have to be aware of the user profile and the communication means with the tool in order to interchange data of the user profile. For this purpose, the user profile template is available through an xml schema definition to third-party requestors via Web services. In the storage layer, user records are stored in a relational database and manipulated through SQL queries.

The Learner Profile

In successful learning organizations, individual learning is continuous, knowledge is shared, and the organizational culture must support learning (Gephart, Marsick, Van Buren, & Spiro, 1996; Marsick & Watkins, 1999). Learning entities transform themselves by acquiring new knowledge, skills, or behaviours in their everyday work, through study, instruction, or experience. That is why software tools facilitating working practices for individuals, communities, or organizations should also be conceived and designed as environments where learning takes place. In our approach, collaboration tools should satisfy the community members’ needs to construct and refine their ideas, opinions, and thoughts in meaningful ways, in order to successfully assist individual and community learning. At the same time, individual standpoints should be articulated in such a way that can be proven useful for the rest
of the community’s members. In addition to that, support should be offered for the development of learning skills, such as the interaction with other actors, as well as growth of the learners’ autonomy and self-direction. Moreover, identification of CoP members’ individual characteristics, as well as the culture, norms, and incentive schemes of the community should be appropriately handled.

Research findings about learners’ modelling prove that due to the complexity of human actors and the diversity regarding the learning context, the development of a commonly accepted learner profile is a highly complex task (Dolog & Schäfer, 2005). For instance, the learner model proposed in Chen and Mizoguchi (1999) depicts a learner as a concept hierarchy, but it does not refer to issues such as the learning object, or the learners’ interactions with their environment and other people. However, it provides interesting information about a learner’s cognitive characteristics, and it provides a representation of knowledge assessment issues. Another related approach, the “PAPI Learner” conceptual model, comprises preferences, performance, portfolio, and other types of information (PAPI, 2000). Yet, this model is too generic, as its primary aim is to be portable in order to fit a wide range of applications, and it does not provide any information about a learner’s profile dynamic aspects. The IMS Learner Information Package specification (IMS LIP, 2001) is a useful collection of information that addresses the interoperability of Internet-based Learner Information Systems with other systems that support the Internet learning environment.

After the careful consideration of the above, we developed a generic Learner Profile (see Figure 1) that can be employed for the representation of both individuals and communities as learners (Vidou, Dieng-Kuntz, El Ghali, Evangelou, Giboin, Jacquemart, & Tifous, 2006). The proposed model can be used for developing customized services for both individual and group learners. More specifically, the proposed Learner Profile consists of two types of information, namely static information and dynamic information in compliance with the computational and noncomputational data presented. Static information is considered as domain independent in our approach. The Learner Profile dynamic information elements were chosen to reflect one’s individual behaviour during his participation in a specific CoP’s collaboration activities. Thus, all four dynamic elements, that is, preferences, relations, competences, and experience are to be implicitly or explicitly defined through the learner’s interaction with a tool supporting collaboration. Preferences regarding the use of resources and services provided by the tool, as well as relations among individuals, CoPs,

*Figure 1. The proposed Learner Profile*
and learning items (e.g., argument, URL, or document) can reveal the learners’ different personality types and learning styles. Competences refer to cognitive characteristics such as the creativity, reciprocity, and social skills. Experience reflects learners’ familiarity and know-how regarding a specific domain. It should be noted that all dynamic elements of the proposed Learner Profile can be of assistance towards learning. Nevertheless, the domain of the issue under consideration is a decisive factor. Thus, dynamic aspects of a learner’s profile are treated as domain specific in our approach.

**ACQUIRING THE LEARNER PROFILE DATA**

In order to enable the operation of personalized collaboration services, the Learner Profile has to be populated with the appropriate data. Such data can be acquired in two ways: explicitly from the users’ preferences, and implicitly based on the users’ behaviour while using the system. Static information of the Learner Profile is explicitly provided by the user as a required initialization step of the registration procedure. While such information is usually provided when registering to the system, users should be able to edit this set of profile information at any time. Such explicit data acquisition constitutes a subjective way of profiling, since it depends on the statements made by the user (e.g., experience level, competences, etc.). Their subjective nature may influence personalization services in an unpredictable way (e.g., suggesting to a novice user a document that requires advanced domain knowledge because the user misjudged his experience or competence level). To cope with such issues, we are currently in the process of designing methods that assess explicitly stated profile data, based on the users’ behaviour. We refer to these ways as implicit or behaviour-based data acquisition. In general, the aim of implicit or behaviour-based data acquisition is to assess experience, domains, competences of an individual user based on his behaviour. Implicit data acquisition utilizes the users’ actions and interactions, and attempts to extract information that can permit assessing or augmenting a user profile data.

A special part of the system’s architecture should be dedicated to support implicit data acquisition and interpretation. It consists of a number of modules, each of which is responsible for a particular task (see Figure 2). More specifically, the User Action and Tracking module is responsible for observing user actions and recording them in a special repository of the infrastructure called the Action and Event Store. The Action and Event Store only maintains all actions and events that are useful for implicit user action analysis and does not interpret them in any way. Analysis and interpretation of the gathered data as well as triggering of the appropriate computations (i.e., system reactions) is the main responsibility of the Action Interpretation Engine.

![Figure 2. Data acquisition and interpretation structure](image-url)
Interpretation Engine analyses the available information in the actions and event store and triggers computations that either update accordingly the user profile or execute a particular action. The interpretation engine can be configured using rules that are also stored within the infrastructure, making the interpretation engine rule-based. A rule essentially specifies under which circumstances (i.e., the events and actions of a particular user in the store) an action is triggered. The rule-based nature of the interpretation engine makes the engine itself extensible so that even more cases of implicit data acquisition and interpretation are able to be supported.

Based on the explicit or implicit data, explicit or implicit adaptation mechanisms can be supported within the collaboration tool. Explicit adaptation mechanisms refer to approaches where the tool adapts its services based on the explicitly stated characteristics or preferences of the user. Users are usually aware of explicit adaptations since they themselves triggered the initiation and presence of the respective services. On the other hand, implicit adaptation mechanisms refer to approaches that adapt the system’s services to the user, based on his/her actions within it. Such mechanisms work in the background; Users are usually unaware of the origin of these services since they did not explicitly initiate their activation and, thus, do not perceive their operation. Implicit personalization mechanisms are automatically triggered by the system utilizing implicit or behaviour-based data in the proposed Learner Profile.

In order to enable the foreseen functionalities (such as dynamic update of user information, adaptation of the tool according to the user needs, etc.), the most important actions of the entire set of users’ actions should be tracked down. As regards the User Action Tracking Mechanism, the recorded data about user actions contain information about who did the action, when, what type of action was executed, and what objects were affected by the action. In this way, it will be possible for the system to give valuable feedback to other mechanisms so as to be able to both examine and calculate dynamic user characteristics. Furthermore, a variety of statistical reports that cover both the overall and the specific views of usage of the system should also be produced.

Furthermore, a rule-based approach has been chosen so as to facilitate incorporation of new rules once they are observed, or modification of existing ones if they prove to be too restrictive or even harmful. More specifically, we propose the development of a set of rules that deal with resource access, as access to resources are logged, and a number of rules operate on the logged data to provide additional information to resources and/or user profiles. These can be based on the frequency of access, as well as the competence and experience levels of users (e.g., a document that is frequently accessed by novice users should augment the documents metadata with elements that mirror this fact, so that this document can be recommended to any novice user entering a discussion). A second set of rules observing discussion contribution could control how user behaviour in the context of discussions will affect the users’ competence and experience (e.g., users that actively and frequently participate can be assigned with a high experience level). Another useful indicator associated to the proposed learner profile is the reasoning about how a competence level of a particular user changes in time. This may provide useful insights about the learning capabilities of the particular user and the usefulness of the system.

### PERSONALIZED SERVICES FOR COLLABORATION TOOLS

One of the major challenges in developing software is that all users are different, in that they vary in terms of intelligence, knowledge, training, experience, personality, and cognitive style. Therefore, collaboration tools should provide a set of personalized services, with the emphasis
given to the individuals’ learning styles. In the following we present a set of services employed for enhancing software tools supporting collaboration towards learning. The proposed set of services has resulted out of a thorough investigation of the related literature, existing case studies that consider diverse aspects of learning within communities, as well as a transversal analysis of a set of interviews with real CoP members engaged in various domains of practice.

**Awareness**

According to the findings of our research, CoPs’ members consider system awareness services as the most helpful ones for collaboration tools. Participation awareness provides information about CoP members, online members as well as the discourse moves of individual CoP members. Users will be able to see which user is online, how the space changed by a particular member, and so forth. Social awareness provides information on how members are related to other members in the CoP, and includes statistics about how and how many times members within a CoP communicate with each other and social networks representing the community. Based on the data populated in the Learner Profile, personalized services can provide the proper set of notification actions for the provision of helpful personalized information about system events to CoP members. For instance, a collaboration tool could alert users about the entrance of another user to the system, or about new content insertion into the system.

In order to enable this personalized awareness, terms such as “related” or “interesting” that define a relation between the user and the content should be determined by the user himself, or automatically by the system through the manipulation of some characteristics from the user profile. Furthermore, system awareness can play an important role to assist the familiarization on the new learners of the system. By both informing the CoP moderator about the entrance of a new member and proposing some starting guidelines to the incomer, this service can assist the learning of the way of participation within a CoP. On the other hand, the awareness can provide the moderators with the activity monitoring service that helps the moderator to better understand and manage the whole CoPs’ procedures. That, in turn, contributes to the process of learning the CoP’s moderator role.

Awareness services can also be of use towards the self-evaluation of the participation of a community member, providing him with valuable feedback about his overall contribution to the community and assisting him in collaborative learning as well as in self-reflecting. Using statistic reports populated according to the Learner Profile, such services can measure the level of the member’s contribution to the collaboration procedure. More specifically, these kinds of services can provide with reports about the actual usage of the resources posted by a member, the citations of their resources, or the actual impact of posts to the overall process. In this way, one can be aware of the overall impression that other members have about his participation.

**Allocation of Resources**

Allocation of resources is another service that being personalized in collaboration tools can facilitate learning activities, especially for autonomous learners. As regards to searching for instance, a Learner’s Profile can provide useful information to rank search resources according to a number of factors, such as the learner’s preferences, or even his/her competence and experience level. In this way, the system will be able to adapt to an individual user’s needs. Moreover, the information about the user’s domains of interest will provide additional information with which a search can be better contextualized, thus leading to more relevant results. Furthermore, reasoning mechanisms could be employed for providing the necessary filtering features for
capturing and reusing the knowledge shared in past collaboration activities. In this vein, filtering and recommendation of content services can further support learning. For instance, some of the attached documents of posted positions that contribute to the strengthening of an argument should be suggested for view to the users according to their Learner Profile. Furthermore, a document library could recommend some documents that are related to a specific learner (e.g., experienced learner’s recommendations or popular documents). Thus, members will be able to extend their knowledge through explicit learning of associated content.

Services for classifying other learners according to their domain of expertise can also assist learning in the community. Such services enable the community members to request for suggestion, find and communicate with their coworkers in a knowledgeable way. Furthermore, if coinciding with a community’s norms and wills, such services could also be used for the assignment of weights regarding the weight of a member’s arguments. In addition, services that keep tracking of the members’ activity contribute to the procedure of learning by example, in which a member can learn during watching another one’s practice in collaborative activities.

**Visualization**

It has been widely argued that visualization of collaboration conducted by a group of people working collaboratively towards solving a common problem can facilitate the overall process in many ways, such as in explicating and sharing individual representations of the problem, in maintaining focus on the overall process, as well as in maintaining consistency and in increasing plausibility and accuracy (Evangelou, Karacapilidis, & Tzagarakis, 2006; Kirschner, Buckingham-Shum, & Carr, 2003). Personalized representation of the associated processes, such as the process of discoursing or knowledge sharing, is an essential feature for tools providing effective environments for learning. Furthermore, personalized visualization of context should provide learners with a working environment that fits to their preferred visualization style. System personalization includes alterations in colours, fonts, and text effects, enabling and disabling pieces of information in the working panel, predefinition of system responses in user actions and so forth. In this direction, taxonomies and classification schemes should be employed, wherever possible, as a means for “guiding” users’ cognition. In any case, it should be noted that there is no panacea for the design of user-friendly interfaces; the related practices should be interpreted, refined, and exploited according to the needs of the different types of learners involved in the particular environment. Appropriate navigation and help tools should also be provided for users with diverse expertise. Adaptive User Interfaces should adapt themselves to the learner by reasoning about the user, based on his Learner Profile.

**Building Trust**

Privacy policies and access control services are a critical requirement for the employment of all these services, as well as for the building of trust between the CoP members and the software application. These should be provided in order to satisfy the learner/users’ need to know what information about them is recorded, for what purposes, how long this information will be kept, and if this information is revealed to other people. Furthermore, the security assurance, while establishing connections between users and services, or while accessing stored information, should be taken into consideration as well. Towards this end, two major techniques are broadly used to provide denial of access to data, that is, anonymity and encryption. Anonymity cuts the relation between the particular user and the information about him/her, while information encryption provides protection of the exchanged personal data. In our approach, we
employed the Platform for Privacy Preferences Project (P3P) approach, a W3C recommendation that supports the description of privacy policies in a standardized XML-based form, which can be automatically retrieved and interpreted by the user client (Cranor, Langheinrich, Marchiori, Presler-Marshall, & Reagle, 2002).

IMPLEMENTATION ISSUES

According to current trends in developing Web-based tools, for reasons such as the reusability of components and agility of services, our approach builds on top of a service-oriented environment. In order to exploit advantages enabled by the Service Oriented Architecture (SOA) design paradigm, the proposed set of services should be based on Web service architecture so as to enable the reusability of the implemented modules, as well as the integration or the interoperation with other services (from external systems). An overall design for the enhancement of tools supporting collaboration with personalized functionality towards learning is depicted in Figure 3. In this approach, we sketch a generic architecture design in which a Learner Profile Service is the basis for the storage and the provision of each learner’s characteristics to a set of proposed services that contribute to the system’s personalization. In order to support extensibility, the learning profile service can be dynamically augmented with new learners’ characteristics during run-time. Furthermore, targeting to the openness of the service, the service can provide the learner profile schema in the form of XML Schema Definition (XSD) in the service requestors. Considering the set of proposed services as nonexhaustive, our approach is open for the addition of new personalized services (see Figure 3, block “New Service”) and can use the Simple Object Access Protocol (SOAP) for both internal and external communication.

CONCLUSION

In this paper, we presented a set of services enhancing CoPs interactions and collaborative work based on a generic Learner Profile model. Our approach concerns an alternative form of online learning with different forms of interaction, and a new way of promoting community building. Its purpose is to aid researchers and developers in the development of personalized collaboration.

Figure 3. The proposed services
systems, that is, tools that adapt their structure and services to the individual user’s characteristics and social behaviour. Our main goal being to support individual and community learning, the proposed set of services is based on personalized features and functionalities. We argue that it can further support learning, as well as the achievement of learning objectives, as it can assist CoP members in the development of learning skills such as the interaction with other actors, growth of their autonomy, and self-direction. Nevertheless, in order to be creatively adapted in CoPs’ everyday practices, the proposed services must fit into the specific culture, norms, and incentive schemes of the community. Our future work directions concern the appropriate handling of these issues as well as the full development of the proposed set of personalization services and its evaluation in diverse CoPs.

ACKNOWLEDGMENT

Research carried out in the context of this paper has been partially funded by the EU PALETTE (Pedagogically Sustained Adaptive Learning through the Exploitation of Tacit and Explicit Knowledge) Integrated Project (IST FP6-2004, Contract Number 028038). Also, the authors thank the anonymous referees for their helpful comments and suggestions on the previous versions of this paper.

University of Salzburg, Austria

ABSTRACT

The aim of this chapter is to discuss the mutual influence between culture and technology on a broad inter- and transcultural level. Especially, how does information culture shape the meaning of information, communication, and knowledge, and consequently, the design, spread, and usage of ICTs in certain societies? Vice versa, we are interested in the ways in which the spread and usage of ICTs affect the predominating culture. We aim for a model that incorporates cultural as well as technological factors in order to provide a basis for future ICT research that goes beyond both technological determinism and social constructivism. We believe that new technologies indeed can contribute to more justice in the world in terms of access to knowledge and wealth, if sociocultural factors are taken into account more seriously. Current developments in the context of the UN World Summit on the Information Society raise awareness in this direction. At the same time, we are well aware that the loose notion and imprecise definition of the concept of culture allows for the exploitation of the term in empty political and techno-economical policies. Culture degenerates to an indispensable buzzword in the current ICT debate. This chapter is an attempt to introduce the concept of culture into the socioresponsible ICT research on equal terms with technology, economy, and society.
THE RELATIONSHIP BETWEEN CULTURE AND TECHNOLOGY

How can technology be defined? Technology often is considered a means to a particular end, the means being artificially created, not natural, and something that is not directly necessary for the individual or the end user; it serves, rather, to fulfill the need to produce something that is later to be consumed. However, we use the term in a broader sense. We regard technology as being more than just the sum of such artefacts, which are merely the crystallized, concrete manifestations of human behavioral patterns. A method is the how, the way in which a goal is reached and which involves the use of means. A means is a medium in that it mediates between the starting point and the desired result, regardless of what sort of action is involved. Thus, one could speak of social technology (e.g., psychotherapy) as a technology and not merely of technology as something used for (material) production in a society. So, technology also includes the know-how involved in the use and application of the artefacts. In short, technology embraces the ways and means of acting in pursuit of a goal (Hofkirchner, 1999).

How can culture be defined? Using the same analogy for technology, it could be understood to be an equally artefact-based concept, which is not a means to an end but rather an end in itself. That is to say, it is not in itself an essential of life, but rather something that represents a human desire (i.e., what makes humans distinct from other living beings). Here, too, there is a notion that culture is not only the result of a process but also this very process as it moves toward the goal; that is to say, culture is a characteristic of goal-oriented actions (i.e., the striving toward goals as well as the goals themselves) (Hofkirchner, 1999). It is this notion of culture that we refer to in this chapter.

Are there imaginable connections between culture and technology? The two ideal-typical extreme positions are well-known, each making a single direction of determination (Hofkirchner, 1999).

The first position can be referred to as technological determinism, which postulates the total, or at least dominating, influence of technology on culture. Technology is supposed to develop more or less on its own, pushing social development along as it goes. This may be interpreted positively or negatively. An uncritical opinion of Marxist origin saw social advancement as an inevitable result of technical achievements, just as the ideology of the bourgeoisie justified the progress of the technically possible as socially desirable. This view is opposed entirely by fundamentalists who hold technological development responsible for the loss of important values in society. Neither philosophy accepts the possibility of technological development being influenced in any way. Both ignore the fact that there would be no such development if multinational corporations and national governments were to stop investing in research and development; if there were no economic, military, or political interests to divert their resources into these areas; and if there were no values, morals, or norms that underlay these economic, military, or political interests. The fact that on a micro-level there are countless thousands of engineers constantly involved in technology design, and that on a macro-level managers and politicians decide which technological options are realized, supports the second theory—social constructivism—that technology is constructed deliberately to be a part of society. According to this view, the interests of those groups that dominate the genesis of technology finally are embodied in the technology, which in itself cannot be neutral. Here again, both a critical and an approving variant may be distinguished. While the one bemoans the inability of existing technology to pursue ethically justified, socially acceptable, and peaceful and environmentally sound objectives, the other sees the existing economic, democratic, and human rights structures as the best guarantee
of developing optimal technological options. Both versions neglect the inherent dynamism within technological development.

Do the two theories—technological determinism and social constructivism—together give a realistic view of the relationship between technology and culture? This would mean that two equally matched factors—the technical and the cultural—would not be complete without the other. Furthermore, one also might break away from strict determinism and grant each side a measure of independence, thus denying that one side totally dominates the other. But would we then have a workable proposition to discuss, or would we be reduced to the assumption that one factor partly influences the other but is itself partly influenced by its counterpart? This is a superficial answer. Is it not rather the case that the actions we are talking about, whose dependence on mediating factors we want to stress if we are talking about technology and whose immersion in value judgments we wish to highlight when we are discussing culture, not only have an individual character, but rather, through the availability of technological methods and cultural values on the part of society, acquire a deeply societal nature? The use of technology makes every action no longer unique to any individual person. Technology is based on cooperation, be it in the application of special methods, the implementation of these in specific social areas, their invention and development, or in any situation in which the skills and knowledge of other members of society are required. The same holds true for convictions, value judgments, instructions, standards, behavioral patterns, and the like. These are just as much a part of the context of life of the individual, and they promote certain technological methods but discourage others. Technology makes every technologically mediated action into a socially determined one, and its use is a human characteristic. Technological development is part of cultural development; this means that technology is part of culture, and so their relationship to each other is one of part and whole. Culture is the all-embracing factor in this context.

In each part-whole relationship, the parts are the necessary preconditions for the emergence of the whole but are not the sufficient condition for the complete determination of the result. The whole arises from the parts but then exerts control over them in the form of downward causation; the parts are no longer independent of each other as separate entities but are dominated by the whole. The relation of part and whole in regard to technology and culture is, therefore, as follows: technology has the meaning, the purpose, and the task of functioning as means and method for solving social problems. Social interests, cultural values, norms, and morals are thus in the origin and manifestation of technology in its invention, diffusion, and application in the entire process of its development, as its reason for existence. This, however, is insufficient to enslave technology completely. Technology is ambivalent; sometimes it appears to resist our intentions by wholly or partly failing to do what is wanted of it, and other times it not only fulfills our expectations but goes on to do other useful tasks that originally had not been anticipated. Technology represents potential for the realization of social goals. These technologically realizable goals may correspond to pre-existing goals within society; the practical attainment of these by technological means, however, may cause them to change, at least slightly. It is, of course, also possible that the intended goals may differ from those that can be reached with technological support. In this case, new technology may be developed in order to meet the requirements, or the requirements may, as it were, be adapted to fit the reality of what is technically possible. Realizable goals, therefore, do not always exist at the start of the process but may be discovered as options made available by technology. Whether society decides to pursue these goals on the grounds that they are possible is no longer a question of technology but rather of social decision making (Hofkirchner, 1994).
To conclude, we consider the relationship of technology and culture to be dialectic. A relationship is usually called dialectic if, first, the sides of the relation are opposed to each other; second, both sides depend on each other; and third, they form a relation that is asymmetrical (Hofkirchner, 2004). A part-whole relationship is dialectic since part and whole represents opposites, the whole depends on the parts as well as the parts on the whole, and parts and whole build up a hierarchy in which the different levels cannot be replaced by each other.

Considering this notion of the relationship between technology and culture on a broad and general level, the following section attempts to add further thought in the context of information and communication technologies (ICTs) and culture. The specific meaning of information and communication for different societies, which is predominantly the result of a special culture, determines the meaning and, therefore, the spread and usage of ICTs. Vice versa, ICTs have been developed and will be developed in the future in certain (information and communication) cultures, which leads to the functions and practices of use we are facing when we implement ICTs.

**INFORMATION AND COMMUNICATION CULTURES**

When referring to information and communication cultures, we address the basic significance of having access to information and knowledge and the practices of communication and cooperation in a specific society. The most important consideration involves the relationship between those who have access to information that has a profound effect on the distribution of power of control over flows of information within society. It is assumed that within societies with a strong hierarchical structure, the flow and dissemination of public information is restricted to just a few people, while in more liberal societies, there is a far broader basis for direct access to public information. Furthermore, more hierarchically structured societies are less likely to be expected to adapt to the Internet than liberal societies with a flatter hierarchy (Maier-Rabler, 1995, 2002).

The general attitude toward access to information, toward transparency of structures and processes, and toward empowerment and freedom of expression pertaining to a specific society or state is deeply rooted in traditions and practices of social and cultural conditions. The cultural-social framework of a society is formed mainly by the political-social system, by the legislative system, and particularly by the predominating ethic and religious values. As a result of these diverse dimensions, a continuum between the poles of information-friendly vs. information-restrictive cultures emerges (Maier-Rabler & Sutterlütti, 1992; Maier-Rabler, 1995).

Information-friendly societies foster the development of knowledge throughout all groups of a society by providing equal and universal access to all available public information. In information-friendly societies, people have access to public information, freedom of speech is guaranteed to individuals and institutions, and the concept of universal access is understood as the equitable and affordable access to information infrastructure and to information and knowledge essential to collective and individual human development for all citizens. In information-friendly societies, curiosity is encouraged by education systems, and skills for information retrieval are taught rather than just being fed information. Questions count more than answers, and students are encouraged to research instead of memorize given information (Maier-Rabler, 2002).

The political system in information-friendly cultures is likely to be in a form of communicative democracy within a developed system of civil society. Direct democratic participation is a living practice enjoyed by all social groups. The
legal system is likely to be an information-rich, case-based system in which access to information is vital for legal practice.

The economic system in an information-friendly environment strongly depends on access to information and its dissemination to shareholders and customers. Wealth and success are highly valued, and information on turnovers, revenues, and profits are publicly available. Information-friendly societies experience a great expansion in their limitations, especially through the new information and communication technologies. At the same time, it has become clear that without a capable citizenship and without capable institutions, unintended and even unwanted consequences take place. What is more, the current crises of the stock markets have been due to access to information that neither has been audited nor controlled. On a political level, we face a threat to well-established forms of representative democratic systems through populist political trends. New ways of direct democratic participation turn into the opposite, if utilized by people who have not had the chance to acquire the needed skills. However, in information-friendly societies, the chances to implement successful programs to provide equal chances for all members of society to acquire capabilities (in the context of ICT) are higher than in information-restrictive societies.

If we turn to information-restrictive societies, however, we see that they are characterized by a strong hierarchical order throughout society, leading to fewer chances for social, economic, and cultural movement. In such environments, people obtain access to relevant public information when needed, whereby the information is predominantly defined by the authorities or other higher-ranking institutions or persons within the respective hierarchical system. In such societies, people are accustomed to information simply being provided and not having to actively retrieve it. This attitude characterizes the relationship between citizens and authorities, customers and businesses, the public and the media, and students and teacher. The education system in information-restrictive cultures does not encourage curiosity or question-based learning. The “right” answer is the measure of success. What is right and what is wrong again are defined by authorities in the education system. People are not trained to address their environments and to pose questions critically. These answer-oriented societies are an obstacle for the optimal utilization of new information and communication technologies. Digital communication networks such as the Internet work best with a question-oriented approach that leads to a variety of plausible answers in different contexts. Expecting the right and only answer (as people in information-restrictive societies are trained) leads to predictable disappointments and, therefore, less motivation to get involved in new media.

In information-restrictive cultures, the flow of information between authorities and citizens as well as between businesses and customers follows the push principle, whereby authorities and businesses decide which information is being passed on. In such cultures, the Internet is perceived merely as a new and additional (mass) medium to transfer information to a mass audience. Consequently, a huge amount of information and communication capacities of the Internet simply are left unused. As there are not any geographical, national, or cultural borders within digital communication networks, information and applications from information-friendly cultural environments compete with those from information-restrictive cultures on a global stage.

We assume that information-friendly cultures provide a competitive advantage for their members in the global information society.

**THE HUMAN-CENTERED AND CULTURALLY SENSITIVE ICT ADOPTION PROCESS**

This chapter aims toward a better understanding of ICT adoption processes being dependent
from different information and communication cultures. This process, in most societies, is driven by predominantly techno-economic e-policies that are still striving to overcome the Digital Divide and to foster economic growth by means of ICTs on the macro-level of state policy. This approach has been criticized by various authors in recent years (Preston, 2004; van Dijk, 2005; Warschauer, 2002).

Most critics have in common the need to turn away from techno-deterministic viewpoints to human-centered and culturally sensitive approaches. This also can be characterized as a shift from building infrastructures to creating identities, or from bridging the digital divide to closing the knowledge gap. This means putting the individual in the center of the adoption process of technology; therefore, cognitive, cultural, and social factors must be considered in order to achieve a comprehensive understanding.

Following Mansell (2001) and Garnham (1997), we suggest adopting a rights-based capabilities approach in the ICT adoption process to ensure that people have the possibilities to make informed decisions about the specific ways in which they want to make use of ICTs. Acquiring those capabilities first demands awareness processes on an individual cognitive level. Only when people understand the individual and social implications of ICTs will they be able to make informed choices about their specific usage patterns. The stage when people shift from technology-driven skills to culturally embedded understanding is the stage that brings the ICT adoption process from the macro-level of state e-policy to the micro-level of the individual—an indispensable precondition to bring about the skilled user.

This process requires socially or culturally motivated individuals on the one hand and governments who want to offer a set of alternative choices for their citizens to allow them to achieve whatever new-media-lifestyle they want on the other.

As we have already mentioned, the development of these adoption processes depends strongly on the predominating information and communication culture in a given society. In information-friendly environments, people have a greater chance of developing capabilities in the
context of ICT and, therefore, making informed decisions based on the degree of their involvement with new information and communication technologies.

The following model aims to visualize two dimensions of the ICT adoption process: (1) the stages from access to capabilities and (2) the helical transformation of adoption processes (p) as a result of the mutual relation between technology and culture. Every culturally embedded adoption process leaves the new capable user on an advanced stage that itself is the ground for the access step to technology.

**Model of a Human-Centered and Culturally Sensitive ICT Adoption Process**

The adoption process, which also can be considered the major stage for targeted ePolicy measures, starts with the problems of technology-determined access. We need access to technology in order to make experiences and to trigger the following steps. Unfortunately, many processes get stuck in the access stage; “If they build it, they will come” could be the motive for access-only strategies. Most countries favor this access-dominated strategy, which is predominantly in the interest of the technology industry and, therefore, an industry policy measurement.

The critique of the access-only strategy led to a human-oriented enhancement of the same strategy. People need to have adequate skills in order to use the accessed technology. At first glance, this could solve the problem—not only provide people with technology but also train them to use it. Similar to the access stage, the skills stage also is geared predominantly to the interest of the technology industry; in this case, the big international or global software monopolists. Acquiring skills means dealing with a given technology. The creative potential of people in the context of technology is not addressed (National Research Council, 2004).

A further step has to be taken in order to involve the individual in the process of adopting new information and communication technologies. People must know why they should make use of ICTs and not only how to use them. On the cognitive level, the awareness of technology in the specific cultural sphere has to be raised. Here, there is a cultural translation of technology. Only when people understand the diverse patterns of different practices of ICT usage will they be able to make the informed choices as preconditions for gaining capabilities. And only the capable user will provide the basis for economic growth and competitiveness for which most countries, regions, and cultures are striving.

The capable user is the point of departure for the next iteration of the ICT adoption process (p'). Capable users have different demands for access to new technology and also represent a different level for skills training. Such qualified users, who differ in terms of cultural and social backgrounds, represent the input into p'', and so forth.

**DIGITAL CULTURES**

**Cultural Shifts: Transculturality**

In recent decades, the concept of interculturality has been very popular and influential in regard to the fairly young discipline of intercultural communication (Leeds-Hurwitz, 1998). In this context, communication was understood to be an action taking place between countries that were perceived as self-contained units. In this traditional definition, cultures are seen as types of autonomous islands that are virtually completely closed-off, which Beck (1997) called metaphorically the “container theory of society” (p. 49). But modern societies are very diverse entities. They contain and incorporate many elements of different origins, and the boundaries between foreign and indigenous cultures get blurred and finally become untraceable. Tsagarousianou (2004) sug-
suggests that diasporas should not be seen as “given communities, a logical, albeit deterritorialized, extension of an ethnic or national group, but as imagined communities, continuously reconstructed and reinvented” (p. 52). Welsch (1999) developed a new approach of connected cultures, which he called transculturality. This approach emerged due to cultures being interconnected and similar lifestyles merging and being assimilated. Cultures cannot be perceived as homogenous units anymore, because they are complex and diverse in themselves. “Cultures today are extremely interconnected and entangled with each other. Lifestyles no longer end at the borders of national cultures, but go beyond these, are found in the same way in other cultures. The way of life for an economist, an academic or a journalist is no longer German or French, but rather European or global in tone” (Welsch, 1999, 197f.).

This also can be observed in the Internet community. People from different countries use a sort of transcultural ideological language in chat rooms and are united by common interests. Even though they come from very different parts of the world, they have more in common with each other than they have with some members of their respective national communities. The mutuality derived from their similar interests prevails over the mutuality derived from nationality.

Enhancing Welsch’s (1999) concept of transculturality, we consider that this concept needs a more focused perspective on the permeability between global and local cultures, which means that transculturality allows the individual to switch between different identities according to current needs, feelings, interests, and demands. People want to belong to a certain group and want to be identified as a member of such a group; they do not want to constantly act, think, and live on a global level. The identity of the self cannot exist only on a global level, and therefore, “the search for identity, collective or individual, ascribed or constructed, becomes the fundamental source of social meaning. … Yet identity is becoming the main, and sometimes the only, source of meaning in an historical period characterized by widespread destructuring of organizations, delegitimation of institutions, fading away of major social movements, and ephemeral cultural expressions” (Castells, 2001, p. 3).

LINKING CULTURE, KNOWLEDGE, AND ICTS

At this point, we introduce the extended concept of culture, which is intertwined with the concept of knowledge with the aim to discuss the correlation between culture, knowledge, and the role of ICTs. This endeavor eventually should lead to an approach that allows us to connect the complex concept of cultures with its impact on various spheres of our respective lives and, therefore, on our identity. Therefore, the term digital culture will be used to describe the model of mutual influence between culture and technology, which we use as a fundamental framework to develop a new understanding of the use of ICTs. This model aims at an understanding of cultural differences in handling information to guarantee a beneficial development of society.

If the concept of transculturality is introduced into the notion of knowledge, there is a rapid increase of global knowledge. ICTs allow direct communication between vast numbers of people with different cultural backgrounds but do not automatically distribute access to knowledge equally. In fact, many citizens cannot gain access to global knowledge or even local knowledge other than to their own knowledge because of their low economic status (digital divide) and their low educational levels (cultural divide). These divides create groups of haves or have-nots, communication-rich or communication-poor, winners or losers in the globalization process. Concerning identities, these divides determine
the different opportunities of switching identity levels. However, the more people are capable of assuming different identities, both on a local and global level, the more they are capable of gaining advantages in the digital culture.

To avoid getting caught in this gap-trap and to guarantee a sort of mutual benefit, we have to find a way to reconcile some aspects of knowledge production and acquisition, which means that global knowledge has to be incorporated locally (pull factor) in order to allow people to benefit from global knowledge on a local level. Also, local knowledge has to be introduced into the cycle of global knowledge production (push factor) in order to make sure that there is an awareness of the existence of this local identity in a global society. Thus, developments in this global society can be influenced with regard to local positions. We face the challenging task of creating a permeable flow of communication that allows for global and local knowledge bases to interact.

**COMBINING ICTS AND CULTURE TO A NEW APPROACH**

As already mentioned, technology and culture influence each other and are mutually dependent on each other. It is, however, important to discuss the terms *culture* and *technology* and the respective points of view. It is equally important to demonstrate that culture and technology influence each other by using the term *digital culture*.

Drawing upon these basic insights, we will discuss the dialectic of shaping, diffusion, and usage of ICTs in societies and different cultural knowledge bases along the following dimensions: content, distribution, and context.

**DIGITAL CONTENT CULTURE**

This indicator refers to the concept of knowledge production or, in other words, how data are converted into knowledge. According to Willke (2004), one has to distinguish between data and knowledge, even though knowledge management often is mistaken for data preparation and data exchange.

In fact, data are nothing but raw material for knowledge, and in the age of ICT, getting ahold of useful data is not difficult. What is difficult, however, is reducing and filtering huge amounts of potentially useful data and converting them into information first by putting them into a broad context that adds relevance to them; knowledge is gained by putting information into a practical context and modifying or creating a practical due to it in order to make the information practically useful (Willke, 2004).
ICTs, like the Internet, can transport and make available huge amounts of data and information. The content to be distributed is taken from this basic range of knowledge. In a metaphorical sense, the Internet can be linked to a sea of information, all of which is useful in principle. Yet, to get ahold of the invaluable essence of relevant information, we have to siphon off all irrelevant information. The focus is on translating data and information into helpful insights that can be used to improve real-life situations by adding practical relevance to the data.

To guarantee the success of knowledge transfer and the adaptation of new knowledge, a transdisciplinary approach, in addition to an interdisciplinary approach, has to be adapted. This means that different scientific approaches are used, but an effort also is made to involve the local community in the process. In that way, one can ensure that the goals are adapted to the local culture, which increases the likelihood of locals accepting them.

There are three main topics that have to be discussed: knowledge management, learning strategies, and educational approaches.

**DIGITAL DISTRIBUTION CULTURE**

The second dimension illustrates the relationship between the channel that is used for information transport and the dissemination of knowledge—the pull/push strategy.

The first aspect is the communication code: if a message is to be transported, it has to be converted into numbers, text/words, and/or pictures (Willke, 2004). There are limits to the amounts and kinds of information that can be transported in a certain channel. This depends on the type of channel as well as the respective circumstances (e.g., legal, technical, environmental, infrastructural) that, in fact, might influence the usage of the channel.

If we distinguish between explicit and tacit (i.e., structured and unstructured) knowledge, we can see how difficult it is to distribute knowledge. While explicit knowledge (represented in documents, databases, products, and processes) is easy to transfer, tacit knowledge “is more dependent on action, context and personal experience, which makes it difficult to formalize and communicate” (Martin, 2003, p. 44).

The next aspect can be observed in culturally influenced communication rituals. Each and every one of our actions is influenced by culture (i.e., norms, values, beliefs), and by performing these actions repeatedly, we permanently reinforce our cultural understanding. A similar cycle of conditioning can be found in technology. We develop technology by drawing upon our cultural understanding. We then use this technology on a daily basis and, thereby, cause it to impact our identity (reinforcement).

This development can be observed with the personal computer. The term *personal* already indicates that this technology was invented in a very individualistic culture. The more time we spend interacting with computers/technology in this way, the more our patterns of thought and conveying knowledge are assimilated to those used by computers/technology. Our way of thinking becomes more abstract, and knowledge is reduced to mere words and graphics, which lead to future inventions being more abstract as a logical result. The term *digital culture* means that we shape our ICTs and are shaped by them in reverse.

The same applies to the Internet, whose basic technology was developed in the academic-military information culture in California in the late 1950s and early 1960s. This implies a certain practice of converting data into knowledge using the Internet as a practical source for information. In similar information cultures, it is clearer how one can use this kind of data. But people from a different cultural setting who have a different concept of knowledge acquisition might not be
able to make adequate use of the Internet. They might not be familiar with the work processes dominating the information culture within which the Internet was developed. Therefore, it could lead to difficulties to connect to and make use of the Internet. Besides, the way the Internet is used might not cohere with their cultural behavior.

**DIGITAL CONTEXT CULTURE**

There are factors that influence culture and technology on a meta-level. The central questions are: What culture do we live in? What culture do we work in? What culture do we act in?

An important indicator is knowledge as a commodity or as a free public good. First, costs are linked to the question of whether knowledge can be circulated freely or whether it should be treated as property (IPR—intellectual property rights; DRM—digital rights management). Second, costs refer to the investment and maintenance of infrastructure (hardware, software, bandwidth), and finally, we have to calculate the costs for educating people to use ICTs successfully and to develop the ability to convert data into knowledge.

Another important indicator deals with power, which can be explained by using the game theory. It seems that most political and economic decisions are based on the zero-sum game theory, which means that any gain for one player represents an equal loss for the other. We have to face the fact that empowering people also means a loss of power for the powerful to some extent. The powerful create new competitors by empowering other people, societies and/or subcultures. This is not so much about unlimited development as it is about creating a situation of equal opportunities.

Content, distribution, and context are influenced by technology as well as culture. It is not enough to focus only on the digital divide but also on the cultural divide, and by using the concept of digital culture, we can develop a kind of empathy with the goal that we have to create inclusion and development as a central value, if we really want to change from a segregated to an inclusive society.

**THE ONE AND THE MANY**

In this respect, it is worth discussing the relationship of the one and the many. Due to global challenges that endanger the species as a whole and that must be met by a single set of intelligently coordinated actions, the partitions of humankind are on the brink of forming a unit on a planetary scale, and many cultures are on the brink of forming one culture. The awareness of this required delicate relationship between the

</table>
one and the many may serve as a normative idea that guides the measures to be taken to advance world society.

The question is how one of the many relates to another one and how the many relate to the oneness that is made up of the manifold. Is the world society to become the common denominator of the various identities? Or is one of the many the only one? Or are the many merely summands of the individual? Or do the many participate in a one that goes beyond them?

The reductionist way of thinking in intercultural discourse is called universalism. Cultural universalism reduces the variety of different cultural identities to what they have in common. Identities are homogenized by a sort of melting pot that was named McWorld (Barber, 2001). Modernism (i.e., the pursuit of human rights, democracy, and capitalism based on the same mode of metabolism carried out by the same technology everywhere) is universalistic—shimmering between a claim to liberal and pompous imperialistic behavior as it is witnessed by its adversaries. In either case, it gets rid of the richness of cultural identities, the many are reduced to a shallow one, and there is no diversity in the unity.

A second strand in intercultural discourse revolves around the way of thinking that overuses projection. It may be called particularism or totalitarianism. Cultural particularism or totalitarianism extrapolates what separates one cultural identity from the rest and construes an imaginary common. It also leads to homogenization. The melting pot in this case, however, was named Jihad (Barber, 2001), because it is the anti-modern fundamentalism that may be a good example for imposing a certain one out of the many on the rest of them. Here, a culture that is accredited with very specific social relations is raised to the level of the ideal, which is to serve as a model for all other cultures to copy. Thus, a specific form is built up to be the general norm. Inasmuch as it is something particular that is raised in this manner, it concerns particularism.

A third way to conceive intercultural discourse is relativism. Cultural relativism rests on the figure of dissociation. By denying any commonality of different cultural identities, it yields fragmentation. The many fall apart. These concepts of multiculturalism and separatism suit postmodern thoughts. Here, each of the many cultures is seen as something with the right to exist and remain free from external interference. Each special case is made into a norm in its own right. Inasmuch as it is one of many that is made into a norm, we may speak of pluralism. Inasmuch as every special case is treated thus, we must, however, speak of indifferentism. Relativism does not claim general validity and does not wish to unify anything or anyone. The postmodernist form leaves differences as they are. World society would simply be diversity without unity.

None of these three options can satisfy. Either the one is regarded as the necessary and sufficient condition for the many, the many are considered necessary and sufficient for the one, or one and many are deemed independent.

Cultural thinking that reconciles the one and the many is achievable only on the basis of an integration and differentiation way of thinking. It integrates the differences of the manifold cultural identities and differentiates the common as well. Welsch (1999) coined the term transculturalism and notions of glocalization (Robertson, 1992) or new mestizaje (a term coined by John Francis Burke in “Reconciling Cultural Diversity With a Democratic Community: Mestizaje as Opposer to the Usual Suspects” in Wieviorka (2003), which are useful in this context.

The process of emergence of a new sustainable world society may be sketched in terms of dialectics. Diversity is not abolished but rather sublated and leads in an evolutionary leap to a unity through diversity, which, in turn, enables and constrains diversity in order to make it diversity
Culture and Technology

in unity, which then builds the new base for unity through diversity. World culture is located on the macro-level; the partitions of world culture that are located on the micro-level take care of the world culture in order to preserve humanity.

CONCLUSION

Starting with a critique of both techno-deterministic and social-constructive approaches toward the relationship between technology and culture, we argue for a dialectical, mutual-shaping approach. Especially in the context of information and communication technologies (ICTs) and society, this dialectical relationship between culture and technology is important. To strive for the capable user, cultural dimensions have to be incorporated into a model that transfers the spread and usage of technology on the one hand and the social shaping of technology on the other. The concept of digital culture represents a framework that embraces the techno-cultural dimensions of content, distribution, and context. This framework provides an applicable instrument that allows addressing the important questions in the context of technology and society, such as equal knowledge distribution, provision of capabilities, and social inclusion.

Chapter 3.4
Importance of Interface Agent Characteristics from End-User Perspective

Alexander Serenko
Lakehead University, Canada

ABSTRACT

This article reports on an empirical investigation of user perceptions of the importance of several characteristics of interface agents. Interface agents are software entities that are incorporated into various computer applications, including electronic mail systems. As evidenced by the growing body of empirical studies and the increasing number of interface agent-based applications on the software market, there is a strong need for the development of this technology. According to a meta-review of agent-related literature by Dehn and van Mulken (2000), there are several characteristics of interface agents that require special attention from agent developers. However, prior to this study, the importance of these characteristics from the end-user perspective remained unclear. In order to identify the significance of these characteristics, a group of actual users of an e-mail interface agent was surveyed. The results indicate that information accuracy and the degree of the usefulness of an agent are the most salient factors, followed by user comfortability with an agent, the extent of user enjoyment, and visual attractiveness of an agent. The implications of the findings for both theory and practice are discussed.

INTRODUCTION

To create an artificial being has been a dream of men since the birth of science. Professor Hobby (William Hurt) in “Artificial Intelligence” (Spielberg, 2002)

For thousands of years, people have thought of someone doing basic tasks for them. That could be a robot, a cyborg, or a well-trained pet. Not until the beginning of the 21st century did it become possible. Now, with the recent development of telecommunications networks and computer technologies, a new type of software application plays the role of virtual assistants that potentially may alleviate some of the problems associated with the employment of software systems. This class of applications often is referred to as intelligent agents, software agents, avatars, or interface agents. As demonstrated by the growing body of academic literature and by the increasing number of agent-based software applications on the market, there is...
Importance of Interface Agent Characteristics from End-User Perspective

increased interest in the creation of such software entities. In this article, these software systems are labeled as interface agents.

Interface agents emerged from the recent developments in the field of intelligent agents. The idea of software agents was first introduced by John McCarthy (1956, 1958) and later coined by the MIT Lincoln Laboratory computer scientist Oliver Selfridge. In the 1980s, this concept was explored by agent visionaries such as Marvin Minsky and Alan Kay and further utilized in the recent classic works of Pattie Maes, Nicolas Negroponte, Jeffrey Bradshaw, Hyacinth Nwana, and Divine Ndumu. The past few years have witnessed the rapid development of prototypes and working models of intelligent agents, many of which already are incorporated in end-user commercial applications. A number of recent studies demonstrate the fruitfulness and viability of using agent-based technologies in various areas; for example, in automatic negotiation (Castro-Schez et al., 2004; Fatima et al., 2005), natural-language customer support services (Lester et al., 2004), education (Takacs, 2005), and user notification systems (Horvitz et al., 2003). Some academics have shifted their research from human-agent interaction to human-agent cooperation (Rickel & Johnson, 2000; Rickel et al., 2002) and man-machine symbiosis (Klein et al., 2004; Lesh et al., 2004; Lesh et al., 1999), when the human user and the software agent collaborate toward achieving shared goals.

In terms of this article, an interface agent is defined as an autonomous (i.e., independent), continuous (i.e., long-lived), reactive (i.e., it monitors an external environment and reacts to any changes), and collaborative (i.e., it cooperates with other software processes or agents) software entity that exhibits strong visual or audio presence in the computer interface and that communicates with a user directly (i.e., by bypassing intermediaries) (Detlor, 2004; Lieberman & Selker, 2003; Serenko & Detlor, 2004). “Interface agents draw their strength from the naturalness of the living-organism metaphor in terms of both cognitive accessibility and communication style” (Laurel, 1997, p. 68). Typically, interface agents are personalizable and implemented in the form of humanlike or cartoonlike animated characters, electronic figures, graphical user interfaces, textual boxes, or any other visual components (Godoy et al., 2004; Schiaffino & Amandi, 2004).

Having the available agent technology is insufficient; it also should be accepted and utilized appropriately by its target users. For the past 10 years, there have been various attempts to understand what people like or dislike in interface agents and why they adopt or reject them. The goal of this stream of research is to develop a valid, complete list of characteristics that interface agents should possess that would warrant the end-user acceptance of this technology.

By performing a meta-analysis of the human-computer interaction literature, Dehn and van Mulken (2000) presented a comprehensive yet exhaustive list of characteristics of interface agents that potentially may influence the human-interface agent interaction process. Most of these characteristics are drawn from various independent investigations conducted in laboratory settings. At the same time, no study reports how real-life users value the characteristics of an interface agent-based technology. In order to bridge that void, the present investigation attempts to solicit and to analyze the opinions of interface agent users on several key characteristics of the technology. It is assumed that this information potentially may improve the quality of the technology and the way it is delivered to the customer. For example, if agent manufacturers could know what interface agent characteristics are more or less important for users, they would be able to concentrate their short-term efforts to improve positive user perceptions of these characteristics. This, in turn, might increase user satisfaction with agent-based technology and accelerate the rate of innovation diffusion.
As such, Dehn and van Mulken (2000) classified the various characteristics of interface agents (e.g., the user’s subjective experience of the system, the user’s behavior while interacting with the system, and the outcome of the interaction). Each category includes several factors. However, it is not viable to investigate the importance of these characteristics applied to all types of interface agents in a single project. Since interface agents may be incorporated in the form of personal secretaries, Internet guides, electronic commerce assistants, or educators, a separate study is required for each kind of interface agents. It is believed that interface agents embedded in different types of software environments may require certain system-specific features and facets. For example, users who work with an interface agent that facilitates online shopping may look for effectiveness and efficiency. In contrast, people who employ an interface agent as entertainers may emphasize the aspect of enjoyment over that of effectiveness or efficiency.

With respect to the present study, interface agents for electronic mail were chosen for two reasons. First, e-mail is an important telecommunications medium that is utilized heavily by both individuals and organizations. However, today’s e-mail systems provide inadequate support for constantly changing user needs, fail to convey ambiguous content and human emotions, overload people with continually growing flows of unstructured information, and exhibit an inefficient direct manipulation interface. As a result, many individuals feel frustrated utilizing e-mail. The use of interface agents is a potential solution to the currently challenging task of e-mail management. Second, the software market presents several versions of interface agents that have been delivered to end users. Currently, most other types of interface agents have been realized in the form of pilot studies, working prototypes, or beta versions. This identifies the opportunity to reach the actual users of this technology and to poll them directly. It is for these reasons that interface agents for e-mail were selected.

A review of the general characteristics of interface agents presented by Dehn and van Mulken (2000) allowed the identification of several factors that were believed to be applicable to the e-mail environment. Table 1 offers a list of these char-

characteristics. However, little is known about how important these characteristics are for the actual users of e-mail interface agents. As noted by Dehn and van Mulken (2000), the results of the empirical studies that identified these characteristics appear to be mixed and inconsistent.

To bridge this void and to rank the importance of the previous characteristics, this study polled the actual users of e-mail interface agents. It was believed that the end users who have utilized this technology for a long period of time may present valid and reliable information that will be of interest to agent researchers and developers. The following research question was proposed:

*How important are the characteristics of e-mail interface agents identified in Table 1 from the end-user perspective?*

**METHODOLOGY AND RESULTS**

In order to answer the study’s research question, a survey of current and past users of an interface agent-based application for e-mail was conducted. Despite the extensive work underway in the incorporation of interface agents in e-mail applications, most previous studies and projects have been realized in forms of conceptual discussions, preliminary empirical investigations, and pilot systems (Bergman et al., 2002; Dabbish et al., 2005; Florea & Moldovanu, 1996; Griss et al., 2002; Gruen et al., 1999; Lashkari et al., 1994; Maes, 1994; Voss, 2004) rather than in end-user products. E-mail notification applications are one of the first commercial systems that utilize interface agent technologies in the electronic mail environment. This type of interface agents was chosen to conduct a user survey. Out of all commercially available interface agent systems for e-mail, Blind Bat Software was chosen randomly by the researcher, the executives of the company were approached, and agreement was reached. The list of customers who potentially might serve as the study’s participants was sent to the researcher. Figure 1 presents a screenshot of the software product.

In order to poll e-mail agent users on their perceptions of the importance of the characteristics of interface agents, a survey instrument was designed. The questionnaire provided basic instructions, a definition of an interface agent for e-mail, and a list of characteristics. The participants were asked to rate the importance of each characteristic on a scale of 1 to 5, with 1 being not important and 5 being very important.

![Figure 1. E-mail announcer developed by Blind Bat Software (http://www.blindbat.com)](image-url)
and several screenshots of the agent developed by Blind Bat. Users were asked to indicate their opinion on perceptions of the importance of agent characteristics outlined in Table 1. Particularly, the question stated, “Based on your experience with interface agents for e-mail, how important is it for you?” After this, eight statements were provided, measured on a seven-point Likert-type scale ranging from totally unimportant to very important. In addition, demographic information was solicited. The data for this investigation were collected as part of a larger project conducted by Serenko (2005).

By utilizing the total design method (Dillman, 1999), the four-phase survey process was developed. As such, all respondents were e-mailed an initial request to participate in the study and then three follow-up reminders. Fifty-nine usable responses were obtained. An acceptable response rate was achieved. Note that the actual response rate may not be revealed as per the nondisclosure agreement with Blind Bat Software.

Eighty percent of the surveyed users were male, and 20% were female. Over 65% of all users were between 31 and 50 years old, and the 46-to-50-age category was the most frequent user group. Over one-half of the respondents were occupied in the information technology sector; most of them were well-educated and financially well-off and demonstrated a high degree of personal innovativeness in the domain of IT. According to Rogers (2003), this group of people corresponds to innovators, who constitute 2.5% of all people that adopt a particular product or service.

Recall that respondents were asked to rate their perceptions of the importance of eight characteristics of interface agents on a seven-point Likert-type scale. The purpose was to understand what characteristics were more or less imperative from the end user’s point of view. Figure 2 visualizes the results, and Table 2 presents the list of questions sorted by the mean.

To analyze whether there were differences in these eight means, the ANOVA test was conducted. The goal of this statistical method is to determine the existence of differences among several population means (Aczel, 1996). This technique is an extension of the two-sample \( t \) test. The results demonstrated that there was a high degree of confidence that at least some of the means differed from one another (\( F = 12.846, \) d.f. between = 7, d.f., within = 456, significance

level = 0.000). To measure the practical value of the detected differences, the effect size was calculated as the ratio of sum of squares between the sum of squares total. The effect size was very strong ($\eta^2 = 0.16$).

After it was determined that differences existed among the means, the Tukey Honestly Significant Difference test was done by using SPSS. The Tukey post hoc test is a statistical method of pairwise comparisons of the population means. It allows the comparison of every possible pair of means using a selected single level of significance. The test yielded a matrix where asterisks (*) indicated significantly different group means at an alpha level of 0.1. Table 3 presents the results of mean comparisons.

Based on these results, several statistically significant differences in item means were observed. Overall, the means of the questions positioned on the left-hand side and right-hand side of Figure 2 strongly differed from one another. This demonstrated a strong degree of confidence that respondents were able to distinguish among the questions and that the results presented in Figure 2 were statistically sound.

**DISCUSSION AND CONCLUSION**

Recall that the purpose of this study was to obtain strong empirical evidence on the importance of interface agent characteristics to bridge the gap in the human-agent interaction literature. The results of the survey showed that trust in an agent (i.e., information accuracy) as well as an agent’s utility (i.e., the persona effect) were the most important factors from the end user’s point of view. They were followed by the degree of conformability and enjoyment with an agent.

First, agent users believed that the accuracy of any information provided by an agent was the most critical factor. This finding is consistent with prior research that points out the importance of trustworthiness in human-agent interaction (Bickmore & Cassell, 2005; Bickmore & Picard, 2005; Hertzum et al., 2002). Indeed, in order to delegate tasks to an agent, a person must believe that the agent will perform them accurately and report back the true rather than the desirable state.

Second, respondents indicated the significance of an agent’s usefulness. This, again, is consistent with prior empirical research and speculations on the importance of the persona effect in agents. The persona effect emerges when an interface agent adds the positive perceptions of usefulness, ease of

</table>
use, or enjoyment with an existing system. The key outcome of the persona effect is the improvement of existing software applications by embedding interface agents. By emphasizing the importance of an agent’s usefulness, subjects demonstrated that value-added services were the key factors influencing their adoption decisions.

Third, perceptions of the importance of comfortability and enjoyment with an agent were also high. The extent to which a user feels comfortable employing an agent partially corresponds to the ease of use of the agent.

Fourth, items pertaining to non-distraction and the naturalness of interactions received lower scores. Prior work suggests that a user should perceive all interactions with an agent to be natural, and the agent is not supposed to disrupt current user activities. However, this item received a lower score compared with information accuracy, usefulness, comfortability, and enjoyment.

Finally, in contrast to prior research, respondents stated that the appearance of an agent should not necessarily correspond to its level of intelligence. Two assumptions may explain this contradiction. First, highly innovative individuals might wish to utilize an agent that looks maximally intelligent, regardless of its actual degree of intelligence. Second, if users were not satisfied with the agent’s appearance, they easily might install another one, given that there is a variety of cartoon or humanlike agent characters available on the Web. Thus, end users had control over the interface of an agent that reduced their perception of the importance of the agent’s appearance.

These findings are important for both theory and practice. With respect to theory, the investigation discovered some discrepancies between the view of agent researchers and the opinion of real-life users. With regard to practice, it is suggested that agent designers begin emphasizing the more important characteristics of e-mail interface agents in their products. In the short term, they need to concentrate their efforts on the development of interface agents that provide accurate and reliable information and are perceived to be really useful by the end users. After the issues of information accuracy and usefulness are addressed, agent developers may attempt to improve several other characteristics of interface agents. They may improve the degree of user comfortability with the software, increase user enjoyment, and advance the visual appeal of an agent. In the long term, agent manufacturers may want to decrease the degree of an agent’s intrusiveness and facilitate the naturalness of human-agent interactions. However, it is unlikely that they will need to create an interface agent whose appearance would correspond to its level of intelligence. Instead, they should offer a variety of agent interfaces and leave it up to the end users to decide which one to utilize.

Overall, this investigation is one of the first documented attempts to explore the importance of interface agent characteristics by polling the actual users of this technology. The author hopes that other researchers will continue to explore this field that will lead to the creation of really useful interface agents.

INTRODUCTION

Over the last decade, we have witnessed an explosive growth in the information available on the Web. Today, Web browsers provide easy access to myriad sources of text and multimedia data. Search engines index more than a billion pages and finding the desired information is not an easy task. This profusion of resources has prompted the need for developing automatic mining techniques on Web, thereby giving rise to the term “Web mining” (Pal, Talwar, & Mitra, 2002).

Web mining is the application of data mining techniques on the Web for discovering useful patterns and can be divided into three basic categories: Web content mining, Web structure mining, and Web usage mining. Web content mining includes techniques for assisting users in locating Web documents (i.e., pages) that meet certain criteria, while Web structure mining relates to discovering information based on the Web site structure data (the data depicting the Web site map). Web usage mining focuses on analyzing Web access logs and other sources of information regarding user interactions within the Web site in order to capture, understand and model their behavioral patterns and profiles and thereby improve their experience with the Web site.

As citizens requirements and needs change continuously, traditional information searching, and fulfillment of various tasks result to the loss of valuable time spent in identifying the responsible actor (public authority) and waiting in queues. At the same time, the percentage of users who acquaint with the Internet has been remarkably increased (Internet World Stats, 2005). These two facts motivate many governmental organizations to proceed with the provision of e-services via
their Web sites. The ease and speed with which business transactions can be carried out over the Web has been a key driving force in the rapid growth and popularity of e-government, e-commerce, and e-business applications.

In this framework, the Web is emerging as the appropriate environment for business transactions and user-organization interactions. However, since it is a large collection of semi-structured and structured information sources, Web users often suffer from information overload. Personalization is considered as a popular solution in order to alleviate this problem and to customize the Web environment to users (Eirinaki & Vazirgiannis, 2003). Web personalization can be described, as any action that makes the Web experience of a user personalized to his or her needs and wishes. Principal elements of Web personalization include modeling of Web objects (pages) and subjects (users), categorization of objects and subjects, matching between and across objects and/or subjects, and determination of the set of actions to be recommended for personalization.

In the remainder of this article, we present the way an e-government application can deploy Web mining techniques in order to support intelligent and personalized interactions with citizens. Specifically, we describe the tasks that typically comprise this process, illustrate the future trends, and discuss the open issues in the field.

BACKGROUND

The close relation between Web mining and Web personalization has become the stimulus for significant research work in the area (Borges & Levene, 1999; Cooley, 2000; Kosala & Blockeel, 2000; Madria, Bhowmick, Ng, & Lim, 1999). Web mining is a complete process and involves specific primary data mining tasks, namely data collection, data reprocessing, pattern discovery, and knowledge post-processing. Therefore, Web mining can be viewed as consisting of the following four tasks (Etzioni, 1996):

- **Information Retrieval—IR (Resource Discovery):** It deals with automatic retrieval of all relevant documents, while at the same time ensuring that the non-relevant ones are fetched as few as possible. The IR process mainly deals with document representation, indexing, and searching. The process of retrieving the data that is either online or offline from the text sources available on the Web such as electronic newsletters, newsgroups, text contents of HTML documents obtained by removing HTML tags, and also the manual selection of Web resources. Here are also included text resources that originally were not accessible from the Web but are accessible now, such as online texts made for search purposes only, text databases, and so forth.

- **Information Extraction—IE (Selection and Pre-Processing):** Once the documents have been retrieved in the IR process, the challenge is to automatically extract knowledge and other required information without human interaction. IE is the task of identifying specific fragments of a single document that constitute its core semantic content and transforming them into useful information. These transformations could be either a kind of pre-processing such as removing stop words, stemming, etc. or a pre-processing aimed at obtaining the desired representation such as finding phrases in the training corpus, transforming the presentation to relational or first-order logic form, and so forth.

- **Generalization (Pattern Recognition and Machine Learning):** Discover general patterns at individual Web sites or across multiple sites. Machine learning or data mining techniques are used for the generalization. Most of the machine learning systems, deployed on the Web, learn more about the
Web mining refers to the overall process of discovering potentially useful and previously unknown information, knowledge, and patterns from Web data. In this sense, it implicitly covers the standard process of knowledge discovery in databases (KDD) and can be considered as a KDD extension applied to the Web (Markellos, Markellou, Rigou, & Sirmakessis, 2004a). Specifically, Web mining can be categorized into three areas of interest based on which part of the Web is mined:

- **Web Content Mining**: Focuses on the discovery/retrieval of useful information from Web contents/data/documents. Web content data consist of unstructured data (free texts), semi-structured data (HTML documents) and more structured data (data in tables, DB generated HTML pages)
- **Web Structure Mining**: Focuses on the structure of the hyperlinks within the Web as a whole (inter-document) with the purpose of discovering its underlying link structure. Web structure data consist of the Web site structure itself
- **Web Usage Mining**: Mines the secondary data derived from Web surfers’ sessions or behaviors and focuses on techniques that could predict user behavior while the user interacts with the Web (Cooley, 2000). Web usage data can be server access logs, proxy server logs, browser logs, user profiles, registration data, user sessions or transactions, cookies, user queries, bookmark data, mouse clicks and scrolls, and any other data as the result of interactions

Recently, Web usage mining (Srivastava, Cooley, Deshpande, & Tan, 2000) has been proposed as an underlying approach for Web personalization (Mobasher, Cooley, & Srivastava, 2000). The goal of Web usage mining is to capture and model the behavioral patterns and profiles of users interacting with a Web site. The discovered patterns are usually represented as collections of pages or items that are frequently accessed by groups of users with common needs or interests. Such patterns can be used to better understand behavioral characteristics of visitors or user segments, improve the organization and structure of the site, and create a personalized experience for visitors by providing dynamic recommendations. In particular, techniques such as clustering, association rule mining, and navigational pattern mining that rely on online pattern discovery from user transactions can be used to improve the scalability of collaborative filtering when dealing with clickstream and e-government data.

**WEB MINING TECHNIQUES IN E-PUBLIC SERVICES**

For the implementation and successful operation of e-government, the proper design, which will be the basis in order to receive a series of strategic, administrative, and operational benefits, is necessary. The application of e-government in the public domain can be gradually performed in fourteen (14) levels (Markellou, Panayiotaki, & Tsakalidis, 2003). This allows the unobstructed flow of information from/to the public sector and
gives the possibility not only to the citizens but also to the enterprises (private sector) to acquire better access in the services that state provides. One of these levels is the upgrade of portal with applications adjusted to every user, where Web mining techniques may be applied to improve access to information through the provided e-services (Markellou et al., 2004a; Markellou, Rigou, & Sirmakessis, 2004b).

Specifically, the deployment of Web mining in the e-government domain relates to the analysis of citizen behavior and the production of adequate adaptations. For example, given a specific citizen, the presentation of required information from an e-government portal can be tailored to meet individual needs and preferences by providing personal recommendations on topics relative to those already visited. This process is typically based on a solid user model, which holds up-to-date information on dynamically changing citizen behavior. This enables on-the-fly portal content assembly, addressing exactly what the citizen needs to know without wasting time on topics the user is already proficient or not interested in. The flowchart of this procedure is shortly illustrated in Figure 1. E-government application constructs users’ profiles integrating various sources of data, pre-processes the data and applies Web mining techniques to provide the users with personalized Web experiences.

In order to personalize an e-government site, the system should be able to distinguish between different users or groups of users. This process is called user profiling and its objective is to create an information base that contains the preferences, characteristics, and activities of the users. In the Web domain, user profiling has been developed significantly, since Internet technologies provide easier means of collecting data about the users of a Web site, which in the case of e-government sites are citizens that must be satisfied by the provided services. A user profile can be either static, when the information it contains is never or rarely altered (e.g., demographic information), or dynamic when the user profile’s data change frequently. Such information is obtained either explicitly (e.g., preferences, background, etc.) using online registration forms and questionnaires, or implicitly, by recording the navigational behavior and other users’ actions from server logs, cookies, and so forth. User profiling is extremely useful to G2C (government-to-consumer) and G2B (government-to-business) applications. For example, a public authority, such as a Ministry of Finance and Economy, can customize its information/services concerning chemical and customs procedures to the relevant actors that import chemical goods. Using this aspect, the actors are facilitated in completing the necessary

![Figure 1. Application of Web mining techniques in e-government domain](image-url)
procedures without getting lost in the “maze” of information provided through a multi-field covering e-government Web site.

Another technique that can be used is the one of clustering. Page clustering identifies groups of pages that seem to be conceptually related according to the users’ perception. User clustering results in groups of users that seem to behave similarly when navigating through a Web site. Such knowledge can be used in e-government in order to perform public services segmentation.

Classification technique can be applied after clustering in order to assign a new user to the defined groups. It uses features with high discriminative ability for defining the various profiles, for example, the profile of an active citizen may include the following values: Sex=male, 34<=Age<=40, Job=worker, Education= basic, MaritalStatus=marital, NumberOfChildren=4, and so forth. This knowledge can be used in applying personalization to e-government services and better supporting the needs of the users providing the right information, to the right people, at the right time.

For discovering relations between different types of available information in an e-government environment association rules can be applied. This technique may identify correlations between pages/users/services or other types of items, not directly connected and reveal previously unknown associations between groups of such items with specific similarities. The form of an association rule can be “65% of citizens that their MaritalStatus=marital search e-government portal for information about LifeEpisodes=having a baby” or “40% of the citizens who accessed help desk asked about online filling-in of tax returns and VAT.” For example, the last rule may indicate that this information is not easily accessible or explanatory enough and requires redesign tasks from the portal technical group.

An extension of the previous technique comprises the sequential pattern discovery that can be used for revealing patterns of co-occurrence, which incorporates the notion of time. For example a pattern may be a Web page or a set of pages accessed immediately after another set of pages: “55% of new businesses who apply for a certain certificate will use the certificate within 15 days” or “Given the transactions of a citizens who has not apply for any information/services during the last 3 months, find all citizens with a similar behavior.”

Finally, as search engines often appear as a helpful tool at e-government, personalized Web search systems may be used to enhance their functionality. In order to incorporate user preferences into search engines, three major approaches are proposed (Shahabi & Chen, 2003):

- **Personalized Page Importance:** Modern search engines employ the importance scores of pages for ranking the search results, as well as traditional text matching techniques.
- **Query Refinement:** A process composed of three steps: obtaining user profiles from user, query modification and refinement.
- **Personalized Metasearch Systems:** Metasearch systems could improve the retrieval rate by merging various ranked results from multiple search engines into one final ranked list.

**FUTURE TRENDS**

On the road to enhance an e-government application and treat each user individually, personalization plays a central role. The benefits for both public authorities and citizens are significant when it really works. However, several issues still remain unclear. First of all, determining and delivering personalization is a data intensive task and requires numerous processing steps. This usually causes intolerably long response times, which in turn may lead to site abandonment. To avoid this constrain, parts of the process can be executed
offline or special algorithms and structures can be used to guarantee fast online operation.

Another challenge is to ensure personalization accuracy. It is true that unsuccessful recommendations can slow down the process, confuse, and disorientate users. It is preferable not to deliver any recommendations than deliver a set of useless or harmful ones. Apart from that, personalization should be delivered in the appropriate way (avoiding user intrusion and loss of concentration) and not deprive users control over the whole process. Moreover, as e-government sites are dynamic environments, issues concerning the content or structure updating e.g. newly added topics, pages, services, etc. can be taken into consideration.

Last but not least, privacy violation during the user profiling process should be encountered (Volokh, 2000). Many users are reluctant to giving away personal information either implicitly as mentioned before, or explicitly, being hesitant to visit Web sites that use cookies (if they are aware of their existence) or avoiding to disclose personal data in registration forms. In both cases, the user loses anonymity and is aware that all of his actions will be recorded and used, often without his consent. Additionally, even if a user has agreed to supply personal information to a site, through cookie technology such information can be exchanged between sites, resulting to its disclosure without his permission. Although the new technologies and products for protecting user’s privacy on computers and networks are becoming increasingly popular, none can guarantee absolutely secure communications. Electronic privacy issues in the foreseeable future will become highly crucial and intense (Markellos et al., 2004b).

CONCLUSION

Governments enhance their attempt to offer efficient, advanced and modern services to their users (citizens and businesses) based on information and communication technologies and especially the Web. The remarkable acceptance of this powerful tool has changed the way of conducting various activities and offers citizens, businesses and public authorities limitless options and opportunities. However, the emerging problem to deal with is the way an e-government can provide its users with the right information and service according to their specific needs and preferences. To this direction, Web mining and personalization are used for supporting tailored Web experiences.

These techniques appear as the most promising for the future, since they help to establish one-to-one relationships between users and governments, improve the performance of provided information and services, increase users’ satisfaction and promote e-loyalty. On the other hand, governments take advantage of them, as long as they save costs (e.g., transactions, communication, task management, etc.), improve response times, automate various processes, provide alternative channels of cooperation and communication, and upgrade and modern their profile and image.

Many research and commercial approaches, initiatives and tools are available, based on Web site structure and contents, user’s navigation, behavior and transaction history, server log files, and so forth. However, personalization requires rich data in order to provide successful output. This is not always feasible, since many users are often negative towards the idea of being stereotyped. Moreover, individuals’ privacy has been put in jeopardy by the tasks of recording their activities and saving the appropriate data into their profiles. Summarizing, governments should work hard in the direction of providing the legal framework for ensuring the protection of users’ privacy and also eliminating the possibility of misuse their personal information.

Web Mining for Public E-Services Personalization

KEY TERMS

Clickstream: It is a record of a user’s activity on the Internet, including every Web site and every page of every Web site that the user visits, how long the user was on a page or site, in what order the pages were visited, any newsgroups that the user participates in and even the e-mail addresses of mail that the user sends and receives. Both ISPs and individual Web sites are capable of tracking a user’s clickstream.

Cookie: The data sent by a Web server to a Web client, stored locally by the client and sent back to the server on subsequent requests. In other words, a cookie is simply an HTTP header that consists of a text-only string, which is inserted into the memory of a browser. It is used to uniquely identify a user during Web interactions within a site and contains data parameters that allow the remote HTML server to keep a record of the user identity, and what actions she/he takes at the remote Web site.

Data Mining: The application of specific algorithms for extracting patterns (models) from data.

Knowledge Discovery in Databases (KDD): The nontrivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data.

Server Log: Web servers maintain log files listing every request made to the server. With log file analysis tools, it’s possible to get a good idea of where visitors are coming from, how often they return, and how they navigate through a site. Using cookies enables Webmasters to log even more detailed information about how individual users are accessing a site.

Web Mining: The discovery and analysis of useful information from the Web.

Web Personalization: It is the process of customizing a Web site to the needs of specific users, taking advantage of the knowledge acquired from the analysis of the user’s navigational behavior (usage data) in correlation with other information collected in the Web context, namely structure, content and user profile data. Due to the explosive growth of the Web, the domain of Web personalization has gained great momentum both in the research and the commercial area.

Web Usage Mining: The application of data mining techniques to Web clickstream data in order to extract usage patterns.

This work was previously published in Encyclopedia of Digital Government, edited by A. Anttiroiko and M. Malkia, pp. 1629-1634, copyright 2007 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).
INTRODUCTION

The decreasing cost of networking technology and network-enabled devices is driving the large scale deployment of such networks and devices so as to offer many new and innovative services to users in ubiquitous computing. For example, when you carry your mobile laptop or personal digital assistant (PDA) around, or drive on the road, various services have been made available, ranging from finding a local printer to print a file, to instantaneously knowing about the traffic situation from traffic-cameras and other sensors along a highway.

To achieve the above, every participating network-enabled end-device must solve an interesting technical problem, i.e., to locate a particular network service or device out of hundreds of thousands of accessible services and devices. Such service advertising and discovery is important as mobile devices and mobile wireless devices proliferate on networks. For this reason, a service discovery and advertising protocol is an
important tool to help these devices find services on the network wherever they connect, and to let other network users know about the services they are offering.

Context-aware service discovery, on the other hand, would help users to find services that are most appropriate based on fast-changing client conditions, such as location. For example, most laptops are statically configured to print to dedicated office printers. With the help of the context-awareness, a laptop could find the nearest accessible printer attached to the network that the laptop is currently plugged into.

**SERVICE DISCOVERY PROTOCOLS**

As new services are made available, clients would be able to obtain services based on a set of client-defined keywords or attributes. These attributes would allow the client to narrow the scope of the search so that only those services that pertain to its needs would be discovered. Furthermore, the client would be able to automatically start interacting with the newly discovered services without any programming (Intel).

For the past few years, competing industries and standards communities have been hotly pursuing the technologies for service discovery. E-speak (HP, 2002), UDDI (Universal Description, Discovery, and Integration), Sun’s Jini (Arnold, ed. 2001), Microsoft’s Universal Plug and Play (UPnP), IBM’s Salutation (Salutation Architecture Specification), Service Location Protocol (SLP) of IETF (Guttman, 1999), and Bluetooth’s Service Discovery Protocol (SDP) (Helal, 2002) are among the front-runners in this new race. E-speak and UDDI are designed specifically for discovering Web services. On the other hand, Jini, UPnP, and Salutation are geared toward services furnished by hardware devices such as printers, faxes, etc. We elaborate each of these in detail next.

- **E-speak** is an open software platform designed by HP (Hewlett-Packard Co.) to facilitate the delivery of e-services (electronic services) over the Internet. Based on Extensible Markup Language (XML), the E-speak Service Framework Specification makes it possible for e-services to advertise, discover, negotiate, and form contracts, learn each other’s interfaces and protocols, and invoke each other’s services, all without human intervention.

- **UDDI** protocol is one of the major building blocks required for successful Web services. UDDI creates a standard interoperable platform that enables companies and applications to quickly, easily, and dynamically find and use Web services over the Internet. UDDI is a cross-industry effort driven by major platform and software providers, as well as marketplace operators and e-business leaders within the OASIS (Organization for the Advancement of Structured Information Standards) consortium.

- **Jini** is a distributed service discovery and advertisement architecture that relies on mobile code and leverages the platform independent of Java language. Jini entities consist of services, lookup servers that catalog available services, and clients that require services. All service advertisements and requests go through the lookup servers. To register service availability or to discover services, a service or client must first locate one or more lookup servers by using a multicast request protocol. This request protocol terminates with the invocation of a unicast discovery protocol, which clients and services use to communicate with a specific lookup server. A lookup server can use the multicast announcement protocol to announce its presence on the network. When a lookup server makes an announcement, clients and services that have registered interest in receiving announcements of new lookup services are notified.
• **UPnP** is considered at some levels to be a natural extension of Microsoft Plug and Play to the networking scenario. The UPnP specification describes device addressing, service advertisement and discovery, device control, event, and presentation. AutoIP (Troll, 2000) protocol is used to allow devices to dynamically claim IP addresses in the absence of a DHCP server. UPnP uses simple service discovery protocol (SSDP) for service discovery. SSDP uses HTTP over multicast (HTTPMU) and unicast UDP (HTTPU) to announce a device’s presence to others and discover other devices and services. Each service can be searched by any of its three associated IDs—service type, service name, and location. An UPnP service description includes a list of actions to which the service responds and a list of variables that model the service’s state at runtime. After discovery, a control point sends a message to the service’s specified control object URL (Uniform Resource Locator) according to the Simple Object Access Protocol (SOAP). The device or service returns action-specific values. A control point can also subscribe to receive event notifications which are updates of services’ state in a format of General Event Notification Architecture (GENA).

• **Salutation** is an architecture for service advertisement, discovery, and invocation among devices and services of dissimilar capabilities. The architecture is composed of three fundamental components: functional units, Salutation managers, and transport managers. In Salutation, the concept of a “service” is broken down into a collection of functional units with each unit representing some essential feature. A service description is then a collection of functional unit descriptions, each having a collection of attribute records (name, value, etc.). These records can be queried and matched against during the service discovery process. The Salutation manager contains a registry to keep information about services, and a client can register or un-register itself. An ensemble of Salutation managers can coordinate with one another to exchange registration information, even with those on different transport media. Communication between Salutation managers is based on remote procedure call (RPC). A discovery request is sent to the local Salutation manager, which in turn will be directed to other Salutation managers. This cooperation among Salutation managers forms a conceptually similar lookup service to Jini. One difference, though, is that it is distributed over the network. The transport manager isolates the implementation of the Salutation managers from particular transport-layer protocols and hence gives Salutation network transport independence.

• **SLP** is an Internet Engineering Task Force (IETF) standard for decentralized, lightweight, and extensible service discovery. It uses service URLs, which define the service type and address for a particular service. For example, “service:printer:lp://hostname” is the service URL for a line printer service available at hostname. Based on the service URL, users (or applications) can browse available services in their domain and select and use the one they want. SLP establishes a framework for resource discovery that includes three “agents” that operate on behalf of the network-based software: User Agents (UA), Service Agents (SA), and Directory Agents (DA). UAs perform service discovery on behalf of client software. SAs broadcast the advertisement of the location and attributes on behalf of services. As a centralized service information repository, the DA caches advertisements from SAs and processes discovery queries from UAs.

• **Bluetooth SDP** is specific only to Bluetooth devices (Specification of the Bluetooth System). It defines a very simple service
discovery mechanism for peer-to-peer type networks. It does not provide access to services, brokering of services, service advertisements, or service registration, and there is no event notification when services become unavailable (Helal, 2002). Since there is no centralized directory for service registration, the attributes about a service are stored in the local service discovery server in each mobile device. Clients can search for available services either by service classes, which correspond to unique 128-bit identifiers and uniquely identify types of devices, or by matching attributes. The server replies whether a service is available on the queried platform only and a higher level protocol must provide specific actions to utilize the service.

All of the above mentioned discovery mechanisms have their pros and cons and are valuable within their own infrastructures. The comparison of service discovery protocols is shown in Table 1. Most of them promise similar functionalities which are targeted at reducing configuration hassles, improving device cooperation, and automating discovery of required services. However, due to the lack of a widely adopted service discovery mechanisms, these different products have different APIs and do not work together. In addition, current service discovery frameworks do not consider important context information. Therefore, none of them offer a universal solution to context-aware service discovery.

**CONTEXT-AWARE SERVICE DISCOVERY**

The basic areas we need to address in order to create a context-aware service discovery architecture are:

1. **Interoperability:** Our proposed architecture can interoperate with and provide value added functionality to existing service discovery mechanisms.

2. **Context-awareness:** It will acquire and search for context, and carry out context reasoning to find the most appropriate services for users/applications.

3. **Security, privacy, and trust:** All of this must be done in a manner that provides a sufficient level of security, privacy, and trust to meet the customer’s needs.

Based on the above requirements, we propose a context-aware service discovery architecture as shown in Figure 1. In order to interoperate with existing service discovery mechanisms, we adopt OSGi (Open Service Gateway Initiative) architecture (Marples, 2001; Dobrev, 2002; Kim, 2001) to accommodate the different service collaboration.

Founded in March 1999, the OSGi creates a set of open specifications for the delivery of a wide array of services to end users. The OSGi mission is to enable the deployment of services over wide area networks to local networks and devices (Marple, 2001). The key benefits of OSGi are the following:

- Platform independent. Based on Java technologies, the OSGi gateway can run on most operating systems.
- Multiple network technology support. Home network technologies, such as Jini and UPnP, facilitate device and service discovery in the OSGi gateway (Dobrev, 2002).

![Figure 1. Context-aware service discovery architecture](image-url)
Multiple services support and service collaboration. Multiple applications from different service providers are able to run on a single service platform and provide functionality to other services.

**Interoperability**

The benefits of OSGi provide a feasible interoperability platform for different service discovery mechanisms. Each of the existing service discovery mechanisms has a wrapper to communicate with the OSGi. Wrappers transform the functions of those entities into the form of services and publish those services in the OSGi framework service registry. In the OSGi framework, entities discovered by existing service discovery protocol are represented in the form of services in a standardized way. As the functions of every entity are described using common convention, entities can thus understand each other and collaborate to achieve a certain goal.

**Context-Awareness**

Context information plays an important role in making the physical spaces “smart.” Users and applications often need to be aware of their surrounding context and adapt their behaviors to context changes. Context-awareness involves the use of context to provide relevant services to the user, where relevancy depends on the user’s task (Dey, 2000).

An appropriate model should address different characteristics of context information, such as dependency and uncertainty. Context acquisition is closely coupled with sensors to acquire context data from physical or virtual sensors. In our earlier work, we have proposed an ontology-based context model to describe context information in a semantic way, which exhibits features such as expressiveness, extensibility, ease of sharing and reuse, and logic reasoning support (Zhang, 2006). Context search provides users and applications both synchronous context query service and asynchronous context event notification service. A context processing and management engine called Semantic Space has also been implemented to support context reasoning (Wang, 2004). Context reasoning uses context to carry out logical reasoning to provide the most appropriate services to the users/applications.

**Security, Privacy, and Trust**

In the service discovery, the interaction and information exchange between clients and services must be secure, private, and trustworthy. OSGi defines SSL (Secure Sockets Layer) service for secure network communication and enforces policy-based fine-grained control mechanisms to permit local resource access. The relevant techniques will be exploited and the research works in this area are still ongoing as shown in orange color in Figure 1. We will elaborate more in the future trends.

**FUTURE TRENDS**

The pervasive availability of embedded devices in the environment imposes significant technical and research challenges in service cooperation and interaction. One aspect that captures more attention at the present is security, privacy, and trust which are explained briefly next.

**Security** includes the three main properties of confidentiality, integrity, and availability (Stajano, 2002). **Confidentiality** is concerned with protecting the information/service from unauthorized access; **Integrity** is concerned with protecting the information/service from unauthorized changes; and **Availability** is concerned with ensuring that the information/service remains accessible.

**Privacy** is the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information is communicated to others. Privacy is about protecting
users’ personal information. Privacy control relates not only to the process of setting rules and enforcing them, but also to the way privacy is managed/controlled adaptively according to changes in the degree of disclosure of personal information or user mobility from one space to another (Cook, 2005).

**Trust** management is to develop a trust specification that can be analyzed and evaluated before appropriate interactions/transactions really start. As clients and services often interact and collaborate with each other in an ad-hoc manner, those clients and services may come from unfamiliar administrative domains and therefore be completely unknown to each other. To safely take advantage of all the possibilities, it is essential to assess the confidence level of involved parties, estimate the likely behavior of entities, and recommend a certain level for interactions, which is so called trust management. Trust management involves the trust model, the trust and recommendation specifications for different entities from different certified authorities, and risk thresholds. The trust management service uses the trust model to compute the trust value for each interaction. The trust value indicates the degree of confidence and is used as a parameter to determine the access level of services or degree of information interaction or exchange.

From the above elaboration, we may predict that the future trends for context-aware service discovery will involve addressing the issues related to security, privacy, and trust. The techniques related to authentication, authorization, cryptography, and trust management will be exploited for the interaction and information exchange between clients and services.

**CONCLUSION**

This paper surveys the existing service discovery protocols, such as E-speak, UDDI, Jini, UPnP, Salutation, SLP, and SDP, and discusses the different mechanisms. All of the above mentioned mechanisms have their pros and cons, but none of them offer a universal solution to context-aware service discovery. Next, we identified the requirements of service discovery mechanisms and described a context-aware service discovery architecture to support the interoperability and context-awareness which are required in ubiquitous computing. Finally, the future trends for context-aware service discovery will involve addressing the issues related to security, privacy, and trust.

**KEY TERMS**

**Client:** An application that is interested in or requires some other application to perform some type of work for the client (Intel).

**Context:** Any information that can be used to characterize the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and the application themselves (Dey, 2001).

**Context-Awareness:** To use context to provide relevant services to the user, where relevancy depends on the user’s task (Dey, 2000). A **service** is a component or application that performs the work on behalf of a requesting application or client (Intel).

**Service Advertisement:** Is responsible for advertising a given service description on a directory service or directly to other hosts in the network. The effectiveness of an advertisement is measured as a combination of the extent of its outreach and the specificity of information it provides up front about a service (Sen, 2005).

**Service Description:** Is responsible for describing a service and the type of context information in a comprehensive, unambiguous manner that is machine interpretable to facilitate automation and human readable to facilitate rapid formulation by users (Sen, 2005).
Context-Aware Service Discovery in Ubiquitous Computing

Service Discovery: Is the keystone and carries out three main functions. It formulates a request, which is a description of the needs of a service consumer. This request is formatted in a similar manner to the service description. It also provides a matching function that pairs requests to services with similar descriptions, so that the service which can best fulfill service consumer’s needs on peer devices is selected. Finally, it provides a mechanism for the service consumer to communicate with the service provider (Sen, 2005).

Service Invocation: Is responsible for facilitating the use of a service. Its functions include transmitting commands from the service consumer to the service provider and receiving results. It is also responsible for maintaining the connection between the consumer and the provider for the duration of their interaction. A good invocation mechanism abstracts communication details from the service consumer and, in the case of network failure, redirects requests to another provider or gracefully terminates (Sen, 2005).

Ubiquitous Computing (ubicomp, or sometimes ubiqcomp): Integrates computation into the environment, and enables people to move around and interact with information and computing naturally and casually. One of the goals of ubiquitous computing is to enable devices to sense changes in their environment and to automatically adapt and act based on these changes according to user needs and preferences.

ABSTRACT

Pervasive computing is a broad and compelling research topic in computer science that focuses on the applications of technology to assist users in everyday life situations. It seeks to provide proactive and self-tuning environments and devices to seamlessly augment a person’s knowledge and decision making ability, while requiring as little direct user interaction as possible. Its vision is the creation of an environment saturated with seamlessly integrated devices with computing and communication capabilities. The realisation of this vision requires that a very large number of devices and software components interoperate seamlessly. As these devices and the associated software will pervade everyday life, an increasing number of software and hardware providers will deploy functionality in pervasive computing environments (PCE). That poses a very important interoperability issue, as it cannot be assumed that the various hardware and software components share common communication and data schemes. We argue that the use of Semantic Web technologies, namely the ontologies, present a intriguing way of resolving such issues and, therefore, their
INTRODUCTION

The vision of pervasive computing presents many technical issues, such as scaling-up of connectivity requirements, heterogeneity of processors and access networks, and poor application portability over embedded processors. These issues are currently being addressed by the research community; however, the most serious challenges are not technological but structural, as embedded processors and sensors in everyday products imply an explosion in the number and type of organisations that need to be involved in achieving seamless interoperability (O'Sullivan, 2003). In a typical pervasive computing environment (PCE) there will be numerous devices with computing capabilities that need to interoperate (Nakajima, 2003). These devices might be of different vendors and may operate based on different protocols. Therefore, the key issue in deploying a PCE is achieving application level interoperability. The complexity of such a venture is considerable. It is extremely difficult to reach agreements when the players involved expand from all the hardware and software providers (e.g., IBM, HP, Microsoft) to all the organisations that will equip their products with computing and communication capabilities (e.g., coffee machines, refrigerators). Therefore, we cannot rely on shared a priori knowledge based on commonly accepted standards to resolve the issue. Instead, software components must adapt to their environment at runtime to integrate their functionality with other software components seamlessly. An intriguing way of resolving this issue is the use of semantics, namely the use of Semantic Web technologies such as ontologies. In this manner, software entities provide semantically enriched specifications of the services that they provide and the way they should be invoked. Moreover, the data that are exchanged are also semantically enriched, enabling the entities to reason and make effective decisions. This is particularly important for the description of contextual information, which is of main interest in a PCE. As context we identify any information that is, directly or indirectly, associated with any entity in the environment.

The novelty of the Semantic Web is that the data are required to be not only machine readable but also machine understandable, as opposed to today’s Web which was mainly designed for human interpretation and use. According to Tim Berners-Lee, the Director of World Wide Web Consortium, “the Semantic Web’s goal is to be a unifying system which will (like the Web for human communication) be as un-restraining as possible so that the complexity of reality can be described” (Berners-Lee, 2001). With the realisation of a Semantic Web it would be easy to deploy a wide range of services that would be almost impossible to manage in the current Web. Semantics enable developers to create powerful tools for complex service creation, description, discovery, and composition. The application areas of the Semantic Web extend from knowledge repositories to e-commerce and from user profiling to PCE.

New standards are being developed as a first step in realising the Semantic Web. The Resource Description Framework (RDF), which is a Web mark-up language that provides basic ontological primitives, has been developed by the W3C (Beckett, 2004). RDF is a language for representing meta-information about resources in the World Wide Web. However, by generalising the concept of a “Web resource”, RDF can also be used to represent information about things that can be identified on the Web, by means of URIs. The DARPA Agent Markup Language + Ontology Inference Layer (DAML+OIL) extends RDF with a much richer set of modelling primitives (Rapoza, 2000). The DAML+OIL have been submitted to W3C as a starting point for the Web Ontology Working Group and led to the creation...
Ontological Engineering in Pervasive Computing Environments

of the standard for Web ontologies, namely the Web Ontology Language (OWL) (McGuinness, 2004; Noy et al., 2001).

In this chapter, we survey the research that has been carried out regarding ontology and knowledge engineering and try to map the key findings to the requirements of a PCE. We present standards and tools that are being used for the development of ontologies. Furthermore, we discuss efforts regarding the management of multiple, overlapping, and evolving ontologies and the semantic mappings among them. We also depict how ontologies can help in searching mechanisms and in profiling users and data sources. Moreover, due to the diverse nature of PCE using interoperability standards is not a sufficiently scalable approach. Hence, we show the important role that ontologies can play in achieving service interoperability, a key requirement in PCE. Finally, we present the efforts that have been carried out linking the pervasive computing paradigm with ontologies and illustrate with an example our vision that brings these two worlds together in terms of semantics usage.

The rest of this chapter is structured as follows: In section 2, we outline our vision of a service oriented PCE and some arguments in the use of the ontology paradigm. Section 3 deals with ontological engineering aspects by providing definitions related to ontologies, presenting current Semantic Web standards for developing ontologies and describing the work that has been carried out regarding their management and manipulation. Section 4 introduces issues related to how ontologies might be used to provide semantic searching mechanisms related to information retrieval. In this section also, we give an overview of ontology-based profiling. In section 5, we portray how ontologies assist in providing semantic based service interoperability and how ontologies may be useful in a PCE. Section 6 outlines some several examples of semantic-based service interoperability through ontologies. Finally in section 7, we provide our conclusions and outline future research directions.

A SERVICE-ORIENTED PERVERSIVE COMPUTING ENVIRONMENT

Service-oriented architectures focus on application-level interoperability, in terms of well-established service ontologies (Martin, 2003; Fensel, 2002). This is achieved by means of well-defined interfaces to various software components. In this fashion, rapid integration of existing functionality is achieved in the design and implementation of new applications. Object Management Group’s (OMG) Common Object Request Broker Architecture (CORBA) (Orfali, 1998) is an example of such widespread service-oriented architecture. One of the most important issues in a PCE is the establishment of ad-hoc relationships between applications or between applications and devices. As a result, the use of a common mechanism, which will be able to provide interoperability in a dynamic fashion, is essential. Furthermore, the separation of the application’s functionality from the adopted communication schemes is of considerable importance, as it enables system developers to distinguish between service functionality (e.g., functional and no-functional context-aware service features, as referred in McIlraith et al., 2001) and system functionality. Hence, the deployment of a PCE reduces to the problem of ad-hoc service discovery, composition (e.g., WSFL, service composition context-aware paradigm) and execution with minimum a-priori knowledge of the service’s functionality. While OWL-S is based on the combination of OWL, WSDL and SOAP, WSMO uses F-Logic and XML-based features of Web Services (WS). Based on the previous languages, significant research has been devoted to semantic WS (e.g., ODE SWS [Gómez et al., 2004], METEOR [Aggarwa et al., 2004]).

However, interoperability is a difficult task to accomplish in a highly heterogeneous and volatile environment. Therefore, for service-oriented architectures to be applicable a well-defined mechanism is required to describe the communication schemes which are employed, provide data with
semantics and describe the profiles and the policies of the entities that constitute the PCE. Furthermore, ontologies may be employed for defining entity-specific policies that govern the context access, usage, and manipulation. They may also provide abstract descriptions of the physical and software components (i.e., conceptual modelling via ontology paradigm) that comprise the PCE. Hence, considerable flexibility in deploying such environments is provided.

Accurate and expressive context models are required to represent context in an efficient and effective way, as the manipulation of the context will be based on its model. The model will determine the variety of the actions that may be applied on it, as well as the accuracy of the results. Moreover, context knowledge and manipulation enable the system to be context aware and proactive and employ more efficient decision making mechanisms. Therefore, we consider the context representation to be of great importance, since formal context modelling (in terms of developing an object-centred or frame-based knowledge manipulation system) achieves multirepresentation knowledge, by rendering heterogeneous nature of PCEs. Moreover, model-mapping and context multirepresentation techniques should be employed to transform the whole context or part of it from one form (i.e., representation formulae or dissimilar semantic conceptual model) to another (e.g., [Ding et al., 2002]). As long as the appropriate mappings exist, the entities may exchange contextual information while preserving their own context model (i.e., localised ontologies [Bouquet, 2002]). Additionally, inference engines (e.g., rule-based systems [Friedman, 2005]) may be used to deduce previously unknown derivative context from primitive contextual information. In this fashion, a pervasive computing system is able to produce knowledge and provide proactivity, assisting the user in an unobstructive way. Last but not least, the profile and policy management for the descriptions of the physical and software entities and the definition of the rules that govern the context access, usage, and manipulation may be based on the ontological engineering paradigm. Therefore, we envisage an environment where all entities interact with services through abstract interfaces and argue that the use of Semantic Web technologies is useful in achieving semantic based service interoperability in PCEs.

ONTLOGICAL ENGINEERING

The word ontology comes from philosophy, where it means a systematic explanation of being. In the last decade, this word has become relevant to the knowledge engineering community. The authors in Guarino (1995) propose the words “Ontology” (with capital “o”) and “ontology” to refer to the philosophical and knowledge engineering concepts, respectively. There are a lot of relevant definitions, but we keep only two terms that are relevant, to some extent, to the pervasive computing paradigm. In Neches et al. (1991) an “ontology” is defined as follows:

An ontology defines the basic terms and relations comprising the vocabulary of a topic area as well as the rules for combining terms and relations to define extensions to the vocabulary.

Such descriptive definition informs us what to do to build an ontology by giving some vague guidelines: This ontology description denotes how to identify basic terms and relations between terms and how to identify rules combining terms and their relationships. Through such a definition one can deduce that ontology does not include only terms that are explicitly defined in, but also the knowledge that can be inferred from it. In this point, the authors in Guarino (1995) consider an ‘ontology’ as:

A logical theory, which gives an explicit, partial account of a conceptualisation, where conceptualisation is basically the idea of the world that a person
or a group of people can have. Consecutively, one may consider that the ontology distinguishes terms that are mainly taxonomies from dissimilar human senses and models a specific domain in a ‘deeper’ way by providing well-documented restrictions on such domain semantics.

In the pervasive computing area it can be claimed that ontology is used to provide a vocabulary with explicitly defined and machine comprehensible meaning. In multi-agent systems, ontologies are essential for providing a common vocabulary and a shared perception of domain knowledge to allow communication in an open environment. An ontology provides an explicit specification of the structure of a certain domain and includes a vocabulary for referring to the subject area, and a set of logical statements expressing the constraints existing in the domain and restricting the interpretation of the vocabulary. Thus, the developing of ontologies, especially for pervasive environments, provides the means by which distributed software components share common semantics of the terms being used for communication and knowledge representation.

**Ontology Languages for the Semantic Web**

As already mentioned, several standards for Web ontologies have emerged. We will provide a brief description of the most widely used standards, namely RDF, DAML+OIL and OWL.

The RDF is a language for representing information about resources in the WWW. It is particularly intended for representing metadata about Web resources, such as the title, author, and modification date of a Web page. However, by generalising the concept of a “Web resource”, RDF can also be used to represent information about things that can be identified on the Web, even when they cannot be directly retrieved on the Web. Examples include information about items available from online shopping facilities (e.g., information about specifications, prices, and availability). RDF is intended for situations in which this information needs to be processed by applications, rather than only being displayed to people. RDF provides a common framework for expressing this contextual information that it can be exchanged between applications without loss of meaning. It represents a simple graph model and uses a well-documented XML schema for datatypes by identifying all elements by means of URIs. The structure of any expression in RDF is a triplet (Figure 1), consisting of a subject, an object, and a predicate (also called property).

RDF provides a way to express simple statements about resources, using named properties and values. However, RDF user communities also need the ability to define the vocabularies (i.e., terms or taxonomies in ontology community) they intend to use in those statements, specifically, to indicate that they are describing specific kinds or classes of resources, and will use specific properties in describing those resources. RDF itself provides no means for defining such application-specific classes and properties. Instead, such classes and properties are described as an RDF vocabulary, using extensions to RDF provided by the RDF Schema (RDFS) (Brickley, 2004). The RDFS provides the facilities needed to describe such classes and properties, and to indicate which classes and properties are to be used together. In other words, RDFS provides a type system for RDF. The RDFS type system is somehow similar

---

| Subject | Predicate | Object |
```

```
- rdf:Subject
- rdf:Object
- rdf:Predicate
```

*The SPO conceptual model of RDF*
to the type systems of object-oriented programming languages, such as Java.

DAML+OIL is also a semantic markup language for Web resources. It builds upon earlier W3C standards such as RDF and RDFS, and extends these languages with richer modelling primitives (e.g., in terms of class subsumption or object properties). It adds the familiar ontological primitives of object-oriented and frame-based systems, and the formality of a very expressive description logic (i.e., an ALC Description Logic language).

OWL is a semantic markup language for publishing and sharing ontologies on the World Wide Web. OWL is intended to be used when the information contained in documents needs to be processed by applications, as opposed to situations where the content only needs to be presented to humans. OWL can not only be used to explicitly represent the meaning of terms in vocabularies and the relationships between those terms, but also may serve implicitly representing inferred terms or whole taxonomies by means of logical reasoners (i.e., applications, such as RACER, FaCT, DLP (Haarslev, 1999), based on Description Logics axioms that provide inferred knowledge with respect to certain First Order Logic algorithms, such as Structural Subsumption and Tableau algorithms). OWL has more facilities for expressing meaning and semantics than XML, RDF, and RDFS, and thus OWL goes beyond these languages in its ability to represent machine interpretable content on the Web. OWL is an enhanced revision of DAML+OIL Web ontology language. OWL provides three increasingly expressive sublanguages designed for use by specific communities of implementers and ontology developers. The OWL class (i.e., Concepts and conceptual formulas in Description Logics) expressions are built with Knowledge Representation primitives that are properties. These will be organised in two groups. The first group includes primitives defined for OWL Lite while the second group includes primitives defined for OWL DL and OWL Full.

In the previous paragraph, we discussed a set of concept models (i.e., interpretations in the ABox that satisfy the TBox formulas) that are decidable and satisfiable, but with restricted expressiveness due to representation of an sublanguage of the ALC DL. In this context, there is no disjunction and negation concept formulas and the property restrictions (owl:Restriction) of objects (i.e., the instances of concepts in the ABox) are set to cardinality (owl:cardinality).

The latter group stands for fully expressive OWL languages, but the OWL DL is the only sublanguage that can be considered as a machine comprehensible ALCN Description Logic language for the Semantic Web. The OWL Full is not a decidable language in terms of Description Logics, since the ABox and the TBox may overlap (e.g., an instance of the ABox can be interpreted as a concrete concept of the TBox) according to their concept definitions and there is no such a reasoner (i.e., DL algorithm) that can infer whether an interpretation expressed in OWL Full is satisfiable or not. The OWL DL is a DL language enabling the definitions of conjunction, disjunction, and negation for any interpretation of the concept models and deals with certain value (i.e., owl:allValuesFrom, $\forall R.C$ in DL semantics), existential (owl:someValuesFrom, $\exists R.C$ in DL semantics) and number (e.g., owl:maxCardinality, $\geq n$ in DL semantics) restrictions with arbitrarily cardinalities of their fillers (i.e., instances that satisfy Roles in a Knowledge Base ABox).

Due to the dynamic nature of the contextual information in PCEs and the vague, temporal or probabilistic knowledge representation, there have been many extensions in OWL DL language in order to cope with such models (e.g., imprecise information representation, probabilistic knowledge concept definitions, temporal information representation). Such OWL DL languages deal with fuzzy context modelling (e.g., the proposed
temporal contextual concepts (e.g., the proposed [Artale, 1998]) and probabilistic knowledge representation in terms of Bayesian Networks (e.g., the proposed P-OWL language). Such OWL extensions are based on novelty extensions of the classical DLs (e.g., the OWL is a kind of a SHIN language) with the use of Modal Logics (Elgesem, 1997) that provide different world assumptions in well-defined DL Tboxes.

Moreover, in order to deduce new knowledge by reasoning over contextual facts (i.e., set of instances, such as the Abox interpretations), certain extensions in the ontological community by representing rules have been proposed and standardised. The SWRL (Horrocks et al., 2003) is a language for a Semantic Web Rule Language based on a combination of the OWL DL and OWL Lite sublanguages with the Unary/Binary Datalog RuleML sublanguages of the Rule Markup Language (Boley, 2001). Such language extends the set of OWL axioms to include Horn-like clauses. Hence, Horn-like clauses can be combined with an OWL knowledge base by defining rules for the ABox instances reasoning. A high-level abstract syntax is provided that extends the OWL abstract. An extension of the OWL model-theoretic semantics is also given to provide a formal meaning for OWL ontologies including rules written in this abstract syntax.

Managing the Ontology

Taking into account the distributed nature of a PCE, several key challenges emerge concerning the use of ontologies. One has to be able to deal with multiple and distributed ontologies (i.e., distributed knowledge representation in terms of ontological modularity of taxonomies) to enable reuse, maintainability, evolution, and interoperability. Furthermore, support is needed in managing the evolution of multiple and distributed ontologies, in order to ensure consistency. In fact, the ability of logical reasoners to link independent ontology modules, to allow them to be separately maintained, extended, and re-used is one of their most powerful features. In PCE we encounter large and distributed ontologies (i.e., in terms of number of concepts), representing semantically similar contexts (e.g., equivalent concepts or roles).

In highly distributed systems such as the Semantic Web, modularity naturally exists in terms of conceptual modelling. Large ontologies (e.g., medical or biological ontologies such as GALEN (Rector, 2003; Rector et al., 1999) may be split in smaller and reusable modules in order to meet the needs of ontology maintenance and distributed reasoning. Requirements for managing ontologies in such a distributed environment include the following:

- The semantic loose coupling, which refers to the conceptualisation sets of ontologies that are irrelevant (in terms of concept perception).
- The self-standing or self-containment of concepts is the idea of defining concepts that enable the automatic inference of other, classified concepts without having to access contextual information in other ontologies.
- The ontology consistency, which performs integrity checks to assess whether relevant knowledge in other systems has changed, and, updates the self-standing ontological module, if needed.

In Maedche (2003), the authors present a framework for managing multiple and distributed ontologies in a Semantic Web environment. They describe a conceptual modelling framework for single, multiple, and distributed ontologies, which renders feasible the realisation of ontology-based systems using well-established technologies such as relational databases. The authors make use of the object-oriented paradigm and extend it with simple deductive features. In their approach, information is organised in Ontology-Instance
models, which contain both ontology entities and instances. They introduce the “single ontology consistency” and the “dependent ontology consistency” definitions and propose an evolution strategy that ensures the consistency of the evolving ontologies by unambiguously defining the way in which elementary changes will be resolved.

In another approach, discussed in Rector (2003), the key is modularity. Modularity is acknowledged as a key requirement for large ontologies in order to achieve reuse, maintainability, and evolution. Rector, motivated by the fact that mechanisms for normalisation are standard for databases, proposes the concept of normalisation for ontologies. He proposes a two-step normalisation implemented using OWL or related description logic-based formalisms. For the first step, namely the “ontological normalisation”, he makes use of the analysis in Guarino (2000). For the second step (implementation normalisation) he proposes an approach based on decomposing the ontology into independent disjoint skeleton taxonomies restricted to simple trees, which can, then, be recombined using definitions and axioms to explicitly represent the relationships between them. The main requirement, though, for implementation normalisation is that the modules to be reused can be identified and separated from the whole, so as to evolve independently.

In Guarino (1999), the authors introduce the OntoSeek, a system that employs an ontology server for ontology management. The server provides an interface for applications willing to access or manipulate an ontology data model (i.e., a generic graph data structure), and facilities maintaining a persistent Lexical Conceptual Graph (LCG) database. End users and resource encoders can access the server to update the LCG database encoded in a markup language, (e.g., XML). The main function of the ontology server is to create, edit, evaluate, publish, maintain, and reuse ontologies. Particularly important is the ability to support the collaborative works through the Web.

Semantic Mappings Among Ontologies

Clearly, it would be desirable in a PCE that the various services are capable of interoperating with existing data sources and consumers. It is very difficult to build a consensus about the terminologies and structures that should be used. In order to introduce the significance of the ontology matching issue in the computing paradigm, we support the Semantic Web to make information on the World Wide Web more accessible using machine-readable metadata. Since the ontological development deals with conceptualising specific domains, the notion of context modelling could be imperative by using specific domain ontologies. Thus, an ontology is contextualised when its concepts are kept local (i.e., self-standing concepts that are not shared with other ontologies) and are associated only with the concepts of other ontologies, through well-defined explicit mappings (or implicit mappings, through distributed reasoning tasks, such as Compilation of Implied Knowledge with Queries).

An architecture is needed for building a Web of data by allowing incremental addition of sources, where each new source maps to the sources considered most convenient. Therefore, information processing across ontologies is only possible when semantic mappings between the ontologies exist. Technological infrastructure for semantic interoperability between semantically autonomous communities (i.e., ontological development that is compliant with the requirements in subsection 3.2) must be based on the capability of representing local ontologies and contextual mappings between them, rather than on the attempt to create a global and possibly shared conceptualisation. Manually finding such contextual mappings is tedious, error prone, and clearly not possible on a large scale. This is what researchers call semantic heterogeneity in the Semantic Web paradigm, namely, a situation in which different meanings use the same concept
Ontological Engineering in Pervasive Computing Environments

to mean the different things and use different granularity to describe the same domain forming explicit different perspectives of the world. In this context, the lack of uniformity prompts for the meaning negotiation among different agents, since they do not understand each others as they use languages with heterogeneous semantics.

A lot of work has been performed during the last years in this direction, which resulted in the development of systems that provide mappings semi-automatically (Doan, 2003; Halevy, 2003; Fowler et al., 1999; Chalupsky, 2000). In this way, given the semantic mappings between different ontologies, one may match them in order to be able to reason about a specific domain.

Given two ontologies, the ontology-matching problem is to find semantic mappings between them. The simplest type of mapping is the one-to-one mapping between the elements of the different ontologies, namely each element of one ontology is associated with at most one element of the second ontology and vice versa. Mappings between different types of elements are possible, meaning that a property may be mapped to a class. More complex mappings are possible, such that a class or an instance may map to a union of classes or instances. In general, a mapping could be specified as a query that transforms instances, classes and properties from one ontology into instances, classes, and properties of another.

To illustrate the above, suppose that we want to provide mappings between two WWW sites that sell books. In Figure 2, the ontology-matching problem between an author-centric ontology and a book-centric ontology is depicted. A matchmaking process must provide semantic mappings between the nodes in the two ontologies in an automatic manner.

In Doan (2003), the authors describe GLUE, a system that employs machine-learning techniques to determine such mappings. Given two ontologies, for each concept in one ontology the system finds the most similar concept in the other ontology. A key feature of the GLUE is that it uses multiple learning strategies, each of which exploits well a different type of information either

in the data instances or in the taxonomic structure of the ontologies.

The first issue to address such conceptual matching is the notion of similarity between two concepts. The approach in Doan (2003) is based on the observation that many practical measures of similarity can be defined based solely on the joint probability distribution of the concepts involved. The second challenge is that of computing the joint distribution of any two given concepts A and B. Specifically, for any two concepts A and B, the joint distribution consists of $p(a \in A \land B)$, $p(a \in A \land \neg B)$, $p(a \in \neg A \land B)$, $p(a \in \neg A \land \neg B)$, where a term such as $p(a \in A \land \neg B)$, is the probability that an instance in the domain belongs to concept A but not to concept B. GLUE, also, uses a multi-strategy learning approach employing a set of learners and then combining their predictions using a meta-learner. Furthermore, it exploits domain specific constraints using general heuristic algorithms to improve the matching accuracy.

In another approach, described in Halevy (2003), the authors provide a mediating schema between RDF and XML data sources. Most of these sources provide XML representations of the data and not RDF; XML and the applications that depend on it rely not only on the domain structure of the data, but also on its document structure. In order to provide interoperability between such sources, one must map between both their domain structures and their document structures. Second, data management practitioners often prefer to exchange data through local point-to-point data translations, rather than mapping to common mediated schemas or ontologies. Therefore, the authors built the Piazza system, which addresses these challenges. Piazza offers a language for mediating between data sources on the Semantic Web, which maps both the domain structure and document structure. Piazza also enables interoperation of XML data with RDF data that is accompanied by rich OWL ontologies. They proposed a language for mediating between nodes that allows mapping simple forms of domain structure and rich document structure. The language is based on Xquery (Fernández et al. 2005), the emerging standard for querying XML. They also showed that this language could map between nodes containing RDF data and nodes containing XML data.

In Fowler et al. (1999), the authors propose InfoSleuth, a system that can support construction of complex ontologies from smaller component ontologies so that tools tailored for one component ontology can be used in many application domains. Examples of reused ontologies include units of measure, chemistry knowledge, and geographic metadata. The mapping is explicitly specified among these ontologies as relationships between terms in one ontology and related terms in other ontologies.

In another approach, the OntoMorph system of the Information Sciences Institute (ISI) of the University of Southern California aims to facilitate ontology merging and the rapid generation of knowledge base translators (Chalupsky, 2000). It combines two powerful mechanisms to describe Knowledge Base transformations. The first of these mechanisms is syntactic rewriting via pattern-directed rewrite rules that allow the concise specification of sentence-level transformations based on pattern matching, and the second mechanism involves semantic rewriting which modulates syntactic rewriting via semantic models and logical inference. The integration of ontologies can be based on any mixture of syntactic and semantic criteria.

**ONTOLOGY-BASED PROFILING AND INFORMATION RETRIEVAL**

In a typical PCE there exists a vast amount of contextual information available for retrieval. The traditional solution to the problem of information retrieval employs keyword-based searching techniques. This solution is inadequate and, therefore, new searching mechanisms must be developed.
The context should be modelled in a semantically enriched manner, namely by means of ontologies, and searching techniques that make use of this semantic information must be applied in order to provide superior results. Furthermore, PCEs usually integrate sensor networks, which differ considerably from current networked and embedded systems. They combine the large scale and distributed nature of networked systems with the extreme energy constraints and physically coupled nature of embedded control systems. Sensors, however, produce raw data. Ontologies could be used to transform the raw data to a semantically enriched representation that could be queried by an advanced searching mechanism.

The proliferation of Semantic Web technologies, such as ontologies, has led to the development of more sophisticated semantic query mechanisms. Semantic querying techniques will exploit the semantics of content to provide results that are superior to those delivered by contemporary techniques, which rely mostly on the lexical and structural properties of a document. There are a number of proposals for querying data (e.g., Anyanwu et al., 2003) expressed by means of ontologies, but most of them are constrained in such a way that one is able to form queries only of the type “Get all elements that are related to element A through a relationship R” where R is, typically, specified as a path expression. Recently, research is being conducted in order to be able to express queries of the type “How is element A related to element B?”

In Khan (2004), the authors propose a framework for querying databases of a specific context using an ontology-based index structure. The traditional solution employs keyword-based search. The only documents retrieved are those containing user specified keywords. But many documents convey desired semantic information without containing these keywords. One can overcome this problem by indexing documents according to context and meaning rather than keywords, although this requires a method of converting words to meanings and the creation of a meaning-based index structure. In the discussed work, the authors have solved the problem of an index structure through the design and implementation of a concept-based model using domain dependent ontologies. In other words, the ontology provides index terms/concepts that can be used to match with user requests. Furthermore, the generation of a database query takes place after the keywords in the user request are matched to concepts in the ontology. To achieve this, they employ a proprietary method for query expansion and SQL query generation.

In Wang et al. (2003), a system for classifying text documents based on ontologies for representing the domain specific concept hierarchy (an example is depicted in Figure 3) is presented. Many researchers have shown that similarity-based classification algorithms, such as k-nearest neighbour and centroid-based classification, are very effective for large document collections. However, these effective classification algorithms still suffer disadvantages from high dimensionality that greatly limit their practical performance. Finding the nearest neighbours in high dimensional space is very difficult because the majority of points in high dimensional space are almost equi-distant from all other points. The k-nearest neighbour classifier is an instance-based classifier. This means that a training dataset of high quality is particularly important. An ideal training document set for each particular category will cover all the important terms, and their possible distribution in this category. With such a training set, a classifier can find the true distribution model of the target domain. Otherwise, a text that uses only some keywords out of a training set may be assigned to the wrong category. In practice, however, establishing such a training set is usually infeasible. Actually, a perfect training set can never be expected. By searching the concept hierarchy defined by a domain specific ontology, a more precise distribution model for a predefined classification task can be determined.
The experiments that were carried out indicated that, by using this approach, the size of the feature sets can be effectively reduced and the accuracy of the classifiers can be increased.

An extension of the ontological reasoning, in terms of information retrieval, is discussed in Maedche et al. (2001). In this work, the authors, in order to define and exploit the semantics of domain ontologies, perform the context retrieval process by clustering the pre-classified concepts with several similarity measures. The metrics of the semantic distances among concepts, which are referred to as similarity measures, are the Taxonomy similarity, the Relation similarity, and the Attribute similarity. Such measures form the input to the hierarchical clustering algorithm. In this context, one may deduce about new relations among concepts, something that enriches the notion of the distributed domain ontologies in PCE. Furthermore, the classification process, with respect to the context retrieval, is not feasible with undefined relations among conceptual formulas (i.e., primitive concept, defined concepts, and complex concept definitions).

Moreover, such new relations may denote new activities (i.e., constraints), behaviours (i.e., axioms), and roles on entities or concepts in ontologies. In the pervasive computing paradigm we encounter a large number of interacting entities. The rules that govern that interaction are complex and should be based, among others, on the profiles of entities. According to the Cambridge Dictionary (1980), a profile is “a portrait, drawing, diagram, etc., of a side view of the subject”. A model of an entity’s characteristics, activity, behaviour and its role in the PCE is the entity’s profile. Based on this knowledge, complex mechanisms manage interaction of entities in the most efficient and effective way.

Several methods have been proposed for using ontologies for user and data sources profiling, as well as for describing communication mechanisms. Hence, complex queries over data sources may be exploited and auto-learning systems may propose content sources to users based on their preferences.

In Middleton et al. (2004) the authors explore an ontological approach to user profiling in the context of a recommender system. Their
system, called Foxtrot, addresses the problem of recommending online research papers to academic researchers. Their ontological approach to user profiling is a novel idea to recommender systems. Researchers need to be able to search the system for specific research papers and have interesting papers recommended. Foxtrot uses a research-paper-topic ontology to represent the research interests of its users. A class is defined for each research topic and is-a relationships are defined where appropriate. Their ontology is based on the CORA (McCallum et al., 2000) digital library, as it classifies computer science topics and has example papers for each class. Research papers are represented as term vectors, with term frequency/total number of terms used for a terms weight; terms represent single words in a paper’s text. Research papers in the central database are classified by an IBk (Kibler, 1991) classifier, a k-nearest neighbour type classifier, which is boosted by the AdaBoostM1 algorithm (Freund, 1996).

In Parkhomenko et al. (2003), the authors present an approach that uses ontologies to set up a peer profile containing all the data, necessary for peer-to-peer (P2P) interoperability (Milojicic et al., 2002). The use of this profile can help address important issues present in current P2P networks, such as security, resource aggregation, group management, etc. They also consider applications of peer profiling for Semantic Web built on P2P networks, such as an improved semantic search for resources not explicitly published on the Web but available in a P2P system. They developed the ontology-based peer profile in RDF format and demonstrated its manifold benefits for peer communication and knowledge discovery in both P2P networks and Semantic Web.

In another approach regarding P2P networks, the authors in (Nejdl et al., 2003), focus on peer profiling so as to enable complex user queries and routing algorithms. RDF-based P2P networks allow complex and extendable descriptions of resources, and they provide complex query fa-

**SEMANTIC-BASED SERVICE INTEROPERABILITY THROUGH ONTOLOGIES IN PERSVASE ENVIRONMENTS**

Although, the Web was once just a content repository, it is, now, evolving into a provider of services. Web-accessible programs, databases, sensors, and a variety of other physical devices realise such services. In the next decades, computers will most likely be ubiquitous and most devices will have some sort of computing functionality. Furthermore, the proliferation of intranets, ad-hoc, and mobile networks sharpen the need for service interoperation. However, the problem of service interoperability arises because today’s Web is designed primarily for human use. Nevertheless, an increased automation of services interoperation, primarily in business-to-business and e-commerce applications, is being noted. Generally, such interoperation is realised through proprietary APIs that incorporate hard-coded functionality in order to retrieve information from Web data sources. Ontologies can prove very helpful in the direction of service description for automatic service discovery, composition, interoperation, and execution.

In McIlraith et al. (2001), the authors present an agent technology based on reusable generic procedures and customising user constraints that exploits and showcases WS markup. To realise their vision of Semantic WS, they cre-
Ontological Engineering in Pervasive Computing Environments

ated semantic markup of WS that makes them machine understandable and easy to use. They also developed an agent technology that exploits this semantic markup to support automated WS composition and interoperability. Driving the development of their markup and agent technology are the automation tasks that semantic markup of WS will enable, in particular, service discovery, execution, and composition and interoperation. Automatic WS discovery involves automatically locating WS that provide a particular service and adhere to requested properties. Automatic WS execution involves a computer program or agent automatically executing an identified WS. Automatic WS composition and interoperation involves the automatic selection, composition, and interoperation of appropriate WS to perform some task, given a high-level description of the task’s objective. They use ontologies to encode the classes and subclasses of concepts and relations pertaining to services and user constraints. The use of ontologies enables sharing common concepts, specialisation of these concepts, and vocabulary for reuse across multiple applications, mapping of concepts between different ontologies, and the composition of new concepts from multiple ontologies.

In Gibbins et al. (2003), the authors describe the design and implementation of an ontologically enriched WS system for situational awareness. Specifically, they discuss the merits of using techniques from the multi-agent systems community for separating the intentional force of messages from their content and the implementation of these techniques within the DAML Services model. They identify that the world of WS may be characterised as a world of heterogeneous and loosely coupled distributed systems where adaptability to ad-hoc changes in the services offered by system components is considered advantageous. The term loosely coupled, means that the interactions between system components are not rigidly specified at design time. Instead, system components may opportunistically make use of new services that become available during their lifetime without having been explicitly told of their existence from the outset. The task of searching for a system component which can perform some given service (i.e., service discovery) is the enabling technique that makes loosely-coupled systems possible, and provides a process by which system components may find out about new services being offered. Service descriptions are more complex expressions, which are based on terms from agreed vocabularies and attempt to describe the meaning of the service, rather than simply ascribing a name to it. An essential requirement to service discovery is service description. A key component in the semantics-rich approach is the ontology. In the conventional WS approach exemplified by Web Services Definition Language (WSDL) or even by DAML Services, the communicative intent of a message (e.g., whether it is a request or an assertion) is not separated from the application domain. This is quite different from the convention from the Multi-Agent Systems world, where there is a clear separation between the intent of a message, which is expressed using an Agent Communication Language (ACL), and the application domain of the message, which is expressed in the content of the message by means of domain-specific ontologies. In this approach, there is a definite separation of the intent of the messages and the application domain.

In Medjahed et al. (2003), the authors propose an ontology-based framework for the automatic composition of WS. An important issue in the automatic composition of WS is whether those services are composable (Berners-Lee, 2001). Composability refers to the process of checking if WS to be composed can actually interact with each other. A composability model is proposed for comparing syntactic and semantic features of WS (Figure 4). The second issue is the automatic generation of composite services. A technique is proposed to generate composite service descriptions while obeying the aforementioned composability rules. Such technique uses as
input a high-level specification of the desired composition. This specification contains the list of operations to be performed through composition without referring to any composite service. Based on their composability model, they propose an approach for the automatic composition of WS. This approach consists of four conceptually separate phases: specification, matchmaking, selection, and generation. The authors define an XML language, which adopts an ontology-based model to cater for Semantic Web-enabled WS, for the specification of composite services. Once specifications are provided, the next step is to generate appropriate composition plans using a matchmaking algorithm. The general principle of the matchmaking algorithm is to map each operation of the composite service to one or more operations of existing services. At the end of the matchmaking phase, several composition plans may have been generated. To facilitate the selection of relevant plans, they define three parameters for the quality of composition: ranking, relevance, and completeness. The ranking of a composition gives an approximation of its “importance”, the relevance gives an approximation of the composition soundness and the completeness gives the proportion of composite service operations that are composable with other services. The last phase in their approach aims at generating a detailed description of a composite service. This description includes the list of outsourced services, mappings between composite services and component service operations, mappings between messages and parameters and flow of control and data between component services.

Let us imagine a PCE where all devices interoperate through services. In this way, a service-oriented architecture for functionality integration is being employed. Therefore, the problem of deploying a PCE reduces to the problem of service description and ad-hoc service discovery, composition, and execution.

We propose that the services/agents that represent the various devices share a common communication scheme, possibly by means of an ACL or a common ontology that describes the communication details. However, they do not share any a priori knowledge about the se-
Ontological Engineering in Pervasive Computing Environments

The semantics of the functionality that these devices provide. As described above, through the use of the device-specific ontologies one can achieve runtime service discovery and execution based on an abstract description of his objectives. In other words, a device will query its environment, giving the description of its objectives and employing complex semantic querying mechanisms. After obtaining a service reference, it will proceed with its execution. As new devices join the PCE and while others abandon it, the cycle of service description, discovery, and execution will continue forever with minimum external interference.

Furthermore, the work that has been carried out in the field of ontology management and ontology mapping ensures that the consistency of the ontologies is maintained as they evolve throughout time. Furthermore, webs of complex services are being created as devices join in or withdraw from the PCE and as new composite services are being created based on noncomposite (i.e., primitive) or even other composite services. This is only possible when one can provide semantic context mappings between the different services and automatically produce semantic descriptions of the composite services. Hence, a complicated hierarchy of services may be created. Such a hierarchy should be both manageable and highly flexible.

EXAMPLES OF SEMANTIC-BASED SERVICE INTEROPERABILITY THROUGH ONTOLOGIES IN PCE

To illustrate the key issues, consider the following simple scenario (Figure 5). Bob has an important professional meeting (i.e., human society context) in his office (OfficeA) with Alice. For this meeting it is important that Bob has a certain postscript file (FileA) printed (i.e., application context). Unfortunately, the printer in his office (PrinterA) is not capable of printing postscript files. However, there is one such printer (PrinterB) in another office (OfficeB), but Bob is unaware of its existence (i.e., service registry context). In addition, the two offices are adjacent (i.e., spatial context). Bob is engaged in the activity of editing (i.e., human activity-oriented context) the file and finishes just 15 minutes before his appointment (e.g., temporal context). The PCE, by recording the time at which Bob finishes editing the file and knowing that the appointment is scheduled in 15 minutes, (i.e., contextual history) infers that Bob wants this file for the appointment (e.g., applying deduction rules over certain contexts). Furthermore, it judges that there is sufficient time for Bob to go to the next office and print the file and, consequently, issues the suggestion (i.e., ambient notification to human).

There are several types of semantically enriched contexts in this scenario. First of all the system knows the location of Bob, as well as the locations of the offices within the building. It also has knowledge about the equipment that is present at the offices and its capabilities (i.e., terminal profile). The system has access to his personal agenda and monitors the activities that he is engaged in (i.e., user profile). It is, also, capable of associating any activity with specific entities, which, in turn have specific attributes (i.e., inference over context facts). Furthermore, it employs an inference engine to deduce new contextual information (Bob wants the files for his appointment) and uses this information to issue suggestions.

In another scenario, a system for observing and assisting elderly people, who are alone at home, may be considered. Ontologies may be used to define simple cases (e.g., the person is sleeping for the past fifteen hours or has been in the bathroom for too long) in which the system must take specific actions, wake the patient by ringing a bell or informing the attending doctor. Furthermore, with the addition of a rule engine, complex conditions may be defined that were, previously, required to be diagnosed by a trained doctor. For instance, the system may constantly
monitor the patient’s Electro Cardiogram (ECG) and, based on time depended composite rules, may decide that the patient requires immediate medical attention.

Research has been reported in the association of Semantic Web technologies and pervasive computing. In Chen et al. (2004), the authors describe a framework for an agent-based PCE. Central to their framework is the presence of an intelligent context broker that accepts context related information from devices and agents in the environment as well as from other sources, including information available on the Web describing the space and events and activities scheduled for it. The context broker integrates and reasons over this information to maintain a coherent model of the space, the devices, agents, and people in it, and their associated services and activities. A key to the realisation of this architecture is the use of a set of common ontologies (e.g., specialising an Upper Level Ontology or semantics similarity measures). They identify ontologies as a key component for building open and dynamically distributed PCEs in which agents and devices share contextual information. They describe the use of OWL and other tools for building the foundation ontology for the Context Broker Architecture (CoBrA). The CoBrA ontology models the basic concepts of people, agents, place, and presentation events in an intelligent meeting room environment. It provides a vocabulary of terms for classes and properties suitable for building practical systems that model context in PCEs.

In Wang (2003), the author describes “The context broker”, a broker-centric agent architecture, which aims to support context-aware computing in intelligent spaces. In this architecture, a broker maintains and manages a shared context model on the behalf of a community of devices and agents. It provides necessary common services including ontology mediation and teamwork support, and enforces policies for security, trust, and privacy. A reasoning engine is responsible for reasoning with ontological and contextual knowledge. As ontological knowledge, the author identifies the static knowledge derived from the underlying
ontology model (expressed in OWL), and as contextual knowledge, the dynamic knowledge that is inferred from acquired situational information.

In Ranganathan et al. (2003) and Ranganathan-GAIA (2003), the authors describe GAIA, an infrastructure for Smart Spaces, which are ubiquitous computing environments that encompass physical spaces. GAIA converts physical spaces and the ubiquitous computing devices they contain into a programmable computing system. It offers services to manage and program a space and its associated state. GAIA is similar to traditional operating systems in that it manages the tasks common to all applications built for physical spaces. Each space is self-contained, but may interact with other spaces or modular ontologies (e.g., via context mappings). GAIA provides core services, including events, entity presence (e.g., devices, users and services), discovery, and naming. By specifying well-defined interfaces to services, applications may be built in a generic way so that they are able to run in arbitrary active spaces. The core services are started through a bootstrap protocol that starts the GAIA infrastructure. Finally, GAIA allows application developers to specify different behaviours of their applications for different contexts. The use of contextualised ontologies makes easier for developers to specify context-sensitive behaviour.

One of the main uses of ontologies is that it allows developers to define all the terms that can be used in the environment. Ontological engineering allows the attachment of precise semantics to various terms and the clear definition of the relationships between different terms. Hence, it prevents semantic ambiguities where different entities in the environment have different ideas from what a particular term means. Different entities in the environment can refer to the ontology to get a definition of a term, in case they are not sure (e.g., due to the imprecise conceptual modelling or the nature of the contextual information). Furthermore, developers employ ontologies for describing both entities (e.g., concepts) and contextual information (domain specific conceptual modelling). In this manner, they can determine whether these descriptions are valid with respect to the schema defined by the ontology. When a new entity is introduced into the system, its description can be checked against the existing ontology to see whether it is satisfiable (Roman et al., 2002). If the description is not consistent with the concepts described in the ontology, then the description is faulty. Moreover, ontologies are used to provide semantic discovery of objects and services. Conventional object registries provide a limited capability for object discovery and the existing discovery protocols support limited ability to spontaneously discover entities on a network. However, in PCEs it must be possible to discover only the “relevant” entities, without knowing, in advance, what will be relevant (Amann et al., 2003). This process has also been termed “match-making”. Finally, a key feature of applications in PCEs is that they are context-aware, i.e., they are able to obtain the current context and adapt their behaviour to different situations.

CONCLUSION AND FUTURE WORK

The vision of pervasive computing introduces structural issues, as in a typical ubiquitous environment there will be numerous devices with computing capabilities that need to interoperate. Therefore, we cannot rely on shared a priori knowledge based on commonly accepted standards to resolve such issues. Software components must adapt to their environment at runtime to integrate their functionality with other software components seamlessly. We argued that the concept of Semantic Web, by the means of ontologies, could prove to be a satisfactory solution to the aforementioned problem, as it enables the system and the software providers to deal with semantically enriched specifications of services and semantically enriched data. “Models” based on ontologies may be used to provide objects, and
mainly contextual information, with semantics. The context representation is thought to be of the utmost importance, as context knowledge and manipulation enables a system to be context aware and proactive and to employ more effective and efficient decision-making mechanisms. In addition, profile and policy management could be based on ontology models, in order to provide maximum flexibility for describing entities and rules regarding resource usage and manipulation.

Moreover, we surveyed the research that has been carried out regarding ontologies and tried to map the key findings to the requirements of a PCE. We have discussed efforts dealing with the management of multiple, overlapping, and evolving ontologies and the semantic mappings among them. We, also, depicted how ontologies can help in searching mechanisms and in profiling of users and data sources. Furthermore, due to the diverse nature of PCEs, the use of interoperability standards is not a sufficiently scalable approach. Hence, we showed the important role that ontologies could play in achieving service interoperability, a key requirement in PCEs, and depicted how one may use ontologies in the deployment of PCE.

Research on the association of ontologies and PCEs is rather restricted. Mainly the artificial intelligence community is carrying out the research regarding ontologies, whilst the research regarding pervasive computing is mostly conducted by the network community. Thus, the need of collaboration between the two communities is clearly visible. Nevertheless, a significant trend is identified. More and more researchers acknowledge the necessity of incorporating ontologies into the development of systems for supporting PCE. In this way, the emerging standard for Web ontologies, such as the (OWL), may prove to be a significant factor in the road ahead.

However, there are several future research directions that should be considered. Description logics may perform well in defining domain vocabularies and concepts but lacks in describing modal entities, such as temporal entities, vague knowledge, and probabilistic knowledge. Several extensions have been proposed (Baader et al., 2003) in that direction. These extensions include the following: the ability to predefined specific predicates over concrete domains (e.g., the greater-than or less-than operators over the domain of integers), the use of modal extensions in order to define concepts like belief and obligation, temporal extensions for describing time dependence, representation of uncertain and vague knowledge (probabilistic and fuzzy logic extensions) and nonmonotonic reasoning. These extensions should be incorporated into the Semantic Web standards in order to achieve maximum expressiveness. Last but not least, collaboration between various scientific communities should be employed, so as to see the Semantic Web reach its full potential, pervading in everyday life.

MASACAD: A Multi-Agent System for Academic Advising

Mohamed Salah Hamdi
University of Qatar, Qatar

ABSTRACT
The evolution of the Internet into the Global Information Infrastructure has led to an explosion in the amount of available information. Realizing the vision of distributed knowledge access in this scenario and its future evolution will need tools to customize the information space. In this article we present MASACAD, a multi-agent system that learns to advise students and discuss important problems in relationship to information customization systems and smooth the way for possible solutions. The main idea is to approach information customization using a multi-agent paradigm.

INTRODUCTION
In our previous work (Hamdi, 2005), we have presented an e-learning system that provides a service to a student that checks whether lecturers are offering information that matches the profile of the student and informs the student of the information found. The student is registered in many courses and seeks course materials from the sites of the different lecturers. These diverse resources can be physically distributed. They also are dynamic so that course materials can be added, updated, or deleted. The student profile, that includes the courses currently attended and possibly much more information, changes also over time because the student can leave a course or register in a new one. All of this means that the customized presentation of information for the student should be updated continuously as new information becomes available. This happens with no user intervention using an autonomous multi-agent system.

In this article, following the same long-term objective of providing a complete e-learning environment for students and aiming for the more general goal of information customization, we describe MASACAD (Multi-Agent System for
ACademic ADvising; “MASACAD” is also the Arabic word for “courses”), a multi-agent system that advises students by adopting a machine learning paradigm. The decision for employing the multi-agent approach combined with machine learning is supported by the following general arguments (more specific arguments are discussed in Section 3.5).

Humans often deal with problem complexity by organizing teams and cooperating in the search for solutions. Group problem solving techniques have evolved into powerful strategies in areas where any single individual would simply be overwhelmed. AI research has paralleled this approach by developing the distributed problem-solving paradigm. Problem-solving systems can distribute among them the processes needed to accomplish a given task.

Given the amount of problems that can be approached through distributed processing, AI has directed significant effort towards exploring possibilities to develop specialized problem-solving systems that can interact in their search for a solution. One way to embody this approach is represented by the multi-agent system paradigm.

An agent is a collection of knowledge and methods that are intended to embody a well-defined functionality. Agents cooperate in solving a problem by contributing various parts of the problem-solving process. Agents can be modified independently and they are well focused on their tasks. Such subsystems are often easier to design, develop, and validate, than their counterparts that combine the equivalent functionality within one system.

Because it is not possible to account for all the aspects of multi-agent problem-solving at development time, a good problem-solver has to be able to compensate autonomously for the dynamic and unpredictable aspects of its execution environment through adaptation. Adaptation is reached by letting the system learn from experience.

In the following, we start with presenting some background material and then introduce the problem of academic advising and argue that a multi-agent system would be a good approach for addressing this problem. The paper then presents the architecture of the proposed system and discusses in detail its individual components. The following section discusses the student evaluation of the system and provides preliminary evidence that it is helpful. Benefits and limitations of MASACAD, future directions of work, and related research are discussed respectively in each of the next sections. The final section presents a short summary of the paper.

BACKGROUND

The MASACAD system makes use of a wide range of technologies. These are discussed briefly in the following paragraphs.

E-Learning: Several years ago, online education was considered as an experimental approach with more disadvantages than advantages. However, today it should be considered not only a complementary educational resource but also a serious alternative that competes with conventional and now classical methods. The adaptation to the new features and services of the e-learning environment is not immediate and requires experience, time, investment, pedagogical and technical resources, and government or campus administration support. At the UAE University there exists enormous interest in the area of online education. Rigorous steps are taken towards the creation of the technological infrastructure (hardware, software, and communications) and the academic infrastructure (course materials, teacher-student communication) for the improvement of teaching and learning. MASACAD, the academic advising system described in this article is to be understood as a tool that uses network technology to support learning and as part of the e-learning environment at the university. We use it to demonstrate the capability of exploiting the digital infrastructure, enabled by the online mode
of teaching and learning, to extract and infer useful knowledge and to point out the potential of computational intelligence in the area of intelligent Web-based education.

**Information Customization:** Building software that can interact with the range and diversity of the online resources is a challenge and the promise of information customization (IC) systems is becoming highly attractive. It would be wonderful if an IC system can identify and present the information with little or no user intervention. The system should also be able to update the presentation as new information becomes available. This will release the user from continually observing the resources. This raises, of course, questions about robustness and persistence of the system. An important point in relationship with IC systems concerns therefore their evaluation. The best test of an IC system’s ability to help a user is a user trial. In the present work, we evaluate the IC system for academic advising both by standard tests (performance of the learning algorithm) and by user trials (performance of the whole system).

**User Modeling:** An IC system is a kind of software that acts in accordance with a user’s preferences in an environment. To realize an IC system acting in accordance with a user’s preferences, user modeling is needed. User profiles are of great importance for information extraction and information customization since they are essential for deciding what kind of information is needed, where this information can be found, how this information can be retrieved, and how this information should be presented to the user. User profiles will therefore have a great influence on the solution to be adopted for implementing an IC system. In our case they will have a strong impact on the multi-agent system to be created.

**Agent Approach:** Agents can be viewed as a new model for developing software to interact over a network. This view has emerged because of the predominance of networks in the world. Information, knowledge, and electronic resources in general, are distributed across a network and programs and methods are needed to access them and present them in a customized manner. Using agents adds a layer of abstraction that localizes decisions about dealing with local peculiarities of format, knowledge conventions, and so on, and thus helps to understand and manage complexity. Agents therefore should be seen as an abstraction that appears to provide a powerful way of conceptualizing, designing, and implementing a particularly complex class of software systems. Multi-agent systems are systems composed of multiple interacting agents, where each agent is a coarse-grained computational system in its own right. The approach of multi-agent systems seems to be a suitable framework for developing IC systems since many of the properties of IC systems or requirements on these systems coincide with those required on multi-agent systems and on agent-based systems in general. The IC system proposed in this article for dealing with the problem of academic advising adopts the multi-agent paradigm.

**Machine Learning:** Human expertise, needed for solving problems, should be transferred and transformed from some source of knowledge to a program. This transfer is usually accomplished by a series of lengthy and intensive interviews between a knowledge engineer, who is normally a computer specialist, and a domain expert who is able to articulate his expertise to some degree. Unfortunately, the productivity of the interviewing process is typically poor for many reasons (see Jackson, 1999). This has led researchers to look upon the knowledge acquisition phase as “the bottleneck problem” of expert systems applications (Feigenbaum, 1977). This dissatisfaction with the interview method has encouraged some researchers to try to automate the process of knowledge acquisition by means of machine learning methods. Artificial neural networks are a particular method for empirical learning. They have proven to be equal, or superior, to other empirical learning systems over a wide range of
domains, when evaluated in terms of their generalization ability (Shavlik, Mooney, & Towell, 1991). Although the almost complete ignorance of problem-specific theory by empirical learning systems may mean that they do not address important aspects of induction, it is interesting to see in the following study, how domain-specific knowledge about academic advising of students can be employed by a domain free neural network learning algorithm.

**Web Mining:** Current Web mining research aims at creating systems that (semi) automatically tailor the content delivered to the user from a Web site. This is usually done by mining the Web — both the contents, as well as the user’s interaction (Cooley, Mobasher, & Srivastava, 1997). To mine data from the Web is therefore different from mining data from other sources of information. For the problem of academic advising at hand, the Web represents the main source of information. A solution to this problem will therefore mine the Web. The Web mining technique adopted, bases on the multi-agent paradigm combined with machine learning and ideas from user modeling.

**THE PROBLEM OF ACADEMIC ADVISING**

We will illustrate our ideas using MASACAD, an example consisting of an e-learning application. In this application the focus is on the academic advising for students.

**Academic Advising**

The general goal of academic advising is to assist students in developing educational plans which are consistent with academic, career, and life goals and to provide students with information and skills needed to pursue those goals. More specifically, advisors will assist students in the following ways:

- Guide students through the university’s educational requirements;
- Assist in scheduling the most appropriate courses;
- Introduce them to pertinent resources;
- Promote leadership and campus involvement;
- Assist in career development;
- Assist students with the timely completion of their degree; and
- Help students find ways to make their educational experience personally relevant.

**Why is a Software Assistant Needed for Academic Advising?**

In order to help the student, improve the advising process and make it easier, and overcome the many problems that may occur, an intelligent assistant in form of a computer program will be of great interest. Such an intelligent assistant will automate the advising process in the university. It will also simplify the task of faculty, staff, students, and professional advisors and make it possible to save time and effort and prevent mistakes. These benefits are added to the many other advantages of any assistant software that is used to solve problems that ordinarily require human expertise.

**Restriction of the General Goal of Academic Advising**

The goal of academic advising, as stated previously, is too general because many experts are involved and because a huge amount of expertise is needed. Hence, realizing an intelligent software assistant that is able to deal with all the details shown previously will be too difficult, if not impossible. In the following implementation we will therefore restrict academic advising and understand it as just being intended to provide the student with an opportunity to plan programs of study, select appropriate required and elective
classes, and schedule classes in a way that provides the greatest potential for academic success.

The task is still interesting and of moderate size since when planning a program of study and selecting classes, there are quite a lot of things to consider such as prerequisites, course availability, effective course sequencing, work load, and instructor-student match-ups. Later, when the major problems are understood, improvements and extensions can be attempted, and attempts can be made to tackle the advising problem in a more general framework.

**Resources Needed for Academic Advising**

There are a lot of diverse resources that are required to deal with the problem of academic advising (see Table 1).

First of all, one needs the student profile that includes the courses already attended, the corresponding grades, the “interests of the student” concerning the courses to be attended, and perhaps much other information. The part of the profile consisting of the courses already attended, the corresponding grades, and so on, is maintained by the university administration in appropriate databases to which the access is restricted to some administrators. The part of the profile consisting of the “interests of the student” concerning the courses to be attended exists actually only in the head of the student and should therefore be asked for from the student before advising is performed. However, attempts may be made to let the system learn the interests, for example, by monitoring the student or/and looking at his profile.

The second resource needed for solving the problem of academic advising are the courses that are offered in the semester for which advising is needed. This information is as well maintained by the university administration in appropriate Web sites and is accessible for everyone.

The third resource needed for solving the problem of academic advising is expertise. Expertise is the extensive, task-specific knowledge acquired from training, reading, and experience. It is the knowledge that allows experts to make better and faster decisions than non-experts when solving complex problems. It consists of facts, theories, as well as rules and procedures about a problem area.

For the problem of academic advising this type of expertise may be referred to as the university regulations concerning academic advising. They consist of all the details concerning courses, programs, and curricula such as names/codes of courses, in which term (fall, spring, etc.) courses are offered, prerequisites for courses, descriptions of courses, teaching and assessment methods, statuses (compulsory, elective, etc.) of courses.

number of credit hours of courses, definitions and implications of curriculum terminology (e.g., cross-listing, interdisciplinary, etc.), established programs, established tracks, curriculum total credit hours and their distribution (e.g., compulsory vs. elective), titles of academic degrees offered by the university, and so on. This kind of information is provided by the university and is accessible for everyone. It is published in Web pages, booklets, and in many other different forms such as printouts and announcements. The sources of knowledge are many; however, the primary source will be a human expert. A human expert should possess more complex knowledge than can be found in documented sources. This kind of knowledge includes rules (heuristics) of what to do in a given problem situation, global strategies for solving specific problems, and meta-knowledge.

Because, as mentioned earlier, knowledge acquisition is the major “bottleneck” in developing expert systems, we will approach a solution to gaining the expertise needed for academic advising by adopting a machine learning paradigm.

Why a Multi-Agent System?

First of all, academic advising is intended to be a good domain and problem to test the adequacy of the multi-agent paradigm for dealing with information customization. It provides a complex and dynamic environment and constitutes a wonderful experimental test-bed for investigating the issue. Conversely, dealing effectively with the problem of academic advising will require a multi-agent system. The multi-agent paradigm seems to be appropriate and even superior to other approaches such as a traditional distributed database approach enhanced with an intelligent user interface for the reasons elaborated in the following.

The resources needed for academic advising are physically distributed and dynamic:

- **Their content may change:** It is for example frequent that, at the beginning of a semester, some of the offered courses are canceled, and some other ones are added. The profile of the student also changes frequently, for example when the grades of the exams taken are entered. Also the interests of the student concerning the courses to be attended may change. As an example, students usually want to enroll themselves in courses that are attended by some of their friends. Changes to the university regulations, in contrast, especially those concerning the advising process like the curriculums for the different majors, are comparatively less frequent.
- **Their form (structure) may change:** They may be available via a Web page, an intelligent agent, a data base, a legacy system, and so on.
- **Their location may change:** Existing ones may be moved and new ones may be incorporated.

Hence, dedicating a separate intelligent agent to each individual resource for coping with all of its peculiarities will have many advantages such as:

- **Reduction of the scope of changes:** There is no need to change the whole system when changes concern only a specific resource. In this case, only the concerned agent is changed.
- **Easy incorporation of new resources:** Only one new agent is needed for each new resource.
- **Easy extension and improvement of the system:** We may think, for example, of a self adjusting system, that is, the system itself searches for appropriate resources and each time a resource is identified, it is wrapped with an appropriate agent.
DETAILS OF THE MULTI-AGENT-BASED SOLUTION

MASACAD, the multi-agent system described in the following, offers a service to a student who needs academic advising, that is, he wants to know which courses he should enroll himself in for the coming semester. The service is currently available only for computer science students. In the current version, no attempt is made to learn the student profile, that is, the part the profile consisting of the interests of the student regarding the courses to be attended. The interests are therefore asked for from the student before advising him. The focus in the current version is on the individual agents of the system, on how they cooperate to solve the problem, and on how one of them, namely, the “Learning Agent”, learns to perform the advising process by adopting a supervised learning solution using neural networks (see “Advising Procedure”).

As a solution to the problems of network communication, we use Bee-gent (Bonding and Encapsulation Enhancement Agent) (Kawamura, Hasegawa, Ohsuga, & Honiden, 2000), a communication framework based on the multi-agent model. The Bee-gent framework is comprised of two types of agents. “Agent Wrappers” are used to agentify (i.e., providing an agent interface) existing applications, while “Mediation Agents” support inter-application coordination by handling all communications. The mediation agents move from the site of one application to another where they interact with the agent wrappers. The agent wrappers themselves manage the states of the applications they are wrapped around, invoking them when necessary. MASACAD consists of 3 “Agent Wrappers” (Learning Agent, Data Base Agent, WWW Agent) and one “Mediation Agent” (Searcher).

System Architecture of MASACAD

MASACAD consists of a mediation agent that provides the information retrieving service (Searcher) and of a “User System”, a “Grading System”, and a “Course Announcement System” that are technically applications, each of them existing within an agent wrapper, that is, they represent different agents of the advising system (see Figure 1).

The student (user) uses a Graphical User Interface (GUI) to utilize the service of the advising system. When the student enters his identifier and

Figure 1. Process flow through MASACAD

GUI: Graphical User Interface
JDBC: Java DataBase Connectivity
IRS: Information Retrieval Service
DB: Data Base
URL: Uniform Resource Locator
password, the agent wrapper for the “User System” application creates a mediation agent (Searcher), which migrates to the agent wrappers of the “Grading System” application and of the “Course Announcement System” application to retrieve the needed information (“courses successfully taken by the student with the corresponding grades” and “courses offered in the semester for which advising is needed”). After that, the student has to enter his interests by choosing courses among those that are offered in the semester for which advising is needed by checking some boxes showing the course names. When the student finishes entering his interests, he has to just click on the “Get Advice” button to obtain a list of courses sorted in descending order of importance in which he is advised to enroll himself in.

In the following, each of the individual components of the system is be described in detail.

### Grading System

The application “Grading System” is a data base application for answering queries about the students and the courses they have already taken. The agent wrapper for the application “Grading System” is responsible for invoking the database by using JDBC (Java DataBase Connectivity), transforming requests for information about the students and courses into queries to the database system, collecting the results of the queries, and finally replying these results to the mediation agent. Table 2 summarizes the steps performed by the agent wrapper of the application “Grading System”.

### Course Announcement System

The application “Course Announcement System” is a Web application for answering queries about the courses that are expected to be offered in the semester for which advising is needed. The agent wrapper for the application “Course Announcement System” takes on the invocation of the Web application. It is responsible for initiating communication with the Web application, transforming requests for information about the courses into queries to the Web application, collecting the results of the queries, and finally replying these results to the mediation agent. Table 3 summarizes the steps performed by the agent wrapper of the application “Course Announcement System”.

### Mediation Agent

The mediation agent realizes services by interacting with the agent wrappers on the basis of conversations (sending and receiving XML [eXtensible Markup Language] messages). When the mediation agent migrates, it carries its own program, data and current state. Frequency of communication is reduced compared to a purely message-based system and network loads are decreased largely because communication links can be disconnected after the launch of the mediation agent. Processing efficiency is improved because the mediation agent communicates with the applications locally. The behavior of the mediation agent is described in Table 4.

### User System

The agent wrapper for the “User System” application creates a mediation agent (Searcher), which migrates to the agent wrappers of the applications “Grading System” and “Course Announcement System” to retrieve the needed information. After that, the “GUI Application” is contacted to give the opportunity to the student to express his interests. The “Advising Procedure” (see next
The agent wrapper for the “User System” application also monitors changes in the offered courses and in the student profile and alerts the user by sending an e-mail. Table 5 summarizes the steps performed by the agent wrapper of the application “User System”.

### The Advising Procedure

The “Advising Procedure” is focused on advising computer science students. Computer science students, in order to complete their degree, must accomplish during their study a total of 132 credit hours by choosing at each term courses among the 85 courses that are specified by the curriculum. Some of these courses are compulsory, others are elective. The choice should of course occur according to the university regulations and in a way that provides the greatest potential for academic success as seen by a human academic advisor.

Taking into account the adequacy of the machine learning approach for gaining human expertise added to the availability of experience with advising students makes the adoption of a paradigm of supervised learning from examples obvious. Back-propagation is the best-known example of a supervised neural network training algorithm Patterson (1996) and is therefore used to implement the “Advising Procedure”. The known information (input variables) consists of the profile of the student and of the offered courses grouped in a suitable way. The unknown information (output variables) consists of the advice expected by the student. In order for the network to be able to infer the unknown information, prior training is needed. Training will integrate the expertise in academic advising into the network.

### Settings of the Neural Network Solution

For the problem of academic advising, information about 250 Computer Science students in different stages of study was collected, which means that 250 examples were available for the learning procedures. The 250 examples were used to form three sets: a training set containing 150 examples, a selection set consisting of 50 examples, and a test set consisting of 50 examples. In an attempt to reduce the number of parameters that should be tuned, we decided to use two hidden layers.

To implement the network, a slightly modified version of the package developed by Mark Watson (2005) was used.

Each one of the 250 examples consists of a pair of input-output vectors. The input vector summarizes all the information needed for advising a particular student. It consists of 85 components.
Table 4. Mediation agent

- Receive request for information retrieval from agent wrapper for “User System”
- Move to agent wrapper for “Grading System”
- Judge the migration result:
  - If failure: end
  - If success:
    - Request for retrieval of (course, grade) pairs for the given student ID
    - Receive the reply
    - Move to agent wrapper for “Course Announcement System”
    - Judge the migration result:
      - If failure: end
      - If success:
        - Request for retrieval of IDs of offered courses for the given semester, college, and subject
        - Receive the reply
        - Move to agent wrapper for “User System”
        - Judge the migration result:
          - If failure: end
          - If success:
            - Report retrieved results to agent wrapper for “User System”
            - End

Table 5. Agent wrapper for “User System”

- When GUI event occurs (student enters ID, Password, and Email address the first time, or asks again for advice by clicking the button “Get Advice Again”) or when periodic monitoring of changes in student profile and offered courses is due:
  - Create mediation agent
  - Request mediation agent to perform information retrieval
  - Receive results from mediation agent
  - If information retrieval was initiated by a GUI event then:
    - Output information concerning the offered courses to the GUI (the “GUI Application” represents this information appropriately (boxes that can be checked by the student))
    - When GUI event occurs (student clicks on “Get Advice” button):
      - Prepare input (input vector stored in a text file) for “Advising Procedure”
      - Invoke “Advising Procedure”
      - Process results (the results are found in a text file) and output them to GUI
    - Else (periodic monitoring): compare retrieved information with old version and alert the user via Email in the case that something has changed

Each of them containing a number for one of the 85 courses in the curriculum. The number consists of the grade earned if the student has already passed the given course. Otherwise, the number encodes the availability of the course in the semester for which advising is needed and the interest of the student in the course. The output vector encodes the final decision concerning the courses in which the student actually enrolled himself in based on the advice of the academic advisor. This happens by assigning priority values to each of the 85 courses in the curriculum.
Learning Phase

The aim of the learning phase was to determine the most suitable values for the learning rate, the size of the network, and the number of training cycles that are needed for the convergence of the network.

**Learning Rate:** To determine the most suitable learning rate, experiments with 10 network configurations 85-X-X-85 with X in \{3, 5, 7, 9, 20, 30, 50, 85, 100, 120\} were performed (85-X-X-85 represents a network with 85 input neurons, X neurons in each of the two hidden layers, and 85 output neurons). For each of these networks, experiments with the five learning rates: 0.01, 0.25, 0.50, 0.75, and 1.0 were conducted. In each of these 50 experiments, the network was allowed to learn for a period of 1,000,000 cycles. After each epoch of 50,000 cycles the average selection error for the 50 pairs from the selection set was calculated. From the 50 experiments it was clear that the learning rate 0.01 is the most suitable one for this application because it produces the smallest selection error in most of the cases and more importantly, it causes the selection error to decrease continuously which forebodes the convergence of the network.

**Network Size:** Figure 2 shows the average selection error for the 50 pairs from the selection set plotted as a function of the number of training cycles for the 10 different network configurations 85-X-X-85 with X in \{3, 5, 7, 9, 20, 30, 50, 85, 100, 120\}. In all 10 cases the network was allowed to learn for a period of 1,000,000 cycles and the learning rate was set to 0.01. The network configurations 85-X-X-85 with X in \{50, 85, 100, 120\} seem to work best in combination with the learning rate 0.01. To determine which one of them is more suitable, a longer learning period is needed. The results for a learning period of 10,000,000 cycles are illustrated in Figure 3. The configurations 85-100-100-85 and 85-120-120-85 cause the selection error to decrease continuously and reach a very satisfactory level. Both networks have similar performances. However, following the standard scientific precept that, all else being equal, a simple model is always preferable to a complex one, we can also select a smaller network in preference to a larger one with a negligible improvement in selection error. The network configuration 85-100-100-85 is therefore retained as the best network configuration (in terms of selection error).

**Number of Training Cycles:** After a given number of training cycles, when the selection error and consequently the performance reaches a satisfactory level and when the improvement becomes negligible, learning can be stopped and the network producing the smallest selection error can be retained as a solution for the problem of academic advising. In our case, this happens with the learning rate 0.01 and the network configuration 85-100-100-85 after a training period of 800,000 cycles.
Testing Phase

The final model was tested with the test set data. For 42 of the 50 test cases (84 percent) the network’s actual output was exactly the same as the target output, that is, the network suggested the same courses in the same order as specified by the test examples. In the remaining eight test cases, the target courses were always present at the beginning of the course list produced by the network. However, the network proposed some additional courses. The courses proposed additionally occur always at the end of the course list. This, in addition to the fact that the system is an advisory one, makes these errors tolerable. In four of the eight cases the additional courses were correct choices. In the other four cases some of the additional courses were wrong choices because the student has not yet taken their prerequisite courses.

Benefits and Limitations of the Neural Network Solution

The research reported showed the applicability of the neural network approach to academic advising. The rewards of a successful “marriage” of neural networks and expert systems are too enticing. The back-propagation network performed favorably and seems interesting and viable enough to be used to automate the process of knowledge acquisition, usually looked upon as “the bottleneck problem” of expert systems applications, and help in extracting human expertise, needed for solving the problem of academic advising. In this vein, a possible way to incorporate neural networks into expert systems was described. This would smooth the way for a real and significant “fusion” of neural networks and expert systems. With a network topology of 85-100-100-85 and systematically selected network parameters (learning rate of 0.01, 8000000 training cycles), the multiple-layered, fully connected back-propagation network was able to deliver a considerable performance.

Despite the promising results demonstrated in various applications, back-propagation network development still requires extensive experimentation, parameters selection, and human judgment. Developing a good neural network is not a trivial task as the technique currently stands. Some interesting research questions about adopting neural networks remain to be answered. For example, can we develop a systematic and simple methodology and blueprint for neural network modeling and analysis? Can we automate the selection of topology and parameters? Can we let the network “learn” incrementally without major network re-training when new information is discovered (e.g., curriculum changes)? Incremental learning would require the exploration of other neural network models, such as fuzzy ARTMAP (Carpenter, Grossberg, Markuzon, Reynolds, & Rosen, 1992) and ARAM (Tan, 1995).
SYSTEM EVALUATION

To evaluate the advising multi-agent system in real academic environment, 20 computer science students in different stages of study were involved. Each of them was asked to use the system to get academic advice for the coming term. Most of the problems that occurred at the beginning were of technical nature, mainly concerning the communication over the network. It took a while to deal with this kind of problems and to obtain a relatively stable system.

The advice delivered by the system in each of the 20 cases was analyzed carefully by the concerned student together with an academic adviser with the aim of evaluating its suitability and detecting possible errors. The results were very encouraging. In none of the 20 cases was the advice found to contain errors, that is, to contain courses that, if chosen, will violate the university regulations such as those concerning course prerequisites. Also, all of the results (suggested courses) were judged by the concerned students and academic advisers to be suitable and in most of the cases even very appropriate to be taken by the students. Actually, 15 of the 20 students took during the term for which advising was needed exactly the courses suggested by the advising system. In one of the remaining five cases, the student, because of her poor health, was later (at the beginning of the term) forced to drop three courses and to take only two of the five suggested ones. In another case, the student didn’t take any course during the term because of leave of absence for the whole term. In the other three cases, each of the students exchanged a suggested course (the same course in all three cases) with another one. Later, it became clear that the three students were in a clique and that one of them didn’t care for the instructor of the course, so they moved all to the other course.

BENEFITS AND LIMITATIONS OF MASACAD

MASACAD, in addition to providing a solution for the problem of academic advising, was also used to demonstrate, on an example, the suitability of the multi-agent paradigm for dealing with information customization and personalization. Information customization and personalization provides users with relevant content based on their needs and interests and this is exactly what MASACAD does. It provides the user (student) with an interactive, personal Web experience and customizes the information to the user’s desire and needs. The preferences (profile) of the user determine the behavior of the system. Using the multi-agent approach combined with other techniques, we were able to devise an elegant solution to a problem that depends on distributed information existing in differing formats. Conversely, as mentioned earlier, the distributed and dynamic nature of today’s information resources makes the adoption of the multi-agent approach necessary.

However, there are some other important characteristics of information customization systems that were not demonstrated on this example. In general, in an information customization system there should be some strategy for discovering the location of potential useful information for example among the whole Web, among a reasonable part of the Web, among a set of databases, or among any other heterogeneous set of resources. Also it should be possible to automate the creation of the mediation agent and the agent wrappers, that is, the creation of the whole multi-agent system. The multi-agent system to be created depends on the resources to be invoked and on their locations. The automation task may therefore be very difficult: the resources can be numerous and may have very different formats (they may be unstructured Web pages, databases, agents) and
this complicates the creation of the agent wrappers (how to wrap an unknown application?), as well as the creation of the mediation agent (which route to take to navigate to the different agent wrappers, how to communicate with the different agent wrappers).

FUTURE DIRECTIONS OF WORK

As mentioned earlier, the MASACAD system in its current version is available only for computer science students. The next step for this work is therefore to focus on extending the system to cope with all other degrees in the university. This will imply that for each of these degrees, data about advising students should be collected in order to construct the training, selection, and testing sets. Also, for each degree, a neural network should be developed which requires extensive experimentation, parameters selection, and performance judgment.

However, before extending the system to cope with other degrees, the system should be tested on a larger scale to detect possible errors, be convinced of its usefulness, and better assess its power. This will be done by trying to involve all Computer Science students (more than 300) in evaluating the system. Before allowing a student to register to any course, the student should get advice from the system and discuss its appropriateness with his human academic adviser.

Another improvement, necessary to think about, is how can we let the neural networks “learn” incrementally without major network retraining when new information that is suspected to affect the process of academic advising is discovered (e.g., curriculum changes)? This will make the system more flexible and avoid the repeated new development of neural networks each time a change occurs.

Another problem that should be considered is how can the system be made flexible against changes in the location of course announcements and student profiles (where do they reside?) and against changes in the type of application that enables access to this information (is it a Web site, a database, an intelligent agent, etc.?). To solve this problem, one can think of automating the multi-agent system, that is, creating the mediation agent and the agent wrappers automatically. This will, of course, require knowing which sites should be wrapped by agent wrappers (i.e., knowing the location of resources), and how this wrapping should be done (based on the type of the site/application).

RELATED RESEARCH

In recent years, the administration of academic advising has undergone radical transformation as technological developments have altered the processes by which information is collected, stored, and accessed; the systems by which communication is enabled; and the structures by which transactions are conducted. Technological innovations have created an abundance of opportunities for new practices and enhanced services “frequently characterized as ‘real-time’, ‘student-centered’, and ‘any time, any place’” (Moneta, 1997, p. 7). The technological environments on many campuses are evolving rapidly and comprise numerous elements: information dissemination, transactional interaction, communications applications, and educational technologies. Steele and McDonald (n.d.) contains an annotated bibliography compiled by George Steele and Melinda McDonald for research related technology and advising.

The problem of course assignment has been studied in the literature from different angles. Advising tools are usually intended to complement the student-advisor relationship. The course-planning consultant (CPC), for example, is a computerized Web-based prerequisite checker developed for students in the General Engineering undergraduate curriculum at the University of Illinois at Urbana-Champaign. It was reported that
the program has been field-proven to have helped prevent costly mistakes when planning future courses (Course Planning Consultant, n.d.).

There are also few learning environments where similar problems, such as learning objects assignment, were addressed using the multi-agent system approach. In Sheremetov and Arenas (2002), for example, personalized learning trajectories are constructed by agents in the learning space based on users’ profiles.

It is surely difficult to compare the performance of MASACAD with these systems because they do not perform exactly the same task. However, the technical novelty of MASACAD seems to lay in its ability to perform academic advising while taking into account not only visible static information but also hidden expertise. MASACAD also demonstrates the capability of exploiting the digital infrastructure, enabled by the online mode of teaching and learning, to extract and infer useful knowledge. This is done in an elegant way through a multi-agent system inspired from human teams and organizations involved in the problem-solving activities.

**CONCLUSION**

Academic advising is an important area in any university, which seldom gets adequate resources. Hence, any system that can support this operation will be worthwhile. The idea of realizing such a system is very interesting and highly related to the current research and development trends. In this paper, MASACAD, a well defined architecture for a multi-agent system for addressing the problem of academic advising was proposed. It uses intelligent agents and neural networks for learning and recommendation. The prototype implementation and preliminary testing show that the multi-agent paradigm, combined with ideas from machine learning, user modeling, and Web mining, would be a good approach for the problem of information customization. It was very interesting to see an e-learning system that is able to learn and react according to the characteristics of the client (in this case the student). The results are encouraging and future work will be focused on improving the system and studying how such simple examples, built with insight, should lead to the identification of key difficulties, useful abstractions, and a general method for solving the problem and revelation of the issues.

Chapter 3.9
Human Factors Problems of Wearable Computers

Chris Baber
The University of Birmingham, UK

James Knight
The University of Birmingham, UK

ABSTRACT

In this chapter wearable computers are considered from the perspective of human factors. The basic argument is that wearable computers can be considered as a form of prosthesis. In broad terms, a prosthesis could be considered in terms of replacement (i.e., for damaged limbs or organs), correction (i.e., correction to ‘normal’ vision or hearing with glasses or hearing aids), or enhancement of some capability. Wearable computers offer the potential to enhance cognitive performance and as such could act as cognitive prosthesis, rather than as a physical prosthesis. However, wearable computers research is still very much at the stage of determining how the device is to be added to the body and what capability we are enhancing.

INTRODUCTION

There is a wide range of technologies that have been developed to be fitted to the person. Depending on one’s definition of “technology,” this could range from clothing and textiles, through to spectacles, to cochlear implants. The use of these different technologies can be basically summarized as the supplementation or augmentation of human capability, for example the ability to regulate core temperature (clothing), to see (spectacles) or to hear (cochlear implant). One reason why such supplementation might be required is that the current capability does not fit with environmental demands, either because the environment exceeds the limits over which the human body can function or because the capability is impaired or limited. From this perspective, a question for wearable computers should be what are the cur-
rent human capabilities that are exceeded by the environment and require supplementation by wearable computers? In the majority of cases for wearable computers, the answer to this question hinges on communicative, perceptual, or cognitive ability. As Clark (2006) notes, “...the use, reach, and transformative powers of these cognitive technologies is escalating” (p. 2). But the essential point to note is that “Cognitive technologies are best understood as deep and integral parts of the problem-solving systems that constitute human intelligence” (p. 2). Thus, such technologies could represent a form of ‘cognitive prosthesis’ in that they are intended to support cognitive activities, for example, having a camera (performing face-recognition) to advise the wearer on the name of the person in front of them. The immediate challenge is not necessarily one of technology but of cognition. If the technology is ‘doing the recognition,’ the question is raised what is the human left to do? To draw on a commonly cited analogy, spectacles serve as a perceptual prosthesis, that is, to improve or correct a person’s vision. For wearable computers (and the related field of augmented reality), the ‘improvement’ could be to reveal to the person objects that are not present by overlaying an artificial display onto the world. The display could simply take the form of labels or directional arrows, or could be more a sophisticated presentation of moving (virtual) objects. In both cases, the ‘augmentation’ could either enhance the person’s understanding of the environment or could substitute this understanding.

In terms of communication, mobile telephones and MP3 devices contain significant computing power such that they can easily be considered as being computers, albeit with limited functionality. These devices can be worn, for example MP3 players can be worn on the upper arm, attached to belts or neck-straps, or placed in hats, and mobile telephones can be attached to belts. Furthermore, with the wireless (Bluetooth) headset, the user interface of a mobile telephone can be worn on the ear at all times. Thus, both can be always present and both can be considered part of the person. A definition of wearable computers ought to, at least, allow differentiation from devices that can slip into the user’s pockets (if this technology is to be treated as a new area of research and development). Two early definitions of wearable computers, from Bass (1996) and Mann (1997), emphasize that wearable computers are designed to exist within the corporeal envelope of the user and that this makes them part of what the user considers himself or herself. In many respects this allows an analogy to be drawn between wearable computers and prosthetic devices. Having something added to the body, whether externally, such as spectacles, artificial limbs, hearing aids, or internally, such as pace-makers, or cochlear implants, changes the performance of the person and (for external prosthesis) the appearance of the body. This now becomes a very different concept from the mobile telephone, MP3 player and the computer that we traditionally encounter. This raises all manner of interesting questions relating to physical, perceptual, and cognitive aspects of human factors, as well as a whole host of emotional aspects of wearing devices (for the wearer and the people with whom they interact). At the moment, there remains a gap between what a wearable computer is intended to be and what mobile telephones and MP3 players currently are. This gap can best be considered as a form of perceptual and cognitive prosthesis, in which the wearer’s ability to view the world, retrieve pertinent information, and respond to environmental demands are enhanced by the technology across all aspects of everyday life. At present mobile telephones and MP3 players are able to be tailored (by the user) and can deal with a limited set of situations (relating to communications or music playing) but do not fill the specification that one might have for a wearable computer. The basic difference between a wearable computer and these other technologies lies in the question of how well the user can interact with both the device and the environment.
simultaneously. Obviously, listening to an MP3 player or speaking on a mobile telephone can be performed while walking through an environment. However, performing control actions on the devices can be sufficiently demanding to draw the user’s attention from the environment. The ideal wearable computer would allow the user to manage attention to both device and environment. In other words, it should allow the user to manage both foreground and background interaction (Hinckley et al., 2005).

**FORM-FACTOR AND PHYSICAL ATTACHMENT**

Moore’s law continues to guarantee that the processors will get smaller, and work in the field of micro-electrical-mechanical systems (MEMS) shows how it is possible to create application specific processors that are small enough to be incorporated into buttons on clothing or into jewelry (Figure 1a).

Furthermore, it is feasible to assume the widespread development of general purpose processors, such as the mote (and similar) concept, that combine low power with sufficient processing capability to deal with a number of different sensors (figure 1b).

One direction for wearable computers is that the miniaturization of technology will mean it is possible to implant processors under the skin (or embed them into clothing). This is not a particularly novel idea as the medical world has been experimenting with mechanical implants for many years and has, over the past decade or so, developed digital implants that can, for example, regulate drug administration or improve hearing ability. While the development of such technology is exciting and likely to lead to fascinating discoveries, it lies somewhat outside the remit of this chapter. The problem is how can these extremely small devices support interaction with the person wearing (or supporting) them? To a great extent, the human simply has these devices fitted into them. While this represents the logical extension of the argument that the wearable computer exists within the wearer’s ‘corporeal envelope,’ it does preclude the possibility of developing means of interacting with the device. Indeed, as technology continues to get smaller, ever more difficult the challenge of supporting human-computer interaction becomes, for example, how can one read displays with very small font or press buttons that are much smaller than the human finger? This could mean that we should redefine our concept of interaction, for example, one could argue that ‘interaction’ should be any activity that the person performs, that is sensed by the device and that allows the device to make a response. A potential problem with such a concept is that the person might not be able to selectively control what the device senses or to fully understand why the device is behaving in the manner that it is. This

*Figure 1a. MEMS device*  
*Figure 1b. Intel’s Mote prototype*
means that one either locks the human out of the interaction (in which case one has a sensor system that acts on the environment and which coincidentally affects people in that environment) or one must develop different ways in which the person can understand and manage the behavior of the device. This is not a trivial problem and one can point to many developments in the ubiquitous and pervasive computing domain in which the role of the human in device performance is merely one of passive recipient of device activity. From the point of view of human-computer interaction, this will not only lead to the ‘irony of automation’ but also to frustration, annoyance and a perceived lack of control. In other words, who wants to live in a world that is basically run by the descendants of the Microsoft Office Paperclip?

**Physical Effects of Wearing Computers**

We might expect a computer to consist of a processor and storage, some form of power, a display, and an interaction device. For wearable computers, each of these components can be separated and worn on different parts of the body. Thus, as the prototypes in Figure 2 illustrate, the processor and storage could be incorporated into a single unit and mounted on the waist or the back, the display could be mounted on the head (either near the eyes or the ears, depending on the feedback provided to the wearer), the power could be located near the processor unit, and the interaction device could be mounted within easy reach of the hand (if manual control) or the mouth (if speech input). These prototypes are typical of much contemporary work on wearable computers in terms of the relative size and placement of components.

Wearable computers represent a load on the person and consequently can affect the physical activity of the person (Zingale et al., 2005). Legg (1985) proposes that the human body can carry loads at the following points: head, shoulder, back, chest, trunk, upper arm, forearm, hands, thighs, feet, a combination of these, and aided (i.e., by pulling, pushing or sharing a load). A glance through the literature of wearable computers shows that most of these sites have been experimented with in various designs. Gemperle et al. (1998) offer the term ‘wearability’ to describe the use of the human body to physically support a given product and, by extension, the term ‘dynamic wearability’ to address the device being worn while the body is in motion. Given this notion of wearability, there is the question

*Figure 2. Wearing prototype wearable computers*
of where a device might be positioned on the body, and, once positioned, how it might affect the wearer in terms of balance, posture and musculoskeletal loading. Given the notion of dynamic wearability, there are the questions of how the device will be carried or worn, how this might affect movement, and how this might lead to either perceptions of differences in movement patterns, physiological strain or psychological stress on the wearer. These changes can be assessed, using subjective self-report techniques (Bodine & Gemperle, 2003; Knight et al., 2002, 2006; Knight & Baber, 2005) and through objective analysis (Nigg & Herzog, 1994).

**Energy Expenditure, Muscle Activity and Using Wearable Computers**

An attached load to the body will have a direct affect on the energy expended by the body, as the muscles burn more energy to generate force to counteract the weight of the load. This situation sees a wearer of a wearable computer potentially increasing their overall energy expenditure to overcome inertial changes. Thus, any additional weight on the body can create demands on the musculoskeletal system to support and move the object. In addition, the kinematics of posture and movement can compound the loading effects of a wearable computer. Knight and Baber (2004) report the following about head-mounted loads, such as head mounted displays: (1) different head postures have a measurable effect on musculoskeletal loading; (2) the heavier the frontal load (as is representative of the loading of a HMD), the greater the muscle activity required to keep the head in a fixed position and; (3) in neutral or extended postures, the wearer can sustain larger loads than if the head is in a flexed or rotated head position. Thus, it is not simply a matter of reducing load of head-mounted equipment, but one must determine the posture that the wearer of such equipment is likely to adopt. An alternative location for display technology is on the forearm. In their study of pointing devices, Thomas et al. (1998) demonstrate that for general purpose activity, the forearm would be an appropriate place to mount the device. This location is attractive as it allows the wearer to easily move the display into the field of vision. However, Knight and Baber (2007) have questioned this location or at least raised concerns. Recording shoulder and upper arm muscle activity and measuring perceptions of exertion while participants interacted with arm mounted computers of different weights they found that the mere act of holding the arm in an appropriate posture to interact with an arm mounted computer was sufficient to exceed recommended levels of muscle activity for sustained activity. In addition it induced symptoms of fatigue after only two minutes where the addition of weight in the form of the mounted technology compounded this physical effect.

**Reducing Size and Separating Components**

The discussion so far has suggested ways in which weight and placement of loads on the body can lead to problems. The implication is that most wearables take the form factor of the ‘brick-on-the-back’ (as illustrated by Figure 2). It is possible to reduce the size of components further by removing the interaction and display components. Thus, the Bluetooth headset for a mobile phone effectively reduces the user interface (for talking on the phone) to a unit that clips on the ear. Various MP3 players can be worn on the upper arm while jogging (see comment about usability). Alternatively, there has been much interest in the use of ‘active badges’ that signal a person’s location to a network (Want et al., 1992). These devices can be made small enough to be worn as badges or incorporated into items of clothing, for example Schmidt et al. (1999) report a device, mounted in the wearer’s tie, which detects changes in ambient sound levels or wearer movement. In these examples, the ‘on-body’ part of the computer system is basically a sensor and/or transmitter and/or receiver that link the wearer
to a network of other technologies. BodyMedia have developed a device that places sensors on the person’s upper arm in order to record data relating to everyday activity (in much the same way that an MP3 player is a data display device) and needs to be connected to a computer in order to process the tunes on it (see Figure 3). However, it makes sense to ask whether reducing the size of the devices will reduce or even eliminate these problems. Physical discomfort may arise from pressure of the device on the body. The pinnar is very sensitive and many users complain of discomfort around the ear from using ear plugs and ill-fitting head phones. HMDs place pressure around the forehead and crown. Even the small displays produced by Microoptical (see Figure 4) can cause discomfort around the ears and nose; especially given that the glasses they come with are hard plastic, not specifically fitted for the individual wearer. Items attached around the arm, specifically during physical activity (i.e., for jogging), have to be attached tightly so that they do not bounce against the arm or slip down, as such they may result in discomfort and result in vasoconstriction leading to sensations of numbness and tingling in the lower arm and hand, not to mention that the display is not easily viewable when the device is in position which raises usability issues.

**Perceptual Impacts of Wearing Computers**

A wearable computer can be considered a ‘perceptual prosthesis’ in the ways that it can provide additional information to, or enhance perceptual capability of, the wearer. Information provision can simply mean allowing the wearer access to information that is not currently present in the world, for example through a visual or audio display. The underlying concept in many of these applications is that the wearer’s perception of the world can be augmented or enhanced (Feiner et al., 1998). Before considering this argument, we can consider the MP3 player as a device that can present media that is added to the world (in the form of a personal soundtrack to the person’s activity). To some extent this could be considered as form of augmenting perception. What makes augmented reality different from simply displaying information is that (in most systems) the information is presented in accordance with the context in which the person is behaving. Such information could be in the form of an opaque visual display or could be visual information overlaid onto the world. In basic systems, the information can be called up by the wearer, or pushed from another source, for example a radio or telephone link. In more sophisticated systems, the information is presented on the basis of the computer’s interpretation of ‘context.’

While augmented reality displays could be beneficial, there are potential problems associated with the merging of one source of information (the computer display) with another (the world). Contemporary wearable computers tend to combine monocular head-mounted displays (see Figure 4) with some form of interaction device, for example keyboard, pointing device or speech. NRC (1997) point out that monocular head-mounted displays could suffer from problems of binocular rivalry,
that is, information presented to one eye competes for attention with information presented to the other, which results in one information source becoming dominant and for vision to be directed to that source. A consequence of this phenomenon is that the wearer of a monocular display might find it difficult to share attention between information presented to the ‘display eye’ and information seen through the ‘free eye.’ This problem is compounded by the field of view of such displays.

The field of view for the commercial monocular HMDs ranges from 16°-60°, which is considerably less than that of normal vision (around 170° for each eye, Marieb 1992). Narrow field of view can degrade performance on spatial tasks such as navigation, object manipulation, spatial awareness, and visual search tasks. Restrictions on field of view will tend to disrupt eye-head coordination and to affect perception of size and space (Alfano & Michel, 1990). One implication of a restricted field of view is that the wearer of a see-through HMD will need to engage in a significant amount of head movement in order to scan the environment (McKnight & McKnight, 1993). Seagull and Gopher (1997) showed longer time-on-task in a flight simulator when using a head down visual display unit than with a head-mounted, monocular display. Thus, it appears that a monocular display might impair performance. Apache helicopter pilots currently wear monocular, head-mounted displays and a review of 37 accidents concluded that 28 of these accidents could be attributed to wearing of the display (Rash et al., 1990).

**Computer Response to Physical Activity**

While it is possible that wearing technology affects user performance, it is also possible that the physical activity of the person can affect the computer, for example through the use of sensors to recognize actions and use this recognition to respond appropriately.

Given the range of sensors that can be attached to wearable computers, there has been much interest in using data from these sensors to define and recognize human activity. This has included work using accelerometers (Amft et al., 2005; Junker et al., 2004; Knight et al., 2007; Ling & Intille, 2004, Van Laerhoven & Gellersen, 2004; Westeyn et al., 2003) or tracking of the hand (Ogris et al., 2005). The approach is to collect data on defined movements to train the recognition systems, and then use these models to interpret user activity. At a much simpler level, it is possible to define thresholds to indicate particular postures, such as sitting or standing, and then to use the postures to manage information delivery (Bristow et al., 2004). The use of data from sensors to recognize human activity represents the merging of the research domains of wearable computers with that of pervasive computing, and implies the recognition not only of the actions a person is performing but also the objects with which they are interacting (Philipose, et al., 2004; Schwirtz & Baber, 2006).

An area of current interest for the wearable or ubiquitous computing communities is the interpretation of human movement related to maintenance and related activity. The artifacts with which the person is interacting could be instrumented. For example, a simple approach is to fit switches on
components (in a self-assembly furniture pack) and for the user to depress the switches when each component is handled (Antifakos et al., 2002). A less intrusive approach would be to fit radio frequency identification person is using (Schwirtz et al., 2006) and to use the activation of these tags to infer user activity. This requires that either the components or the tools be adapted to the task. The decreasing costs of RfID suggest that, within a few years, tags will be universally used in a wide range of consumer products. Alternatively, the activity of the user could be taken to develop predictive models in order to infer the activity that is being performed. For some activities it might be sufficient to use data from very generic sensors, such as microphones, to collect data to define actions (Ward et al., 2006), while in other it might be necessary to rely on more specific sensors, such as the use of accelerometers to define movements that are characteristic of assembly and maintenance tasks (Schwirtz & Baber, 2006; Westyn et al., 2003). Steifmeier et al. (2006) show how tracking the motion of the hand (e.g., using ultrasonic tracking and inertial sensors) can be used to define specific types of movement that relate to maintenance tasks, such as spinning a wheel or rotating the pedals, unscrewing a cap or using a bicycle pump. In a related domain, there is some interesting work on the collection of activity data relating to nursing, for example through a combine infra-red proximity sensing and accelerometers (Noma et al., 2004).

**USING WEARABLE COMPUTERS**

Given that a wearable computer provides a means of ‘anytime, anywhere’ access to information, most forms of cognitive activity have been mooted as possible areas that can be supported. In this section, we consider three areas: (i.) supporting memory; (ii.) supporting navigation; and (iii.) information search and retrieval.

**Supporting Memory**

A common example used to illustrate the benefits of a wearable computer is what can be termed the ‘context-aware memory.’ Imagine you are attending a conference (or any large social gathering) and having to remember someone’s name. Systems using some form of badge or face-recognition have been proposed to help with such situations; the computer would register the person and provide you with name and some additional details about the person, for example when you last met, what research interests are listed on their web-page, where they work, and so forth. There has been little research on whether and how these systems improve memory, and this example points to a possible confusion between supporting processes involved in recalling information from memory and the provision of contextually-relevant information. An associated question is whether wearable computers (particularly having a head-mounted display) positioned on the eye can have an impact on recall. The analogy is with the tourist watching a parade through the lens of a video camera—does the act of recording something weaken the ability to process and recall information? Baber et al. (2001) use a search task coupled with surprise recall to show that, in comparison with not using any technology, participants using a digital camera and wearable computer conditions showed lower performance, and that overall the wearable computer showed the biggest impairment in recall. There are many reasons why interruption at initial encoding can limit the ability to remember something, and the question is whether the head-mounted display serves to interrupt encoding; either due to distraction (with a host of information appearing on the screen), or through limitations of field of view, or for some other reasons.
Navigation and Way-Finding

Wayfinding requires people to travel through the world in order to reach specific locations. Thus, there is a need to manage both the act of traveling (for wearable computers this usually consists of walking) and relating a view of the world to the defined location. Sampson (1993) investigated the use of monocular, head-mounted displays for use when walking. Participants were presented with either ‘spatial’ or alphanumeric information and required to traverse paths with or without obstacles. In general, participants performed equally well when standing or when traversing paths without obstacle, but were significantly worse when obstacles were present. Thus, the need to maintain visual attention on display and environment can be seen to impair performance which suggests that the amount and type of information which can usefully be presented on such displays needs to be very limited. As global positioning systems (GPS) become smaller, cheaper, and more accurate, there has been an increase in their application to wearable computers. Seager and Stanton (2004) found faster performance with a paper map than GPS, that is routes completed faster. This was due, in part, with the increase in time spent looking at the GPS display and the number of updates made on the digital view (presumably because the GPS was moving a marker along the map to show the participants location). Participants also were less likely to orientate the digital view in the direction of travel (possibly because they might have assumed that the display would orient to their direction of travel rather than North up). Studies into the effect of perspective views, that is aligning a map with direction of travel, have not shown significant performance advantage over 2D views to date (Suomela et al., 2003), although this approach does seem beneficial in systems that support wayfinding in moving vehicles (Aretz, 1991). Systems that overlay routes onto the head-mounted display (Figure 5) could also assist in simple wayfinding tasks.

The use of visual support for navigation requires the user to divide attention between the environment and a visual display. In terms of the background or foreground of activity (discussed by Hinckley et al., 2005), this essentially places all the tasks in the users foreground. It is possible that navigation prompts could be provided using auditory cues. In simple terms, the heading could be indicated by varying the parameters of simple ‘beeps,’ for example changing in pitch or in intensity as the person deviates from a path (rather like auditory glide-slope indicators in aircraft). More recent developments have replaced the simple ‘beeps’ with music. In this way, a more subtle

Figure 5. Displaying a route overlay on a head-mounted display
(background) form of cueing can be achieved to useful effect. The music could be manipulated to vary quality with deviation from a path, for example through distortion (Strachan et al., 2007, 2005), or through modifying the panning of music in stereo presentation (Warren et al., 2005).

Finding and Retrieving Information

Having the ability to access information as you need it is a core concept of wearable computer research. Early examples had the user enter queries and view information on a monocular display. This approach of having the user ask for information has been superseded by having the computer push information, on the basis of its interpretation of context. In such examples, the benefit of wearing the computer comes from its permanent presence and state of readiness, allowing access either of data stored on the computer or via the World Wide Web. Rhodes and Starner (1997) describe the ‘re-membrance agent,’ which monitors the information that a user types into a computer and makes associations between this information and data it has stored. Obviously this creates an overhead on the user, in terms of the need to type information into the computer. However, it is only a relatively small modification to replace the typed entry with speech recognition (see Pham et al., 2005). While the ‘agents’ in either of these examples can run on desktop computers, it is the fact that they are continuously running on the computer worn by the user that makes them interesting. The role of the wearable computer in these examples is to discretely run searches in the background and alert the wearer to interesting links and associations between the current topic of conversation (or typing) and information to which the computer has access. It might also be useful for the computer to track user activity and then to either record patterns of activity (in order to refine its model of context) or to offer information relevant to the user. Thus, a very common application domain for context-aware, wearable computer research is the museum visitor (Sarini & Strapparava, 1998). The idea is that when the visitor stands at a certain location, say in front of a painting, the computer offers information relating to the objects in that location. The manner in which the location (and other contextual factors) is used to select information and the manner in which the information is presented to the user might vary across applications. The examples considered thus far present the wearable computer as a device that is able to ‘push’ potentially relevant information to the wearer. However, rather than simply overloading the wearer with information, the role of the agents or context-awareness is to manage and tailor the information to the person.

Impact on User Performance

While there are many applications reported in the literature, there is a surprising lack of research into how effective these applications are in improving or otherwise changing user performance. One domain in which wearable computers have received both interest and support has been in maintenance (Mizell, 2003). A study exploring the use of head-mounted displays to support maintenance work show that performance could be improved, providing information was displayed in an appropriate format (Kancler et al., 1998). However, other studies have been more equivocal. Tasks requiring participants to follow instructions on a wearable computer or printed on paper have shown both the wearable computer (Baber et al., 1998) and the paper (Baber et al., 1999c; Ockerman et al., 1997; Siegel & Bauer, 1997) to lead to superior performance. One explanation of these differences lies in the design of the information that was presented, for example the manner in which information is presented can impact on overall performance times (Baber et al., 1999b; Sampson et al., 1993). One implication of these studies is that participants using the wearable computer tend to follow the same sequence of tests (as defined on the visual display), whereas
In terms of interacting with wearable computers and the appropriate devices to use, there has been very little work to date. While one might assume that the optimal interaction techniques would be ones that support hands-free interaction, such as speech recognition, studies suggest that walking has a negative impact on speech recognition performance (Oviatt, 2000; Price et al., 2004). In terms of entering data, Thomas et al. (1997) showed that a forearm mounted QWERTY keyboard led to superior performance over a five-button chording device or a virtual keyboard controlled using an isometric button. However, one might question the recommendation of a forearm mounted device, based on consideration of musculoskeletal strain. In terms of selecting objects on a display, Thomas et al. (1998) found that a touchpad mounted on the forearm was preferred by users, but that one mounted on the thigh lead to superior performance when sitting, kneeling or standing. Thus, the mounting of a pointing device can have a bearing on performance (although one might question whether pointing is an appropriate means of performing selection tasks on a wearable computer). Zucco et al. (2006) considered the performance of ‘drag and drop’ tasks while stationary and whilst walking, using different devices. They found that a gyroscopic mouse lead to best performance while stationary, but that touchpad or trackball were lead to better performance when the user was walking (and that all devices were superior to the Twiddler keypad).

Rather than seeing these studies as recommendations for specific interaction devices, I feel that they illustrate that the relationship between the activity that a person is performing and the demands of the ongoing activity in the environment interact in ways that require careful planning in the design of wearable computers. This brief discussion raises questions on one might develop standards for the deployment of wearable computers in these (and related) applications, and also what level of performance improvement one might expect from this technology.

SMART CLOTHING AND TEXTILES

It is worth mentioning the efforts to incorporate at least some aspects of technology into clothing and textiles (Berzowska, 2005). This could then take the form of clothing that has been adapted to incorporate some of the components (see Figure 6).

Alternatively, the textiles can exhibit some form of ‘smartness.’ Often this refers to “Textiles that are able to sense stimuli from the environment, to react to them and adapt to them...” (Van Langehoven & Hertleer, 2004). Taking these terms separately, we can ask how could textiles sense, react and adapt. In terms of sensing, there is a wide range of possible approaches, including thermal, chemical, mechanical, as well as

Figure 6. Incorporating consumer electronics into clothing—the Philips-Levi Strauss jacket

![Figure 6. Incorporating consumer electronics into clothing—the Philips-Levi Strauss jacket](image-url)
biosensors. Buechley (2006) shows how simple off-the-shelf sensors and actuators can be incorporated into items of clothing. In particular, this work, following the earlier work of Post and Orth (1997) demonstrates how fabrics can be knitted or woven to provide some electrical conductivity, and then fitted with components. In contrast, other researchers report ways in which it is possible to use to electrical properties of prepared fabrics, such as change in resistance, inductance or capacitance (Wijesiriwardana et al., 2003, 2004), to incorporate specific sensing capabilities, such as stretching (Farrington et al., 1999; Huang et al., 2006) or impact (Lind et al., 1997). What has yet to be fully realized from this smart textile work is that manner in which the user would interact with the ‘computing’ aspects in order to entry data or perceive displayed information. Thus, much of the research is still concerned with the development of the ‘bus’ onto which sensors, processors, displays, batteries, and so forth can be mounted.

**EMOTIONAL IMPACT OF WEARING COMPUTERS**

There are three broad categories of impact that will be considered in this section. The first concerns the emotional response to wearable computers by the people wearing these devices and the people with whom they interact. The second concerns the response of the computer to the emotions of the wearer, that is affective computing. The third concerns the manner in which collaboration can be supported within a group of wearable computer wearers.

While head-mounted displays have been used for many years in the domain of military aviation, they have yet to find widespread use on the ground. Most cinema goers will be familiar with concepts of wearable computers from science fiction films and might feel uncomfortable with ‘cyborgs’ in their midst. This discomfort could be particularly acute in stressful situations (as one of the paramedics in an earlier study pointed out to us, *If you’re just coming round from a heart attack, the last thing you’d expect to see if some robot headed bloke trying to take your pulse*). As there are so few commercial applications of wearable computers, these devices still represent something of a novelty and there has been very little research into how people might respond to people wearing such devices. One collection of anecdotal evidence can be found in Thad Starner’s Ph.D. Starner completed his Ph.D. at MIT, and with Brad Rhodes and Steve Mann developed a variety of wearable computers that they wore for prolonged periods of time. This meant that they would encounter members of the public on a regular basis and Starner recorded some of the reactions. A common response was to assume that the wearable computer was simply some form of familiar technology, perhaps a very sophisticated video camera or an advanced form of video game console or a medical device. The implication of this is that people might try to explain the technology using a familiar mental model but, as Starner points out, people have yet developed a mental model of a wearable computer on the basis of familiarity and exposure. While this is partly a matter of the unfamiliar appearance of the wearer it is also related to the manner in which the wearer interacts with the device. For example, Starner points out that when you ask someone the time they will raise their wrist in order to consult their watch, but with a head-mounted display one might simply glance up at the screen. This means that the physical behavioral cues might be far less obvious. This is, of course, similar to the way in which Bluetooth headsets allow people to speak on their mobile telephone in a manner that makes it looks as if they are speaking to themselves (indeed, some users of Bluetooth headsets make gestures that look as if they are holding a phone, for example holding the microphone or holding their hands near their faces). There will be a trade-off between the familiarity of wearable
computers, their appearance, and the ability of people to explain their use. However, there is an additional factor at play here (which is also hinted at by the Bluetooth headset discussion), and that is that the wearable computer provides information to an individual in a highly individualized manner—it is not possible for other people to see what the wearer is looking at or guess what they are doing. An analogy can be drawn in this instance with the person on a train reading a humorous book at laughing out loud—the other people feel uncomfortable because they can not read the what the person is reading. The removal of the observer from the source of information can be disconcerting and can lead to such comments as (from Starner) “we can’t tell if you’re talking about us behind our backs” or “when you wear your display, how can I tell if you are paying attention to me or reading your e-mail?”

One implication of the physical appearance and individualized interaction of wearable computers is the sense that people who wear such technology are different from ‘normal’ people. As Sheridan et al. (2000) note, people wearing computers could be perceived (by themselves or by the people around them) as a ‘cyborg community’ that is different from other people. With the use of communication and networking capabilities, it is possible for a group of wearable computer users to be able to share information and maintain contact as a community (Wellman, 2001). However, we should be careful to distinguish between the ability to maintain contact with other people (which one can do easily with mobile telephones, even to the extent of setting up talk groups) and the ability to share the wide range of information that wearable computing can support. This could simply mean the sharing of the same documents or video, but could also allow new forms of collaboration, sharing and exchange of information.

Context could be defined by changes in the physiological state of the wearer (Picard, 1997). This requires a more intimate means of recording data from the wearer, perhaps through monitoring of pulse or heart activity. The use of ‘context’ to initiate image capture has been demonstrated by several projects; most notably in Healey and Picard’s (1998) ‘StartleCam,’ in which changes in galvanic skin response (GSR) was used to trigger image capture. There has been surprisingly little attempt at extending this work in the years since it was reported, although over uses of ‘context’ in image capture have explored the use of ambient sound which is captured at the same time as the image (e.g., Frolich & Tallyn, 1999; Ljunblad et al., 2004). Bristow et al. (2005) used a set of context identifiers to take still images when ‘context’ changed, and showed that these were surprisingly consistent with photographs taken by humans. In addition to the computer ‘sensing’ the physiological responses of the wearer (and hence drawing some inference as to the affective state), it is also possible to infer the state of people with whom the wearer is interacting in order to develop ‘emotionally intelligent interfaces.’ By monitoring the changing facial expressions of ones conversational partner, it might be possible to provide support for people who find it difficult to judge the emotional response, for example people with Autism (El Kaliouby & Robinson, 2003).

**DISCUSSION**

Wearable computers continue to raise many significant challenges for human factors research. These challenges involve not only cognitive aspects of presenting information but also perceptual aspects of displaying the information against the backdrop of the everyday environment and physical aspects of mounting the devices on the person. This chapter has overviewed some of the developments in the field and offered some consideration of how these human factors can be considered. While the field is largely motivated by technological advances there is a need to carefully ground the developments in the physical and cognitive characteristics of the humans who are intended to wear them.

Human Factors Problems of Wearable Computers

**KEY TERMS**

**Activity Models:** Predictive models of human activity, based on sensor data

**Augmentation Means:** Devices that can augment human behavior—a term coined by Doug Engelbart, and covering: **Tools & Artifacts:** the technologies that we use to work on the world which supplement, complement or extend our physical or cognitive abilities; **Praxis:** the accumulation and exploitation of skills relating to purposeful behavior in both work and everyday activity; **Language:** the manipulation and communication of concepts; **Adaptation:** the manner in which people could (or should) adapt their physical and cognitive activity to accommodate the demands of technology.

**Comfort:** Subjective response to wearing a wearable computer (ranging from physical loading to embarrassment)

**Context-Awareness:** The capability of a device to respond appropriately to changes in a person’s activity, environment, and so forth.

**Form-Factor:** The overall size (and shape) of a device

**Sensors:** Devices that produce digital output in response to some change in a measured parameter, for example dependent on environmental change or on user activity

**Wearable Computers:** Devices worn on the person that provided personalized, context-relevant information

**ENDNOTES**

2. Bainbridge (1987) argued that full automation can lead to the ironic situation that, the role of the human operator is to intervene when something goes wrong. However, the automation is such that the human is locked out of the process and has little understanding as to what is happening. Consequently, the human will not be able to intervene in an informed and efficient manner. Ultimately, it means that, by designing the human out of the system, the potential for a flexible and intelligent response to unknown situations is lost.

ABSTRACT

In this chapter we discuss a number of recent studies that demonstrate the use of rational analysis (Anderson, 1990) and cognitive modelling methods to understand complex interactive behaviour involved in three tasks: (1) icon search, (2) graph reading, and (3) information retrieval on the World Wide Web (WWW). We describe the underlying theoretical assumptions of rational analysis and the adaptive control of thought-rational (ACT-R) cognitive architecture (Anderson & Lebiere, 1998), a theory of cognition that incorporates rational analysis in its mechanisms for learning and decision making. In presenting these studies we aim to show how such methods can be combined with eye movement data to provide detailed, highly constrained accounts of user performance that are grounded in psychological theory. We argue that the theoretical and technological developments that underpin these methods are now at a stage that the approach can be more broadly applied to other areas of Web use.

INTRODUCTION

With the rapid increase in Internet use over the past decade there is a growing need for those engaged in the design of Web technology to understand the human factors involved in Web-based interaction. Incorporating insights from cognitive science about the mechanisms, strengths, and limits of human perception and cognition can provide a number of benefits for Web practitioners. Knowledge about the various constraints on cognition, (e.g., limitations on working memory), patterns of strategy selection, or the effect of design...
Modelling Interactive Behaviour with a Rational Cognitive Architecture

decisions (e.g., icon style) on visual search, can inform the design and evaluation process and allow practitioners to develop technologies that are better suited to human abilities.

The application of cognitive psychology to human-computer interaction (HCI) issues has a long history going back to Card, Moran, and Newell’s (1983) introduction of the goals, operators, methods, and selection rules (GOMS) task analysis technique and model human processor (MHP) account of human information processing in the early 1980s. Since then, their cognitive engineering approach has developed into a family of methods (John & Kieras, 1994; Olson & Olson, 1990) which are widely used to produce quantitative models of user performance in interactive tasks.

Another, more recent approach to modelling human performance in interactive tasks has emerged in the last decade from theoretical and technological advances in research into cognitive architectures. Cognitive architectures are theories of the fundamental structures and processes that underlie all human cognition, of which there are several currently in existence including EPIC (executive process / interactive control; Kieras & Meyer, 1997), Soar (Laird, Newell, & Rosenbloom, 1987; Newell, 1990), and ACT-R (Anderson & Lebiere, 1998; Anderson et al., 2004). An important feature of these architectures is that they are all implemented as computer programming systems so that cognitive models may be specified, executed, and their outputs (e.g., error rates and response latencies) compared to human performance data.

Originally ACT-R and Soar were theories of central cognition only and did not explicitly specify mechanisms for perception or motor control. EPIC however, was unique in that from its inception it incorporated processors for cognition, perception, and motor control. Recent adaptations to ACT-R (Byrne & Anderson, 1998) and Soar (Chong & Laird, 1997) have now ensured that both architectures incorporate perceptual motor components that allow models to include visual attention processes and manual interactions with a keyboard and mouse. This is an important development for the study of HCI as cognitive models can now be embodied (Kieras & Meyer, 1997) in the sense that the architectures are now able to simulate perceptual-motor contact with computer interfaces and devices and so capture the complex interactions between the task environment, cognition, and perceptual-motor behaviour.

Modelling interactive behaviour with an embodied cognitive architecture has a number of advantages over the traditional cognitive engineering approach exemplified by GOMS and its relatives. Perhaps the most important of these is that computational models can actually execute the task, allowing a direct test of the sufficiency of the hypothesised processes. Second, although most cognitive architectures contain built-in timing parameters taken from the psychological literature, unlike cognitive engineering models, they do not require prior estimated times for all subcomponents of a task. In addition, some architectures — such as ACT-R and Soar — contain learning mechanisms which allow them to model various effects of practice on performance. This allows cognitive architectures to be used to model novel tasks, novice users, or tasks involving components without prior time estimates.

One of the promises of embodied cognitive architectures is that, once they are equipped with sufficient knowledge, they will begin to provide a priori predictions of user performance and eventually evolve into artificial users that can be employed to evaluate novel tasks and environments (Ritter, Baxter, Jones, & Young, 2000; Young, Green, & Simon, 1989). In this chapter we will describe one of these architectures, ACT-R, and show how it has been used to provide detailed and sophisticated process models of human performance in interactive tasks with complex interfaces. ACT-R is an appropriate choice for this discussion because, in contrast to other cognitive architectures, ACT-R also embodies
the rational theory of cognition (Anderson, 1990) which analyses cognitive phenomena in terms of how they are adapted to the statistical structure of the environment. Rational analysis and ACT-R’s mechanisms have been used recently to provide novel insights into Web-based interactions. The chapter proceeds as follows: First we describe the basic assumptions and mechanisms of rational analysis and the ACT-R cognitive architecture. We then show how these have been used to develop a model of information foraging on the Web and discuss the model in relation to a rational analysis model of the task and the data from eye-tracking studies of interactive search. In the final sections of this chapter we briefly outline ACT-R models of two interactive tasks; graph reading (Peebles & Cheng, 2003) and icon search (Fleetwood & Byrne, in press). Although neither of these studies involves a specifically Web-based task, they both describe user interaction with items commonly found on Web pages. They are also illustrative of a methodology that combines task analysis, eye tracking, and formal modelling to provide a detailed account of the cognitive, perceptual, and motor processes involved in the performance of the task. These studies are also useful because in both cases the model is validated by comparing the simulated eye movements with those recorded from human subjects. Both studies, therefore, are clear demonstrations of a novel approach to understanding interactive behaviour that can be applied to Web-based tasks.

RATIONAL ANALYSIS

Rational analysis (Anderson, 1990) is a method for understanding the task an agent attempts to complete. It assumes that humans have evolved cognitive mechanisms that are useful for completing tasks that we encounter in our environment, and that these mechanisms work in an efficient way to complete these tasks. Therefore, rather than concerning ourselves with firstly trying to define the cognitive mechanisms required by the agent to solve the task, rational analysis suggests that we should consider the structure of the task itself, the environment in which it is encountered, together with some minimal assumptions about the computational limitations of the system. From these initial statements the analysis proceeds by the specification of an optimal solution to the problem and the comparison of human behavioural data to see how close an approximation it is to the optimal solution.

By identifying the best way to complete the task (the optimal strategy) we can often infer what the cognitive mechanisms of a rational agent must be as although humans do not always complete tasks in the most optimal way their behaviour is usually similar to the optimal strategy. That is, humans usually behave in such a way that they appear to be trying to complete their tasks in the most efficient manner, that is, they try to maximise their returns while minimising the cost of achieving their goals.

Rational analysis has been applied to several aspects of human cognition (see e.g., Oaksford & Chater, 1998), from the original analyses of memory, categorisation, causal inference, and decision making conducted by Anderson (1990), to more recent analyses of exploratory choice (Cox & Young 2004; Young, 1998) and the updating of memory during tasks in dynamic environments (Neth, Sims, Veksler, & Gray, 2004).

THE ACT-R COGNITIVE ARCHITECTURE

ACT-R is a theory of human cognition developed over a period of 30 years by John Anderson and his colleagues (Anderson & Lebiere, 1998; Anderson et al., 2004) that incorporates the theory of rational analysis. It is a principal effort in the attempt to develop a unified theory of cognition (Newell, 1990). As a cognitive architecture, ACT-R attempts to specify the basic cognitive
structures and processes that underlie all human cognition.

Figure 1 illustrates the components of the architecture relevant to our discussion. ACT-R consists of a set of independent modules that acquire information from the environment, process information, and execute motor actions in the furtherance of particular goals. There are four modules that comprise the central cognitive components of ACT-R. Two of these are memory stores for two types of knowledge: a declarative memory module that stores factual knowledge about the domain, and a procedural memory module that stores the system’s knowledge about how tasks are performed. The former consists of a network of knowledge chunks whereas the latter is a set of productions, rules of the form “IF <condition> THEN <action>”: the condition specifying the state of the system that must exist for the rule to apply and the action specifying the actions to be taken should this occur. The other two cognitive modules represent information related to the execution of tasks. The first is a control state module that keeps track of the intentions of the system during problem solving, and the second is a problem state module that maintains the current state of the task.

In addition to these cognitive modules there are four perceptual-motor modules for speech, audition, visual, and motor processing (only the latter two are shown in Figure 1). The speech and audition modules are the least well-developed and, at present, simply provide ACT-R with the capacity to simulate basic audio perception and vocal output for the purpose of modelling typical psychology experiments. The visual and motor modules are more well-developed and provide ACT-R with the ability to simulate visual attention shifts to objects on a computer display and manual interactions with a computer keyboard and mouse.

Each of ACT-R’s modules has an associated buffer that can hold only one chunk of information from its module at a time, and the contents of all of the buffers constitute the state of an ACT-R model at any one time. Cognition proceeds via a pattern matching process that attempts to find productions with conditions that match the current contents of the buffers. There then follows a process to select the “best” production from those that match the conditions, after which the most appropriate production “fires” and the actions (visual or manual movements, requests for the retrieval of a knowledge chunk from declarative memory, or modifications to buffers) are performed. Then the matching process continues on the updated contents of the buffers so that tasks are performed through a succession of production rulefirings. As an example, two production rules (written in English rather than in ACT-R code) that instantiate part of a search task may look something like Box 1.

The processing in ACT-R’s modules is serial but the modules run in parallel with each other so

**Box 1.**

```
IF the goal is to find the meaning of “eudaimonia” (control state)
AND there is nothing in declarative memory about “eudaimonia” (declarative)
THEN set the goal to search the WWW for “eudaimonia” (control state)

IF the goal is to search the WWW for “eudaimonia” (control state)
AND the Web browser is open (problem state)
THEN look for the menu labelled “Bookmarks” (visual)
AND update the problem state to “looking for Google” (problem state)
```
that the system can move visual attention while also moving the mouse and attempting to retrieve knowledge from declarative memory. ACT-R processes also have associated latency parameters taken from the psychology literature. For example, it typically takes 50 ms for a production to fire and the time taken to move the mouse cursor to an object on the computer screen is calculated using Fitts’ Law (Fitts, 1954).

ACT-R implements rational analysis in two ways. The first is its mechanism for retrieving knowledge chunks from declarative memory which is based on the notion of activation. Each chunk in declarative memory has a level of activation which determines its probability and latency of retrieval, and the level of activation for a chunk reflects the recency and frequency of its use. This enables us to understand how rehearsal of items in a short-term memory task can boost the activation levels of these chunks and consequently increase the chances of recall/retrieval from declarative memory. The level of activation of a chunk falls gradually over time, and without retrieval or activation spreading from chunks in the current goal, it may fall below a threshold level which then results in retrieval failure. This enables ACT-R models to forget knowledge without having to explicitly delete chunks from the declarative memory store.

The second way that ACT-R implements rational analysis is in its mechanism for choosing between alternative production rules. According to rational analysis, people choose between a number of options to maximise their expected utility. Each option (i.e., production rule) has an expected probability of achieving the goal and an expected cost. It is assumed that when carrying out computer-based tasks people interact with the task environment and choose actions that will optimise their efficiency (i.e., maximise the probability of achieving the goal while minimising the cost, usually measured in units of time). At each decision step in the cycle, therefore, all possible production rules that match against the current goal are proposed in a choice set, and the one with the highest level of efficiency is chosen and executed.

ACT-R has been used to model a wide range of cognitive phenomena (Anderson & Lebiere, 1998), and in recent years, with the inclusion of the perceptual-motor modules, it has been applied to a number of complex interactive tasks in the area of HCI and human factors research, for example, menu selection (Byrne, 2001), cell phone menu
interaction (St. Amant, Horton, & Ritter, 2004), and driving (Salvucci & Macuga, 2002). Although individually these models do not yet offer us a virtual “user” which can be sat in front of a Web browser and asked to complete any goal, together they provide us with insights into how and why users behave in particular ways, for example, when searching for information on the Web. In this chapter we will concentrate on three particular areas of work that are relevant to understanding Web behaviour: icon search, graph reading, and information foraging on the WWW.

MODELLING INTERACTIVE BEHAVIOUR

In the following section, we will summarise a number of recent studies which employ rational analysis, cognitive modelling, eye tracking, or a combination of all three, to understand human performance in Web-based or HCI tasks. We first discuss recent efforts to model information foraging and interactive search on the WWW. These studies show how ACT-R and rational analysis can be successfully applied to explain different aspects of people’s behaviour when conducting interactive search tasks. This can include both high-level behaviours such as backtracking through Web-pages and low-level behaviours such as patterns of visual attention obtained from eye-tracking studies. We then describe two studies which combine experimental data collection, eye movement recording, and cognitive modelling methods using ACT-R to provide detailed accounts of the cognitive, perceptual, and motor processes involved in the tasks. These studies were chosen because both develop a detailed process model which not only captures the human response time data from the experiment, but also provides a close match to the patterns of visual attention revealed by the eye movement study. This level of detail in modelling is still relatively uncommon and the strong constraints added by seeking to match model and human eye movement scan paths during the course of the task provide a further validation of the models.

Information Foraging on the World Wide Web

Information foraging theory (IFT; Pirolli & Card, 1999; Pirolli, 2005) describes an account of information gathering behaviour based on the ecological behaviours of animals when foraging for food. The account can be applied to situations in which people are searching for information in a number of different situations such as in a library or on the WWW. The theory rests on rational analysis in that it proposes that human behaviour is directed by the objective to maximise gain and minimise effort, and that this process is sensitive to changes in the environment. In contrast to animal studies, where the assumption is that animals seek to reduce the ratio of calorie intake to energy expenditure, the assumption in IFT is that people attempt to reduce the ratio of information gained to time spent.

The way in which the environment is structured determines the costs of search for information. For example, the structure of a Web site will determine how many pages the user has to navigate through in order to satisfy his/her goal. When searching for information on the WWW, many people make use of search engines. After entering some key words the user is presented with a list of search results which are usually ordered in terms of their relevance to the key words. Each of the results returned can be considered to be a “patch” of information. The user has to choose to either investigate one of the patches or to redefine their search criteria. Conducting another search using different key words will result in a change in the environment. This process is known as enriching the environment as it is hoped that the result is that the cost of obtaining the required information will be reduced compared to the perceived cost of obtaining it in the previous environment. Deci-
sions about whether or not to pursue a particular information patch or to continue enriching the environment are based on a number of factors such as the perceived value of the information returned, the perceived costs of acquiring that information, interface constraints, and previous knowledge.

The decision to forage within a particular patch of information is based on an ongoing assessment of information *scent*. Information scent is the perception of the value of the distal information based on the proximal information available, that is, it is an estimate of the relevance of the information contained on a yet unseen page based on the cues from the icon or wording of the link on the page currently viewed. The theory predicts that as more time is allocated to within-patch foraging, the rate of information return increases but only up to an optimal point, after which the rate starts to decrease. Therefore, after a particular amount of within-patch foraging (searching within a Web site) it becomes more profitable to move to the next patch (select another Web site from the list of search results) even though there are still pages within the previous patch that have not yet been visited.

**SNIF-ACT**

Scent-based Navigation and Information Foraging in the ACT architecture (SNIF-ACT) (Pirolli & Fu, 2003) is a model of human behaviour in an interactive search task. The model makes use of ACT-R’s spreading activation mechanism so that the information scent of the currently viewed Web page activates chunks in declarative memory as does the spreading activation from the goal. Where these two sources of activation coincide there are higher levels of activation and this indicates a high degree of relevance between the goal and the page being attended to. This activation is what ultimately drives the behaviour of the model. The model includes the use of search engines to provide a set of search results and the processing of the page that is returned. The links on the page are attended to and eventually one of the links is selected.

The behaviour of the model is compared to user behaviour and successfully demonstrates that people tend to select the highest scent item in a list. SNIF-ACT does this by assessing the information scent of all the links on a page and then choosing the highest one. The model is also able to explain the point at which a user abandons a particular Web site and returns to the search results in order to select another item from the list or selects a link that takes them to another Web site. If the mean information scent of the currently viewed page is lower than the mean information scent of a page on another site the model selects that action that takes them to the other site.

**Eye-Tracking Experiments in Interactive Search**

When presented with a list of search results or items on a menu within a Web site (i.e., a patch of information), the user has to choose between selecting an item which will move him/her to another patch and doing some assessment on either the currently attended item or some other item in the list (i.e., consume the information presented within the current patch). As has been mentioned previously, IFT proposes that the user will make use of the information scent of the items to guide their behaviour. If the information scent of a particular item in the list is higher than the rest (i.e., that item appears to be relevant to the task and the user believes that clicking it will lead them to better information) then the item will be selected.

Eye-tracking experiments have been used to investigate what people attend to when conducting interactive search tasks (Brumby & Howes, 2004; Silva & Cox, 2005). Participants were given an information goal and a list of items and asked to select the label that they thought would lead to the
Modelling Interactive Behaviour with a Rational Cognitive Architecture

Brumby and Howes demonstrated that people often examine only a subset of the list before selecting the target item, and that this behaviour is affected by the relevance of the other items in the list. When the other items in the list are more relevant to the goal (i.e., they have high levels of information scent), people tend to look at more items in the list and also tend to look at individual items on more occasions than when the items are irrelevant. When there are a number of items with high scent (i.e., two or more items look like they would lead to relevant information) people need to consider more items than when only one item looks sensible.

However, one limitation of this work is that the analysis of eye-tracking data is rarely sensitive enough to determine whether a lack of fixation of the eyes on an item really means that people have not assessed the relevance of the item. In order to address this, Silva and Cox (2005) additionally employed a recognition task in their study in order to assess the level of processing of each item in the list.

Figure 2 represents a simplified scan path of a participant completing one of these tasks. The items are represented on the y axis with time along the x axis. The highlighted item is the target item and was selected by the participant. The figure demonstrates how the user starts at the top of the list and scans down the list fixating items in the list. Some of the items (3 & 6) are skipped over. The results from Silva and Cox’s (2005) recognition task suggest that in such cases the lack of fixations of particular items in the menu can be explained by parafoveal processing. However, parafoveal processing can only explain lack of fixations on up to two items below the last fixation (i.e., items 8 & 9) and cannot explain why the user does not attend to other items in the list (i.e., items 10 to 16).

SNIF-ACT would be able to produce a trace that would match the behaviour of users in these studies in terms of which items from the menus the user selected. However, the model does not account for the fact that some of the items in the menus were not assessed by the users as it assumes that users have knowledge about information scent of all the items in the list and then selects the item with the highest level of scent. Consequently, SNIF-ACT is unable to provide us with any explanation for why users should choose to select an item when they have not even read the entire list presented to them.

Cox and Young (2004) propose an alternative model to that of SNIF-ACT that is able to capture this fine-grained level of detail of user behaviour. Their model is a rational analysis of an interactive search task that provides a rational explanation of why the user would select an item without first assessing all the items in the list.

In interactive search, the agent has the goal of selecting the item that will lead to goal completion. However, as the menu presented is novel, the first thing that the model has to do is to gain some information about the menu. The model

**Figure 2. A simplified scan path of a participant performing an interactive search task**
therefore includes two types of exploratory acts (EAs) (these are the different types of things the model can do): assess information SCENT and ANTICIPATE the result of selecting this item. The SCENT EA should be thought of as being an amalgamation of perceiving the label, reading the label (at a lexical level), and considering the semantic similarity between the label and the current task. The ANTICIPATE EA should be thought of as some additional cognitive effort that considers whether the label is likely to lead to the goal. For example, given the goal of finding an armchair for your living room on a furniture shop Web site, imagine the model considering the first item in the menu “home.” The SCENT EA would return a moderately high rating as the label has a moderately high level of information scent given the goal (“home” and “armchair”). The ANTICIPATE EA models the agent’s consideration of whether the label home is likely to lead to the home page of the site, or to a list of home furnishings. Each of these EA types has a cost associated with it with the ANTICIPATE EA type being more expensive in mental effort than the first type. There is also a fixed cost of moving attention from one item in the menu to the next.

Before assessing any items, the model “knows” the number of items in the menu and considers each of these items to be equally (ir)relevant to completing the task. The scent ratings of the items in the menu are used as the basis for determining the new relevance (R) value of an item following an assessment. On each page, the set of relevancies R_i are mapped into a set of probabilities P_i by the transformation P_i = odds(R_i)/∑odds(R_j), where odds(R) is defined in the standard way as odds(R) = R/(1–R). Note that ∑P_i = 1, reflecting the fact that exactly one option on the page leads to the goal.

When the model is run on a set of menus it demonstrates how different patterns of information scent result in different behaviours. As Brumby and Howes (2004) demonstrated, the levels of information scent of both the goal item and the distractors affect behaviour. However, it is also interesting to note that the model predicts that just the change in position of the goal item relevant to the distractors results in different patterns of behaviour: Sometimes the model predicts that users will scan to the bottom of the menu before selecting the target item, and other times they will select the item immediately after assessing the item leaving other items in the menu unassessed. To explain how this occurs we will compare the behaviour of the model when the high scent item is in position two (as an example of occurring early in the menu) and in position 12 (as an example of occurring late in the menu) in more detail. In both examples, initially, all 16 menu items are rated equally and all have an R value of 0.06. The relevance values are translated into efficiencies (E) which are then used to determine which of the EAs is most likely to lead to the goal and therefore which EA is executed in each cycle. In the first cycle, the EA that proposes assessing the scent of the first item in the menu is rated as having the highest E value due to it having the lowest cost. Consequently, the model assesses the first item which gets rated as very low scent. As a result, the new R value of this item is set at 0. On the next cycle, the EA that proposes SCENT assessment on the second item in the list is the most efficient (due to the lower cost) so this item gets assessed. This behaviour continues until the model assesses the high scent item.

In menus where the high scent item occurs early on in the menu, the second item in the menu gets an R value of 0.5097 which raises the probability that this item will lead to the goal to 0.6220. On the following cycle the R value of the high scent item leads to an E value of 0.008 while the second best item (an item yet to be assessed) has an R value of 0.06 which results in an E value of 0.006. Although the E values of the two EAs are very similar, one is larger than the other, and this is what determines which EA is chosen.
In our example of a menu where the high scent item occurs later on in the menu, the relevance of each of the low scent items that have already been assessed falls to 0. When the model assesses the twelfth item its R value is 0.5097, which raises the probability that this item will lead to the goal to 0.6220. On the following cycle the R value of the high scent item only has an E value of 0.005 while the item with the best efficiency (an item yet to be assessed) has an R value of 0.05 which results in an E value of 0.006. The result is that the model continues to assess each item in the menu until it reaches the bottom because the efficiency of conducting a SCENT assessment of a new item is greater than the efficiency of conducting the ANTICIPATE assessment on the high scent item in position 12. This has the effect of slowly increasing the probability of the item in position 12 leading to the goal.

The detail of the model explains that the reason the behaviour is different for the two types of menus is because the detail of the mathematics of the rational analysis. Comparisons of the traces of the model with the empirical data suggest that the model provides a good explanation of the cognitive processes involved in this task. This suggests that participants make an assessment of the relevance of a label to the current goal and then, together with the estimated relevance of previous items, choose to either (1) select that item as the one that will lead to the goal, (2) conduct some further assessment of the current item, or (3) move on to another item and assess that. Which of these EAs is chosen is driven by the pattern of information scent that has been experienced so far.

The model provides us with an explanation of how and why the position of the goal and the quality of the distractor items affect the behaviour of the participants on the task. Regardless of the pattern of scent of the menu, the model predicts that the agent will tend to stop exploring the menu as soon as it comes across a menu item that has high information scent (self-terminates) if this is encountered early in the menu. On menus where there is one high scent item among a set of low scent items and the high scent item occurs later in the menu, the agent continues to assess the other items in the menu before conducting further assessment of the high scent item and finally selecting it. The model enables us to explain why we see these different patterns of behaviour on menus which have such similar patterns of information scent. This is due to the effect of the interdependence of the probability that each of the items will lead to the goal. The actual point on the menu at which the model swaps from one behaviour to the other is sensitive to a number of factors such as the length of the menu and the costs of the EAs. It would appear therefore that it is in the nature of interactive search that there are close calls which suggest that people can rationally do either behaviour and that a number of factors have an effect on the behaviour of participants exploring real menus.

Together the two models described previously provide us with a good understanding of how people perform search tasks on the WWW. SNIF-ACT and the rational model explain different aspects of the interaction: SNIF-ACT demonstrates the higher level, page by page, link following behaviour seen in such tasks, whereas the rational model explains the lower level interactions with just one page. Given information about the information scent of the items on a new Web site both models are able to make predictions about user behaviour on the site.

**Modelling Graph Reading**

Peebles and Cheng (2003) conducted an experiment, eye movement study and cognitive modelling analysis to investigate the cognitive, perceptual, and motor processes involved in a common graph-reading task using two different types of Cartesian graph. The purpose of the study was to determine how graph users’ ability to retrieve information can be affected by presenting the same information in slightly different types of the same
class of diagram. The two types of graph, shown in Figure 3, represent amounts of UK oil and gas production over two decades. The only difference between the two graph types is in which variables are represented on the axes and which are plotted. In the Function graphs, the argument variable (AV: time in years) is represented on the x-axis and the quantity variables (QV: oil and gas) on the y-axis whereas in the Parametric graphs, the quantity variables are represented on the x and y axes and time is plotted on the curve.

In the experiment, participants were presented with the value of a “given” variable and required to use the graph to find the corresponding value of a “target” variable, for example, “when the value of oil is 2, what is the value of gas?” This type of task has typically been analysed in terms of the minimum sequence of saccades and fixations required to reach the location of the given variable’s value and then from there to the location of the corresponding value of the target variable (Lohse, 1993; Peebles & Cheng, 2001, 2002; Peebles, Cheng, & Shadbolt, 1999). Experiment participants (some of whom had their eye movements recorded) completed 120 trials, each participant using only one graph type. The 120 questions were coded into three classes (QV–QV, QV–AV, and AV–QV) according to which variable’s value was given and which was required (QV denotes a quantity variable, oil or gas, and AV denotes the argument variable, time). On each trial, a question (e.g., “GAS = 6, OIL = ?”) was presented above the graph and participants were required to read the question, find the answer using the graph on the screen and then enter their answer by clicking on a button labelled Answer in the top right corner of the window which revealed a circle of buttons containing the digits 0 to 9. RTs were recorded from the onset of a question to the mouse click on the Answer button.

Figure 3. Function and parametric graphs used in Peebles and Cheng (2003) depicting values of oil and gas production for each year

Notes: The graphs on the left (labelled 1) show years 1970 to 1979 while those on the right (labelled 2) show years 1980 to 1989. Dashed lines indicate the optimal scan path required to answer the question, “when the value of oil is 3, what is the value of gas?”
the screen and then enter their answer by clicking on a button labelled Answer in the top right corner of the window which revealed a circle of buttons containing the digits 0 to 9. RTs were recorded from the onset of a question to the mouse click on the Answer button.

The RT data from the experiment, displayed in Figure 4, showed that the graph used and the type of question asked both had a significant effect on the time it took for participants to retrieve the answer. This was all the more surprising because, for two of the three question types, participants were faster using the less familiar parametric graphs by nearly a second.

The results of the eye movement study were also surprising. It was found that in 63% of trials (irrespective of the graph used or question type being attempted), after having read the question at the start of a trial, participants redirected their visual attention to elements of the question at least once during the process of problem solving with the graph. This was not predicted by the simple minimal fixation sequence account outlined previously but two possible explanations may be provided: (1) participants initially encode the three question elements but are unable to retain all of them in working memory and retrieve them by the time they are required to do so, or (2) to reduce the probability of retrieval failure, participants break the problem into two sections, the first allowing them to reach the given location and the second to then proceed to the target location corresponding to the solution.

Peebles and Cheng (2003) constructed two ACT-R models of the experiment (one for each graph type) that were able to interact with an exact replica of the experiment software. The models consisted of a set of productions to carry out the six basic subgoals in the task; (1) read the question; (2) identify the start location determined by the given variable; (3) identify the given location on the graph representing the given value of given variable; (4) from the given location, identify the target location representing the required variable; (5) identify the target value at the target location; and (6) enter the answer. Many of the productions were shared by the two models, the main difference between them being the control structure that sequences the execution of the productions. Figure 4 shows that the mean RTs from the parametric and function graph models are a good fit to the observed data ($R^2 = .868$, RMSE = 0.123, and $R^2 = .664$, RMSE = 0.199 respectively). Perhaps more importantly however, were the insights into the observed eye movement data that came from the modelling process itself. When ACT-R focuses attention on an object on the screen, representations of the object and its location are created in

Figure 4. Mean response times for experimental participants and ACT-R models for each question type (Peebles & Cheng, 2003)
the system’s visual buffers which can be accessed by productions. Eventually these representations go into declarative memory with initial activation values and, as long as these values are above a certain threshold, they can be retrieved by the cognitive system and replaced in a buffer. However, ACT-R includes a mechanism by which the activation of representations in declarative memory decreases over time which allows it to simulate processes involved in forgetting. These mechanisms played a crucial role in the ACT-R models’ ability to capture the eye movement data observed in the experiment. At the start of each trial, the models read the three question elements and during the problem solving these elements are placed in declarative memory. As a consequence, at least one question element must be retrieved from memory at each stage of the problem in order to continue. However, as soon as a question element is placed in declarative memory its activation starts to decay and, as a consequence, the probability that it cannot be retrieved increases. Typically, if a retrieval failure occurs, an ACT-R model will halt as it does not have the appropriate information to solve the problem. During the process of model development it was found that on a significant proportion of trials the model was not able to retrieve question elements at the later stages of the trial because their activation had fallen below the retrieval threshold. As a consequence new productions had to be added to allow the model to redirect attention to the question in order to re-encode the element and then return to solving the problem. This was precisely the behaviour observed in the eye movement study. This is illustrated in Figure 5 which compares screen shots of the model scan path and eye movements recorded from one participant for the same question using the 1980’s parametric graph. The numbered circles on the model screen shot indicate the sequence of fixations produced by the model. The pattern of fixations in both screenshots is remarkably similar.

Modelling Icon Search

Fleetwood and Byrne’s study of icon search (2002, in press) is another demonstration of how an ACT-R cognitive model can provide a detailed account of the cognitive and perceptual processes involved in a common HCI task that closely matches people’s response times (RTs) and

![Figure 5. Screen shots showing an experimental participant’s eye movement data (left) and the ACT-R model’s visual attention scan path (right) for the QV–QV question “oil = 6, gas = ?” using the 1980's parametric graph.](image)

Note: In the model screen shot, numbered circles on the scan path indicate the location and sequence of fixations.
patterns of eye movements. Fleetwood and Byrne’s model differs from that of Peebles and Cheng (2003) in that it incorporates eye movements and movement of attention (EMMA) (Salvucci, 2001), a computational model of the relationship between eye movements and visual attention. EMMA can be easily integrated into the ACT-R architecture, allowing models to make more detailed predictions of actual eye movements, rather than simple shifts of visual attention.

One of the main aims of Fleetwood and Byrne’s research is to investigate the notion of icon “quality” (defined in terms of an icon’s distinctiveness and visual complexity) and to examine the effect that differences in quality may have on identification performance. They created three classes of icon (examples of which are shown in Figure 6). “Good” quality icons were designed to be easily distinguishable from others based on the primitive features of colour and shape. All icons in this set were a combination of one colour (from six) and one shape (from two).

In contrast, “poor” quality icons were designed to be distinguishable only by a relatively careful inspection but to be relatively indistinguishable in a large distractor set. These poor quality icons were all of the same basic shape and colour (a combination of black, white, and shades of grey). An intermediate class of “fair” quality icons was also designed with shapes more distinctive than the poor quality icons but more complex than the good quality icons, and with the same range of greyscale colours as the poor quality icons. The main effect of the manipulation was to produce a different similarity structure for each class of icons. Good quality icons could be identified as a single combination of features, for example, “yellow triangle.” In contrast, fair quality icons were defined by more than one combination of features (typically three, for example: “grey rectangle; black square; black diagonal-right”), some of which were shared with other icons. In the poor quality group, icons were defined by an average of four feature combinations and many more of these were shared by several other icons in the group. From the visual search literature, it can be predicted that search time will increase as icon distinctiveness decreases. An additional factor in Fleetwood and Byrne’s (2006) study also known to affect search time (at least for certain stimuli) is the number of distractors in the display, with search time increasing with the number of distractors in the search set. In their experiment, Fleetwood and Byrne had search sets of 6, 12, 18 and 24 icons.

In the experiment, participants were required to find, as rapidly as possible, different quality target icons in search sets of differing sizes. On each trial, a target icon and file name were presented followed 1500 ms later by a button labelled Ready for the participant to click when he/she felt ready to continue. When this button was clicked, the target icon was replaced by the search set and the participant had simply to look for the target icon and click on it as quickly as possible; when an icon was clicked upon, the next trial started. Participants completed a total of 144 trials, involving all levels of the search set and icon quality variables, and on each trial the participant’s RT (the duration between clicks on the Ready button and an icon in the search set) was recorded. The results of the experiment (shown in Figure 7) revealed that, as predicted, both icon quality and search set size had a significant effect on search time.

Figure 6. Examples of icons of good, fair, and poor quality used in the experiment of Fleetwood and Byrne (in press)
To provide an explanation of their data, Fleetwood and Byrne (2006) produced an ACT-R model of the task that was able to interact with the same experiment software as the participants. As described previously, each experiment trial is comprised of two stages, the first where the target icon and its file name are encoded and the second in which it is sought. The model has a set of seven productions to carry out the first stage: (1) locate the target icon and (2) encode an attribute pair (e.g., "grey rectangle"), (3) look below the icon and (4) encode the associated file name, and finally (5) locate and (6) click on the “Ready” button. In the second stage, the model locates and attends to an icon with the previously encoded target feature and then shifts visual attention to the file name below it. If the file name matches the target file name, visual attention is returned to the icon and the mouse clicks on it. If the file name is not the target, however, the model continues the search by locating another icon at random with the same target features. This sequence of events requires four productions and takes 285 ms to complete.

Figure 7 reveals a close correspondence between the mean RTs produced by the model and those of the experiment participants ($R^2 = .98$, RMSE = 126ms) and shows that an ACT-R model based on the similarity structure of the search set and the strategy of identifying a single combination of features and random search can provide a reasonable account of the data. However, Byrne, Anderson, Douglass, and Matessa (1999) had shown in an earlier study of visual search in a menu selection task that alternative strategies can produce similar aggregate RTs, necessitating the incorporation of eye movement data to add further constraints on the proposed theory. As a result, Fleetwood and Byrne (2006) carried out an eye movement study to test their model further and found two major discrepancies between the observed eye movements and the patterns of visual attention produced by their model. First, they found that, although the model successfully reproduced the patterns of visual attention across the icon quality and set size conditions, for all conditions the number of saccades per trial produced by the model was significantly greater than those recorded in the experiment. Second, when analysing the eye movement data, Fleetwood and Byrne found that patterns of icon search were not random as their model predicted, but were systematic, in the sense that participants sought to minimise the distance between successive fixations, typically looking at target icons closest

---

**Figure 7. Response time by set size and icon quality for Fleetwood and Byrne's (in press) revised model and the experiment data**
to their current fixation point. This produced a search pattern that revealed a systematic scanning of areas of the display.

Both of the discrepancies between the model and human data are explained by Salvucci’s (2001) EMMA model. It has been demonstrated previously that the relationship between eye movements and visual attention is not direct, and that people often do not move their eyes to their focus of attention (e.g., Henderson, 1992; Rayner, 1995). EMMA attempts to capture this relationship by providing an account of if and when eye movements occur, and if they do occur, the location of their landing relative to their targets. Integrating EMMA into ACT-R allows models to simulate actual eye movements rather than just visual attention shifts and provides a more realistic output to be compared with human eye movement data. In addition, EMMA predicts that efficient search strategies minimise average saccade distance, resulting in search patterns in which objects nearest to the current fixation point are examined soonest.

Fleetwood and Byrne (2006) modified their model’s search strategy according to the EMMA account and incorporated EMMA’s eye movement computations into their model, resulting in a greatly improved fit (shown in Figure 8) to the human eye movement data ($R^2 = .99$, RMSE = 0.58).

CONCLUSION

In this chapter we have presented a number of recent examples of research that we believe clearly demonstrate the value of rational analysis and cognitive modelling in the study of complex interactive behaviour. Such tasks typically involve the complex interaction of three elements: (1) the perceptual and cognitive abilities of the user; (2) the visual and statistical properties of the task environment; and (3) the specific requirements of the task being carried out. The use of rational analysis and an embodied cognitive architecture such as ACT-R allows all three of these elements to be brought together in an integrated theoretical account of user behaviour. Rational analysis provides a set of assumptions and methods that allow researchers to understand user behaviour in terms of the statistical structure of the task environment and the user’s goal of optimising (i.e., reducing the cost/benefit ratio of) the interaction. Developing

Figure 8. Mean number of shifts of visual attention per trial made by Fleetwood and Byrne’s (in press) revised model relative to the mean number of gazes per trial made by participants
cognitive models of interactive behaviour in a cognitive architecture such as ACT-R allows researchers to specify precisely the cognitive factors (e.g., domain knowledge, problem-solving strategies, and working memory capacity) involved. In addition, the recent incorporation of perceptual-motor modules to cognitive architectures allows them to make predictions about users’ eye movements during the entire performance of the task, which can be compared to observed eye movement data — a highly stringent test of the sufficiency and efficacy of a model. The use of these methods has increased rapidly over the last 5 years, as has the range of task interfaces being studied. Although we are still a long way from achieving the goal of an artificial user that can be applied “off the shelf” to novel tasks and environments, the models of interactive behaviour described here demonstrate a level of sophistication and rigour still relatively rare in HCI research. As these examples illustrate, developing more detailed accounts of interactive behaviour can provide genuine insights into the complex interplay of factors that affect the use of computer and Web technologies, which may inform the design of systems more adapted to their users.

ABSTRACT

In this chapter, we will study the localization problem in ubiquitous computing environments. In general, localization refers to the problem of obtaining (semi-) accurate physical location of the devices in a dynamic environment in which only a small subset of the devices know their exact location. Using localization techniques, other devices can indirectly derive their own location by means of some measurement data such as distance and angle to their neighbors. Localization is now regarded as an enabling technology for ubiquitous computing environments because it can substantially increase the performance of other fundamental tasks such as routing, energy conservation, and network security. Localization is also a difficult problem because it is computationally intractable. Furthermore, it has to be implemented in a highly dynamic and distributed environment in which measurement data is often subject to noise. In this chapter, we will give an overview of localization in terms of its common applications, its hardware capacities, its algorithms, and its computational complexity.

INTRODUCTION

In a ubiquitous computing environment, devices are often connected to one another on the fly to form an infrastructure-less network that is fre-
Device Localization in Ubiquitous Computing Environments

quenty referred to as a mobile ad hoc network (MANET). Since MANET serves as an abstract model that can be seen as a superset of diverse sub-areas such as sensor networks, mesh networks or an enabler for pervasive computing, it has attracted significant research interests in the past several years. A major advantage of MANETs over regular wired or wireless networks is their infrastructure-less nature, as MANETs can potentially be deployed more rapidly and less expensively than infrastructure-based networks. However, the lack of an underlying explicit infrastructure also becomes a major disadvantage in adapting MANETs to a wider array of applications, since existing network algorithms and protocols are often not “plug-in” solutions for such dynamic networks. New algorithms need to be designed for fundamental network tasks such as addressing, topology discovery, and routing.

Location discovery is emerging as one of the more important tasks as it has been observed that (semi-) accurate location information can greatly improve the performance of other MANET tasks such as routing, energy conservation, or maintaining network security. For instance, algorithms such as location aided routing (LAR) (Ko, 2000), GRID (Liao, 2001), and GOAFR+ (Kuhn, 2003) rely on location information to provide more stable routes during unicast route discovery. The availability of location information is also required for geocast (multicast based on geographic information (Jiang, 2002)) algorithms such as location-based multicast (LBM) (Ko, 1999), GeoGRID (Liao, 2000) and position-based multicast (PBM) (Mauve, 2003). To minimize power consumption, the geographical adaptive fidelity (GAF) algorithm (Xu, 2001) uses location information to effectively modify the network density by turning off certain nodes at particular instances. Furthermore, in (Hu, 2003), the authors have shown that wormhole attacks can be effectively prevented when location information is available. As more algorithms are being proposed to exploit location information of devices in ubiquitous networks, it is clear that obtaining such information efficiently and accurately becomes of great importance.

A direct way of obtaining location information is to install global positioning system (GPS) receivers on devices. However, this is currently impractical as GPS receivers are still relatively expensive, power-hungry, and require clear line of sight (i.e., making indoor usage impossible) to several earth-bound satellites. In ubiquitous environments (e.g., sensor networks), devices are imagined as small as possible and operating on a very restricted power source, thus, it may not be feasible to install GPS receivers onto all sensor nodes. Localization in MANET refers to the problem of finding the locations of those non-GPS enabled nodes based on limited information such as the locations of some known beacons (also referred to as anchors) and measurements such as ranges or angles among the neighbors. In this chapter, we will study why localization is important and how it can be accomplished within the ubiquitous computing environment.

BACKGROUND

The localization problem is hard for a number of reasons:

1. **Geometric limitations**: To pinpoint its exact location in 2-D, a node needs to know the locations and its distances to at least three beacons. Alternatively, nodes could calculate their own location based on a distance and an (absolute) angle measurement from one beacon. However, even if obtaining such measurements were possible and the measurements were exact, guaranteeing that the right number of beacons surround each node is often impossible since MANETs may be randomly deployed and that in general only a small percentage of nodes are indeed beacons. Thus, localization algorithms often
need to take advantage of multi-hop information, that is, estimating node locations based on other nodes’ location estimates.

2 **Availability of measurements:** For localization algorithms that require distance or angle measurements, certain sensory devices will need to be available to provide such readings. However, it is likely that not all nodes have the same sensory capacity. In other words, there is a need for the localization algorithm to work in a heterogeneous environment, in which devices with different location sensory capacities coexist.

3 **Measurement error and error propagation:** Even when measurement devices are available, there is a general consensus that those measurements are prone to errors. For instance, a distance measurement can be derived based on a received signal strength indication (RSSI) reading, in which a receiving device measures the strength of the signal from a sending device and obtains the distance via an estimated signal propagation model. RSSI reading is prone to multi-path fading and far field scattering. The error can be especially high when there are a significant number of obstacles in between the sender and the receiver. Since most localization algorithms require measurements from nodes several hops away, the measurement error is likely to aggregate along the path and eventually completely throw off the location estimate.

Despite the difficulties listed above, there is an increasing amount research effort spent on the localization problem. The amount of effort is justified because localization is considered an enabling technology that needs to be resolved with the best possible outcome upon which other location-dependent technologies for MANETs can be successfully employed. Researchers have been working on problem in both hardware (i.e., improving measurement accuracy of devices) and software (i.e., improving the localization algorithm design). This chapter covers the latest advances in this field, including the following topics:

1. **Applications of localization:** In this section, we will establish the need for better localization techniques by surveying a number of proposed algorithms for MANETs that rely on localization.
2. **Measurement types for localization:** In this section, we will cover the latest advances in hardware design that enables localization on the smaller devices commonly seen in the ubiquitous computing environment, including the devices that measure distance ranging, angle of arrival (AoA), and interferometric ranging.
3. **Survey of localization algorithms:** We will survey some of the most popular localization algorithms, including those using connectivity information, ranging, and angle information. We will study the pros and cons of each algorithm, and suggest their appropriate applications in ubiquitous computing.
4. **Localization theory:** We will cover the theoretic basis of localization techniques. We will study the necessary and sufficient conditions for a network to be localized based on the latest results from graph theory. We will show that the localization problem in general is NP-Complete. We will also introduce the reader to the Cramer Rao Bound (CRB) that is often used to analyze the hardness of different localization scenarios.
5. **Future directions:** We will look into a number of promising future directions for the localization techniques.

**APPLICATIONS OF LOCALIZATION**

There have been numerous algorithms proposed for MANETs that rely on localization data; in this section, we provide a brief survey of these
algorithms. We will consider algorithms in four categories based on their functionalities: unicast routing; multicast routing; energy consideration; and network security.

**Unicast Routing**

Routing refers to the task of finding the correct route from a sending device (source) to a receiving device (destination). Routing is an especially challenging task for MANETs because their frequent topology change implies the underlying instability of any established routes. As such, routes are needed to be frequently rediscovered, reestablished, and repaired. In general, routing (i.e., route discovery and repair) involves flooding the routing control packets throughout the network. Flooding can often be expensive in terms of delay and bandwidth usage it incurs, both of which can greatly affect the network performance. Thus, there is a strong incentive to design efficient routing algorithms that minimize the overhead caused by any unnecessary packet flooding. Unicast routing based on location information, often called geometric routing or location based routing, has shown to be one of the viable solutions to this problem.

**Location-aided routing (LAR)** (Ko, 2000) protocol is the first MANET routing algorithm proposed that uses location data. In LAR, every node is assumed to know its own location, and each individual location is then periodically broadcast throughout the network. Thus, at any time $t$, every node knows the locations of any other nodes at some previous time $<t$. Based on this location information and an estimated velocity, a node can derive an estimated location range, called “expected zone,” of a target node at the current time. Instead of flooding the entire network, the routing request packets can be directed to search for the target node only at this expected zone. Global flooding is performed only after the location based routing request has failed. Limiting route discovery to a smaller expected zone with LAR reduces the number of routing requests compared to the standard flooding scheme.

**GRID** (Liao, 2001) protocol uses location information as a way to form geographical clusters within the network. Based on node locations and their residency within a pre-determined grid system, nodes within the same grid block are grouped into a cluster. A cluster head or “gateway” in (Liao, 2001) is then selected for each grid block. The cluster head is responsible for servicing the routing packets. Furthermore, the cluster head can monitor the status of existing routes and reroute packets as deemed necessary. Since the cluster formation effectively simplifies the network topology, the routing overhead is reduced. A critical requirement of forming such geographical-based clusters is the availability of node location information.

In (Kuhn, 2003), the authors provided a theoretical bound to the geometric routing problem and proposed an algorithm called GOAFR+. Assuming that node locations are known using some localization technique, GOAFR+ first tries to greedily route the packet by forwarding it to the neighbor located closest to the destination. However, such greedy selection does not guarantee message delivery since the intermediate node closest to the destination might not have a route to it. In such cases, GOAFR+ explores the boundaries of the faces of a planarized network graph by employing the local right hand rule (i.e., always turn right) to escape the local minimum. This method of escaping local minima is also called “parameter routing,” which is used in a number of other location based routing protocols as well.

In terms of performance, simulations performed by (Ko, 2000) and (Liao, 2001) have shown up to 50% of reduction in routing packets when using geographic routing compared to standard flooding. Since the overhead of flooding is proportional to network density, it has been observed that the amount of performance gain becomes more significant when network density
is increased. Furthermore, although the routing performance is impacted by the localization error, such impact is observed to be minimal. This indicates that in the case of routing, highly precise location data is not required. After all, location data is used by routing algorithms to give a direction that guides the routing packets; imprecise location data can still be used as long as the general direction is valid.

**Multicast Routing**

Similar to unicast routing, multicast routing can also benefit from location data. Multicast routing using geographic information is often referred to in the literature as geocast routing. The Location-Based Multicast (LBM) algorithm (Ko, 1999) is a multicast extension to the unicast Location-Aided Routing (LAR). Like LAR, which forwards the routing requests according to the location of the destination node, LBM forwards the requests according to the direction of the geocast region that contains all the multicast destinations. GeoGRID (Liao, 2000) is the multicast extension to GRID (Liao, 2001). Like in GRID, location information is used by GeoGRID to identify the grid block where nodes reside. Multicast is done through the gateway node selected at each grid block. Based on the location of the source node and the geocast region, LBM and GeoGRID define a “forwarding region” that contains the intermediate nodes responsible for forwarding packets. The size and shape of the forwarding region have a direct impact on the overall performance; shapes such as rectangles and cones have been proposed in (Ko, 1999).

While the standard shapes such as rectangles and cones work well in most cases, there are situations where viable routes exist only outside the forwarding region. For instance, a network can be partitioned into two sub-networks connected only through a narrow linkage due to some obstacles (e.g., two islands connected by a bridge). When the source and the destination are in separate partitions, a geometrically defined forwarding region is unlikely to cover the linkage. To prevent routing failure in such a case, a routing zone based on Voronoi diagrams was proposed in (Stojmenovic, 2006), which partitions the network graph based on the proximity of the nodes. Again, the proximity information relies on localization information.

The Position-Based Multicast (PBM) protocol proposed in (Mauve, 2003) attempts to optimize the multicast tree it generates by minimizing the overall path length and the overall bandwidth usage; two often contradictory objectives. To minimize the overall path length, PBM takes a greedy approach using location information. At each intermediate node, packets are forwarded to a set of neighbors based on their overall distances to the multicast destinations. In particular, a set of the neighbors with the minimum overall distance to every destination is selected as the next set of forwarding nodes. To take account of the bandwidth usage, the greedy selection also tries to minimize the size of the forwarding set. PBM also uses parameter routing to deal with local minima. Both greedy routing and parameter routing employed by PBM rely on the location information.

**Power Management**

MANET is often used as the model for sensor networks, an emerging technology for pervasive computing. One of the major challenges of sensor networks is power management. Since sensors are commonly small in size and are battery powered, conserving energy would prolong their service time and, thus, the lifespan of the entire network. The Geographical Adaptive Fidelity (GAF) algorithm (Xu, 2001) is a network topology management algorithm with reduced energy consumption as its primary objective. The idea behind GAF is that there are often a large number of nodes that are redundant during packet routing in MANETs. If the redundant nodes can be identified, they
Device Localization in Ubiquitous Computing Environments

can then turn off their radio to save energy. For GAF, the identification of redundant nodes is accomplished by analyzing the relative location information among the neighboring nodes. More specifically, GAF divides the network into virtual grids such that all nodes in grid block $A$ are the neighbors of all nodes in grid block $B$. This way, all nodes within the same virtual grid block can be considered equivalent. To conserve energy during packet routing, GAF only turns on the radio for one of the nodes in each grid block. The active node is periodically “round-robin” to achieve load-balancing. Analysis and simulations performed in (Xu, 2001) show that GAF can reduce overall energy consumption by 40% to 60%.

Security

In (Hu, 2003) the authors proposed a technique called “packet leashes” to defend against wormhole attacks in MANETs. A wormhole attack is a type of security breach where an adversary intercepts incoming packets and tunnels them to another part of the network via a single long-range directional wireless link or through a direct wired link. From there, the adversary can retransmit the packets to the network. Note that this type of “capture-and-retransmit” attack can be immune to common packet encryption methods, since the adversary does not need to read the packet content. Wormhole attacks can severely disrupt ad hoc routing protocols such as Ad hoc On-Demand Distance Vector Routing (AODV) or Dynamic Source Routing (DSR), and cause a denial of service to the network. The core of “packet leashes” is based on two assumptions: i) all nodes know their own locations; and ii) all nodes are synchronized. To enable packet leashes, the sender node encloses its location and transmission time-stamp within the packet. At the receiver node, the packet leash is validated against the receiver’s own location and clock. In particular, the sender location information gives the distance from the original sender to the receiver, and the time-stamp gives the transmission duration of the packet. Based on the transmission duration and signal propagation model, factored in some error tolerance, the receiver can validate the estimated distance the packet has traveled against the true distance to determine whether the packet is indeed coming from the original sender or an imposer at some other location. Thus, the location information and time-stamp provide a virtual leash to limit the effective range of the packet so that it cannot be exploited by wormhole attackers.

From the previous discussion on the location-dependent algorithms that encompass a wide range of problem domains, it is clear that providing location information (i.e., localization) to MANETs is becoming an increasingly important task. In fact, localization is now widely regarded as an “enabling technology” for MANETs that needs to be addressed before other location-dependent techniques can be realized in the real world (Patwari, 2003).

Measurement Types for Localization

In this section, we study a number of measurement types provided by onboard hardware devices that enable localization in MANETs for ubiquitous computing environments. A Global Positioning System (GPS) (Parkinson, 1996) receiver can provide the absolute location. However, its cost, size, and power requirement prevent it from being installed at every network node. How do nodes not equipped with GPS obtain their location information then? They have to rely on sensory measurements provided by alternative hardware devices. There are five general types of measurements: i) connectivity only; ii) RSSI (radio signal strength indicator) ranging; iii) ToA (time of arrival) ranging; iv) AoA (angle of arrival), and v) interferometric ranging. We will describe each of their capacity, usage and mathematical models when applied to the localization problem.
CONNECTIVITY ONLY MEASUREMENT

At a minimum, a node can detect connectivity to its immediate neighbors, that is, its one-hop neighborhood. The connectivity only measurement is a binary reading between two nodes of either “true” or “false” indicating whether they are neighbors. Based on this connectivity information, one can derive the general proximity of the nodes as a way to localize the network.

RSSI Ranging Measurement

A node can be localized using multilateration (Niculescu, 2001) if the distances (i.e., the ranges) to three or more known locations are obtained. The distances can be obtained, for example, by measuring RSSI (radio signal strength indicator) or ToA (time of arrival). In RSSI, the receiver measures the received signal strength and compares it with the transmitted signal strength. The difference (in dB) is then applied to the inverse of the signal propagation model to provide a distance estimate. Sensors that measure RSSI are widely available to mobile devices. Indeed, most off-the-shelf technologies implicitly provide such information (e.g., most WiFi, Bluetooth, and IEEE802.15.4 chipsets do). The drawback of RSSI-based measurements is that they can be very inaccurate because an exact model of the propagation environment is often unavailable. Experiments in (Savvides, 2001) have shown that when no obstacle exists between the sender and the receiver, RSSI can provide a distance estimate of accuracy within a few meters. However, in a less than ideal environment, the result is often unpredictable. Furthermore, low cost RSSI receivers are often variable in their transmission power due to the lack of calibration.

In the outdoor environment with a minimum of obstacles, signal propagation decay is proportional to $d^{-p}$, where $d$ is the distance the signal has traveled, and $p$ is an environment-dependent path loss exponent. However, in the actual environment where obstacles exist, multipath signals and shadowing become two major sources of noise that impact the actual RSSI. In general, those noises are commonly modeled as a random process during localization. Let $P_{i,j}$ be the RSSI (in dB) obtained at the receiver node $j$ from the sender node $i$. $P_{i,j}$ is commonly modeled as a Normal distribution (Patwari, 2003)

$$P_{i,j} = N(\bar{P}_{i,j}, \sigma_{dB}^2)$$

where $\bar{P}_{i,j}$ is the mean power in dB and $\sigma_{dB}^2$ is the variance caused by noise factor such as shadowing. $P_{i,j}$ is further defined as the power reduction from a reference location:

$$P_{i,j} = P_0 - 10n_p \log_{10}(d_{ij} / d_0)$$

where $P_0$ is the power at a reference location at the distance $d_0$ (commonly $d_0 = 1m$), $p$ is an environment-dependent path loss exponent that is assumed to be known from prior measurements (theoretically $p = 2$). $d_{ij}$ is the Euclidean distance between nodes $i$ and $j$.

ToA Ranging Measurement

Although ToA is used for radio signals in GPS, it is mostly used in the context of acoustic or ultrasonic signals in inexpensive ToA tracking (as propagation speeds are five orders of magnitude less). For instance, the Medusa node in (Savvides, 2001) is an implementation of ToA ranging using ultrasonic signals. ToA measures the time signals travel from the sender to the receiver. The distance between nodes is obtained by multiplying this time with the signal propagation speed. In spite of the additive noise and multipath, in general distance measures based on ToA are more accurate than RSSI-based measures. However, special acoustic transceivers have to be employed on each node and synchronization among the nodes needs to be established. Clock synchronization algorithms...
design for sensor networks that are accurate to the order of 10 µs have been reported (Sivrikaya, 2004). As mentioned earlier, ToA may also be used together with radio signals, but current technology is not mature enough to provide satisfactory precision over smaller distances inexpensively.

Let \( i \) be the sender node and \( j \) be the receiver node, ToA measurement \( T_{i,j} \) is often modeled as a Normal distribution (Patwari, 2003):

\[
T_{i,j} = \mathcal{N}(d_{i,j} / c, \sigma^2)
\]

where \( d_{i,j} \) is the Euclidean distance between \( i \) and \( j \), \( c \) is the signal propagation speed, and \( \sigma \) is the variance caused by noise.

**AoA Measurement**

A node can be localized if the angles between it and two beacons are known. Thus, the angle information (i.e., bearing, or angle of arrival (AoA)) can be used to localize the network. Currently, there is no off-the-self device that offers AoA sensing capability. However, a number of prototype devices are available. For instance, Cricket Compass (Priyantha, 2001) is a small form device that uses ultrasonic measurements and fixed beacons to obtain acoustic signal orientations. In (Niculescu, 2004) a rotating directional antenna is attached to an 801.11b base station; by measuring the maximum received signal strength, a median error of can be obtained from the sensor. The challenge here is to design AoA sensing devices with small form factor and low energy consumption. In (Chintalapudi, 2004), the authors outline a solution with a ring of charge-coupled devices (CCDs) to measure AoA with relatively low energy consumption.

In general, AoA is also modeled as a Normal distribution. Let the true angle between the sender \( i \) and \( j \) be \( \hat{A}_{i,j} \), the AoA measurement between \( i \) and \( j \) is therefore

\[
A_{i,j} = \mathcal{N}(\hat{A}_{i,j}, \sigma^2)
\]

where \( \sigma^2 \) is the angle variance. Theoretical results for acoustic-based AoA estimation show standard deviation \( \sigma_A \) is between 2° to 6°, depending on range (Patwari, 2005). RSSI-based AoA method with \( \sigma_A \) on the order of 3° has been reported in (Ash, 2004).

**Interferometric Ranging Measurement**

Interferometric ranging is a “widely used technique in both radio and optical astronomy to determine the precise angular position of celestial bodies as well as objects on the ground (Kusý, 2006).” Interferometric ranging exploits the property that the relative phase offset between two receivers determines their distances to two simultaneous senders. Due to the recent advancement in hardware, it is now possible to implement interferometric ranging sensors in much smaller form factor to be used for localization (Marótí, 2005). By synchronizing the transmission at the two senders, each of which sends a signal at a slightly different frequency, the receivers can derive the relative phase offset of the two signals by comparing the RSSI readings. The distance difference (also called the \( q \)-range) can then be calculated from the relative phase offset with high accuracy. A \( q \)-range obtained from interferometric ranging from two senders \( A \) and \( B \), and two receivers \( C \) and \( D \) is the distance difference

\[
d_{ABCD} = d_{AC} - d_{BD} + d_{BC} - d_{AD} + e
\]

where \( e \) is the measurement error (Figure 1). A major advantage of interferometric ranging is that the measurement could be extremely accurate compared to noise-prone RSSI readings. In a recent experiment (Marótí, 2005), in which 16 nodes are deployed in a 4x4 grid over a 18x18 meter flat grassy area with no obstruction, the maximum \( q \)-range error was shown to be around 0.1 meters while the medium error was less than 0.04 meters. However, interferometric ranging is more difficult to implement due to the following reasons.
The measurement can be impacted by various sources of noise such as frequency drift, ground multipath error, and time synchronization error (Maróti, 2005). Frequencies of the transmissions need to be precisely calibrated, as any carrier frequency drift and phase noise would directly impact the observed phase offset. Precise time synchronization is needed at the senders of a q-range. Thus, there will be overhead to maintain clock synchronization.

A significantly larger number of measurements are required for localization than using direct ranging techniques. While there are also a large number of measurements available \(O(n^4)\) even for a small network, only a small subset of them are independent of each other. The rest merely provide redundant information. It has been shown in (Kusý, 2006) that the number of independent measurement using interferometric measurements is \(O(n^2)\), which is significantly higher than with RSSI and AoA ranging \(O(n)\). Considering the localization problem in relative coordinates, for a network of \(n\) nodes there are \(2n-3\) unknowns in two dimensions and \(3n-6\) unknowns in three dimensions. This is because the relative coordinates are invariant under translation, rotation, and reflection. Thus, in two dimensions, we have \(2n-3\) degrees of freedom, where translation, rotation, and reflection each reduce one degree of freedom. Thus, the smallest network that can be localized using interferometric measurements is a fully-connected network with a population of \(n=6\), where there are 9 independent measurements available to cover 9 unknowns. The large number of q-ranges available/required indicates a scalability issue for larger networks.

Since each measurement involves four nodes, more collaboration is required between nodes. Due to the requirement of synchronized transmission, the senders have to collaborate in scheduling their transmission. Also, the receivers have to collaborate to derive the relative phase offset. Such collaboration requires sophisticated protocols to be implemented in order to reduce the communication overhead.

Those difficulties rooted in the physical characteristics of interferometric ranging devices affect the algorithmic design of the localization algorithm. As we will see in the following section, the localization algorithms based on interfero-

metric ranging measurements tend to be more difficult to design.

Table 1 summarizes the five measurement types described in this section.

**LOCALIZATION ALGORITHMS**

The previous section introduced the primary types of measurement that can be used for localization. However, obtaining measurements such as distance ranging and angle of arrival is only the first step of localization. To calculate the actual node location, we will have to mathematically incorporate those measurement readings to derive localization algorithms. While there are various ways of classifying localization algorithms, we feel it is more logical to classify them according to the measurement assumptions as follows: i) connectivity-only; ii) range-based; iii) angle-based; iv) interferometric ranging based; v) hybrid, and vi) mobility-based.

**Connectivity-Based Algorithms**

A number of localization methods rely on connectivity information only. These types of methods are also referred to as “range-free” methods in the literature. For instance, the Centroid method (Bulusu, 2000) estimates the location of an unknown node as the average of its neighboring beacon locations. Clearly, in order for the location estimate to be reasonably accurate, a large number of beacons need to be heard. Thus, to provide sufficient localization coverage, the Centroid method requires more powerful beacons with a large transmission range.

The APIT (Approximated Point-In-Triangulation) method (He, 2003) estimates the node location by isolating the area using various triangles formed by beacons. For each triangle formed by three beacons, the node is either in or out of the triangle. For instance in Figure 2(a), if it can be determined the node G is inside ABC and DEF, G’s location can be isolated to the shaded overlapping area of the two triangles. To determine whether a node is inside or outside the triangle, APIT

between node \(A, B, C\) and \(D\). Noise to each q-range is modeled using a Normal distribution
compares the RSSI readings from the beacons at the node with those at its neighbors. Intuitively, smaller RSSI reading means a shorter distance (i.e., closer to the beacon) and vice versa. If there does not exist a neighbor that is further from (or closer to) all beacons simultaneously, then the node is inside triangle with high probability. For instance in Figure 2(b), a neighbor of $D$, $E$, can be measured to be further away from the beacon $A$, $B$ and $C$ because it has smaller RSSI readings comparing to $D$. Thus, $D$ is considered as to be outside $ABC$. Conversely, if $D$ is inside $ABC$ (Figure 2(c)), then it is likely that its neighbors will be closer to (or further away from) some (but not all) of the triangle points. Clearly, this test does not guarantee correctness every time. However, since there are a large number of triangles available for the test ($\mathcal{O}(n^3)$ for $n$ beacons), error can be effectively controlled. Indeed, simulations performed in (He, 2003) indicated that APIT gives more accurate localization than the Centroid method when the beacon density is higher. Note that although APIT makes use of RSSI, it is only used to derive the relative proximity, but not the absolute distance. Thus, we classify APIT as a connectivity-based algorithm.

Both the Centroid and APIT methods try to localize the node directly from the beacons 1 hop away. Thus, to provide better localization coverage, they require either a large number of beacons or an extended beacon transmission range. The DV-Hop method (Niculescu, 2001) relaxes such requirement by providing a way to localize from the beacons several hops away. In DV-Hop, each beacon floods its location to the entire network much like the distance vector (DV) routing protocol (Perkins, 1997). The algorithm contains two phases. In the first phase, a distance-per-hop estimate is obtained using DV. In the second phase, each node calculates its location estimate using the beacon locations and the distance-per-hop estimate. Each node maintains a DV table of the beacon locations it has heard along with the shortest hop count to them. A node will only forward the location broadcast if it has a shorter hop count than the current one in its table. In addition, when a beacon has heard the broadcast originated from another beacon, it can derive the distance-per-hop information based on the physical distance between the two beacons and the hop count accumulated along the path. The distance-per-hop information is then broadcast to other nodes. To localize, a node extracts the hop counts to the beacons from its DV table and converts them into distances using the average distance-per-hop information it has received. The node can then estimate its location using multilateration based on the distances to the beacons. For instance in Figure 3, the node $D$ can triangulate based on the location broadcast from the beacons $A$, $B$, and $C$ stored in its DV table. The distance-per-hop is calculated as the average of the distances per hop among all the beacons. Compared to Centroid and APIT, DV-Hop re-
requires a much lower number of beacons. It does, however, have greater communication overhead since it requires multiple message flooding.

The above connectivity-based localization methods assume the nodes are stationary. The MCL (Monte Carlo localization) method (Hu, 2004) takes a novel approach by making use of node mobility. As a node moves, it becomes connected or disconnected to other nodes. Based on the connectivity observation, a unit-disk connectivity model, and a simple random movement model of the node, MCL updates the probability distribution of the possible node location. Simulation in (Hu, 2004) has reported as many as three times of localization accuracy when compared to the Centroid method.

In general, connectivity-based localization algorithms such as Centroid, APIT and DV-Hop tend to be simple to implement, and they depend less on special hardware. However, due to the lack of more precise measurement, the location estimates they provide tend to be less accurate. A large number of beacons need to be deployed in order to improve their accuracy. However, sparse networks by nature contain less connectivity information, and, thus, they are more difficult to localize accurately using connectivity-based localization methods.

**Figure 3. DV-Hop**

$$\text{distance-per-hop} = \frac{|BC|/6 + |AB|/6 + |AC|/6}{3}$$

### RSSI and ToA Range-Based Algorithms

Many algorithms use the RSSI and ToA measurement to derive the distance to the senders. The DV-Distance method (Niculescu, 2001) behaves much like the connectivity-based DV-Hop method. But instead of incrementing the hop count, DV-Distance increments the distance between hop to hop as beacons broadcast their locations. Since the distance at each hop can be quite different, DV-Distance can obtain a more accurate range to the beacons compared to DV-Hop, which only considers the average case. However, its performance becomes dependent on the ranging measurement accuracy.

The Euclidean method (Niculescu, 2001) tries to derive the distance to a beacon that is several hops away by measuring RSSI or ToA to its neighbors. The distance is obtained by observing some simple Euclidean constraints. For instance in Figure 4, the node $D$ is several hops away from the beacon $A$. To derive its distance to $A$, $D$ obtains the distance using RSSI or ToA to two neighbors $B$ and $C$, where the distance $AB$, $AC$ and $BC$ are known. The distance $AD$ is the second diagonal of the quadrilateral $ABDC$. Depending on whether $ABDC$ is convex or concave,
two solutions of $AD$ exist. This ambiguity can be resolved by examining multiple quadrilaterals like $ABDC$. Once the distances to at least three beacons have been obtained, both DV-Distance and Euclidean method estimate the node location using multilateration.

The Collaborative Multilateration method (Savvides, 2001) is also based on multilateration from ranging. However, it allows nodes being triangulated from non-beacon nodes. Initially, all non-beacon nodes are assumed to be at some random locations. As a node receives its neighbors’ estimated locations, it tries to triangulate its new location with the least mean square error. The newly estimated location is then sent back to the neighbors for their own multilateration. The process is iterated multiple times, and the idea is that eventually the location information from the beacons will propagate to remote nodes via collaborative multilateration. However, it is foreseeable that the nodes further away from the beacons would be slow to converge. The HopTERRAIN method (Savarese, 2002) makes an improvement in this regard by using the DV-Hop method to derive an initial coarse location. It then runs the collaborative multilateration to further refine the localization results from the distance and location information from the neighbors. The n-Hop Multilateration method proposed in (Savvides, 2003) uses a bounding box model instead of DV-Hop to provide initial location estimates. For instance in Figure 5, while node $D$ is two hops away from the beacon $B$ and one hop away from the beacon $A$, it is still bounded by distance constraints. The bound on the $x$ coordinates is $[x_{D} - a, x_{D} + b + c]$, where $a = |AD|$, $b = |BC|$ and $c = |CD|$. Using this kind of geometric bounding through multiple hops, an initial location of the node can be derived.

The iterative multilateration provides a way to deal with the difficult question of how to effectively apply the beacon information several hops away. However, since it treats location estimates from non-beacons the same as beacons, the beacon information can be quickly watered down by the inaccuracy of non-beacons. The probabilistic localization method in (Huang, 2005) explicitly considers the location uncertainty of non-beacons by the means of probability distributions. In particular, each node location is not represented by a singular value, but a probability distribution in terms of particles. Initially, all non-beacons have a uniformly distributed particle distribution. To localize, nodes exchange their particle distributions among the neighbors and run Monte-Carlo filtering based on the RSSI or ToA measurement data to update the particles. Eventually, the particles will be refined to the true location of where the node resides. The particle filtering method allows collaborative localization as shown...
in Figure 6. Here, nodes 2, 3, and 4 are beacon nodes, while nodes 0 and 1 are non-beacons. Of the beacons, node 0 can receive signals only from nodes 1 and 4, and node 1 can receive signals from only nodes 0, 2, and 3. From the signal strength readings, non-beacons estimate their distances to their neighbors. The probability distribution of the estimated location is represented by the particles (dots) in the graph. In sub-figure (a), where node 1 is removed, node 0 can only receive signals from node 4; thus, as the particle distribution indicates, the probability distribution where node 0 is most likely located concentrates on a circle around node 4. In sub-figure (b), where node 0 is removed, node 1 can receive signals from nodes 2 and 3; thus the most likely locations for node 1 center around two areas where “transmission circles” around node 2 and 3 intersect. Intuitively, in order to localize itself, a node needs to receive location information from a minimum of three beacons either directly or indirectly. In both case (a) and case (b), the exact location of the nodes 0 and 1 cannot be deduced because they do not receive location information from all three beacons. In (c) and (d), where all nodes are available, nodes 0 and 1 are able to communicate to each other and exchange their particle distributions. Thus, their probability densities will represent their actual locations much closer even though neither node receives location information from all three beacons directly.

This section introduced range-based localization methods. Compared to range-free methods, range-based methods give more accurate location estimates when ranging data is reliable. However, depending on the deployment environment, ranging techniques based on RSSI tend to be error-prone and strong filtering is required. The ranging error could ultimately throw off the localization accuracy if it is allowed to propagate through the network unbounded. Furthermore, different methods generally exploit the trade-off between the estimation accuracy and the estimation coverage. For instance, given the same network scenario, the Euclidean method is capable of generating more accurate location estimates of a smaller subset of nodes, whereas the DV-Hop method has better coverage but worse accuracy. Regardless of the tradeoff, a common characteristic shared by many range-based localization algorithms is that they require a relatively high network density in order to achieve better results. Based on the extensive simulation of DV-Distance, Euclidean and multilateration methods performed in (Chintalapudi, 2004), it can be concluded that those range-based localization algorithms “require an average degree...
of 11-12 nodes within the ranging neighborhood in order to achieve 90% localization coverage with 5% accuracy (Chintalapudi, 2004).”

** AoA-Based Algorithms **

Even though the future of AoA sensing devices is still unclear, some works have been published on localization using angle information. Simulation studies in (Chintalapudi, 2004) also show that when AoA of the signals is used in addition to the distance measurement, the localization accuracy and coverage can be drastically improved. This should not come as a surprising conclusion, as nodes need to communicate with only one neighbor to perform localization if they can obtain
both AoA and distance measurements. The work in (Chintalapudi, 2004) also presents three variations of a weighted mean square error algorithm that localizes the nodes, each of which is designed to work with one of the three measurement types: i) distance-only measure; ii) distance plus a more accurate AoA measure (up to of precision); and iii) distance plus a less accurate AoA measure (up to of precision). The less accurate AoA measurement method is sometimes referred to as *sectoring*. Simulations in (Chintalapudi, 2004) show that the localization accuracy and coverage can be greatly improved even with such coarse sectoring measurement as well.

In order to localize with only AoA measurement, the AoA triangulation method proposed in (Niculescu, 2003) can be used. The triangulation takes several AoA measurements from beacons and estimates the node location with least square error. To propagate the AoA measurement for more than one hop, the AoA triangulation method uses a method called *orientation forwarding* that is similar to the Euclidean method for distance ranging. For instance in Figure 7, let AoA measurement be the bearing against South. For node $D$ to derive its bearing to the beacon $A$ (i.e., $D$), it can contact two neighbors, $B$ and $C$, with known AoA measurements from the beacon $A$ (i.e., $B$ and $C$ are known). Furthermore, $B$, $C$, and $D$ can measure the AoA of each other to give the readings of $B$, $C$, $D$ and $D$. From there, all angles in $\Delta ABC$ and $\Delta BCD$ can be determined. The bearing from $A$ to $D$ can be derived as $DD$, where $D$ is known, and $\angle CDA$ can be determined from $\Delta ABC$ and $\Delta BCD$. Using the orientation forwarding method, the bearing to beacons can be propagated through multilops, which can then be used to triangulate from remote beacons. However, much like the case of distance propagation, measurement error becomes aggregated at each hop. Simulations in (Niculescu, 2003) have reported a near linear error increase to the hop count.

In summary, due to the limited availability of AoA sensing devices, relatively few algorithms have been proposed for AoA. However, it is conceivable that some localization algorithms originally proposed for RSSI or ToA ranging can be adapted to AoA. For instance, the probabilistic algorithm in (Huang, 2005) can be updated to accept AoA measurements by simply providing an alternative measurement model for AoA during particle filtering.

**INTERFEROMETRIC-RANGING BASED ALGORITHMS**

Due to the fact that interferometric sensing devices for localization are relatively new, there have been only a limited number of localization

---

*Figure 7. Multihop Distance Derivation in AoA Triangulation*
algorithms proposed for this type of measurement. When compared to RSSI/ToA ranging and AoA, all of which involve two nodes for each measurement, interferometric ranging involves four nodes for each measurement and, thus, makes it more difficult to propagate location information through multihops. To eliminate the multihop propagation issue, a simple genetic optimization approach was taken in (Maróti, 2005), which propagates all interferometric readings within the network to a centralized location and runs a genetic algorithm to find the node locations that match the readings. Such an approach is of more theoretical (and prototyping) interest than practical use, since any centralized method is not scalable to large networks. A Pair-wise Distance method was proposed in (Patwari, 2006) that uses both interferometric and RSSI ranging. The method uses the interferometric ranging to derive pair-wise distances among the nodes. The node locations can then be optimized using the least square error method from the pair-wise distances. The algorithm then repetitively applies the RSSI ranging measurements to fine-tune the location estimates. Compared to the genetic algorithm, the Pair-wise Distance method is able to converge much faster. However, it is currently still a centralized algorithm, which presents the same scalability issue as the genetic algorithm.

Both of the above algorithms try to optimize for a global solution given an entire set of interferometric measurements. Intuitively, finding a global solution to the localization problem is often difficult because of the large search space and the large number of constraints given by the interferometric measurements. Thus, it is desirable to find solutions in some subspaces first and then incrementally build up to the global solution. For instance, an iterative approach has been proposed in (Huang, 2007) that localizes from a small set of seeding beacons. At each round, a set of nodes that can hear from the seeding beacons are localized. As additional nodes are localized at each round, they act as pseudo-beacons that allow other nodes to be localized at subsequent rounds. The iterative method is fully distributed. However, error propagation can be an issue since any localization error at pseudo-beacons would adversely affect the localization result at subsequent rounds. Simulation results in (Huang, 2007) have shown a linear increase of localization error at each round.

**Hybrid Algorithms**

A combination of the above techniques can be employed to form hybrid localization methods. For instance, a hybrid method is proposed in (Ahmed, 2005) that uses both DV-Distance (Niculescu, 2001) and Multi-Dimensional Scaling (MDS) (Shang, 2003). The algorithm contains three phases. In the first phase, a small subset of nodes is selected as reference nodes. In the subsequent phase, the reference nodes are then localized in relative coordinates using MDS. The final phase uses DV-Distance to localize the rest of the nodes in absolute coordinates. The rational behind such hybrid algorithms is to exploit the tradeoff between different localization algorithms. For example, MDS gives good localization accuracy, but as the network size is increased, MDS can be costly. Meanwhile, DV-Distance is less costly, but it only works well when beacon ratio is high. With the hybrid algorithm, the cost is minimized by only running MDS on the reference nodes, and then the reference nodes are used as beacons for DV-Distance.

**Localization Using Mobility**

While most previous methods assume stationary beacon locations, an alternative method is to localize devices using a mobile beacon. In this method, a mobile beacon travels through the deployment area while broadcasting its location along the way. Devices localize themselves by monitoring information coming from the beacon. A straightforward technique using the above method is de-
Device Localization in Ubiquitous Computing Environments

scribed in (Ssu, 2005), where devices are required to receive at least three communications with the same RSSI reading from the beacon. Given that the same RSSI reading implies similar distances to the beacon locations, the physical device location can be derived using simple geometric functions. This method is computationally simple, making it suitable for resource-limited sensors. However, it requires the beacon to directly pass by the ranging area of the device. In addition, in most cases, the beacon has to pass by the device twice because the sampling positions of the beacon when the three RSSI readings are taken should not be on the same line. This method also assumes that errors are insignificant in the RSSI to distance translation.

Instead of computing the location directly, a probabilistic approach may be taken; here device location is viewed as a probability distribution over the deployment area. In (Sichitiu, 2004), devices measure a series of RSSI readings from the mobile beacons and localize themselves by a sequential update process to the probability distributions of their locations. Each device starts with a uniform distribution covering the entire deployment area. As the beacon passes through, the distribution is updated to fit the received RSSI readings (using a signal propagation model). The method is further improved in (Peng, 2005) by adding the negative information (i.e., the information that the beacon is out of range), as well as RSSI readings from the neighbors. These probabilistic methods provide with much improved location estimates, but have the drawback of being complex. For a deployment grid of \( n \) by \( n \) units, the time and space complexity is \( O(n^2) \). As the devices such as sensors at present time have very limited resources, it is difficult to directly implement these methods for large sensor deployment scenarios. Indeed, the experimental results shown in (Sichitiu, 2004) are performed on pocket PCs, which are much more powerful than cheap devices like sensors.

A similar method of localizing the networks using a mobile beacon is presented in (Galstyan, 2004). Instead of the actual probability distribution, the possible device locations are represented with a bounding box. As the beacon passes by, the area contained by the bounding box is progressively reduced as positive and negative information is processed. The bounding box method drastically simplifies the probability computation, making it possible to implement this method on sensor devices. However, such large simplification has its side-effects in that it sacrifices the preciseness of the distribution for its simplicity as the box cannot precisely describe multiple possible locations. There is also the problem of noise from ranging devices. This method may work well when ranging error is minimal; however, when noise is present (which is inevitable when using RSSI ranging), there might be situations where no bounding box exists to satisfy all readings.

Table 2 lists all the localization algorithms described in this section. In summary, different measurement types and their unique properties to a large degree dictate the design of localization algorithms. For instance, connectivity-based measurements can only provide coarse localization without a higher beacon ratio or nodal degrees. Range and AoA-based measurements can provide much finer localization results, but they are more prone to measurement error. A quantitative comparison between the more well-known algorithms such as DV-Hop, Euclidean and multilateration can be obtained from (Langendoen, 2003), in which the comparison is done in the context of specific constraints of sensor networks, such as error tolerance and energy efficiency. Their results indicate that there is no single algorithm that performs “best” and that there is room for further improvement.

THEORETICAL RESULTS

While there have been many localization algorithms proposed for various scenarios, only recently have researchers started to address the

Theoretical aspects of the localization problem. In this section, we briefly cover the latest theoretical results with regard to the localization problem. Since ubiquitous computing environment is often modeled as a graph, it is not surprising that much of the theoretical work is based on graph theory. With regard to localization, we are particularly interested in the following three theoretic problems: i) localizability; ii) complexity of localization; and iii) localization error bounds.

First of all, we would like to know that given a network scenario (i.e., the nodes and their relative measurements such as ranging and angling) whether it is theoretically possible to uniquely localize the network. Such knowledge of localizability is important to us because if we can easily identify the scenario that is impossible to localize uniquely, then it would be pointless to run any localization algorithm on it. Instead, we would have to request additional nodes or measurement data to be available (by possibly deploying more nodes or beacons) so that the localizability requirement is satisfied. The following theorem gives the necessary and sufficient condition for distance-constrained network localizability in two dimensions.

**Theorem 4.1** The network is localizable in two dimensions if and only if the network graph is redundantly rigid and triconnected (Hendrickson, 1992; Berg, 2003).

The above theorem makes use of some graph theory concepts. In graph theory, rigidity (or first-order rigidity) in general refers to the situation in a graph where there are no continuous motions of the vertices satisfying distance constraints on edges. A graph is redundantly rigid (or second-order rigid) if the induced graph remains rigid after removing any single edge.

Theorem 4.1 holds for two dimensions only. The sufficient condition for higher dimension is currently unknown. To test the localizability, there exists a polynomial time algorithm (O(n²) where n is the number of nodes) that tests for the first-order rigidity; see (Hendrickson, 2002) for one implementation. However, it is a known NP-Complete problem to test for the second-order rigidity of a graph (Saxe, 1979). A related but even more difficult problem is node localizability, which asks if a particular node (instead of the entire network) is localizable. No sufficient condition of node localizability is currently known even in the two dimensional case and, thus, no deterministic algorithm currently exists.

A second problem asks for the theoretic complexity of localization itself. In particular, we would like to know that given a network scenario that satisfies localizability whether there exists a deterministic polynomial time algorithm that would localize the network. This problem deals with the NP-Completeness of localization. Unfortunately, the hardness of graph realization
has been shown as NP-Complete under the measurement of distance (Eren, 2004), angle (Bruck, 2005), connectivity (Breu, 1998; Kuhn, 2004), and interferometric ranging (Huang, 2007).

The above theoretical results indicate the general intractability of the localization problem even in the ideal case where measurements (such as edge distances) are 100% accurate. Unfortunately, measurements in the real world are a far-cry from being accurate, and any optimization method has to deal with not only different measurement types, but also noise. The localization inaccuracy attributed to the measurement types and noise can be statistically qualified using Cramer-Rao Bounds (CRB) (Patwari, 2005). The CRB is a lower bound on the covariance of any unbiased location estimator that uses measurements such as RSSI, ToA, or AoA. Thus, the CRB indicates a lower bound of the estimation accuracy of a given network scenario regardless of the localization algorithm. In other words, with CRB we have a way to tell the best any localization algorithm can do given a particular network, measurement type, and measurement noise scenario. CRB formulas of individual measurement types such as RSSI, ToA, and AoA under most common noise models (mostly Gaussian) are currently known.

The CRB of the localization error for a sample network is shown in Figure 8 as rings of radius being the standard deviation of the minimum localization error that can be possibly attained at the node. Here, the nodes represented by squares are beacons while circles represent nodes to be localized using RSSI ranging. The edges indicate the communication links available to measure RSSI readings. We assume the measurement model to be RSSI with the path loss exponent $p$ and the standard deviation of the noise $dB$. A ring with smaller radius (i.e., a smaller CRB) signals that more accurate localization result can be theoretically obtained. Conversely, a larger ring indicates a larger localization variance and, thus, a less accurate result. In the figure, two types of nodes do not have rings. First, all beacons have a CRB of 0. There are also regular nodes that have infinite CRB indicating that those nodes are theoretically impossible to localize. The latter case can be seen at nodes 38, 48, 49, and 78 in the top left corner. At a minimum, three beacons are needed to localize a connected network. However, those nodes in the top left corner are isolated to a different partition. Since they are connected to only one beacon (node 91), those nodes clearly cannot be localized. Other than those cases, the CRB rings at the main network partition clearly show the level of localization difficulty under various scenarios. In general, we observe that nodes closer to the beacons tend to have a smaller CRB than the ones that are several hops away. Even smaller CRB can be obtained when a node is closer to more than one beacon. All of the above observations are consistent with our common intuition about localization difficulty.

It is important to note that CRB is essentially a theoretic bound that depends on the measurement model. In the real world, its usefulness is limited by how accurate the measurement model reflects the reality. Nevertheless, CRB can be a useful tool in comparing various localization algorithms. It can be used to validate how close a particular algorithm can come to this theoretic lower bound and to see if there is any room for improvement in the algorithm design.

**CONCLUSION**

In this chapter, we studied the localization problem in ubiquitous computing environments. Localization in general refers to the problem of identifying the physical location of devices using a limited amount of available measurement data. The most common measurement types include device connectivity (i.e., whether two devices are neighbors), ranging using RSSI and ToA, angle of arrival (AoA), and interferometric ranging. Given a small number of nodes with accurate geometric location (e.g., using GPS receivers), localization
algorithms try to derive the location of those devices that are not “GPS-enabled.” The motivation of localization can be justified by the large number of algorithms proposed for ubiquitous computing that rely on (semi-)accurate location information and the fact that current technology prevents GPS from being installed on all network devices due to power constraints and form factors. It has been shown that localization in general, regardless of the measurement types used, is an NP-Hard problem. Thus, current effort in solving it relies on some sort of stochastic optimization. Meanwhile, as with other network-related problems in ubiquitous computing environments, the ideal solution calls for a distributed but efficient implementation, which leads to additional challenges.

Like other aspects of ubiquitous computing, the localization problem is relatively new. The problem is also conceptually straightforward to characterize, and many results from other disciplines such as graph theory, optimization theory, online algorithms can be readily applied to this problem. Thus, researchers from other disciplines can provide valuable insight that could lead to better solutions to the problem. It is our hope that this brief introduction will provide the readers motivation and inspiration to perform research in this exciting field.

Figure 8. The CRB of the sample network is depicted as rings of the radius i. There are two exceptions: 1) beacons, depicted as squares, have 0 CRB, and 2) some regular nodes have infinite CRB (such as node 38, 48, 49 and 78 at the top left corner) indicating that they cannot be localized.
Device Localization in Ubiquitous Computing Environments

FUTURE DIRECTIONS

Device localization within ubiquitous computing environment has been an active research field in the past several years. Much work has been done in the area of hardware/sensor design (in particular, reducing the form factor and power consumption of sensory devices), algorithmic design and theoretical analysis. However, like many areas of ubiquitous computing, localization is still a relatively new front with much of the work yet to be done. In this section, we will briefly discuss a few directions which we feel could produce fruitful results in the near future. We hope our discussion will encourage the readers to actively participate and contribute their own ideas to this exciting and important field.

Implementation and Testing Environment

When reviewing the previous works on localization, one cannot help but notice a disturbing trend; a majority of works on localization have been based on either theoretical models or numerical simulations, while works based on the result of actual hardware implementation have been relatively few. It is not difficult to project that the primary reason for such trends is the hardware cost. To perform meaningful experiments for localization, especially for those collaborative localization methods such as DV-Distance and Euclidean, one would normally need a large number (100+) of devices. Although simple mobile ad hoc network devices (e.g., sensor motes) are becoming cheaper by the day, it is still quite costly to implement algorithms on physical devices on such a large scale. In addition, the sensing capacities of the current devices are usually limited to RSSI. Currently, there is no cheap hardware that implements AoA, ToA, or interferometric ranging and, thus, most works using these measurement types are all based on simulations. In a sense, the advances in algorithmic work on the localization problem are currently outpacing the advances in hardware. Future work needs to be done to significantly improve the hardware design to fill this gap.

Another issue related to the testing environment is that there is no common localization test bed. While large scale network simulators such as NS2 have modules for simulating mobile ad hoc networks, these modules do not contain localization. Smaller simulators for sensor networks such as SENSE (Chen, 2004) usually lack features on localization as well. Another simulator SENS (Sundresh, 2004) does explicitly implement localization, but it uses a rather primitive Centroid method and lacks more sophisticated methods. Since NS2 is the most widely-used network simulator, it would be very helpful for researchers to implement an interface to NS2 that allows a “plug-in” for future localization algorithms. This would give a common test bed for different localization schemes. More importantly, it would also allow those location-depended algorithms (such as location-aided routing methods) to be implemented and compared based on the result of localization. The localization module should also implement the Cramer Rao Bounds (CRB) so that the theoretic error bound can be calculated for different localization scenarios.

Interferometric Ranging

Since interferometric ranging is a relatively new type of measurement available to the localization problem, there are still many open problems in this area. Of the localization algorithms proposed for interferometric ranging, all but the iterative algorithm proposed in (Huang, 2007) is centralized. There is a definite need to design distributed localization algorithms for interferometric ranging so that it can be implemented with reasonable efficiency and scalability. To reduce the number of beacons, the distributed algorithms should make use of multi-hop location information, which unfortunately is much more difficult for interferometric ranging because each measure-
Device Localization in Ubiquitous Computing Environments

The localization process involves four nodes. For instance, there is a scheduling issue, both at a high level and low level, of when a device should be scheduled to send or receive interferometric readings. At a high level, since not all q-ranges are independent, it is more desirable to schedule the senders and receivers in order to generate more independent q-ranges. At the low level, after the senders and receivers are selected, they have to be scheduled to coordinate the signal transmission because the transmission needs to be synchronized. The design of the scheduling algorithm can have a substantial impact on the overall performance of the localization algorithm in terms of the localization accuracy and communication overhead.

Furthermore, a simulation study in (Huang, 2007) has shown that the multi-hop error propagation has a big impact on interferometric ranging, which increases almost linearly as the localization results are propagated at each hop. Therefore, the control of the error propagation is another research issue. There is also a need for an algorithmic independent theoretic error bound (like CRB) for interferometric ranging. The bound would be more difficult to derive than those for distance ranging and angling because more than two nodes are involved in each measurement. Thus, the inter-dependence between the error and the relative locations of senders and receivers becomes more challenging to characterize mathematically. However, the payoff of obtaining such bound is that it would allow us to ultimately compare interferometric ranging with other measurement types and identify the scenarios that are preferable for each measurement type.

Collaborative Localization of Multiple Measurement Types

Previous localization algorithms often assume that the entire network has to be localized using the same type of measurement (such as connectivity-only, RSSI, ToA, AoA, or interferometric ranging). However, to be true to the spirit of ubiquitous computing, it is foreseeable that future networks will consist of devices of vastly different capacities in terms of i) different transmission coverage, ii) power requirement, and iii) measurement sensors. Thus, during localization it is often desirable to explicitly consider various devices capacities in such heterogeneous networks. For instance, in terms of power requirements, the localization algorithm should exploit the devices with more power capacity and try to minimize the calculation performed on less powerful devices. Furthermore, different measurement types have different error characteristics. It would be interesting to investigate how to collaborate multiple measurement types during localization, and in particular how the collaboration would impact the localization error. Intuitively, incorporating multiple measurement types in the same localization scenario should improve performance since such collaboration can potentially cover the drawbacks of individual measurement types for each other. Unfortunately, such collaboration could mean an increased complexity of the localization algorithms since heterogeneous networks would invalidate some assumptions often made by simple localization algorithms (such as uniform transmission range). While it is worthwhile to consider collaborative localization algorithms, it is equally imperative to keep the localization overhead under control.

Chapter 3.12
Socio-Cultural Interpretations to the Diffusion and Use of Broadband Services in a Korean Digital Society

Dal Yong Jin
Simon Fraser University, Canada

ABSTRACT
This chapter attempts to ascertain the causes of the rapid growth of broadband services in the context of the broader socio-cultural elements. It recognizes technology as a socio-cultural product which has historically been constituted by certain forms of knowledge and social practice, so this chapter explores cultural elements contributing to the diffusion of broadband services in the context of the cultural environment in Korea. Further, this chapter discusses the significant role of the people, as users, in the process of the rapid diffusion and growth of broadband services. In particular, it emphasizes the way in which the 1997 economic crisis, as one of the most significant socio-cultural turning points in modern Korean history, has influenced the deployment of broadband services as high-speed Internet connections have developed since 1997.

INTRODUCTION
The widespread availability of broadband services (high-speed Internet) throughout the world significantly influences people in their life. Broadband services have made it easier to download digital music and movies, and the wide penetration of broadband services has enabled customers to engage in online stock transactions and online games. Many schools, from elementary to universities, in various countries are also connected to broadband services and utilize information technology (IT) for education, while Internet broadcasters have rapidly become popular.

A wide range of developed countries, such as the United States and the United Kingdom to developing countries in the Third World, have initiated modern telecommunications networks that support broadband access, providing high-speed access and always-on connections to both homes
and offices, to develop the social and technical landscape of cyberspace (Han, 2003; Ishii, 2003; Lee & Lee, 2003; Jin, 2007). Korea is among the leading performers in broadband (Lee, Oh, & Shim, 2005). As of January 2006, about 77% of Korean households were connected to broadband services, which is one of the highest throughout the world (MIC, 2006).

Consequently, Korea has become the world’s best laboratory for broadband services—and a place to look to for answers on how the Internet business may evolve (Taylor, 2006). Much scholarly analysis and discourse (Yun, Lee, & Lim, 2002; Lee, O’Keefe, & Yun, 2003; Reynolds & Sacks, 2003; Choudrie & Lee, 2004; Lau, Kim, & Atkin, 2005; Lee et al., 2005; Jin, 2005) has focused on the roles of the government and competition among telecommunications companies in developing broadband services in Korea. They emphasize several factors contributing to the rapid growth of broadband services caused by the deregulation and competition policies in the telecommunications sector, such as a variety of promotion policies to boost Internet use and the strategies of broadband Internet providers. Previous studies, however, have not paid much attention to socio-cultural factors, which would be one of the most important contributing factors given that people are the major users of broadband services. Although a few papers examine cultural factors that contribute to broadband services, their discussions are neither comprehensive, nor informative.1

Unlike these preceding studies, this chapter attempts to ascertain the causes of the rapid growth of broadband services in the context of the broader socio-cultural elements. It recognizes technology as a socio-cultural product which has historically been constituted by certain forms of knowledge and social practice, so this chapter explores cultural elements contributing to the diffusion of broadband services in the context of the cultural environment in Korea. Further, it discusses the significant role of the people, as users, in the process of the rapid diffusion and growth of broadband services. In particular, it emphasizes the way in which the 1997 economic crisis, as one of the most significant socio-cultural turning points in modern Korean history, has influenced the deployment of broadband services, as high-speed Internet connections have developed since 1997.

**TECHNOLOGY AS CULTURAL FORMS**

It is generally recognized that technologies are primarily neutral because they operate essentially under the same norm of efficiency in all situations. Many users of technology argue that technology is essentially amoral and an entity devoid of values (Rescher, 1969; Mesthene, 1970). This instrumental theory, the dominant view of modern governments and the policy sciences on which they depend, argues that “if people use technology for destruction or pollution, as in the case of nuclear weapons and chemical pollution, it should not be blamed on technology, but on its misuse by politicians, the military, big business and others” (Pacey, 1983, p. 2).

For many scholars, however, technology is not simply a means to an end, but has become an environment and a way of life; this is its substantive impact (Borgmann, 1984). This substantive theory of technology holds that technology is not neutral, but has a substantive value bias. Substantive theory, best known through the writings of Jacques Ellul, Arnold Pacey, and Martin Heidegger, claims that technology constitutes a new type of cultural system that restructures the entire social world as an object of control. Substantive theory explicates cultural aspects of technology, such as values, ideas, and the creative activity of technology (Feenberg, 1991). This type of cultural system is characterized by an expansive dynamic which ultimately mediates every pre-technological enclave and shapes the whole of social life.
Among these, Ellul (1964) pointed out that we have to examine technology through its sociological aspects: “We should consider the effect of technique on social relationships, political structures, and economic phenomena.” Technology is not aloof from the social realm; on the contrary, it is an integral part of the social (Webster, 2002). Pacey (1983, pp. 4-6) also discussed how those who write about the social relations and social control of technology should be made aware of the cultural aspects as well as the organizational and technological aspects.

In agreement with Pacey, Christians (1989, pp. 124-125) observes: “Technology is the distinct cultural activity in which human beings form and transform natural reality for practical ends with the aid of tools and procedures.” He clearly argues that cultures are humans’ distinctive and immediate environment built from the material order by men and women’s creative effort. Furthermore, Williams (1992, pp. 127-129) stated: “How technology develops is not only a matter of some autonomous process directed by remote engineers, but is a matter of social and cultural processes.” Technologies are developed and used within a particular social, as well as economic and political context (Franklin, 1999). As these theoreticians emphasized, technology does not develop independently, but is part of a particular social-economic and cultural process. This chapter aims to contribute to this ongoing debate of substantive theoretical discourse with a case study of the rapidly growing broadband services in Korea.

**Historical Background Information on the Growth in Broadband Services**

The rapid deployment of broadband services in Korea began in 1995 when the government enacted the Framework Act on Information, which established the first Master Plan, which set up a comprehensive strategy for the Korean Information Infrastructure (KII) (MIC, 2004). The goal of the KII was to construct an advanced nationwide information infrastructure consisting of communications networks, Internet services, application software, computers, and information products and services (Jin, 2007). The KII project aimed at building high-speed networks by providing over 80% of households with more than 20Mbps (megabits per second) broadband access by 2005 through market competition and private sector investment (Lee et al., 2003).

In the post-1997 economic crisis, efforts bringing about the development of broadband services have accelerated. The economic crisis severely affected the Korean economy due to unprecedented rates of unemployment, corporate bankruptcies, and the demise of the stock market. Korea’s economic condition demanded that Korea change its industrial structure from traditional heavy and chemical industries to a more IT-oriented structure—telecommunications and computers. More importantly, Korea identified information technology as its path to economic recovery, following the 1997 financial crisis (Kim, 2006a). The Korean government has exerted great effort on deploying a high-capacity backbone and pursued a policy of high-speed telecom infrastructure as a foundation for the benefits of IT changes for sustainable economic growth (Lee et al., 2003).

Under these circumstances, both government planning and stable funding had played significant roles in the rollout of broadband services. The Korean government invested a total of $11 billion into broadband services between 1998 and 2002, while the U.S. government planned to invest only $2 billion in the form of tax breaks as of May 2003 (Belson & Richtel, 2003, p. C1). The Korean government has also initiated a variety of promotion policies expediting the growth of broadband services, such as creating Internet-Friendly Classrooms and Ten Million People Internet Education. Clearly, Korea’s rapid and expansive broadband growth can be traced, in large measure, to government initiatives (Lau et al., 2005, p. 351).
Competition among telecom companies was also dedicated to the deployment of broadband access throughout Korea. Broadband services in Korea were first introduced in 1998, and a few telecom companies, including Korea Telecom (KT), the largest telecom company in Korea, Thrunet, and Hanaro, had severely competed with each other in the market. In May 1999, Thrunet, the introducer of broadband services in Korea, held 63% of the market share, followed by Hanaro (35%) and KT (2%). The market has undergone substantive change in recent years. For example, Hanaro Telecom, controlled by U.S. investors American International Group Inc. and Newbridge, absorbed Thrunet to be in a better economic position to compete with the dominant market player KT in late 2005. LG Powercomm, a subsidy company of the LG group, entered the market in September 2005, and cable system operators have expanded their share in the high-speed Internet market (Kim, 2006b). As a result, as of April 2006, KT as the largest player consisted of 49.9% of the market share, followed by Hanaro (28.5%), cable system operators (10.6%), Powercomm (4.4%), and others (Park, 2006, p. 16).

The intense competition among telecom companies led to price (monthly fee) reductions and subsequently a rapid increase in demand for broadband Internet services. In other words, competition among telecom companies for increasing their respective market share has resulted in a drop in the price of broadband subscriptions, and it has certainly contributed to the rapid spread of broadband in Korea. Fierce competition resulted in prices decreasing from $40 per month in April 1999 to $30 in February 2003, and again to less than $20 in May 2006 (ITU, 2003a; Taylor, 2006).

Meanwhile, as a new market trend, Korea has been developing the next generation in high-speed Internet services. The country acknowledges the existence of market saturation, so it has enhanced the capacity of existing broadband services, including its speed and convergence with various types of media. Korea has begun to upgrade its high-speed Internet from less than 5 Mbps to 100 Mbps since 2005 in order to enjoy high-quality Internet telephone service, movies, and online education (Bang, 2005). Further, Korea expects the rapid penetration of 100 Mbps broadband services will expedite the growth of image-related contents, and thereafter the second wave of high-speed Internet services in 10 years. As such, the Korean government along with telecom companies played a pivotal role in the growth of broadband services by providing infrastructure and government initiatives.

**Cultural Characteristics Contributing to the Deployment of Broadband Services**

Although the Korean government and telecom firms have collaboratively initiated and expedited the deployment of high-speed Internet services, the swift growth of broadband services would have been impossible without people readily accepting new technology more than other nations. The diffusion of services and the widespread use of high-speed Internet can be attributable to certain distinct characteristics of the Korean people, since the diffusion of broadband services took place with rapid acceptance by most Koreans (Jin, 2007). Regardless of the fact that many countries around the world have initiated and supported the growth of broadband services, the result varies markedly due to the acceptance of new technology by people, the users, as well as government initiatives.

Therefore, it is crucial to explore the significance of assessing the culture in which technology is created and the context in which it is widely accepted. As ITU acknowledges (2003b), Internet user demand indeed contributed most decisively to the rapid explosion of broadband in many places, particularly in Korea. Again Ellul (1964) emphasized that “the development of technology is not an isolated fact in society but is related to every factor in the life of modern humanity.” In particu-
lar, cultural forms rooted in Korean history after
the 1997 economic crisis should be emphasized
as significant elements which prompted the rapid
deployment of broadband, because members of
the public are the major customers of broadband
services. There are several significant cultural
characteristics (i.e., the mentality of the people)
rooted in Korean society and its historical context
that are important contributing factors to the de-
velopment of broadband, such as rapid acceptance
of new services and technologies, enthusiasm for
'edutainment,' keeping up with their neighbors
(“me-too” culture), as well as developing dual
personalities of two competing forces, social
solidarity and individualism.

The primary characteristic among most Kore-
ans is demanding quick change, which eventually
expedited the growth in high-speed Internet. Only
a few decades ago Koreans were characterized
as calm and patient, as one distinguished Con-
fucian characteristic, but in just a few years, the
demand for quick change became one of the most
distinctive Korean characteristics (Han, 2003, p.
19). Since the 1960s when the country began its
high-speed transition from an impoverished state
to one of Asia’s major economies, Koreans cannot
wait for long periods of time, nor are they very
patient. Koreans have not been known for taking
things slowly. Instead, Korean society is well
known for its impulsiveness—that is, desiring
quick communication, quick contact, and quick
results (Jin, 2007). Most Koreans would certainly
agree that Korea is nothing if not dynamic. In this
regard, Jong Suk Lee (2000), director of the Korea
Culture and Policy Institute, states: “Nine out of
ten Koreans rush into the road as soon as the light
changes to green and they cross the street on or
even before the green light is about to turn red. In
contrast, Chinese would usually wait until all the
traffic is cleared and safe even at the clear green
light. And if the light is about to turn red, they
just stop and wait for the next green light.”

Indeed, “balli, balli”—Korean for “hurry,
hurry”—is heard incessantly on the crowded
streets of Seoul, reflecting the frenetic pace of
Korean life in a global era (Jin, 2007).

Another survey conducted in the 1980s is still
compelling to explain the same trend. Accord-
ing to the survey (Chinese Cultural Connection,
1987), regarding Confucian dynamism which
measures long-term vs. short-term orientation,
Japan showed one of the highest scores, compared
to the U.S., the UK, and Australia. The high Japa-
nese score in the survey reflected the patience or
long-term orientation of Japan compared with
other developing countries (McFadyen, Hoskins,
& Finn, 1998). However, Korea has lost patience
and has become addicted to short-term results,
and this changing Confucian dynamism in Korea
has contributed to the rapid penetration of high-
speed Internet.

This relentless drive, which has led Korea to
chalk up a number of significant achievements,
has driven the rapid spread of broadband Internet
connections. Most Koreans have hurried to have
broadband Internet connections, and it has been
easier to develop these services compared to other
countries, including Japan. What most Koreans
wanted was the same thing: quick communication,
quick games, and quick contact. Everything needs
to go “balli, balli,” and this unique characteristic
of Koreans has expedited the rapid penetration of
high-speed Internet (Shim, 2006). In other words,
for most Koreans, everything needs to be done
right now. For example, in Korea, instant mes-
sage-swapping is comparatively popular mainly
because not answering a message from a friend
with all due speed is considered a faux-pas in
Korean society (Taylor, 2006).

This quick pace has particularly accelerated
with the 1997 economic crisis because Koreans
began to realize that quick change and adoption
of new technology and information was needed
to survive in the globalization era. Korea is full
of ‘early adopters’ who are willing to buy newly
released digital devices for consumer testing. In
a survey by Korean ad agencies in 2004, 43% of
respondents said that they consider themselves
‘early adopters’ in the market (Kwon, 2006). According to a survey by the U.S. market research firm Parks Association in November 2005, Korea ranked second on the list of 13 countries in the adoption of consumer technologies (Parks Associates, 2005). Although balli balli culture has several negative aspects, such as bribery scandals and the collapse of buildings and bridges, in the midst of achieving social and economic successes in the Korean society, rapid adaptability to change is the key to the swift deployment of broadband services.

An excessive enthusiasm for edutainment—the combination of education and entertainment—has also greatly contributed to the unique growth in broadband services. Above all, Korea is one of the most developed countries in terms of education. Its overall school enrollment rate (primary, secondary, and tertiary) of 90% is the highest throughout the world. Korea’s high rate of literacy and school enrollment are essential as prerequisites for the widespread adoption of ICTs, and these factors have helped contribute to the growing impact of ICT in Korean society (ITU, 2003a). Over-enthusiasm for education in Korea is not new, but after the 1997 economic crisis, parents started to realize the potential threats and opportunities of globalization. It became a must for their children to acquire both English and Internet skills in order to survive in the era of globalization (Aizu, 2002). Many parents who have children younger than early teens, for example, have focused on cyber-based English education since the late 1990s. They have acknowledged that their children are able to enjoy online reading, music, game, and animation written in English through the Internet due to high speed and their being 24/7 support services, which is a good alternative to learning English in a classroom. In the Korean context, excessive need for education has also developed so-called edutainment, as a form of studying English while enjoying playing in cyberspace (An, 2001).

Edutainment is not only for children. Many mid-careers have also turned their eyes on the Internet in the midst of a changing working environment. In Korea, the majority of companies have begun to adopt a Western-style five-day workweek system since the late 1990s and early 21st century. The spreading five-day workweek system since then has boosted information technology, such as DVDs, mobile games, and edutainment. With more spare time available, people began to look for a new type of education containing more entertainment factors, instead of the existing cramming type of learning (Cho, 2002). Therefore, having high-speed access to the Internet at home became an advantage for everyone from children to housewives to career persons, or a disadvantage if they did not have it (Jin, 2007). Broadband is an indispensable component for edutainment, which is one of the major contributing factors in broadband services.

Meanwhile, the peculiar Korean “me-too culture,” which means all companies and people end up with the same systems and taste, has substantially contributed to the spread of broadband access. Consumers in various societies are susceptible to social pressure to keep up with their neighbors, (e.g., “keeping with the Jones’s” in the
U.S.); however, Koreans’ eagerness to keep up with their friends and neighbors is comparatively very high (Jin, 2007). As discussed, Koreans tend to be early adopters of technology; however more they significantly are fast followers, as Stephen Ward, consultant manager of the telecommunications group at Deloitte observed: Koreans are always conscious of the need not to be left behind by others, and the young have a great desire to conform with the gadget-carrying norm of their peers (Ward, 2004). The majority of Koreans have not admitted any difference in several sectors. Businessmen should get the same salary if they begin the job in the same company at the same time, and parents cannot accept the fact that their children are left behind others. They must be in the best position in terms of the quality and quantity of their houses, education, and income. Korean people buy new refrigerators when their neighbors buy them, and they buy pianos when their neighbors buy them, although they have refrigerators and pianos good enough to use.

Likewise, many Koreans are eager to have high-speed Internet because they want to keep up with their neighbors. They feel that if they have the service, they could be part of the group; if not, they could not be part of the group. Technology and fashion fads tend to spread like wildfire in Korea. If one individual adopts an innovation, then others feel a social pressure to follow (Bajaj, 2002; Lau et al., 2005). The me-too culture, which is despicable in some senses, works in broadband services. Many old and new apartments are installing broadband Internet connections because the construction companies and apartment complexes do not want to be behind other apartment buildings (Cho Han, 2006). People do not want to be left behind in broadband services because they do not like a feeling of uneasiness as in many other areas. The disdainful me-too culture has ironically contributed to the rapid deployment in broadband services.

Finally, a growing double personality between social solidarity and individualism, in particular in the younger generation, has played a crucial role in the rapid deployment of high-speed Internet. As well known, Korea was a country which was proud of its tradition of social solidarity (Crotty & Lee, 2002). People do not want to be left out. Due to this, the New York Times reported in 2002, “Korea is a group-oriented society, where socializing in bunches is the preferred form of interaction, and Western-style individualism is frowned upon,” while reporting booming online games (French, 2002, p. 8). To take one documented case, after conducting a case study of online games in Korea, Chee (2006) also emphasized the importance of social solidarity of teens and twenties in the process of growing online game communities. Indeed, it is very plausible because the flourish of the online communication matched the culture and emotion of the Korean people and their need to communicate with one another through boards, which are forums to discuss and exchange information, and clubs, which brought together people with similar hobbies (Seong, 2006).

However, this conventional wisdom has changed in recent years, and individualism—the degree to which individuals are able to achieve identity and status on their own rather than through membership in groups (McFadyen et al., 1998)—is on the rise. In this regards, the New York Times did not reflect the rapidly changing environment in Korea. With the swift change in the economy before and after the 1997 financial crisis as well as recent modernization, Korea’s social and cultural situation has shifted on a large scale. The younger generation increasingly seeks Westernized culture, regarding an individual’s success, private property, and nuclear family as important, instead of the value of the Confucian culture emphasizing patriarchy and large families (Jin, 2007). According to a marketing report by SK Telecom, “Those in their 20s and 30s, the first Internet generation in Korea, gives priority to their own time and space, rejecting all invasions of privacy. They are also changing the culture of collectivism to one of individualism” (Joongang
The growing individualism has resulted in a unique culture for developing broadband services and demanding personal time, space, and privacy.

The double personality of many Koreans, on one hand social solidarity and on the other hand growing individualism, has ironically contributed to the rapid growth of broadband services. As Chee (2006) observes, young people enjoyed popular online games sometimes with friends and other times with nobody, but through high-speed Internet. This shows social solidarity on the one hand; however, it also explains growing individualistic mentality, which prefers enjoying games with no virtual friends in cyberspace to playing with one’s peers on the playground. While seeking social solidarity, many young people enjoy high-speed cyberspace by creating their own world, and this changing social cultural characteristic has become crucial for the rapid growth of high-speed Internet.

In sum, the explosion of broadband in Korea has been possible due in large part to various cultural factors, rooted deeply in Korean society and its historical context, in particular the 1997 economic crisis. Korean citizens are the most significant component in broadband diffusion because they are the main users of the service. Without high-speed Internet, nobody can have a normal socio-cultural life, including enjoyable individual cyberspace from online games to edutainment, in contemporary Korea, which is one of the fastest growing information societies. As Aizu (2002) points out, the social and cultural factors, the aggressive mentality of the Korean people, high awareness of the challenges of globalization, and political and historical contexts played the decisive role in its dynamic acceptance of the Internet and acceleration to broadband in Korea.

CONCLUSION

Korea presents a unique example with its rapid deployment of broadband penetration. Several significant factors have contributed to the rapid development of broadband Internet connections. The government and telecommunications companies, as providers, have played important roles in the rapid development of broadband Internet, in particular to providing infrastructure for its development. Favorable government policies and competition among telecommunications companies became driving forces for the rapid deployment of broadband Internet.

The explosion of broadband in Korea, however, was greatly made possible against the backdrop of the 1997 economic crisis and due in large part to various deeply rooted social, historical, and cultural factors. Although political factors can be important driving forces behind broadband penetration, growth also requires an existing receptiveness to using the services and applications that can be provided through broadband (Jin, 2007). In this regards, it was the citizens who actually made inroads into the world’s most shrewd market for broadband services in Korea.

Several socio-cultural factors, which are crucial to the diffusion and use of new technologies, have played significant roles in the swift deployment of broadband services. Cultural characteristics emphasizing quick communication and quick responses, as well as enthusiasm for edutainment, have contributed to the exponential growth of broadband services. A growing complexity of characteristics of the younger generation showing double personality of social solidarity and individualism, which is not easy to find in any other country, has particularly contributed to the rapid growth in broadband services. If the younger generation has only one characteristic of these
two, it could not be the strong cultural factor for the rapid growth of broadband services. In the midst of globalization that expedited with the economic crisis in 1997, the younger generation has developed its unique characteristics, which resulted in one of the most significant cultural factors in broadband Korea. The majority of Koreans have been eager to gain new technology, and their unique cultural characteristics have become the crucial initiative of the rapid deployment of broadband services.

In conclusion, the introduction and development of new technology cannot be explained solely in terms of political structures and economic policy surrounding technology. As Ellul (1964) stated: “One should be looking at technology in its sociological aspect because technology is not an isolated fact in society but is related to every factor in the life of modern man.” Technology does not develop independently, but is part of a particular social-economic and cultural setup. The deployment of broadband in Korea has been possible due to its specific socio-cultural dimensions as well as political and economic environment. Cultural characteristics rooted in the Korean society greatly influence the growth of technology and broadband services throughout the country.

Socio-Cultural Interpretations to the Diffusion and Use of Broadband Services in a Korean Digital Society

KEY TERMS

1997 Economic Crisis: The Korean economy has gone from being an example of one of the most successful development experiences in modern history to economic stagnation and decline in 1997. From the middle of 1997, Korea was beset with a series of financial crises. The trend of decades of rising incomes reversed, and unemployment and poverty were reaching alarming levels. In particular, factors responsible for the decline in the value of exports then include a dramatic fall in the prices of some electronic and information equipment, in particular semiconductors, which had dire consequences for a number of countries in the East and South Asia region.

Confucianism: A philosophy of life developed by Confucius. It stressed the proper relationships in society, such as father/son and ruler/subject. The philosophies of Confucius are emphasizing love for humanity; high value given to learning, and devotion to family, peace, and justice.

Convergence: Also known as digital convergence. The concept that all modern information technologies are becoming digital in nature. The technological trend whereby a variety of different digital devices such as TVs, in particular high-definition TVs, and mobile telephones are merging into a multi-use communications appliance employing common software to communicate through the Internet.

Edutainment: The combination of education and entertainment. Many people in the digital age use the Internet as a form of studying several subjects, in particular English while enjoying playing in cyberspace.

Information Technology (IT): Compared to the labor-led technologies and industries, information technology usually includes semiconductors, computers, and telecommunications, although some economists like to use the term “knowledge-based industry” in order to explain IT.
Online Games: Internet games (also known as online games) are games that are played online via the Internet. They are distinct from video and computer games in that they are normally platform independent, relying solely on client-side technologies. Normally all that is required to play Internet games are a Web browser and the appropriate “plug-in.”

Social Solidarity: The degree or type of integration of a society. In simpler societies, solidarity is usually based on kinship ties or familial networks. In more complex societies, solidarity is more organic, referring to the interdependence of the component parts. Thus, social solidarity is maintained in more complex societies through the interdependence of its component parts.

ENDNOTES

1 For example, Yun et al. (2002) and Lee et al (2003) mention that the strong emphasis on education and academic performance has prompted parents to turn to the Internet for educational goods and services; however, they do not extend their discussion further.

2 Since broadband penetration was above 77% as of January 2006, Korea almost achieved one of the major goals; however, the speed of broadband, another major goal, could not be fulfilled given that an average speed of broadband was only 2.5Mpbs in May 2005 (see Kim, 2005).

3 In 1997, Korea experienced the worst economic recess in modern history, mainly due to the crisis in financial and corporation sectors. Thirteen large conglomerates, including Daewoo and Donga, collapsed or became partially insolvent because of the shortage of currency. The immediate result of these companies’ collapse was the suffering of small companies and workers. When they failed, thousands of small-scale companies collapsed. As of February 1998, 3,377 mid-size and small companies were bankrupt. When companies went bankrupt, workers lost their jobs. By the end of June 1999, the number of jobless reached 1.78 million. This means the unemployment rate rose sharply from 2.6% in the fourth quarter of 1997 to 8.5% in the second quarter of 1999, and real wages fell by 7.9% (see Jin, 2007).

4 The government placed an emphasis on creating Internet-Friendly Classrooms at every level of schooling by connecting them to high-speed Internet free of charge as the main component of educational information infrastructure. The government spent $1.4 billion for the establishment of school information infrastructure between 1998 and late 2000. Of this amount, the government used $600 million to connect classrooms of 10,064 elementary, middle, and high schools around the country with broadband services (see Lim, 2001, p. 3).

5 The relatively low monthly subscription fees have helped the growth of broadband services; however, it is almost certain that a high subscription fee could not deter the spread of broadband services because the majority of Koreans have not taken the price as a factor. For example, most Koreans over teens have had cell phones regardless of high monthly subscription fees. The subscription fees of mobile phones have greatly risen since 1997; however, the penetration rate has also exponentially increased. In the late 1990s, the Korean government officially banned mobile carriers from offering handset subsidies in an attempt to block excessive marketing; however, many local mobile users still wanted to have mobile phones, although the full price of many handsets were priced at more than $500 in 2002. There are major factors other than promotion policies and
competition among telecom companies in the Korean context which would be cultural factors.

6 100Mbps broadband services can download the equivalent of a 32-page newspaper per second and a film (1.4 GB) within two minutes, compared to one hour with 3.5 Mbps broadband services. About 80% of customers used broadband services of 1-4Mbps in Korea as of December 2005.

7 Parks Associates surveyed more than 10,000 households in 13 countries and ranked nations according to their proclivity to adopt and use MP3 players, video-on-demand (VOD), home networks, computers, online services, and similar advanced technologies. The survey found that Taiwan (Digital Living Index: 8.7) and Korea (8.4) lead the world in the adoption of consumer technologies, followed by the U.S. (8.1), Canada (8.0), and Japan (7.9) (see Parks Associates, 2005).

8 It is in some ways despicable because Korean people follow others, not because they need, but because they want to be in the same class and enjoy showing off.

This work was previously published in Handbook of Research on Global Diffusion of Broadband Data Transmission, edited by Y. Dwivedi; A. Papazafeiropoulou; J. Choudrie, pp. 78-89, copyright 2008 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).
Chapter 3.13
Mobility and Multimodal User Interfaces

Christopher J. Pavlovski
IBM Corporation, Australia

Stella Mitchell
IBM T. J. Watson Research, USA

INTRODUCTION

Traditional user interface design generally deals with the problem of enhancing the usability of a particular mode of user interaction, and a large body of literature exists concerning the design and implementation of graphical user interfaces. When considering the additional constraints that smaller mobile devices introduce, such as mobile phones and PDAs, an intuitive and heuristic user interface design is more difficult to achieve.

Multimodal user interfaces employ several modes of interaction; this may include text, speech, visual gesture recognition, and haptics. To date, systems that employ speech and text for application interaction appear to be the mainstream multimodal solutions. There is some work on the design of multimodal user interfaces for general mobility accommodating laptops or desktop computers (Sinha & Landay, 2002). However, advances in multimodal technology to accommodate the needs of smaller mobile devices, such as mobile phones and portable digital assistants, are still emerging.

Mobile phones are now commonly equipped with the mechanics for visual browsing of Internet applications, although their small screens and cumbersome text input methods pose usability challenges. The use of a voice interface together with a graphical interface is a natural solution to several challenges that mobile devices present. Such interfaces enable the user to exploit the strengths of each mode in order to make it easier to enter and access data on small devices. Furthermore, the flexibility offered by multiple modes for one application allows users to adapt their interactions based on preference and on environmental setting. For instance, hands-free speech operation may be conducted while driving, whereas graphical interactions can be
adopted in noisy surroundings or when private data entry, such as a password, is required in a public environment.

In this article we discuss multimodal technologies that address the technical and usability constraints of the mobile phone or PDA. These environments pose several additional challenges over general mobility solutions. This includes computational strength of the device, bandwidth constraints, and screen size restrictions. We outline the requirements of mobile multimodal solutions involving cellular phones. Drawing upon several trial deployments, we summarize the key designs points from both a technology and usability standpoint, and identify the outstanding problems in these designs. We also outline several future trends in how this technology is being deployed in various application scenarios, ranging from simple voice-activated search engines through to comprehensive mobile office applications.

BACKGROUND

Multimodal interaction is defined as the ability to interact with an application using multiple sensory channels (i.e., tactile, auditory, visual, etc.). For example, a user could provide input by speaking, typing on a keypad, or handwriting, and receive the subsequent response in the form of an audio prompt and/or a visual display. Useful multimodal applications can cover a broad spectrum including tightly synchronized, loosely synchronized, and complementary modes of operation. Synchronization behavior must be defined both for input (the way in which input from separate modes is combined) and for output (the way in which input from one mode is reflected in the output modes). The W3C distinguishes several types of multimodal synchronization for input as follows (W3C, 2003a):

- **Sequential**: Two or more input modalities are available, but only a single modality is available at any given time.
- **Simultaneous**: Allows input from more than one modality at the same time, but each input is acted upon separately in isolation from the others.
- **Composite**: Provides for the integration of input from different modes into one single request.

A general framework for multimodal systems is depicted in Figure 1. This diagram elaborates further on several fundamentals positioned by W3C.

The interaction manager is responsible for combining multiple requests, dialog management, and synchronization. The function of receiving and combining multiple inbound requests is the responsibility of the integration manager sub-component. Conversely, the generation manager is responsible for distributing multimodal output to all of the respective output channels (modes) via an interpretation layer, which may involve text to speech (TTS) conversion or transcoding of graphical content to accommodate the needs of the target modality. Earlier work in multimodal systems referred to the integration tasks relating to composition and decomposition of requests as fusion and fission respectively (Coutaz, Nigay, & Salber, 1993).

Speech-based telephone interfaces currently available in the commercial market commonly use varying levels of directed dialog. Directed dialog, as the name implies, employs a style of system prompts that helps to “direct” the user in what to say next. Users are often presented with spoken menu options from which they can make a selection, thus navigating in a controlled manner until the task is completed. Much of the naturalness and power of speech is undermined when the application relies too heavily on the use of directed dialogs. A Natural Language speech interface, which allows the user to phrase their
request in a wide variety of ways, reduces the
cognitive load since there are no commands to
memorize or hierarchies to navigate. A mixed-
initiative interface allows the user to share con-
trol over the direction of the dialog, making the
interaction more efficient for the user.

Device manufacturers can install special-
ized software or firmware on handsets to enable
distributed speech recognition (DSR). DSR tech-
nology digitizes the speech signal and sends it
over an error-protected data channel to a speech
recognizer on a server. Thus the processing is
distributed between a terminal client and a server.
The accuracy of speech recognition can be bet-
ter when using DSR because the degradations
associated with sending speech over the mobile
network, such as low bit rate speech coding and
channel transmission errors, are avoided. In ad-
dition, DSR allows for the implementation of
a multimodal, speech and data, application on
devices which do not support simultaneous voice
and data connections.

MULTIMODAL TECHNOLOGY
IN MOBILITY SYSTEMS

Multimodal applications for small mobile devices
must overcome several technical challenges;
these include device capability and computational
strength, functional and bandwidth constraints of
the network, and limitations of the user interface.
Present work in multimodality is focused upon the
support of two modes of interaction, most typically
data (graphics or text) and speech (Kondratova,
2004; Pavlovski, Lai, & Mitchell, 2004a; Hastie,
Johnston, & Ehlen, 2002; Kvale, Warakagoda, &
Knudsen, 2003). Future trends support additional
modes that include visual gesture, lip reading,
and haptic responses. In this section we present
advances in multimodality supporting speech
and data entry, outlining the current state of the
technology used and the outstanding challenges
yet to be addressed.

Multimodal Architectures

Due to the need to support two or more modes of
input and output, the solutions to support multi-
modal systems are more complex than unimodal
systems. Additional capabilities are required to
support composite input and output requests, 
manage multiple application states, and perform
session management between devices and the
multimodal application services.

There are fundamentally two architectural
approaches to constructing multimodal solutions
for mobile devices such as mobile phones and
PDAs. The most widely investigated architecture appears to involve deployment of an application onto the mobile device, using distributed speech recognition (DSR) and a GUI client application. Such a solution may be categorized as *distributed client architecture* (i.e., thick client architecture). The alternative employs the *browser-based architecture* (thin client), where a standard Web browser is the only client software used.

Several proposed solutions have been studied that support distributed client architectures (Kvale, Narada, & Warakagoda, 2005; Klante, Krösche, & Boll, 2004). Figure 2 provides an overview of the key sub-systems and components of the distributed client architecture. The device is required to host several components of the solution, generally including a multimodal client application and distributed multimodal processing technologies. This may include automated speech recognition (ASR), text to speech (TTS), and handwriting recognition (HR); however, typical distributed client designs to date have such components on the server. Communication between the client and server occurs over a single channel; hence the multimodal input is marshaled (encoded) into one communications stream.

There are several advantages of this type of architecture including true synchronicity in delivery of the multimodal output, distributed processing, and richer user interface. Since the multimodal output is combined before transmission to the client, the client application is able to ensure media synchronization—that is, synchronized presentation of content to the user; this is a key problem to address in multimodal systems. The presence of a client application also provides a richer graphical user interface and consistency in user interface output. Additionally, the capability to distribute some processing tasks to the client provides greater flexibility for multimodal applications, particularly in relation to response time. For instance, a multimodal short message service is able to perform speech recognition locally within the device, rather than returning to the server, and display the utterance to the user before sending as a short text message.

A key drawback to distributed client architectures is the need to manage the client software to be deployed to the mobile device. This is appears to be of particular concern to mobile operators for several reasons. Given the significant numbers of mobile phones in use, software distribution and management to the device is costly. The majority of mobile phone plans are 12 or 18 months, hence new devices are acquired rapidly and continual support becomes cost prohibitive. Additionally, it may not be practical to support all devices available on the market.

Further research suggests that while a limited graphical user interface is of concern to users, in fact the major contributor to improved usability of multimodal user interfaces is the speech inter-
face (Hastie et al., 2002; Pavlovski et al., 2004a). There is also much work on the notion of speech-centric multimodal user interfaces (Johnsen & Kvale, 2005). These observations also support the notion that alternative architectures require consideration.

An alternative approach is a class of multimodal system that does not require client applications to be deployed to the mobile device. Such a framework is also termed a browser-based, or thin client, architecture—only requiring a standard browser on the mobile phone. In order to support the multiple channels, typically speech and data, use is made of a ‘Class A’ mobile phone and the multi-call supplementary service, which is only available in 3G networks. Specifically, each device establishes several bearer channels with the server, one per mode of user interaction. For example, simultaneously a voice circuit is established for speech and a data bearer service for the browsing graphical and text content (see Figure 3).

Thin client architectures have been studied for mobile devices. An initial set of building blocks to support browser architectures for sequential multimodal processing was outlined in Niklfeld, Finan, and Pucher (2001). The approach in Chou, Shan, and Li (2003) and Li, Wong, and Guo (2004) supports a thin client architecture, where use is made of the multi-call supplementary service for simultaneous connections between the mobile phone and the multimodal application server; however, only sequential multimodal input and output is supported. A further solution solves the problem of supporting composite multimodal output response (Pavlovski, Wood, Mitchell, & Jones, 2004b), however only sequential simultaneous multimodal input is supported. The MONA project provides a similar capability for thin client, and extends the device range to support both mobile phones and PDA devices using a multimodal presentation server (Anegg, Dangl, & Jank, 2004).

The browser-based architecture would naturally seem more attractive to mobile phone operators given the dynamic and rapid turnover of mobile phones, hence eliminating the need to manage software distribution and complexity attributed to supporting numerous mobile devices. The disadvantage of course is that coordinating additional channels increases the complexity and introduces the possibly of latency or synchronization errors. One paper points out that media synchronization is an impact to multimodal applications (Pavlovski et al., 2004b). This may be accommodated by delaying one of the responses so that both arrive simultaneously at the client device. However, complex multimodal applications are yet to be studied to comprehensively assess the impact of synchronization.

Several key challenges remain for browser-based multimodal architectures. This includes management of channel latency and media syn-
chronicity. A full implementation that supports both input and output multimodal composite requests remains as an outstanding problem. And, support for three or more multimodal channels is yet to be explored. These problems may be solved by using the distributed client architecture and have been demonstrated (Johnsen & Kvale, 2005)—however, at the cost of introducing additional software management overheads and restrictions on device supportability.

**Standards and Technology**

The W3C organization has defined several multimodal standards, including interaction requirements and an interaction framework (W3C, 2003b). We briefly summarize some further technologies that are specific to multimodal solutions, outlining their applicability to mobile devices.

**Extensible Multimodal Annotation (EMMA)**

EMMA is a set of XML specifications that represents multimodal user input including speech, pen, and keystroke. The XML is intended to be generated automatically, hence is suitable for use between recognition engines and the interaction manager.

**Multimodal Presentation Markup Language (MPML)**

The MPML Language is designed for presenting multimodal output on browsers supporting XML. The limited processing capability of phones is accommodated, with a mobile edition defined for J2ME applications (Saeyor, Mukherjee, Uchiyama, & Ishizuka, 2003). As such, the architecture resembles a distributed client solution.

**Speech Application Language Tags (SALT)**

SALT is a set of extensions to HTML (or XHTML and WML) adding speech capability to these mark-up languages. While it is suggested to support the thin client architecture, applicability to mobile phones is limited due to the requirement of browsers’ support for SALT. The need to manage multiple application versions, one for each device, is also observed as a drawback (Kondratova, 2004).

**XHTML+Voice (X+V)**

X+V is a proposed standard for multimodal markup. Designed for clients that support spoken and visual interaction, X+V technology furnishes traditional Web pages with further voice tags for input and output speech tasks. A goal is to support thin client, however in its current form this technology is most suited to the distributed client architecture. Use of VoiceXML has also been studied (Niklfeld et al., 2001).

**Synchronized Multimedia Integration Language (SMIL)**

SMIL is a relevant standard to managing media synchronization, an important multimodal problem. However, the standard is largely aimed at conventional browser technology that supports XML, DOM, and XHTML. Hence, it is restricted to browsers that may not be deployed to mobile phones.

**User Interface Design**

There is some work treating multimodal user interface design in mobility. A framework for
multimodal interface design has been proposed in Baillie, Simon, Schatz, Wegscheider, & Anegg, 2005). The authors suggest the need to study user behavior in the natural environment. This follows the observation that user behavior differs considerably when comparing a controlled environment to the general freedom of use that mobile devices provide (Baillie & Schatz, 2005). A key feature of the method is a table designating the context in which the multimodal system is used and the users’ preferred mode of interaction. Further work extends these concepts by proposing a tool to more fully analyze user behavior over an extended period of time (Salembier, Kahn, Calvet, Zouinar, & Relieu, 2005).

Given that there is little data on user behavior in a mobile environment, early design efforts will require careful consideration with users on how to maximize multimodal capabilities. Several key factors determine user behavior including response to error recovery, the course of action context, and properties of the implementation of each modality (Calvet, Julien Kahn, Pascal Salembier, & Zouinar, 2003). Further work shows that the speech interface appears to be the major contributor, when complementing a text or graphical interface, to the improvements bestowed through multimodality (Pavlovski et al., 2004b).

Summarizing the literature, the key features that a multimodal user interface design must address include the capability to dynamically alter modes, support for simultaneous composite output, and the ability to review the output request on one mode, using an alternative mode prior to actioning the request; for example, users who may dictate a message would prefer to see a transcript of the message prior to sending.

**FUTURE TRENDS**

There are several industry trends and future areas of research including the extension of multimodal solutions to accommodate haptic response, visual gesture recognition, lip reading, and speech technologies that support natural language understanding. Oviatt (2003) reviews several of these emerging technologies.

The idea of haptic response is already in use with present-day mobile phones, where mobile phones offer a silent mode that alerts the user with a vibration event. Such stimuli has been in use for some time and appear with early flight control systems that provide feedback to the pilots’ control system indicating turbulent flight conditions. More recently, gaming controllers use such feedback. There is some recent work on the design of haptic response (Kaaresoja & Linjama, 2005) in mobile devices, while other work focuses on haptic input to control a mobile device (Oakley & O’Modhrain, 2005). The notion of extending applications in mobility with such haptic responses is relatively new. To extend such a capability to multimodal applications, access to native mobile services such as vibration is required to initiate a haptic response.

Lisetti et al. (2003) describe research progress on a multimodal emotion recognition system. They have developed a prototype that takes input from multiple modes (i.e., camera, microphone, wearable computer) and includes both subjective, as expressed by the user, and physiological components as inputs to its model. Lip reading technology, as an alternative interaction mode, may be used to improve speech recognition. Prior research suggests that bimodal audiovisual speech recognition can improve as much as 40% in accuracy (Chan, 2001), in comparison with using audio input alone. Additional work on the use of Natural Language understanding to augment the multimodal user experiences has been proposed and studied (Pavlovski et al., 2004b).

A final observation is required regarding security and privacy. Traditionally, voice communications are considered relatively secure, due to the transient nature of circuit establishment between parties and the real-time exchange of data between two peer entities. This is no longer the case for
multimodal application, where the utterances are digitally recorded and stored. Furthermore, in order to improve the speech accuracy and fault resolution, there is a desire on the operators’ part to store such data for a perceived user benefit. Of course the storage of personal conversations and requests for information raises several security and privacy issues that have yet to be addressed.

CONCLUSION

The literature has shown that multimodal user interfaces are able to provide a superior user experience when interacting with multimodal applications on mobile devices such as cellular phones. Furthermore, the applicability of multimodality is extending beyond traditional mobile Web applications to a greater range of domains. For instance, due to the plurality of user interface modes, multimodal systems provide a natural improvement for people with disabilities (Kvale et al., 2005). Although studies demonstrate that multimodal user interfaces provide a superior user experience on a mobile phone, it remains unclear whether such an improvement remains consistent for all types of applications.

Distributed client architectures are able to overcome several problems identified in the literature, however the practicality of deployment for mobile phones requires consideration. Browser-based multimodal architectures overcome deployment issues and provide an alternative and easier mechanism for allowing mobile devices to access services. In order to support multimodal applications that make use of three or more interaction modes, the use of thin client architecture is as yet unproven. In addition, further capabilities that may not be inherent within the devices are required, such as local composite management. Hence, distributed clients would seem a necessary choice to support these capabilities and appear most appropriate to address the needs of the increasing complexity due to several modes of interaction, particularly as the media synchronization of modes becomes more complex.

REFERENCES

Mobility and Multimodal User Interfaces

**KEY TERMS**

**Automated Speech Recognition (ASR):** The use of computer processing to automatically translate spoken words into a text string.

**Directed Dialog:** Speech interface where the user receives system prompts that direct the user on available options that usually require a response with simple spoken words.

**Fission:** The decomposition of output from a multimodal application, to be distributed to the different modalities.

**Fusion:** The composition of input from multiple modalities into one input request to the multimodal application.

**Multi-Call Supplementary Service:** Enables several simultaneous circuit-switched calls to the same device, each call using its own dedicated bearer. Only one circuit-switched bearer can be used for speech at any one time.

**Multimodal Interaction (MMI):** W3C term for a class of human to computer interaction that involves multiple modes of user interaction, such as speech, writing, text, and haptics.

**Text To Speech (TTS):** The use of computer processing to transform text into spoken words.

Chapter 3.14
Foreseeing the Future Lifestyle with Digital Music: A Comparative Study Between Mobile Phone Ring Tones and Hard-Disk Music Players Like iPod

Masataka Yoshikawa
Hakuhodo Inc., Japan

ABSTRACT
This chapter aims to explore the future trajectory of enjoying digital music entertainment among consumers comparing the characteristics of the usage patterns of digital music appliances in the U.S. and those in Japan. As the first step of this research, the author conducted two empirical surveys in the U.S. and Japan, and found some basic differences in the usage patterns of a variety of digital music appliances. Next, a series of ethnographical research based on focus-group interviews with Japanese young women was done and some interesting reasons of the differences were discovered. In Japan, sharing the experiences of listening to the latest hit songs with friends by playing them with mobile phones that have the high quality, ring tone functions can be a new way of enjoying music contents, while hard-disk music players like iPod have become a de facto standard of the digital music appliances in the world.

INTRODUCTION: CENTRAL QUESTIONS
The November 2001 debut of iPod and the subsequent opening of iTunes Music Store have brought a rapid expansion of the digital music market around the world. Some estimate that the market will be worth $1.7 billion dollars by 2009 (Jupiter Research). Now, iTunes Music Store service is available in 30 countries around the world, with the total number of downloaded songs surpassing the 500 million mark in July 2005.

The store only opened in Japan in August 2005 and sold over 1 million songs in the first 4 days. This is an astonishing achievement, consider-
Foreseeing the Future Lifestyle with Digital Music

ing that Japan’s largest online music store Mora has monthly sales of around 450,000 songs. In March and April 2005, SONY, which has long led the portable music player market, released a new digital music player under the Walkman brand, offering both the hard disk type and USB flash memory type to launch a marketing drive against iPod. The developments have finally begun to provide Japanese music lovers with an environment whereby digital music contents are broadly enjoyed in terms of both services and hardware devices.

One of the major characteristics of Japan’s digital music market has been the presence of digital music contents for use on mobile phones. The use of digital music contents on mobile phones, which started as regular ring tones, has gradually evolved into Chaku-uta® (true-tone ring tones) by December 2002, and to Chaku-uta Full™ (mobile-phone-based music distribution service launched in December 2004 by the mobile carrier “au”). Chaku-uta® and Chaku-uta Full™ have sold over 100 million songs and 10 million songs respectively, making the digital music service the largest segment in mobile-phone content services.

The environment for enjoying digital music content is set to expand even further into the future. How would such a development affect the way Japanese music fans listen to music in general? This paper examines future ways of enjoying digital music content in Japan, and the competition between music players like iPod for use with personal computers and mobile phones that have adopted the usage as music players.

JAPAN’S DIGITAL MUSIC CONTENT MARKET AND THE PROLIFERATION OF MOBILE PHONES BEFORE 2005

Firstly, let us examine past developments of the digital music content market in Japan. Japan’s first digital music distribution service started in April 1997. A company called MUSIC.CO.JP began offering songs mainly from independent labels. Coinciding with the launch of numerous music download services in the U.S., a number of online music Web sites opened one after another, orchestrated by individual artists and record labels. In December 1999, SONY Music Entertainment became the first major record company to start an online music store bitmusic. Toshiba EMI, Avex Records, and other major companies followed suit. Yet, since early 2005, the system for online distribution of digital music contents has been underdeveloped, as can be seen in the fact that Mora’s supposed largest online music catalog in Japan contained just 100,000 songs, as opposed to iTunes Music Store’s lineup of 1 million songs upon its launch in August in Japan.

There is no denying that mobile-phone-related music services have been the driving force of the nation’s digital music market. The launch of the i-mode service by NTT DoCoMo in February 1999 marked the start of digital content downloading services via mobile phones. The connection speed of 9600bps in those days made it, initially, difficult to distribute songs in high audio quality. Faced with the adversity, businesses began offering Chaku-melo music ring tones, instead of distributing actual music contents, achieving dramatic growth. The Chaku-melo market has rapidly expanded to 80-90 billion yen in 2002. What makes this development unique was the fact that this service was initiated not by record companies rather by major online Karaoke service providers like GIGA and XING, computer game companies like SEGA, and other companies operating in the peripheral areas of the music industry itself. The market size of 80-90 billion yen as of 2002 is among the highest of all mobile-related digital content services, proving the market-led proliferation of digital content services for mobile phones.

Amidst the flourishing success of the Chaku-melo market, supported by peripheral music
Foreseeing the Future Lifestyle with Digital Music

businesses, record companies that lead the music industry initiated a move to provide the Chaku-uta® service, offering true-tone music as ring tones, instead of Chaku-melo MIDI-based ring tone melodies. The service was initially started solely by Japan’s second largest mobile carrier au in December 2002. While the Chaku-melo service was employed by all mobile carriers rapidly, the Chaku-uta® service was not adopted by the industry leader NTT DoCoMo until February 2004 and by the number three mobile carrier Vodafone until March 2004. However, the service picked up substantial support from younger generations. As the preceding proliferation of the Chaku-melo service had already familiarized mobile phone users with the concept of obtaining music over mobile phone, Chaku-uta® sales reached 100 million songs by July 2004, and surpassed 200 million songs by April 2005 to establish a market of substantial scale. Record companies joined forces to establish Label Mobile, which currently provides around 300,000 songs, approximately three times the catalog size of computer-based online music stores.

After Chaku-uta® came the Chaku-uta Full™ service, which provides whole songs as ring tones to become a de facto digital music store over mobile phones. It reached its fifth million download in April, just 6 months after its launch in October 2004. The cumulative total of downloaded songs reached 10 million in June, causing a dramatic expansion in market size. Although the number of songs available remains smaller than Chaku-uta® at 37,000, the catalog is expected to keep on expanding.

As described thus far, the digital-music-content industry has rapidly mushroomed as one of mobile phone services, but it has been less than 1 year since a full-scale music distribution service (Chaku-uta Full™) was launched. Music has been merely distributed as an additional function to mobile phones, that is, the ring tone. Consumption has been initiated by mobile phone use, instead of music itself. In other words, an explosive proliferation of a new communications device called mobile phones, has triggered the consumption of digital music content as a natural course of evolution. Amidst this situation, a series of dedicated digital music players called iPod has emerged with major success, triggering the launch of the iTunes Music Store offering downloads of digital music content. With the development of a fully fledged environment for computer-based consumption of digital music contents, what has been the course of competition between different types of devices in today’s digital music content market? Let us examine the overview based on the results of a quantitative survey.

TODAY’S DIGITAL MUSIC CONTENT MARKETS: JAPAN AND U.S. MARKETS

In order to grasp the state of today’s digital music content market in Japan, we have simultaneously conducted a survey consisting of identical questions for use in both Japan and the U.S. Results from the two countries were compared against each other in order to identify characteristics of the Japanese market. The survey was titled Survey on Digital Contents, and the survey period ran online was between February and March 2005. The following samples were included: Japan, N=677 aged 15-59 and in the U.S., N=700 aged 18-59.

First, let us take a look at the rate of music-terminal use in the two countries: 6.9% of Japanese respondents used hard-disk music players like iPod, whereas the ratio was almost double at 11.5% in the U.S. The ratio of people using USB flash-memory music players was 7.2% in Japan and 16.1% in the U.S., more than double the Japanese figure. However, the ratio of those using mobile phones as music players was 19.8% in Japan, nearly three times the U.S. result of 6.1%. These figures demonstrated a clear tendency of U.S. users opting for hard-disk or flash-memory...
devices with music transferred via computers, and Japanese users choosing mobile phones to listen to music.

Next, the survey examined how samples typically downloaded digital music contents: 28.9% of U.S. respondents have downloaded music via computer, over 10 percentage points higher than the Japanese ratio of 17.4%. On the other hand, 42.2% have downloaded music (music ring tones) over mobile phones in Japan, around three times the equivalent U.S. figure of 14.2%. The ratio of people who have downloaded true-tone ring tones was 20.4% in Japan, an astonishing lead of around seven fold compared to the U.S. result of 3.0%. The clear tendency of computer orientation in the U.S. and mobile phone orientation in Japan, observed in the choice of music-playing terminals, was also evident in terms of the practice of music downloading.

As explained in the previous section, these findings are a natural outcome reflecting how the digital-music-content market emerged and established itself around mobile phones from the early days in Japan in contrast to market development that evolved around computers and the Internet in the U.S. However, there is some interesting data—the survey asked those who do not own a portable digital music player which type of device they would like to possess. The results indicated almost identical tendencies between Japanese and U.S. respondents, unlike the stark differences they demonstrated in previous questions. Those who intend to purchase a hard-disk music player accounted for 26.7% in Japan and 26.1% in the U.S. The figures for flash-memory players were also very similar at 21.4% in Japan and 21.7% in the U.S. Finally, the ratio of those using a mobile phone as a music player is 5.3% in Japan and 3.0% in the U.S. Even though the Japanese figure is slightly higher than the U.S. figure, they can be viewed as almost at the same level, in comparison to the ratio gaps observed in other questions.

This data demonstrates a strong contrast to previous data, which showed a noticeable computer orientation for the U.S., and mobile phone orientation for Japan. In both countries, purchase intention appears higher for computer-based music players based on either hard disk or USB flash memory, and relatively low for mobile phones doubling as music players.

Until now, Japan’s digital-music-content market has been characterized, in terms of hardware, with proliferated use of mobile phones, as opposed to the U.S. market where more users download music via computer. However, as the results of the aforementioned survey suggest, computer-based music players will be used increasingly for the consumption of digital music content, in addition to mobile phones, in the future Japanese market. Then, what changes will emerge in consumer’s music playing styles when such hardware competition (spread of computer-based music players) evolves?

**FUTURE STYLE OF DIGITAL MUSIC LISTENING IN JAPAN: OVERALL TREND**

We have projected future changes in the style of digital music listening in Japan, dividing the samples of the aforementioned survey into the following three groups and comparing the profiles, music listening styles, and mentalities of the current and future users.

3. Nonusers of digital music contents—Those excluding the above two groups N=319.
We made a particular comparison between current digital music content users who have constituted the computer-oriented digital music market, and digital-music-content potential users who intend to join the market from now, so as to identify how the listening style of this market is likely to change, and what impact such changes will have on the market, which has evolved through downloading by means of mobile phones thus far. First, we compared samples’ demographic profiles and basic indicators in music consumption.

**Gender Comparison**

Current digital-music-content users mainly consist of men, accounting for 66.7%, as opposed to women at 33.3%. Digital-music-content potential users have a more even gender distribution, consisting of men and women at respectively 54.4% and 45.6%. Nonusers of digital music contents have a greater proportion of women at 58.4%, compared to men at 43.6%.

**Comparison by Gender and Generation**

The generation factor was then incorporated to characterize the three groups more clearly. Among current digital-music-content users, men in their 20s claimed the largest proportion at 29.6%, followed by women in their 20s at 23.8%, and men in their 30s at 16.7%. These three groups alone represent over 70% (70.1%), indicating that digital music content is primarily enjoyed among younger people—both men and women. In comparison, among digital-music-content potential users, men in various age groups accounted for around 10% each, that is, men in their 20s at 11.1%, men in their 30s at 10.7%, men in their 40s at 15.3%, and men in their 50s at 11.7%. Women in their 20s and 30s also represented, around the same proportion, at 11.4% and 8.5% respectively. Compared to current digital-music-content users, there is a more even distribution of age and gender groups. As for nonusers of digital music contents, women in the middle to high age groups made up over 40%, including women in their 30s at 14.7%, women in their 40s at 12.3%, and women in their 50s at 16.3%. The data analysis incorporating generation factors highlighted distinctive characteristics among the three user categories.

**Comparison of the Number of CDs Owned**

When asked how many CDs they own, 18.7% of current digital-music-content users said 50 to 99, followed by 23.8% owning 100-199 CDs and 11.9% owning over 200 CDs. These three groups represent over 50% (54.4%). Among digital-music-content potential users, 18.2% own 0-9 CDs, whereas those owning 10-19 CDs, 20-29 CDs, and 30-49 CDs accounted for 14.0%, 13.7%, and 16.3% respectively. Combined, over 60% (62.2%) owned less than 50 CDs. Almost 70% (69.8%) of nonusers of digital music contents also own less than 50 CDs, broken down into those with 0-9 CDs, 10-19 CDs, 20-29 CDs, and 30-49 CDs at respectively 31.7%, 14.7%, 12.2%, and 11.6%. As the figures show, current users have a large proportion of people with a substantial CD collection, whereas nonusers have a large proportion of people with limited CD ownership.

**Comparison of Monthly Music Spending**

Similarly to the former, the ratio of those spending over 3,000 yen (equivalent to the cost of one CD album) per month was 61.8% among current digital-music-content users but less than 40% (39.1%) among digital-music-content potential users. Over 70% (75.9%) of potential users spent at least 1,000 yen (equivalent to the cost of one CD single) per month. Nonusers of digital music contents demonstrated a similar tendency to potential users, with 28.8% spending over 3,000 yen, and 66.1% spending over 1,000 yen. As the
figures indicate, current users have a large proportion of people who spend more on CDs, whereas nonusers have a large proportion of people who spend less on them.

Summarizing the results thus far, current digital-music-content users are mainly young men and women in their 20s, with substantial CD ownership and high music-related spending per month. They can be described as *music fans* with substantial music-related consumption. Potential users of digital music content, who are expected to enter this market, are distributed across both genders and broad generations, from youth to those in middle age. They are characterized as middle-level users in music consumption. Nonusers of digital music content are mainly women in higher age groups, with relative inactiveness in terms of music consumption. The results illustrate clear differences in demographic characteristics and music consumption behavior. There are major differences between consumers who have bolstered the computer-based, digital-music-content market until now, and those who will support the market from now on. These facts alone point to the possibility that the current market is set to undergo substantial changes in its nature. In order to examine details of anticipated changes, we have compared the three groups in their attitude and mentality in listening to music.

### Formats of Music Ownership

Of current digital-music-content users 61.9% acknowledge the desire to store all of their CD collection on the computer, a significantly higher ratio than digital-music-content potential users at 26.7% and nonusers of digital music contents at 17.2%. Current users appear to have a strong desire to manage their music by computer and use computers as the main device for handling music content. In comparison, such desire is not as strong among the other two groups.

### Intention Regarding Songs Available for Downloading

Next, in order to examine the number of songs that are available for downloading, we looked at whether people want a greater selection from download services via computer or those via mobile phone. When asked whether the number of songs downloadable via computer on the Internet should be increased, 45.2% of current digital-music-content users said “yes,” much greater than 30.0% among digital-music-content potential users and 15.0% among nonusers of digital music content. As for whether they want to see the number of songs available via mobile phone increased, just 7.1% of current users agreed, whereas the ratio was more than double at 15.0% among potential users, and 9.7% among nonusers. Although with not as stark a difference as the last paragraph, these groups clearly demonstrated different preferences in catalog enhancement between downloading services via computers or those via mobile phones. In short, current users want to see enhancement of the computer-downloadable catalogs, while potential users want enhancement of mobile-phone-based catalogs just as much as of computer-based catalogs. The results, once again, indicate a strong preference among current users on computer-based services. In comparison, potential users are requesting catalog enhancement to both computer-based and mobile-phone-based services. In other words, potential users and nonusers wish to use both computers and mobile phones to listen to music rather than mere computers.

### Style of Using Songs

We also asked several questions on how people wish to use songs they own. Of current digital-music-content users 35.7% said they want to store all CDs they own on a computer and edit them, for
example, compiling a collection of favorite songs. The ratio was 22.5% among digital-music-content potential users and 11.0% among nonusers of digital music contents. These figures again confirmed the computer-oriented style of current users and highlighted another of their characteristics, that is, actively using downloaded songs for their personal enjoyment. This characteristic became even more evident in the next question.

People were asked whether they like to compile a collection of songs from CDs they own according to specific themes and use the original CD as a gift for friends on a suitable occasion of some sort. Of current users 11.9% said “yes,” whereas the ratio was 15.3% among potential users and 6.0% among nonusers. A greater proportion of potential users expressed preference to this style than current users.

The third question was on whether they wanted to burn their favorite songs on CD-R or DVD more casually to give away to friends and acquaintances. The results showed a similar tendency to the results for the second question. Of current users 7.1% agreed, while the ratio among potential users was greater at 12.7%. Even nonusers had a greater proportion at 9.1%. Looking at the results to these three questions, current users have a self-contained approach in enjoying music with a preference to downloading via computers, whereas potential users are more inclined towards exchanging and distributing music with others.

Finally, we asked whether they wanted to give away or exchange songs, downloaded via mobile phone, to friends over the mobile phone. Again, only 7.1% of current users, who have the preference to computer-based song purchase, agreed to the concept, whereas the ratio was greater among potential users (9.1%), with even nonusers reaching the same level as potential users (8.8%). All the numbers point to the computer-oriented and self-contained nature of current users, and the potential users’ tendency of combined computer and mobile phone use and a strong inclination towards distributing and exchanging songs.

When these analysis results are combined with the demographic characteristics and basic indicators in music consumption, current digital-music-content users can be defined as those with a strong computer preference, wishing to use digital music content for their personal enjoyment in a self-contained approach. In contrast, digital music content, potential users who are entering the market from now, are combining computers and mobile phones for this purpose and are inclined towards enjoying music with others in addition to appreciating it by themselves. This group has a particular tendency of using music as one of the tools for communicating with other people around them.

Let us take a closer look as the results to enable us to explore the direction of how Japan’s digital music market may change, while reflecting upon the trends of both hardware and people’s music listening styles.

The digital-music-content market in Japan originally evolved from the distribution of mobile phone ring tones. Then, music content was merely one of the functions or menus available in using mobile phones. They did not go beyond the ring tone boundary. Amidst this situation, the market embraced the emergence of a new type of music device that contains a hard disk or USB flash memory, designed to be used with a computer. Contemporary music fans were among the first to adhere to such devices, consisting of men and women in their 20s that are most active consumers of music. They stored and managed all music content they already had in a computer, thereby converting them into digital content, and began carrying songs in portable music players and in so doing they were enjoying music for themselves in a rather self-contained fashion.

Today, digital music content that takes the form of mobile phone ring tones exists alongside digital music content that can be carried on hard-disk or USB flash-memory music players. We have investigated the future course of the market in view of the profile and music mentality of potential
users of digital music content, who are making a full-scale entry into this market in the future. Future users will be combining computers and mobile phones, and, unlike contemporary users, enjoying music as both a communication tool with others and for personal entertainment purposes.

Digitizing music contents gives music a new function as a communication promotion factor, in addition to the current functions as ring tones and personal enjoyment.

In order to further clarify this new style of enjoying digital music content, we conducted an oral qualitative survey on two groups, that is, current iPod users who represent those enjoying digital music content via computers, and Chaku-uta® and Chaku-uta Full™ users who represent those enjoying digital music content via mobile phones. The survey clarified their styles in listening to digital music content, so as to obtain an insight into the future direction of music-listening styles.

FUTURE OF THE DIGITAL MUSIC CONTENT MARKET IN JAPAN: CHANGES IN MUSIC CONTENT CONSUMPTION

The Survey on the usage of iPod and Chaku-uta® was conducted in the period between December 2004 and February 2005. In-depth interviews were held with three male and female iPod users in their 20s and 30s, and with three male and female Chaku-uta® Mobile users in their 10s and 20s.²

Comments From iPod Users

What follows are typical comments made by iPod users on their style of enjoying music:

*I find the Random Play function to be very refreshing. I can ‘rediscover’ songs on CDs that I did not pay much attention previously. […] I can store a lot of songs without having to worry about how much space is left. Now, I am storing whatever songs I have, even ones that I would skip if I am playing it on CD. [A 37-year-old man who has used iPod for 1.5 years, SOHO, 6,000 songs are held]*

*I now realize how much I have restricted myself with frameworks of genres and artists when listening to music. The Shuffle function highlights the raw power of individual songs. […] Occasions like that have broadened the range of music genres I listen to, making me feel like trying out CDs I would never have dreamed of listening to before. [26-year-old woman who has used iPod for 1 year, office worker, 1,500 songs are held]*

*I never used to carry music around, but now I do not go anywhere without my iPod. This has widened the variety of occasions I listen to music, for example, while on a train or on the way home after a drink. […] There are times when a song I frequently listened to on CD sounds very different on a portable player, because of various situations you are in at the time. That gives me fun. [39-year-old man who has used iPod for 6 months, office worker, 700 songs are held]*

As suggested in the results of the quantitative survey, they typically—to some extent—have a self-contained approach in music entertainment. Their remarks illustrate new ways of enjoying music (consumption styles) they have attained through hard-disk music players like iPod. For them, a hard-disk music player is a device that allows them to randomly enjoy music out of a greater selection of songs than previously possible in conventional devices (cassette player, MD player), loaded from their CD collection. A hard-disk music player is a true portable music player strictly for personal use. In order for the device to be self-contained, it must be able to carry a massive number of songs, which in turn, facilitates random playing. This random playing then releases listeners from the boundaries of
Forseeing the Future Lifestyle with Digital Music

existing music context (by genre, by artist, etc.) and invites the creation of new contexts, thereby enhancing the self-contained nature even further. They are enjoying music in this cycle.

For them, consumption of music content is not about listening to each individual song, but about enjoying a stream of music. It must always be a fresh string or stream of music different from what they have already experienced previously. Their consumption of digital music content is characterized as self-contained context consumption. This is an emergence of a new style of music consumption, only possible for hard-disk music players like iPod. The style is facilitated with the concept of *play list* in iPod and other devices. The ability to compile a new string or stream of music, has diluted the concept of *album*, presented conventionally from package providers and artists as producers, and encouraged individual users to compile their own music streams. Consequently, music is increasingly evaluated on the merit of each song. One example is the way iTunes Music Store presented its proliferation scale in the unit of individual songs downloaded, rather than albums. This kind of presentation appears to depict a transition of mentality, with listeners focusing more on individual songs, rather than embracing the supplier-defined unit of *album*.

The following comments are derived from Chaku-uta® Mobile users on their style of enjoying music:

*During a break time at work, I just leave my mobile phone to play songs to provide some background music. [...] They are all songs that everyone knows, and will not trigger any music talk. However, it is better than having no music, and stimulates conversation. [...] I don’t mind if each song may be just 30 seconds long. It is actually better to have short tunes to enjoy them with my colleagues and build up a lively atmosphere.* [25-year-old man who has used Chaku-uta® Mobile for 6 months, office worker, 10 songs are held]

*I like upbeat Techno music. I use these types of songs as Chaku-uta, and play them during break time when my friends are around, so that I can show them how to dance to the tunes. [...] The other day, I had my mobile hanging around my neck, and playing Chaku-uta, as I danced across a Shinjuku intersection with my friend. [21-year-old woman who has used Chaku-uta® Mobile for 6 months, university student, three songs are held]

*I might listen to and check out music with my friends, but I am more likely to use it as the Sleep Timer when I go to bed. [...] I can operate it by hand, and put it on charge at the same time. It is very convenient. [...] I don’t care about (each song being the ring tone length of 30 seconds and) not having the complete song. I fall asleep as I listen to the same songs repeatedly.* [19-year-old woman who has used Chaku-uta® Mobile for 1 year, vocational school student, five songs are held]

The analysis of the quantitative survey results also indicated that persons entering the digital-music-content market from now use both computer-based music players and mobile phones, and use music to enhance their relationship or communication with their friends and acquaintances instead of merely enjoying music by themselves. Comments from Chaku-uta® Mobile users substantiate the tendency, that is, using music as a tool for sharing various occasions with friends.

As part of the quantitative survey described earlier, people were asked how they use ring tones and Chaku-uta® on mobile phones. The top three answers were as “ring tones (87.3%),” “alarm clock (60.4%),” and “other alarm sounds (46.3%).” The fourth highest ranked answer, however, was to “enjoy them alone as music” (44.0%), and 41.7% said they “enjoy them together with friends or use them to entertain others”—as such indicating that people are beginning to enjoy mobile-downloaded tunes as stand alone songs with friends.

What can be noted in these comments is that songs are enjoyed in the ring tone length of 30
seconds, rather than in their entirety, which is quite different to that of hard-disk music player users, who consume a massive amount of randomly replayed music in various contexts. Their consumption style is summarized as “sharing the occasion of playing popular songs, rather than personal favorites with others to magnify enjoyment.” What counts is how good each NETA (=song as conversation topic) is, rather than how many songs you have in store. Their consumption of digital music content is characterized as “NETA consumption to be shared among friends.” For them, Chaku-uta® Mobile is perceived as a “music player that plays 30-seconds of everyone’s favorite songs for a shared experience.” The emergence of a new service called Chaku-uta® has brought about this new style in music consumption, while now, the style seems to transform formats of music content.

CONCLUSION

As we have examined, Japan’s digital-music-content market—which started off with the distribution of ring tones as one mobile phone service—has embraced the arrival of fully fledged digital music players and online stores, both designed to be used via computers, such as iPod and iTunes Music Store. From the viewpoint of hardware competition, the market has now entered a stage of combined development of mobile-phone-based devices and computer-based devices. It has brought about two contrasting consumption styles with distinctive characteristics (computer-based and mobile-phone-based consumption of digital music content), and diversified people’s styles in enjoying music at the same time.

People who use a computer-based means to enjoy digital music content, have a self-contained style of consuming music in a specific context, loading a hard-disk music player with a greater amount of music from their personal CD collection than previously possible and enjoying songs in random order. In contrast, people who use mobile-phone-based devices, employ a mobile phone as a communal music player for playing 30-second tunes of high popularity and consume music as topics (information) for sharing various occasions with friends or enhancing the atmosphere.

At present, these styles are separate tendencies and can be observed among users of hard-disk music players and users of mobile phones as music players as two extremes. However, a steady proliferation of hard-disk or USB flash-memory music players may cause these styles to merge on the side of individual users. Competition between two types of devices has created two distinctive styles of listening to music. Now, each user may start using both of these devices at the same time, hence adopting both styles alongside each other. Such a user may eventually begin to seek both of the styles in one of the two types of devices, which may amount to hardware integration, brought about by the symbiosis of the two different music-listening styles. Closely paying attention to consumer behavior and practices in the future will then give way to rich empirical data to be used to develop and elaborate the stream of thought outlined in this study further.

ABSTRACT
Diffusion of radio frequency identification (RFID) promises to boost the added value of assistive technologies for mobile users. Visually impaired people may benefit from RFID-based applications that support users in maintaining “spatial orientation” (Mann, 2004) through provision of information on where they are, and a description of what lies in their surroundings. To investigate this issue, we have integrated our development tool for mobile device, (namely: MADE, Bellotti, Berta, De Gloria, & Margarone, 2003), with a complete support for RFID tag detection, and implemented an RFID-enabled location-aware tour-guide. We have evaluated the guide in an ecological context (fully operational application, real users, real context of use (Abowd & Mynatt, 2000)) during the EuroFlora 2006 international exhibition (EuroFlora). In this chapter, we describe the MADE enhancement to support RFID-based applications, present the main concepts of the interaction modalities we have designed in order to support visually impaired users, and discuss results from our field experience.

INTRODUCTION
Starting from the European Union cofounded E-Tour project, we designed the tourist digital assistant (TDA) concept and developed multimedia
widely usable user interfaces on mobile devices with RFID

tour guides on mobile devices (PocketPC and Smartphone devices) for a number of European tourist sites, such as the Costa Aquarium of Genoa, “Strada Nuova” architectonical area and the city of Genoa, the Castellon region in Spain, and the city of Uddevalla in Sweden (Bellotti, Berta, De Gloria, & Margarone, 2002).

The tour guide provides multimedia contents, added-value information, and location-based services to the tourists. Added-value services are implemented by integrating the mobile devices with additional hardware and software tools such as GPS, electronic compasses, wireless connectivity, digital cameras, written text input, databases, and so forth.

See Figure 1 for snapshots of tourist guide applications.

Relying on the argument that “play is a powerful mediator for learning throughout a person’s life,” we developed the “educational territorial-gaming” concept in VeGame (Bellotti, Berta, De Gloria, Ferretti, & Margarone, 2003), a computer-supported educational wireless team-game played along Venice’s narrow streets to discover the art and the history of the city (see Figure 2), and in ScienceGame (Bellotti, Berta, De Gloria, Ferretti, & Margarone, 2004), a sort of treasure-hunt game inviting players to discover the mysteries and the marvels of the science (see Figure 3) during the “Festival della Scienza” exhibition held in Genoa every year.

These applications were developed from scratch. From these first experiences, we identified common needs and came up with a system to support design of multimedia applications for mobile devices, called Mobile Applications Development Environment (MADE) (Bellotti et al., 2002).

MADE includes M3P (MicroMultiMedia Player), a network-enabled multimedia player easily programmable through the micromultimedia services language (MSL). MSL provides high-level components encapsulating advanced services (e.g., positioning, database query, path search, etc.) that can be easily integrated in multimedia applications. This allows building modular software programs that provide information-rich services to the general public through a coherent and homogeneous HCI that can be learned with low mental workload. On the other hand, MADE hides the low-level aspects of multimedia and service management, allowing designers to focus on the modalities of presentation of information and on user interaction, reducing learning, development, and code maintenance time.

In this chapter, we describe the latest MADE enhancement: we have integrated it with a complete support for RFID detection to allow develop-

Figure 1. Snapshots from the Aquarium and Strada Nuova tour guides on PocketPC device
ment of multimedia mobile applications directly connected with the physical world (Want, Fishkin, Gujar, & Harrison, 1999). All low-level aspects of the hardware tag-detection system that are necessary to identify and locate physical objects with attached small RF tags (Want, 2004) are hidden to MSL programmer by the MADE system.

This chapter will also show the use of MADE with the RFID support in a real context such as EuroFlora 2006 international exhibition. This guide differs from others because it has been ad-hoc developed in order to meet strict usability needs. In particular, the novel interface design assists visually impaired people in maintaining “spatial orientation” (Mann, 2004) through provision of information on where they are, hazards that might be in the way, and a description of what lies in their surroundings.
MADE SUPPORT OF RFID TECHNOLOGY

Location-Aware Computing

Recent research has developed several systems, to determinate physical location, that differ by accuracy, cost, and coverage (Boriello, Chalmers, LaMarca, & Nixon, 2005). The global positioning system (GPS), which uses signal from satellite to estimate position (Djuknic & Richton, 2001), is the most used system, but only for applications in outdoor areas. In indoor areas and urban areas with poor sky visibility, the system does not work properly. Moreover, it has a long start-up time.

To overcome these limitations, the first indoor positioning system was the active badge system (Want, Hopper, Falcão, & Gibbons, 1992), which is based on sensors that receive infrared ID broadcast from tags worn by people. This system gives a poor (room-grained) localization precision. After the active badge system, typical indoor location systems are based on radio frequency and on the estimation of position computed from the measured signal strength. Various technologies can be used: Wi-Fi (Howard, Siddiqi, & Sukhatme, 2003), Bluetooth (Bruno & Delmastro, 2003) and nowadays RFID (Liu, Corner, & Shenoy, 2006).

The first two solutions can give an accuracy of around some meters, but require expensive fixed base stations. RFID tags, instead, are very inexpensive and have the same performance. The literature reports also of many location estimation algorithms based on cellular radio networks (Xu & Jacobsen, 2005). However, there is not a generally agreed solution today, and each algorithm has pros and cons, depending on environmental issues. Finally, some vision-based algorithms (López de Ipiña, Mendonça, & Hopper, 2002) are promising because they do not require infrastructure (like tags, satellite, or base station). However, it is difficult to set up a system to locate a user with a 1-meter precision. In the selection of the best methodology for our system, we have taken into account three major issues: the possibility to have a system for outdoor/indoor spaces (like the EuroFlora 2006 exhibition area), a technology with a low cost for the deployment of the infrastructure, and a likely pervasive availability of the system in the near future. All these requirements are satisfied by the RFID technology.

RFID Application Fields

Major RFID application domains include monitoring physical parameters, such as temperature or acceleration, during fragile or sensitive products delivery, monitoring product integrity from factory to retail locations (Siegemund & Floerkemeier, 2003), utilities for home and office automation (Langheinrich, Mattern, Romer & Vogt, 2000). Nowadays we have passive or active inexpensive RFID (approaching 35 cents today, with a goal of 5 cents (Quaadgras, 2005)) that makes these kinds of sensors practical for tourist applications. For example, a museum exposition can place tags attached to each point of interest so that tourists can receive information about exposition in the right moment at the right place; when near to the object. The research community has actively explored this possibility at the Exploratorium, the interactive science museum in San Francisco. The HP Laboratories researchers have implemented a system that uses three types of identification technology: infrared beacon, barcodes, and RFIDs (Fleck, Frid, Kindberg, O’Brian-Strain, Rajani, & Spasojevic, 2002). In Goker et al. (Goker, Watt, Myrhaug Whitehead, Yakici, Bierig, et al., 2004), a special tag that can work with mobile devices to provide ambient information to users on the move is described. In the Cooltown project (Kindberg & Barton, 2001), RFIDs are used to attach pointers from everyday objects to entities in the computational world. A full exploitation of RFID potentials requires study and implementation of human–computer interaction (HCI) modalities able to support usability of the enhanced mobile tool by the general public. This implies the neces-
usability to resort to programming methodologies and tools specifically dedicated to support the RFID technology. Thus, we have extended the MADE toolkit to support a link between applications and physical world through RFID sensors.

**MADE Architecture**

A typical MADE application consists of a set of pages containing multimedia and service objects. The micromultimedia services language (MSL) script specifies pages’ layout and objects’ appearance, synchronization, and user-interaction modalities. MSL scripts are interpreted at runtime by the M3P player that manages presentation of contents and user interaction according to the instructions specified in the input MSL script.

M3P player relies on two-layer architecture (see Figure 4) involving a high-level, platform-independent director and a low-level driver. The director is responsible for creating, initializing, and managing the objects that implement the language functionalities. In order to support incremental development of the player, M3P is composed by a set of modules. In particular, the director has been designed to be independent of the components it manages. According to the object-oriented methodology, this has been achieved by encapsulating the functions of the components in the code of their class, and by structuring the hierarchy so that the director can simply keep a reference to the presentation’s pages and convey them events.

According to the instructions specified by the MSL developer in the script, events (either from the system or from user interaction) are conveyed to the director that simply redirects them to the components of the page currently on show, which is the higher-priority choice or, with lower priority, to the other pages of the presentation.

Events are implemented as string messages that are to be interpreted by the target objects. This design choice allows the director’s code to be independent of the components and the components to be independent of each other. The basic assumption of this schema is that each component exports a well-defined interface (i.e., a set of messages to which it is able to react) and implements this interface (i.e., implements the reaction to such messages).

![Figure 4. MADE architecture](image-url)
Thus, components can be seamlessly added and interchanged (in this last case, as long as they comply with the same interface). Adding a new component (i.e., a new functionality) does not involve any change either in the director’s code, or in the other components’ code.

Such a design choice supports easy incremental development, allowing seamless integration of services within a single application framework. This implies that a homogeneous HCI can be applied to an application that hosts several different services that have been developed independently of each other (e.g., intelligent tour planning, interactive maps, positioning, and database access).

MSL relies on a component-based data structure. That is, an MSL file specifies creation of components, attributes of components, and their reaction as a consequence of user interaction. Components are organized in three main libraries: multimedia (e.g., audio, image, video, button), synchronization (utilities like timers that can be used to implement synchronization and scheduling of contents), and services (objects that encapsulate services such as positioning, shortest path search, tour planning, database query, etc).

Every different type of component has its own kind of attributes (fields). The fields record data for specifying the appearance (such as position) and the behaviour (i.e., reactions to events) of the component. In general, components are contained in a special container component, called CARD, that can be thought of as an empty page on which the developer can add components.

The core of M3P involves a platform-independent director and a platform-dependent driver. The director manages the multimedia objects that implement the presentation. Objects are compounded in hierarchical structures. For instance, a CARD (i.e., a multimedia page) may include several images, buttons, and mpeg players. The driver implements the functions to access the hardware, while the director deals with the logic of the multimedia presentation.

### Integration of RFID Subsystem

A major feature of MADE consists in the possibility of incrementally adding new hardware and software modules, that are integrated into the HCI framework with no need for modifying the M3P core, since every component’s class is responsible for interpreting its receivable messages, independent of the others. MADE can integrate, into a common framework, various hardware modules independently developed to augment the mobile device potentiality. M3P driver’s classes, which have to be developed to integrate every new hardware subsystem, manage low-level aspects of the hardware modules, while the MSL interface to the application developer abstracts the services at high level. This implies that a homogeneous HCI can be applied to an application that hosts several different services that have been developed independently of each other (e.g., automatic positioning, intelligent tour planning, and database access can be integrated in an interactive map), and the MSL developer can simply exploit the service modules focusing on the integration of the HCI. Examples of hardware modules already integrated in MADE are a positioning and orientation module that an MSL developer can exploit to get geographical position from a GPS receiver and direction from a digital compass, and the remote communication module able to exploit the hardware available for connection with the external world (e.g., wired/wireless LAN, Bluetooth, GSM/GPRS cellular networks).

In order to enable applications to react to objects in the physical world, our new M3P module, called RFID sensing module (RfidSM), detects presence of RFID tags in the surrounding space and notifies the M3P run-time objects with events implemented as string messages (see Figure 5). The script interface of the RfidSM is a new MSL component, called RFID, that exposes the fields shown in Table 1.
When the RfidSM component is started, and until it receives a stop event, it scans the surrounding environment to check the presence of tags every “period” of time. The list of detected tags is then sent with the MADE message-exchange modalities to the components specified in the

Table 1. RfidSM fields description
“target” field. In addition, the component has an “id” field to allow programmer expressing interest in a set of tags, and defining (through the field “onFound”) the corresponding events list that should be executed. Each interesting tag is also featured with a signal strength threshold (through the field “dBm”) that specifies a limit under which the tag is considered in range.

There is the problem of collisions, since the scan results are typically imperfect due to not all tags are detected in every scan. To solve this problem, a tag typically awaits a random number of time slots before it answers the RF pulse sent by the reader. However, the problem still remains and grows as the number of tags in the surrounding environment grows. The MADE RFID sensing module tackles this issue, allowing the programmer to specify, through the field “repetition,” a number of times that the reader should repeat the scanning before returning to the founded tags. The list of founded tags is the collection of all tags observed in each scan. A small value of repetition results in a fast scan with high risk of collision, whereas large repetition value results in a slow scan with few collisions. This trade-off should be resolved by the programmer basing his decision on application constrains: long delays can result in human-computer interaction problems if the application allows a user expectation for immediate reaction to tags. This is the case of applications in which user a voluntarily accosts the mobile device to tagged objects to obtain information. Similar problems arise if the application has a short time frame to detect tags, for example, in applications where the user moves at relatively high speed in the environment, like in territorial games. Instead, others type of applications can gain advantage from precise but slow detections. It is the case of a tourist mobile guide for a naturalistic park in which the user moves along a path with some points of interest largely spaced, like tree species or rare flowers.

The other problem affecting the RFID technology is the “tag detection flickering” (Römer, Schoch, & Mattern, & Dubendorfer, 2003): due to the collision problem, some tags can appear and disappear from sequential scanning, generating a fast list of tag identifications. The MADE RFID sensing module allows the programmer to decide how to convert scan results into applications events handling this problem. Programmer can specify, through the “delay” field, a time period (for each interesting tag) starting from the detection. During this time, subsequent detection events of the same tag are discarded; also, the exact definition of this delay is application dependent. Applications with events that occur only one time, like tourist guide for museums with linear path, can have delay values set to infinite. Instead, in applications with events generated multiple times closer each other, like territorial games, the delay should be short or zero.

Currently, we have implemented the low-level driver support for the iCARD Identec reader in a PCMCIA card format (IDENTEC). This card can be integrated in handheld, portable, or laptop computers to communicate with the iQ and iD active RFID tags at a distance of up to 100 meters. The RF signal is in the UHF radio band (915 MHz or 868 MHz), providing long-range communication and high-speed transmission rates for reliable data exchange.

THE EUROFLORA GUIDE

In order to assess the possibility of using RFID technology to develop widely usable interfaces, we present a real-world application (see Figure 6) developed through the MADE toolkit and deployed in an ecological environment (fully operational, reliable, and robust application, used by real users and in a real context of use) at EuroFlora 2006 (the international flower exhibition that is held in Genoa every 5 years). With over 500,000 visitors in 10 days, EuroFlora is one of the most important exhibitions of Europe.
The developed application concerns the research area of assistive technologies for visually impaired people. Such assistive applications have the potential to improve the quality of life of a large portion of population (by 2020, there will be approximately 54 million of blind persons over age 60 worldwide (WHO, 1997)).

In this field, maintaining spatial orientation is a major challenge for people with visual impairment. There is the need of systems in providing blind people with information on where they are, hazards that might be in the way, and a description of what lies in their surroundings (Mann, 2004). The notion of “spatial orientation” refers to the ability to establish awareness of space position relative to landmarks in the surrounding environment (Guth & Rieser, 1997). The goal of our application is to support functional independence to visually impaired people, providing support to indoor awareness of elements in the surroundings (Ross, 2004).

The EuroFlora guide is organized in two parts. One part provides general information about the exhibition, the guide, and their services. The other part provides the description of the selected interest points. While first part is directly accessible by the user at any moment, the second one is event driven. More precisely, every interest point description is associated to an RFID tag, and when a user enters that area (i.e., her/his handheld device recognizes the RFID tag), the software asks the user whether to launch the corresponding description.

We placed 99 RFID sensors on an area of 30,000 mq of exhibition, covering 99 points of...
interest, services, and major areas (see Figure 7). RFID sensors were IP65 compliant in order to resist to water and dust, and self-powered. Power level of sensors could be set in two levels, low and high.

**Design Methodology**

The necessity for combining the flexibility and multimedia potential of a mobile device with the extreme simplicity of interaction, required for use by a wide audience (also visually impaired people), involves facing three main HCI issues:

- **Usability by general users:** The tourist has little time and willingness to learn how to use the new technological tool, since she or he is there to visit the exhibition and not to learn a tool. Most of the tourists use such a tool for the first time and just for a short time (typically, from 30 to 90 minutes). Thus, the complexity of the platform should be hidden from visitors, making the guide immediately usable, with no effort by users. This implies that the interface is to be as simple and intuitive as possible.

- **Usability by visually impaired people:** Visiting an exhibition is a critical task for the blind, mainly for the combination of several reasons: the site is often crowded and unfamiliar to the visitor, it may be noisy, it is difficult to orientate in a highly dynamic place. In this context, the guide should be not intrusive, with few and very recognizable input interface elements (also with tactile feedback), and should give information in a proactive modality when needed by the user.

- **Presentation of information:** Added-value information (e.g., how the various specimens live in their natural environment) should be synergistic with the direct experience of the visitor at the exhibition. Provision of information has to be structured in order to enhance the direct perception of the visitor, leading to a better and more pleasant comprehension of her/his surrounding environment. For example, the guide should make use of environmental sound (e.g., waterfall) and scent (e.g., flower smell) to connect content information and the objects in the space.

We have tackled such issues resorting to the methodologies of the user-centric design (Carroll, 1997), in an iterative development of the guide involving participatory design (Beck, 1993), definition of usability specifications, and contextual design, as shown in the following:

- Participatory design consisted of the participation of botanists at the design decisions, authors skilled in writing for blind people and visually impaired end-users, together with technical developers. The most significant contribution of the first three categories consisted in the definition of the targets and in the concrete perspective they brought into the project.

- Usability specifications provide explicit and measurable targets to verify the suitability of the work done. Examples of such goals are “90% of the users should be able to operate the guide without asking questions to the personnel,” “90% of the users should be able to use the interface with no errors,” “90% of the users should be able to understand the meaning of all the touchable controls within 120 seconds.” All these objectives were verified in early lab and field tests in order to take the appropriate corrective actions.

- Contextual design involved early field tests with experts and users at the exhibition in the preopening days when the infrastructure of EuroFlora was being built. Field tests have been helpful to highlight problems and shortcomings that had been overlooked or ignored in lab.
Structure of the Interface

The interface of the EuroFlora guide has been designed to support immediate use by the general public, also by visually impaired people. To this end, we used general design principles (we already described them in the introduction) such as overall simplicity, low intrusiveness, and support for natural interaction and knowledge acquisition. Moreover, we added further features in order to meet the specific needs of visually impaired people:

- Tactile feedback in the control interface
- Tutorial stage
- Event-driven interface
- Facilities to support orientation

The basic element of the interface is the multimedia card. A multimedia card corresponds to each subject of a presentation (e.g., a flower species). Each multimedia card provides, in an audio format, texts specifically written for visually impaired people (i.e., highlighting olfactive and tactile sensorial information, providing detailed ambient descriptions).

The tactile feedback is necessary to allow impaired people to easily understand the position of the controls and give her/him feedback. Our previous multimedia guides had the interface embedded in the graphic contents, exploiting the touch screen of a pocket-pc device. During the early field tests, visually impaired people pointed out some important shortcomings in these solutions. They felt that the screen was too large and their fingers were lost in a space without roughness. Since most of such users are well acquainted with the common cell phones’ relief keyboard, we studied a new solution exclusively based on the hardware buttons (Figure 8).

The hardware buttons of the interface are highlighted. The choice of this area as navigation control allows visually impaired people to have a tactile feedback. The meaning of the button is “up” to accept a content description (which is automatically triggered when the user enters a new cell), “down” to reject it, “right” to exit from a section of the guide, and back to the main menu, “left” to have contextual information about user’s current position.

The tutorial stage is an initial guide section in which users could freely experiment with the interface of the tool in order to allow people to use the guide in an independent way. In this stage, users are invited to freely press buttons. A speech description briefly explains the meaning of each pressed button. This tutorial stage prevents the necessity for providing papers or long explanations when users rent the guide.

The event-driven interface allows a user to get information about points of interest (POIs) and orientation when they are in the proximity of a POI. For example, in Figure 9, a user near the azalea stand is told about the presence of this flower by a pop-up window (the guide is to be usable by everybody) and a corresponding jingle sound. If she/he wants to listen to this content, she/he can press the “up” hardware button. By
default, the system skips the presentation. This operational mode has low intrusiveness (users are asked whether to listen to a content), but it also provides a certain degree of proactivity. Information is not only botanical, as in the example of azalea, but also concerns the positioning of the user. Many tags are placed in the proximity of facilities, such as lavatories, cafés, exits, and intersections. This localization system lowers the mental workload necessary for the tourist to synchronize the physical space of the exhibition with the virtual space of the program.

This message (accompanied by a jingle) is shown to the user when she/he has just entered a POI area. The combination of audio and graphics is due to the fact that the guide may be used also by not visually impaired people. In the example in this figure, the user is near to the azalea flower, and if she/he is interested in the description she/he can press the “up” hardware button to access the related content.

One of the main tasks of the guide is to assist the visitor in her/his exploration of the exhibition space. A facility to support orientation (not useful for visually impaired people) is a section with the map that helps the tourist to orient herself/himself in the exhibition. The map (see Figure 10) shows the structure of the EuroFlora, including lavatories, café, exits, and so forth, and the location of the points of interests. In order to enhance user’s orientation, the map is centered on the position of the user, as determined by the currently perceived RFID tags.

FIELD EVALUATION

Experimental Framework

Real evaluation of advanced mobile device applications and of the impact on their intended population is difficult and costly. Evaluation requires analysis of real users, in a real context of use. In order to adequately evaluate interaction with computation resources, test-people should use a fully operational, reliable, and robust tool, not just a demonstration prototype (Abowd & Mynatt, 2000). Hence, it is important to perform
early tests in the authentic context of use in order to verify end-user acceptance and overall usefulness of the system, and to receive feedback to inform future design.

In this chapter, we describe the early stage analysis of acceptance and usefulness of the developed multimedia guide. The tests were performed at EuroFlora 2006, the international flower exhibition that is held in Genoa every 5 years. With over 500,000 visitors in 10 days, EuroFlora is one of the most important exhibitions of Europe.

The exhibition area (around 90,000 squared metres) was equipped with an infrastructure of 99 RFID tags. The experimentation involved 120 visually impaired tourists who used the tour guide, and were observed and interviewed by expert of disabilities and HCI designers. Subjects were visually impaired (25%) or blind persons (75%) representing a wide range of age (28% age <30; 32% age between 30 and 50; and age >50 40%). Moreover, the tests involve 64 females and 56 males.

The tour guide consisted of a PocketPC equipped with a special leather package with a lace dropping from the neck for a more comfortable use. Headphones were also used in order to isolate the user from the highly noisy surrounding environment (see Figure 1).

Preexhibition Tests

In an early test session-performed 2 days before the official opening of the exhibition, when some stands were already ready enabling a realistic test-we prepared a prototype software version that was used by five selected visually impaired users visiting 30% of the total exhibition area. We followed and interviewed the users in this phase, in order to understand shortcomings, defects and weaknesses, and strong points of the product. In this phase, we understood and solved some problems on user interface and contents, such as the most suited assignment of buttons to presentation control functionalities and the length of the descriptions. Some test-users found the long silence time between a presentation activation and the next one (i.e., the period of time in which the user is walking through areas not covered by RFID tags) frustrating. We partially tackled this issue by periodically providing a message saying that the user is currently in an area not close to a POI.

Ecological Tests

One hundred and twenty blind people used the guide during the exhibition. Sixty of them (aged from 12 to 78 years old) participated in

an ecological test conducted by the authors. We interviewed the users at the return of the guide. We evaluated three main performance factors: usability (including effectiveness, efficiency and pleasantness of use), usefulness, and capability to support spatial orientation (in particular the approach to the POIs). We asked users to give a general comment on the guide and a 1-5 grade for each factor (which was carefully explained and defined by the interviewers). An overall survey of results is reported in Table 2; it clearly shows the high acceptance by the users.

Analyzing the variables' correlations based on the chi-square test, we observed that usability is correlated with the perceived support for spatial orientation ($\chi=25.3$, df (degree of freedom) $= 16$, 90% confidence), and that perceived utility of the tools is strictly correlated with perceived support for spatial orientation ($\chi=30.2$, df =16, 99.9% confidence). This suggests the importance of our design choice to use mobile technology to support orientation of visually impaired people. Moreover, test results also show that the tool is perceived as useful and usable.

Considering the free comments, the guide was judged as an excellent tool for users to orientate themselves inside the exhibition. Several people expressed a similar concept, which we can synthesize with the words of one visitor: “after always having been guided, for the first time I myself have been able to guide my wife and to explain the exhibition!” Such positive comments were also confirmed by the blind assistance experts, who highlighted the significant degree of independence the blind could reach through the guide.

Shortcomings in the interface were reported by some elderly users, while some people asked for more extended descriptions, though each point of interest included at least one. The high performance and reliability of hardware, software, and batteries assured long sessions of use with no troubles for the user.

**FUTURE TRENDS AND VISION**

The research community is envisaging a new model of a “tagged world” as an intelligent environment that allows providing visually impaired people with information about architectonical barriers, safe paths, points of interest, potential danger areas, and other useful information. A sample scenario description may give an idea of this likely future.

Maria is visually impaired. She is in a foreign city on a business trip. Maria owns a mobile device with a mobility-assistance system (MAS: it is similar to the EuroFlora Guide, but with a much larger action range). The MAS accompanies her in her path to her destination office, and signals pedestrian crossings, traffic lights, safe paths in work-in-progress areas, and so forth. All objects in the world send their signals, but Maria’s wearable device has an intelligent reasoning algorithm (based on user preferences and interpretation of the user’s current activity) and a suitable human-computer interaction (HCI) in order to provide her only with the needed information. This information is extracted from a mass of data that are continuously received from the close-by RFID tags. Thus, the wearable device notifies Maria about a pedestrian crossing only if it knows that this is useful for her current activity (i.e., going to office). Not useful information will not be provided, in order not to distract Maria. Along her path to her destination, Maria passes by a newsagent. The World Guide scans all the magazines and identifies today’s issue of Maria’s favourite magazine. It queries Maria’s database, which replies that Maria has not purchased this issue yet; so, it notifies her about the opportunity to buy the magazine.

**CONCLUSION**

The ubiquitous presence of smart tags will offer, in the near future, a critical mass of information,
Widely Usable User Interfaces on Mobile Devices with RFID

embedded in the world, that will be exploitable to rethink the relationships between people involved in their daily-life activities and the surrounding world.

With MADE we have designed a system that continuously scans the tagged world, interprets the large amount of information coming from the surrounding objects, and provides it to the users through multimedia human-computer interaction. Moreover, the application in the future will filter the raw data coming from the environment (with artificial intelligence behaviour) taking into account the user needs, preferences, and profile.

The field test at EuroFlora 2006 has demonstrated the feasibility of our vision, by deploying the system in a real-world setting (an exhibition area with indoor and outdoor instrumented environments), and performing extensive field tests with real users. In a longer-term view, with such an application, we intend to investigate the future scenarios that will be enabled by a massive presence of RFID tags in our environments. This “early prototyping” has allowed us to understand, as early as possible, costs, limits, strengths, and benefits of the new technology. We have also obtained a significant positive feedback on user acceptance. Usability results show that the guide is perceived as highly usable and useful, in particular because of its ability to support spatial orientation.

The next step towards a “tagged world” will require integration of data and services, and capability of interpreting a variety of sources according to the specific and dynamic user needs. Achieving these goals will involve a huge research effort that will be successful only if it will lead to the deployment of compelling applications that will be perceived as useful by the users. In a user-centered design view, this implies a rapid prototyping of applications and extensive user testing in the real context of use, which was our inspiring principle in the EuroFlora project.

Widely Usable User Interfaces on Mobile Devices with RFID

national Journal of Human-Computer Studies, 46(4) 501-522.

KEY TERMS

Chi-Square Test: The Chi-square is a test of statistical significance for bivariate tabular analysis (crossbreaks). This test provides the degree of confidence we can have in accepting or rejecting a hypothesis.

Ecological Context: The ecological context is a set of conditions for a user test experiment that gives it a degree of validity. An experiment with real users to possess ecological validity must use methods, materials, and settings that approximate the real-life situation that is under study.

Human-Computer Interaction: Human–computer interaction (HCI), also called man–machine interaction (MMI) or computer–human interaction (CHI), is the research field that is focused on the interaction modalities between users and computers (interface). It is a multidisciplinary subject, relating to computer science and psychology.

Location-Aware Computing: Location-aware computing is a technology that uses the location of people and objects to derive contextual information with which to enhance the application behaviour. There are two ways to acquire information about user context: requiring the user to specify it or by monitoring users and computer activity. Sensor technology, such as RFID, could enable mobile devices to extract information from user position automatically.

Mobile Tourist Guide: A mobile tourist guide is a software application with an intuitive interface, that provides users with multimedia information when and where needed during their visit to museums, city centres, parks, and so forth. Such an application runs on PDA-type terminals or on cellular phones, and could be augmented with GPRS (general packet radio service), GPS (global positioning system), and Bluetooth wireless technology. The guide allows tourists to plan routes according to preferences and ambient conditions (weather, timetables, sites of special interest, etc).

Radio Frequency Identification: Radio frequency identification (RFID) is an automatic identification method based on storing and remotely retrieving data using small and cheap devices called RFID tags or transponders. An RFID tag is an object that can be attached to objects, products, or persons to identification using radio waves. Passive tags (with a few centimeter range of sensitivity) require no internal power source, whereas active tags (with more long range of sensitivity, 100 meters) require a power source.

User-Centric Design: User-centric design is a design process that aims at realizing products that meet users’ expectations. The key idea of this design methodology is to start the design strategy taking into account the user’s perspective.

Chapter 3.16
Plagiarism, Instruction, and Blogs

Michael Hanrahan
Bates College, USA

ABSTRACT

This chapter takes as its point of departure the Colby, Bates, and Bowdoin Plagiarism Project (http://ats.bates.edu/cbb), which sought to approach the problem of undergraduate plagiarism as a pedagogical challenge. By revisiting the decision to publish the project’s content by means of a weblog, the article considers the ways in which weblogs provide a reflective tool and medium for engaging plagiarism. It considers weblog practice and use and offers examples that attest to the instructional value of weblogs, especially their ability to foster learning communities and to promote the appropriate use of information and intellectual property.

INTRODUCTION

Alarmist news accounts of student dishonesty and cheating abound. More often than not, such stories describe how universities, colleges, and even high schools have resorted to plagiarism detection services to fight a veritable epidemic of student cheating. The preferred method of combating academic dishonesty, after-the-fact detection, is not the only and is perhaps not the best way to address the problem of student plagiarism. Instead of fighting the lost cause of plagiarism retroactively, technologists and librarians at Colby, Bates, and Bowdoin colleges (CBB) collaborated to develop a program of instruction to educate students about the principles of academic honesty. The resulting plagiarism resource site (http://ats.bates.edu/cbb) includes an introduction to plagiarism, an online tutorial that tests one’s understanding of plagiarism and that provides guidance in the conventions of citation, and a dedicated weblog that publishes links to newsworthy articles, notices, and projects dedicated to plagiarism.

Conceived as a case study, this chapter discusses and evaluates the project’s reliance on a weblog to develop, manage, and publish learning resources dedicated to plagiarism. In the matter of technical choices, the project developers were influenced by their commitment to Open Source Software as well as Creative Commons.
licensing. The former influenced the choice of weblog software, Drupal (http://www.drupal.org), and the latter informed the decision to make all of the project’s learning objects and resources available under an “Attribution-Non-Commercial-Share-Alike” Creative Commons license. These decisions, it turns out, have allowed the project to model the appropriate use of online materials and have retrospectively provided an occasion to reflect on weblogs as an effective medium for engaging plagiarism.

BACKGROUND

Over the past several years, national, regional, local, and campus newspapers across the globe have regularly featured articles on student cheating. While academic dishonesty takes many forms (using a PDA, cell phone, or crib notes during an exam; submitting unoriginal work copied from an existing publication, cut and pasted from an online source, or purchased from a paper mill; or simply peering over a classmate’s shoulder during a quiz), plagiarism has emerged as the most visible form of student cheating. In many ways, the term threatens to subsume all other categories of academic dishonesty. A passing visit to the statistics page at Turnitin’s Web site (plagiarism.org) reinforces this tendency. Turnitin, the world’s leading plagiarism detection service, claims that “A study by The Center for Academic Integrity (CAI) found that almost 80 percent of college students admit to cheating at least once.” Besides generalizing and rounding up the center’s published summary (“On most campuses, over 75 percent of students admit to some cheating”), Turnitin’s claim isolates a common tendency to conflate a number of dishonest “behaviors” with plagiarism. Donald McCabe (personal communication, August 4, 2004) explains that the 75 percent figure published by the CAI “represents about a dozen different behaviors and was obtained in a written survey.” Plagiarism is certainly one form of cheating, but not all cheating is plagiarism.

Reports of plagiarism in the media tend to indulge in hyperbole: it is consistently described as nothing less than an epidemic on campuses. McCabe (1996), who conducted extensive surveys between 1996 and 2003, repeatedly found that the facts do not correspond with “the dramatic upsurge in cheating heralded by the media.” McCabe (2000) has elsewhere observed: “Even though I’ve stated on previous occasions that I don’t believe these increases have been as great as suggested by the media, I must admit I was surprised by the very low levels of self-reported Internet-related cheating I found.” McCabe has subsequently further qualified his view of the problem: “Although plagiarism appears to have remained relatively stable during the past 40 years, . . . it is actually far more prevalent today because many students don’t consider cut-and-paste Internet copying as cheating” (Hansen, 2003, p. 777). More recently, McCabe’s evaluation of his 2002-2003 Survey of U.S. Colleges and Universities identifies an increase in certain kinds of cheating and a continued misunderstanding of plagiarism among undergraduates: “The past few decades have seen a significant rise in the level of cheating on tests and exams. . . . While the data on various forms of cheating on written assignments do not reflect the same trend, this may be due to a change in how students define cheating” (2004, p. 127).

To complicate matters further, statistical estimates of academic dishonesty seem to vary due to contexts (including education level and geography). For example in a recent survey of graduate students enrolled in 32 business programs in the United States and Canada, McCabe, Butterfield, and Treviño (2006) have reported that business students tend to cheat more than other graduate students: “Fifty-six percent of graduate business students, compared to 47 percent of their nonbusiness peers, admitted to engaging in some form of cheating . . . during the past year” (p. 299). The level of self-reported cut-and-paste plagiarism in
this survey, in turn, was “33 percent of the graduate business students . . . compared to 22 percent for nonbusiness students” (p. 300). A recent study conducted by the University of Guelph and co-administered by McCabe and Christensen Hughes (2006) has estimated that 53 percent of Canadian undergraduate students engage “in serious cheating on written work” (Gulli, Kohler & Patriquin, 2007). According to Christensen Hughes, “Serious cheating on written work includes copying a few sentences without footnoting, fabricating or falsifying a bibliography, or turning in a paper that someone else has written” (Cooper, 2007). To help put matters in a global perspective, a recent survey of British higher education conducted by Freshminds.co.uk (with the assistance of the JISC’s Plagiarism Advisory Service and the Center for Academic Integrity) found that “75 percent of respondents have never plagiarized.” This figure in turn approximates what Turnitin representatives have elsewhere estimated: in an interview for the student newspaper at University of California, Santa Barbara, Paul Wedlake, director of sales for iParadigms, the parent company of Turnitin.com, is reported to have claimed that “approximately 30 percent of all students in the United States plagiarize on every written assignment they complete” (Ray, 2001).

Regardless of the figures and statistics, the Internet very much lies at the center of the current fascination with plagiarism. As a result, the fundamentally ethical nature of the offense often gets confused with a technological one. As Patrick Scanlon of the Rochester Institute of Technology has acknowledged: “Plagiarism is not a technological problem—it’s a problem that has to do with ethical behavior and the correct use of sources. And it existed long before the advent of the Internet” (Hansen, 2003, p. 791).

Whether attributed to hype or misperception, plagiarism and the Internet remain entangled in the popular and the academic imaginations. The association is further reinforced by student study habits, especially their research practices. A recent Pew report found that “nearly three-quarters (73 percent) of college students” in the United States claim to “use the Internet more than the library” (Jones, 2002, p. 3). An even greater percentage of students no doubt resorts to the Internet for leisure—to game, surf, IM, and share music files. This reliance on the Internet for study and entertainment has blurred the lines between appropriate and inappropriate cyberpractice and has promoted the intentional as well as unintentional misuse of intellectual and creative property.

The Internet is not the sole source of undergraduate plagiarism. The current manifestation of the problem also can be attributed to non-technological developments, including the increased tendency among students and their parents (at least in the English-speaking world) to perceive higher education as a service industry. That is, the relegation of higher education to a service for which one pays has created a scenario in which students-as-consumers readily expect performance (in the form of good grades) as something to which they are entitled. This sense of entitlement, in turn, overrides concerns about academic honesty. Plagiarism, in this light, emerges as symptomatic of wide-ranging cultural shifts that are not simply or easily reducible to technological shifts and developments. Recent commentary on student plagiarism has provoked observations on this phenomenon. For example, Frank Furedi, professor of sociology at the University of Kent, has observed that “In the ‘customer-client culture’, degrees are seen as something you pay for rather than something you have to learn. It’s the new ethos of university life” (A Quarter of Students Cheating, 2004). This cultural shift and attendant “ethos” may very well lie at the root of the mis-recognition of plagiarism among undergraduates that McCabe has observed (Hansen, 2007, p. 777; McCabe, 2004, 127).

Another significant contributing factor to the rise of plagiarism is an educational culture that resists adapting its instructional methods in the face of advances in technology. This resistance
is forcefully demonstrated by the widespread adoption of plagiarism detection services. In an ostensible attempt to counter technology with technology, schools have settled for a punitive solution to what is a basically an instructional problem, and in doing so have escalated rather than engaged the problem. Turnitin, for example, adds each assignment submitted to its service to its databases. This ethically questionable practice of collecting content has been widely criticized as ignoring the intellectual property rights of students; the issue was raised several years ago by Howard (2001); it surfaced in 2003 at the center of a controversy at McGill University (McGill Student, 2006); more recently Mount Saint Vincent University in Halifax, Nova Scotia, has banned Turnitin for this reason (MSVU bans anti-plagiarism software, 2006); and high school students in suburban Washington, D.C., have protested their school’s subscription to Turnitin on the same grounds (Glod, 2006). In most of these cases, iParadigms has defended its product against this allegation. In a surprising move, however, the company recently took the issue into account when renegotiating its contract with the University of Kansas: “Because Turnitin.com retains student papers, the service has raised intellectual property and copyright issues … Turnitin.com addressed the issue by agreeing to remove papers from the database if requested by the KU Writing Center, which administers the service for KU” (Maines, 2006).

Intellectual property matters aside, the discourse of combating and surveillance that commonly attend the use and promotion of plagiarism detection technology seems ill-suited in an instructional setting. Colleges and universities, after all, have the luxury of privileging learning in their approach to problem solving. Recognizing that after-the-fact detection of plagiarism is a lost cause, faculty, educational technologists, and librarians at Colby, Bates, and Bowdoin jointly developed a plagiarism resource site that attempts to discourage student plagiarism through a program of instruction. The project takes for granted that plagiarism is an inescapable condition of learning. Such a view is by no means unique: Howard (1999, p. xviii), who has published widely on the subject, likens plagiarism to imitation: that is, while trying to find their own voices as writers, inexperienced students invariably adopt and imitate the voices of others and rarely in accordance with the scholarly conventions of attribution. With this view of the problem in mind, instruction would seem to be the desirable as well as the necessary solution to plagiarism. Many educators share this view, and few have been more vocal over the years than librarians, including Burke (2004).

Plagiarism certainly has caught the attention of instructors, librarians, and administrators, but students by-and-large continue to have a vague grasp of it. As Jackson (2006) recently discusses, “there is clearly evidence to support the notion that students, in fact, do not understand plagiarism and lack the necessary skills to avoid it … Many authors agree that students lack understanding of what constitutes plagiarism, how to properly paraphrase, what needs to be cited, and how to cite sources” (p. 420). The many acts of negligence or ignorance that constitute plagiarism also vary in degrees of magnitude: failure to observe accurately the rules for citing sources, for example, is a different order of offense than the inadvertent, unattributed incorporation of another’s language or ideas into a written assignment. These lapses, in turn, are potentially more easily remedied than the conscious, pre-meditated submission of another’s work or ideas as one’s own.

With this range of plagiaristic practices in mind, Howard (1995, pp. 799-800) has usefully identified three categories: outright cheating; non-attribution as a result of unfamiliarity with the conventions of citing sources; and “patchwriting,” or stringing together someone else’s language or ideas without proper attribution. The CBB plagiarism project seeks to promote instruction as the best remedy to help teachers and librarians prevent the last two categories of
plagiarism, which inexperienced students are especially prone to commit. Based on responses to the project’s instructional materials, these goals are being met. For example, Suffolk Community College has used the project’s online tutorial in library workshops on Understanding Plagiarism and Documenting Sources. Students there have found the tutorial helpful, and “they are always particularly interested to learn about the need to cite paraphrases” (Beale 2006). In a recent survey of an online tutorial on plagiarism, Plagiarism: The Crime of Intellectual Kidnapping, created by San Jose State University, Jackson (2006) has produced convincing evidence that “students need more instruction and practice with proper paraphrasing” (p. 426).

To achieve its goal of providing an instructional solution to plagiarism, the project takes full advantage of the Internet and responsible cyberpractice: its developers chose an open source content management system to store, manage, and publish resources; and its resources are freely available not only to be viewed and used via the WWW, but also to be shared, adapted, and re-published under a Creative Commons copyright license.2 The resources include a general overview of academic honesty, an introduction explaining different kinds of plagiarism, an online tutorial for testing one’s understanding of the various practices that constitute plagiarism, and dynamic examples of citations and paraphrasing. The project’s Web site also boasts a dedicated weblog that serves as a clearinghouse on all matters plagiaristic, including news items from around the world and notices on resources, tools, activities, and events concerning plagiarism in higher education. Taking advantage of Web syndication, the project’s weblog makes its content available via RSS feeds. As a result, anyone can import the project’s news updates into individual, departmental, or institutional Web sites or weblogs by means of prepared JavaScripts.3

The CBB Plagiarism Project promotes the responsible use, re-use, and re-purposing of its resources so instructors and librarians can address the problem of plagiarism at the level of local institutional practices, values, and concerns. While plagiarism undoubtedly is a global problem, its solution might best be sought at the local level, where definitions, policies, and expectations vary widely. The decision to publish content by means of a weblog has in retrospect leveraged a technology that has unexpectedly provided a reflective tool and medium for engaging plagiarism. A consideration of weblog practice and use, guided by the concept of plagiarism, provides a framework for understanding the instructional value of weblogs, especially their ability to foster and promote learning communities that discourage plagiarism.

ISSUES, CONTROVERSIES, AND PROBLEMS ASSOCIATED WITH WEBLOGS

Weblogs basically aggregate meta-data: that is, they compile information about information in the form of chronological postings and do not generally publish original content per se. More often than not, weblogs refer and link to other weblogs or Web sites, and the result is a highly interconnected network of communication. The resultant mode of disseminating information has reinforced certain practices that are commonly understood as plagiaristic. Researchers at Hewlett-Packard (HP) Labs have tracked the flow of information in what they call “blogspace” and have identified how ideas, regularly unattributed, spread among blogs (Asaravala 2004). The RSS feeds, moreover, that enable blogs to publish content in various ways are often understood as contributing to plagiarism because they allow unscrupulous users to capture content (specifically textual data) and re-purpose it without attribution. Dishonest practices aside, the HP researchers assert that the dynamic flow of information in blogspace has a generative function: individual weblogs “link
together” to create “a complex structure through which new ideas and discourse can flow.” The HP researchers, Adar, Zhang, Adamic, and Lukose (2004), conceive of the circulation of information among blogs as ultimately creative rather than iterative and original rather than plagiaristic. This interpretation of blogs isolates tensions that have attended the reception of the World Wide Web from its earliest days. Such tensions similarly inform cultural perceptions of our students’ use of the Internet. Their habitual cutting and pasting and sampling and repurposing are commonly dismissed as purposeless, narcissistic self-expression and are censoriously viewed as indicative of their disregard for intellectual and creative property rights and laws. In a recent article, Ellis (2003) productively has situated youth culture’s creative as well as plagiaristic practices in contemporary contexts.

High school and college students operate with the conscious or unconscious understanding (based on a lifetime of practice) that any content available on or accessible via the Web is public property and free. By re-using and re-purposing what they find online, students not only contribute to and reproduce a sub-culture founded on pastiche, but they also develop and acquire the transferable skills that Ellis (2003) suggests will enable those interested to join “the ever-growing ranks of knowledge workers in post-industrial economies.” There are drawbacks as well as benefits to what Ellis envisions as the evolving “new knowledge environment … chunks up human experience into multiple, cross-referenced nuggets dispersed in oceanic cyberspace. Stripped of our distinctively human purposes, the new knowledge environment is what George Trow famously called ‘the context of no context.’” This cutting adrift of knowledge results in its circulation without respect to historical or cultural contexts and creates a number of potential abuses and ethical problems—plagiarism among them. According to Ellis (2003), however, the “new knowledge environment” has some potential benefits that he describes in terms similar to the HP researchers’ description of blogspace: “This environment favors those who can apprehend the interconnectedness of things, create bridges and connections, spark associations and create the éclat of montage. . . . Social network analysis, network topology and other new perspectives are being framed to help us understand the ‘natural’ dynamics of this new environment.”

The dynamics of the blogosphere represent potentially exciting developments in cyber-communication, but they simultaneously revisit many of the criticisms commonly invoked to condemn the WWW. The Web is many things to many people: a commerce tool for business; a recruitment tool for new religions; a protest space for political activism; a play space for dedicated gamers; and so on. Regardless of its intended use or unintended abuse, the WWW has provided interested parties with a readily available means to publish content of all sorts, and its users have responded by taking advantage of its publishing capabilities: according to a recent Pew report, practically half (or 44 percent) of adult users of the Internet in the United States have created and published content (Online Activities and Pursuits, 2004). The value, usefulness, and originality of that content are an endless source of debate, and the popularity of weblogs has provided additional fodder for critics who question the informational and instructional value of the WWW.

Weblogs tend to promote a confessional mode of discourse that celebrates self-referentiality (McDonald 2004). This tendency has fueled the criticism that blogs have ushered in a new era of navel-gazing. The form and content of many personal blogs reinforce this view, but virtual personal diaries do not exhaust the uses and applications of blogs. Adar and Adamic (2005) have suggested that “beyond serving as online diaries, weblogs have evolved into a complex social structure, one which is in some ways ideal for the study of the propagation of information.” Their observation posits an interrelationship of information and its
circulation that previous scholars have variously noted—from McLuhan’s “The Medium is the Message” to Clanchy’s From Memory to Written Record to Brown and Daguid’s “The Social Life of Documents.”

In their approach to the interconnectedness of information and its circulation, Brown and Daguid (1996) have considered the ways in which “developing technologies” have historically “supported social relations in new ways.” A wide range of disciplines and historical examples inform their understanding. Enlisting Anselm Strauss’s notion of “social worlds,” Brown and Daguid (1996) describe a dynamic of group formation that can further the understanding of the culture of weblogs. Following Strauss, Brown and Daguid (1996) observe that “once formed, social worlds continually face disintegration (as dissenting members split off into ‘sub-worlds’).” The blogosphere seems largely populated by such sub-worlds that all too often appear to celebrate a community of one; that is, if one is viewing weblogs as repositories of content rather than as nodes within a network. The flow of information that populates many weblogs, as tracked by the HP researchers, establishes a social matrix that assumes both implicit and explicit communities. Dedicated weblog writers can be roughly divided into two main types: political bloggers and technobloggers. This overly simplistic distinction falls short of capturing the full range of representative blogging sub-worlds (edubloggers, for example), but it conveniently describes two influential communities of bloggers.

Drawing on the theory of the “imagined community” proposed by political scientist Anderson (1991), Brown and Daguid (1996) further consider the ways in which “‘popular’ cultural items, such as journals, novels, pamphlets, lampoons, ballad sheets, and so forth” contributed to the formation of national identity in the American colonies leading up to the Revolution. Citing daily newspapers, in particular, they point out that it was their widespread circulation and not just their content that helped foster Colonial America’s sense of nationhood. The similarities between newspapers and weblogs are instructive. Many observers have noted that blogs have greatly contributed to if not forever changed journalism. McDonald (2004), for example, understands blogging to be “a genuinely positive development in mass communication, and particularly in publishing and journalism.” He attributes the popularity of weblogging to its adoption by “the journalistic establishment.” I would attribute their popularity to their embrace by alternative journalists, especially the proliferation of “warblogging” in the aftermath of 9/11 and the subsequent events leading up to the U.S. invasion of Iraq in 2003.

Weblog pioneer and advocate Dave Winer, moreover, has speculated that newspapers will ultimately be replaced by weblogs as news sources in the not too distant future. This prediction is based in no small part on the publishing ability of weblogs, which has greatly extended the publishing capacity of the WWW. According to Winer, “In a Google search of five keywords or phrases representing the top five news stories of 2007, weblogs will rank higher than The New York Times’ Web site” (Long Bet).

SOLUTIONS AND RECOMMENDATIONS: BUILDING LEARNING COMMUNITIES VIA WEBLOGS

Blogs are powerful and flexible publishing tools: they publish content rapidly and easily; they provide an archive for content that is readily searchable by date, subject, or keyword; and they can also publish their content in a number of ways, including dedicated Web sites as well as RSS feeds that can populate other Web sites, weblogs, aggregators, e-mail clients, and Web browsers. That which has secured their popularity and wide reception (the rapid creation, publication, and circulation of information) also represents
their greatest potential for instruction. Librarians, technologists, and instructors can capitalize on blogs for making available a range of resources and information to targeted users—students, staff, faculty, and colleagues—both on their own as well as on other campuses. They can do so, moreover, with their own content or with content developed entirely by other institutions. This latter ability, importing content from elsewhere, demonstrates how blogs can reinforce the responsible and productive use and circulation of information.

The hallmark features of weblogs (the rapid creation and dissemination of content) are extremely useful for fostering learning communities whose members resort to various methods and media for instruction and information. Certain integral aspects of weblogs further promote their instructional potential. Weblogs have not only made publishing content easier but more social—they open content development up to a group by means of their ability to allow various levels of access to different groups of users; and they invite dialogue between creators and readers of content by permitting the exchange of comments within the blog as well as between blogs. Weblogs are dynamic in a couple of ways: the content posted on them changes as information is added and they allow users to interact by carrying on a dialogue. This dialogic aspect of blogs enables content developers to work towards breaking down the distinction between the creator and the user of content. This feature of blogs participates in the trend already discerned by Pew: that the consumers of Web content are also largely the producers of it.

**FUTURE TRENDS: ENGAGING PLAGIARISM VIA MULTIMEDIA**

The controlled dissolution of boundaries between producers and users of content (or between instructors and students, for that matter) has emerged as a valuable lesson of the CBB project’s use of a weblog. Successful instruction in plagiarism must strive to increase the awareness of the difference between the creation of new and the appropriate use of existing content. The project has sought to promote this awareness in practice by example and in theory by instruction. The content is freely available to be used and re-purposed according to an “Attribution-Non-Commercial-ShareAlike” Creative Commons Deed. The project developers have also sought to create learning objects that help socialize students into the culture of academics, which is founded on what Green (2002, p. 171) has described as the “norm of attribution.” Most teachers take for granted the scholarly conventions used to avoid plagiarism. Recognizing the profound difference that exists between the initiated and the uninitiated, the CBB Plagiarism Project has set out to provide students with guidance and instruction in the standards of academic integrity. In doing so, it strives to facilitate our students’ initiation into the norms and practices of the academic community.

Looking ahead to further development, the project’s next phase will involve creating a more adaptive learning environment for engaging plagiarism. While the weblog provides a valuable means to deliver, create, and respond to content, the text-based nature of that content may reinforce some of the limitations of online tutorials as instructional resources. Jackson (2006, pp. 423-26) has recently considered the effectiveness of plagiarism instruction online. By developing media-rich content about the subject (including audio, video, and animation), the project would create a range of resources that better suit diverse learning styles. In doing so, the project would be more responsive to the needs of its users and would further realize its goal of helping to integrate students into academic cultural practice.
CONCLUSION

An increased use and understanding of media in the curriculum, moreover, may very well allow faculty to harness the creative energies of students in a way that deals with plagiarism in both practical and theoretical terms readily understood by students. Current wisdom on how to avoid plagiarism has emphasized the need to rethink written assignments—for example, essays should be conceived of as ongoing processes consisting of specific, discrete stages or components, all of which are submitted for review, evaluation, and assessment, rather than a single finished product submitted in its entirety only once. In rethinking assignments, instructors may also want to begin to rethink what writing is and to encourage non-traditional forms of writing. I have in mind here the creation of fictional and non-fictional narratives, reports or accounts by means of multimedia—digital video and audio or computer animation and graphics or any combination of these and other media. Just as the weblog has emerged as a reflective tool for considering plagiarism, a media-rich learning environment would allow students to begin to understand plagiarism in new and perhaps more compelling ways. In a recent essay on plagiarism, the novelist Jonathan Lethem (2007) describes what it is like to be cut adrift in our contemporary media environment:

The world is a home littered with pop-culture products and their emblems. I also came of age swamped by parodies that stood for originals yet mysterious to me … I’m not alone in having been born backward into an incoherent realm of texts, products, and images, the commercial and cultural environment with which we’ve both supplemented and blotted out our natural world. I can no more claim it as “mine” than the sidewalks and forests of the world, yet I do dwell in it, and for me to stand a chance as either artist or citizen, I’d probably better be permitted to name it.

In the academy, students are encouraged to name and when appropriate cite their sources, influences, and inspirations. However, finding themselves, like Lethem, in a world already created and populated with signs, they need to learn how to negotiate the conventions and practices of that world and to decode its constituent signs. Educators should begin to make use of the multitude of media that figures our manifold experiences of the world. The energy and creativity generated by such a diversely constituted learning environment would permit powerful models for rethinking our engagement of plagiarism.

Chapter 3.17
Twin Wiki Wonders? Wikipedia and Wikibooks as Powerful Tools for Online Collaborative Writing

Suthiporn Sajjapanroj
Indiana University, USA

ABSTRACT
Web 2.0 technologies empower individuals to contribute thoughts and ideas rather than passively survey online content and resources. Such participatory environments foster opportunities for community building and knowledge sharing, while encouraging the creation of artifacts beyond what any single person could accomplish alone. In this chapter, we investigate the emergence and growth of two of such environments: the highly popular Wikipedia site and its sister project, Wikibooks. Wikipedia has grown out of trends for free and open access to Web tools and resources. While Wikipedians edit, contribute, and monitor distinct pieces of information or pages of documents, Wikibookians must focus on larger chunks of knowledge, including book modules or chapters as well as entire books. Several key differences between these two types of wiki environments are explored. In addition, surveys and interviews, conducted with Wikibookians, shed light on their challenges, frustrations, and successes.

INTRODUCTION
Thomas Friedman, in his 2005 book, The World is Flat, talks about 10 forces that have flattened the world in terms of economic globalization. The word “flat” acts as a metaphor to symbolize the “leveled” playing field on a global scale. In Friedman’s (2005) view, when the playing field is leveled, everyone can take part. And he means...
everyone! Talking from a business perspective, Friedman charts the progress of globalization from what he describes as 1.0 to 3.0. Globalization 1.0 focused on country to country relationships, such as treaties and trade. In Globalization 2.0, such relationships moved down to a company-to-company level. We are now entering an age of Globalization 3.0, where the rise of the individual comes into focus. It is in this third phase of globalization, wherein individuals obtain new powers and freedoms to participate socially, economically, politically, and educationally with others around the world. *Time Magazine* recognized this trend, and in 2006 named “You” as the person of the year (*Time Magazine, 2006/2007*). In effect, the Year 2006 signified the trend toward empowering technology users with what was called Web 2.0 technologies, which allowed individuals to generate ideas online instead of just reading and browsing through someone else’s Web pages (*Grossman, 2006/2007a, 2006/2007b*).

Lessig (2005) called this phenomenon the “read-write Web,” to contrast the read-only Web, where users were merely passive consumers of information. Most fundamentally, the read-write Web dramatically enhances the power of individuals, and fosters a participatory culture of building, tinkering, learning, and sharing (*Brown, 2006*). Typically included in Web 2.0 technology lists are wikis, podcasts, blogs, online photo albums, and virtual worlds such as Second Life. In particular, wikis offer an innovative mechanism of computer-supported collaboration. This highly unique social phenomenon utilizes armies of volunteers who work without pay, recognition, or much acclaim to continually contribute, update, or edit resources online (*Lin, 2006*).

In this chapter, we primarily offer insights into the recent emergence of two wiki developments; namely, Wikipedia and Wikibooks. First, we detail what a wiki is. Subsequently, we briefly review existing wiki-related research, and then document the emergence and growth of what is the most popular wiki today; Wikipedia. After presenting our research findings in Wikibooks, we compare and contrast some of the underlying principles and features of Wikipedia to those found in Wikibooks.

**BACKGROUND**

Brandon Hall (2006) defines a wiki as “a collection of Web pages that can be easily viewed and modified by anyone, providing a means for sharing and collaboration.” These are open-ended, generative, and unstructured environments (*Honegger, 2005; Leuf & Cunningham, 2001; Lio, Fraboni, Leo, 2005*). Pioneered by Ward Cunningham in 1995, wikis are online spaces for recording information, sharing knowledge, typically in collaboration with others. Each modification is recorded as the history of a document. The history page records the time of change, the person who made the change, and the changes that were made. Such a mechanism not only permits page retraction by anyone, it also behaves as a podium for reputation management. In addition, the history page permits open examinations of each revision, allowing each version to be compared and contrasted by anyone.

Many universities have picked up the wiki fever and started using its functions for information sharing. For example, Stanford has an institutionalized wiki wherein students can contribute information on places to eat, workout, study, socialize, and so forth. (*Campus Technology, 2006b*). As this Web site indicates, there is now a wave of student-contributed wiki resources. Similarly, MIT has created the Center for Collective Intelligence, where people from around the planet could come and solve huge scientific, social, and business problems (*Campus Technology, 2006a*). The underlying belief of these wiki projects indicates that, collectively, the human race can act more powerfully than it can at an individual level. As a prime example of this principle, in early February, 2007, Penguin books announced
“A Million Penguins,” a Web site “where people from around the planet will help write a novel” (Reuters, 2007). Similarly, in the academic world, faculty at MIT and Wharton School of Business invited thousands of individuals or potential authors to help write a collaborative online textbook at the site “We are Smarter than Me” (Campus Technology, 2007).

There is scant academic research on wiki technology and resources even though we are in the midst of a proliferation of wiki-based projects. In particular, the research on Wikibooks, which emerged with much enthusiasm in 2003 (Wikibooks, 2007a), is particularly thin. Some Wikipedia-related research has explored the accuracy of the content (Lih, 2004; Rosenzweig, 2006), historical flow visualizations of contributions (Viegas, Wattenburg, & Dave, 2004), the formality of the language used (Emigh & Herrring, 2005), hackers and trolls (Schachaf & Hara, 2006), contributions within collaborative authoring environments (Korfiatis, Poulous, & Bokos, 2006), differences between experts and novices (Bryant, Forte, & Bruckman, 2005), and cultural differences in Wikipedia contributions and editing behaviors (Pfeil, Zaphiris, & Ang, 2006). Such studies are, of course, just the starting point for a long line of research on wikis.

A BRIEF HISTORY OF THE BRIEF HISTORY OF WIKIPEDIA

Wikipedia is a free online encyclopedia to which anyone can contribute. Created in January 2001, Wikipedia started out as a side experiment of a failing project called Nupedia.com, created by Larry Sanger and Jimmy Wales, that also aimed to create a free online encyclopedia. However, Nupedia.com employed a traditional prepublishing review process that demanded an elaborate and often long procedure of coordination among submission, reviewing, and negotiation. Few articles were published as a result of this arduous process. Wikipedia was created as an experiment to bypass this prepublishing review process and empower the postpublication, real-time, peer-review procedure among volunteer collaborators (Ciffolilli, 2003; Voss, 2005).

Today, Wikipedia is perhaps the largest instance of a wiki. With easy to explore and open technology at its core, Wikipedia quickly became an online volunteer community with its devotion to the creation of a free encyclopedia where the division of labor is facilitated by information technology. That volunteer community now includes more than 50,000 individuals who have made at least 10 contributions to Wikipedia (Rosenzweig, 2006).

According to Alexa, a Web ranking service, as of February 7th, 2007, Wikipedia had become the 12th most visited Web site across all languages (alexa.com, 2007). During the past 6 years, Wikipedia has enjoyed tremendous, if not exponential growth in terms of registered users, number of articles, and number of languages. Not surprisingly, Wikipedia quickly overshadowed Nupedia.com and caused Nupedia.com to close in 2002. As of February 2007, the combined Wikipedia site included articles in 250 languages, 6.4 million articles, and almost 3.5 million contributors (Wikipedia, 2007d). The English language version of Wikipedia continues to be the largest site at more than 1,624,000 articles, while some other language versions remain quite small (Wikipedia, 2007b, Wikipedia, 2007c). There are more than 300,000 articles in German, French, Polish, and Japanese languages, with the German Wikipedia site now pushing over 500,000. This is an impressive amount of work to accomplish since inception 6 years ago. It is also quite obvious that a vast number of willing volunteers awaited just such an opportunity to contribute their time and knowledge.

Wikipedia’s exceptional growth was perhaps best captured and described by Voss (2005), who conducted one of the first quantitative analyses of the structure of Wikipedia. From the elaborated
numbers, charts, and mathematic formulas, Voss presented a comprehensive picture of the overall Wikipedia community. As would be expected, Wikipedia experienced a period of linear growth, while the more spiked or exponential growth that is often alluded to in the media did not occur until about 15 months after inception in April 2002. Since that time, the number of new articles in Wikipedia has increased at various speeds among different languages. Even though anyone with Internet access on this planet is invited to contribute to Wikipedia, according to the Voss study, the average number of authors per article remains four to five, a number that is perhaps much lower than most people would assume. Even more interesting is that about half (48%) of the articles had less than five authors and about one-third (28%) of the articles in German Wikipedia had only been edited by one author. In addition, one-third of the Wikipedia authors had only contributed one article, and just one in five Wikipedians had been involved in more than 16 articles. Granted that Voss excluded anonymous edits in his calculation, these numbers indicate that not everyone will contribute, or at least continue to contribute, just because they can.

In summary, then, the Wikipedia community has the following characteristics. It is a volunteer-based project to which everyone can contribute. Wiki technology facilitates certain divisions of labor, enables the ease of contributing and participation, and records all change histories for easy examination and recovery. It is a rapidly growing community where authority is gained through individuals’ active participation. Its social structure does not necessarily recognize people based on their expertise, even though it does employ a promotion mechanism for various roles in the community. Positioning itself as an encyclopedia, Wikipedia inherits the perception of being a reliable reference source. However, its credibility continues to be questioned.

**WIKIBOOKS AND OTHER WIKI SITES**

Sister projects to Wikipedia coordinated by the Wikimedia Foundation include Wikibooks, mentioned previously, as well as Wikispecies, Wikiquotes, Wikinews, Wikiversity, Wiktionary, Wikisource, Commons, and Meta-Wiki. Wiktionary, for instance, is a free, community created online dictionary and thesaurus with more than 300,000 entries in nearly 400 different languages (Wiktionary, 2007). Wikiquotes contains an index of thousands of quotations from famous people from Laozi, William Shakespeare, Aristotle, Helen Keller, and Martin Luther King, as well as from literacy works, television shows and movies, news pages, and other creative efforts (Wikiquotes, 2007). Wikinews, like other online news services, contains current events making headlines. But as folks like Rosenzweig (2006) point out, it often can break leading stories before the other news services since its reporters cover the planet.

In our own work, Wikibooks has been the primary focus. The Wikibooks Web site, originally named the Wikimedia Free Textbook Project and Wikimedia Textbooks, was initiated on July 10, 2003 (Wikibooks, 2007a). It was the brainstorm of Karl Wick, who was searching for a place to host his books on organic chemistry and physics as a means to bring such educational resources to the people of this planet while addressing the high costs and other limitations of existing books and materials on these topics. By the end of that month, there were 123 modules or chapters posted and 47 registered users at that site. Two months later, there were 530 modules and 150 registered users. Since it began, controversies and criticisms have been posed regarding the scope of the Wikibook project, copyright and licensing issues, the quality of the books posted, and the large number of unfinished book projects.
The coordinator of one or more Wikibook projects is called a Wikibookian. Given that in less than 4 years Wikibooks has become a collection of over 1,000 free online book projects containing more than 20,000 modules or chapters (Wikibooks, 2007b), there are many active Wikibookians. The Wikibooks Web site contains collaboratively written textbooks and nonfiction books, study guides, and booklets are socially negotiated documents. There are both books for adult learners as well as the more recent emergence of junior books for younger learners, ages 8 to 11 (Wikibooks, 2007c) (see Figure 1). The junior Wikibooks site is currently creating full-color booklets on topics such as bugs, big cats, the kings and queens of England, and dinosaurs.

Such environments offer hope for someday providing access to educational books, study guides, and other documents to every connected learner and in any language. Nevertheless, there are myriad issues, questions, and problems related to online collaboratively authored books, such as...
Twin Wiki Wonders?

as those found at the Wikibooks site, that need to be better understood. Figure 2 depicts the key aspects of the Wikibook environment.

Studying Wikibookians

During a 4-month period in early 2006, we observed how Wikibookians communicated and shared ideas with each other. Based on our observations and literature review, we designed a close-ended survey that encompassed basic demographic data, as well as a set of questions geared toward issues involved in the process of creating a Wikibook from a sociocultural point of view (Bruns & Humphreys, 2005). Through communication channels frequented by active members, we obtained a user list providing around 45,000 Wikibookian's names who had previously registered an account at the Wikibook Web site. Using this list, in the spring of 2006, we randomly sent survey invitations to around 1,500 Wikibookians whose status was shown as active via the contacting function found at the Wikibook Web site. Using this list, in the spring of 2006, we randomly sent survey invitations to around 1,500 Wikibookians whose status was shown as active via the contacting function found at the Wikibook Web site. We used an online survey tool, SurveyShare, to distribute the survey and collect the data. We received 80 responses to our survey. Ninety percent of the survey respondents had been active in Wikibooks for more than 6 months, 72% for more than one year, and nearly one-third for 2 years or more. In addition, 82% were under age 35, 97% were men, and more than half did not have a four-year college degree (Sajjapanroj, Bonk, Lee, & Lin, 2007).

After tallying the surveys, we randomly selected 15 people from the survey respondents for follow-up e-mail interviews. The e-mails were sent in July 2006, and eight Wikibookian participants joined this part of the study. Participants were asked to answer a 12-question e-mail interview related to how they had started in Wikibooks, previous experiences in such an online collaboration process, the future of Wikibooks, advantages and disadvantages of this environment, whether an online book could ever be complete, and suggestions for improvement.

FINDINGS

The survey and interview data helped us understand the challenges, frustrations, and successes of Wikibookians. From the 8 participants and 12 e-mail interview questions, five key themes emerged. These themes were as follows:

1. The expression of authority in Wikibooks
2. The nature of collaboration process in Wikibooks
3. Completeness and success of one’s Wikibook project
4. Advice to Wikibook wannabes
5. The future of Wikibooks

The following sections describe the themes and present the different views participants offered. Based on these findings, as well as existing wiki literature, we offer a comparison of the Wikipedia and Wikibook environments.

The Expression of Authority in Wikibooks

Authority

Working on a wiki as an editable Web platform could be rewarding and challenging at the same time. The number one critique of Wikipedia has been its authoritative value. It is not surprising that such questions and concerns about authority also appeared in our Wikibook findings. Some participants seemed to disregard the traditional view of an “expert” or authority:

...people can work together on a wiki and come up with a result that is better than something written by one or a couple of “experts.” ...There is not one
person in charge who can make the hard decisions that everyone will respect. (Participant 1)

Nevertheless, some seemed to also demand the skill of “experts” in order to create a good quality book:

I expected it to be not very effective, as it’s hard to let people work together at all, especially on this large amount, and even more when it’s spread over multiple pages with a special subject. You should need at least two specialists, as both have to understand the subject very good. That appeared to be hard indeed. (Participant 6)

Wikibookian views about community or multiple contributor authority over the knowledge of “experts” revealed the nontraditional belief that each one of us possesses our unique knowledge that could contribute to the creation of a Wikibook. On the other hand, there seemed to be a demand for such knowledge to be able to qualify at an acceptable level as an expert.

Control

If looking at the issue of authority at a deeper level, we further discovered the concerns regarding control over contribution. Who has the right to contribute? Who can decide who has the right to contribute? Who can decide whose contribution is superior to others? In other words, is it true that in the world of Wiki, everyone stands equally? Certainly some did not believe so:

The biggest problem I see are the control guilds that have sprung up. They can be the Christian groups, or the anti-metaphysicists that go around labeling everything pseudoscience because they lack the ability to see the difference between the two. (Participant 2)

Most participants addressed the issue about control over contribution from the perspective of being able to monitor changes. For instance, Participant 7 wrote to us about the importance of being able to “track the contributions and changes of each contributor.” Participant 3 elaborated further:

I think the fact that Administrators monitor the content and make sure that if it is inaccurate or copyright protected that it cannot be posted is a very important aspect of WikiBooks/Wikipedia that should be emulated by others. (Participant 3)

One other aspect of control over contributions surfaced as well. As shown in the following quote, Participant 6 expressed the desire to create a temporarily safe environment during the creation of a Wikibook:

Make a special area where one set group of people can take over a book for a time, for example, to enable one class or one group of professors to develop materials in a protected environment where, at least for a time, they have the final authority of whatever happens in that area. (Participant 6)

As indicated, Participant 6 believed that having authority even for a period of time was deemed important. Participant 4 shared that “the biggest disadvantage is a sacrifice in control over the direction of the book,” which seemed to indirectly echo Participant 6’s point. Here, the control issue seems to center on setting the overall goal of the book and the initial creation of the first draft.

As demonstrated, even though most participants did not directly bring up the question about control, through interview excerpts, we observed how multiple dimensions of authority were realized among Wikibookians. Our survey data indicated that an overwhelming majority of the surveyed Wikibookians believed that Wikibooks promote individual accountability in terms of one’s contributions to an online book project (15% strongly agree, 54% agree). However, still
31% of them disagreed that individuals could be held accountable for the accuracy of contents contributed. It is not surprising to see that Wikibookians wrestled with these questions, which leads to the next section about how Wikibookians collaborate.

The Nature of Collaboration Process in Wikibooks

Coordination

Working in a Wikibook project requires coordination, communication, an understanding of the collaborative writing process, and a great deal of time management. In particular, Participant 4 shared many of his perspectives about the inner workings of a Wikibookian and the process of Wikibook creation:

Development has been slower than expected. I expect to be able to finish the book...in about two years.

My experience has been that Wikimedia projects promote much more formal rules of etiquette, but a much less structured writing process.

Maintaining a wiki is much more a challenge for social issues than for technological issues. Above all, a collaborative writing community must have a common vision, specifically a vision to create a written work.

Interestingly, he suggested that software be created that makes it easy to post a positive contribution and more difficult to post something negative.

Communication

Clearly, issues about communication stood out in many of the Wikibookian observations and suggestions. Some of the comments included:

Coordination is key. So [is] communication between editors, contributors, etc. is important. It must also be easy to use, fast and one must quickly be able to see what was changed, who changed the document and if necessary, change it back. (Participant 8)

Collaboration

The concept of a wiki assumes a collaborative process. While many participants clearly showed their agreement, two indicated their disappointment when no other took interest in their book:

I also hoped that collaborators would take an interest in the book as it developed. Although there have been isolated contributions, no one else has taken an interest in making a real investment in the book. I still hope this will eventually happen. (Participant 4)

My expectation was to help create a free, collaboratively written textbook. At this point I have done almost all of the work on the book. Admittedly, word about the book hasn’t gotten out, but hopefully once it does others will begin to contribute. Until that happens, my expectations will not, technically, have been met. (Participant 7)

Resolving Disagreements

Even though some seemed to be lone writers, disagreements are bound to happen when working with strangers from around the world. We asked the Wikibookians about how they resolved differences. Again, communication provided the bridge to reconcile different opinions, including mechanisms such as the talk page, a mediator, private message, or revert the changes. However, Wikibookians differed in how they would approach or resolve the differences. As the following quotes indicate, some would revert the changes, some would discuss them first, and still others
did not know since they had yet to experience such situations:

So revert it :) It’s a Wiki, so everybody can edit it. When s.o.’s edit doesn’t apply to my standards, I can revert it. And that person can revert me too. When we both find it important, we can start talking through the talkpage, and in the end, maybe get a mediator, or ask the community what they think about it. (Participant 1)

This happens frequently. I usually either talk to them via the “Talk” pages or send them a private message regarding the change(s) if they are not an anonymous user. I leave or qualify their changes if they are correct, but if not, I may revert them back to their original form. (Participant 3)

Perhaps such quotes reflect the degree of expertise of the Wikibookian. Byrant, Forte, and Bruckman, (2005), for example, found that expert Wikibookians have a policy not to revert changes or additions in Wikipedia if at all possible. They tend to post their concerns to the talk page first.

From the nature of the collaboration process, we see the complexity of not only the communication process among authors, but a philosophical question about the definition of a finished Wikibook emerged. As an emerging phenomena, Wikibooks draw interest and attention, especially for their education and self-learning value.

**Completeness, Success, and Happiness Regarding One’s Wikibook Project**

**Wikibook Completion**

Given the comments and concerns about the quality of Wikibooks and length of time to complete them, it was important to ask Wikibook contributors about Wikibook completion and overall successes experienced. Using all the methods mentioned here, will the revision process ever be completed? In other words, will a Wikibook ever be finished? We raised this question to all of our participants and had rather interesting findings. In our survey responses, nearly 60% of Wikibookians indicated that a Wikibook could be completed. However, as the following quotes exemplify, respondents to our interview questions were quite varied in their opinions regarding online book completion:

It will probably depend on the subject. When you will try to explain a limited subject, it can theoretically be complete. However, it will be hard to have it finally completed indeed. (Participant 1)

No wiki is ever complete, because it is ever evolving. That’s one of the best things about wikis. I personally think that paper is dead and in many ways the ideas contained within them too. I want my ideas and thoughts evolved and allowing others to improve them makes the work alive. (Participant 2)

Wikibooks can eventually become “complete,” when the authors decide that there is no more to write...so a book is substantially complete once the last “proper” author leaves....It is by dedicated writers that books are written, not casual one-sentence contributors or people who drop in for an afternoon. (Participant 4)

As demonstrated, some Wikibookians thought that completion of the book would naturally be indicated by participant interest in the topic or the scope of the project. One Wikibookian explained that “I think a Wikibook becomes complete when the participants loose interest in the topic.” On the other hand, another Wikibookian suggested that a Wikibook could be complete if all the relevant information on a topic was included or known such as the “Iran-Contra scandal of the early to mid 1980s.” Overall, however, there was some
agreement that a Wikibook is not as a product but a process, because a Wikibook is always evolving and “allowing others to improve them makes the work alive.” From this notion, a more refined question surfaced: who decides whether a Wikibook is finished? Can we say a Wikibook is finished when nobody is contributing to it anymore?

**Wikibook Success and Happiness**

According to our online survey, most Wiki-bookians felt that their Wikibook was a success (see Figure 3). We did not, however, ask what determines that success. This issue relates back to the previous one regarding completion; if Wiki-bookians focus on the process and not the final product, then success is an extremely fleeting concept. At the very least, success is then focused on social interaction and collaboration processes, instead of simply on the quality and use of the final document.

Some Wiki-bookians seem truly inspired by the Wiki-book process and working in any type of wiki environments. For example, Participant 1 simply stated, “Go rockin’ on!” when asked for additional comments, while Participant 2 noted, “I love wikis they’re truly the closest example of the purest form democracy.”

**Advice to Wiki-book Wannabes**

**Technology Skills and Realistic Goals**

Obviously, a Wiki-bookian needs to have the necessary technology skills to operate within a wiki environment. Beyond technological savvy, understanding the magnitude of creating a book and setting realistic goals could help start one on the right foot:

*A little bit is better than nothing, it can always be improved later. Often times there is no book for a topic because everyone thinks “Oh, someone else will make it.”* (Participant 6)

*Get help. Don’t try to do it on your own, it’s a too big amount of work and you will definitely loose the overview.* (Participant 1)

---

![Figure 3. Wiki-bookians perceptions of Wiki-book success](image-url)
Wikibooks are Demanding

As the following quote from Participant 5 indicates, experienced Wikibookians also warned us about the difficulty of chapter organization:

*I'd suggest getting several coauthors from the get go and deciding on a template for the book chapters so it is uniform from the beginning. It's bound to change over time, but you may as well start with a plan. Also, I'd mention that, for the most part, they shouldn't expect many people to contribute to the book. Writing a book is challenging; most people will never attempt it.* (Participant 5)

In addition to getting the flow and direction of the book, Participant 4 advised us the importance of understanding the book-writing process. In this opinion, joining an existing book might be the best way to become involved in Wikibooks:

*I would first offer a warning that writing can be very difficult. Writing a textbook is an involved task, demanding the full scope of your expertise, and requiring a substantial investment before any payoff can be realized. Yet it's extremely rewarding......I would encourage users to consider working on an existing book rather than starting a new one. Starting off with a more manageable goal will let a user test the water without making a big commitment.* (Participant 4)

Wikibooks are Different from Wikipedia

Most Wikibookians seem to have initial wiki backgrounds from editing or contributing to Wikipedia. They may have shifted to Wikibooks on the advice of others that their textbook-related ideas belonged in Wikibooks not in Wikipedia. Still, their prior history in Wikipedia shaped their expectations. Among all the suggestions, Participant 5 brought up the idea that involvement with a Wikibook is different from working on a piece of an article in Wikipedia:

*I think authors have to make concepts before they write a book and think about it, because it's not only an article like in Wikipedia.* (Participant 5)

As a result of this difference, in order to work in a Wikibook, more communication, organization, and compromise is required. Participant 3 shared with us his view about how Wikibooks are different from other collaborative productions:

*I expected WIKIBOOKS to be more in-depth about specific subject areas and to provide more details than Wikipedia articles. In the case of video games, for example, I expected WikiBooks to provide background stories and walkthroughs.* (Participant 3)

Future studies might explore the need for additional planning processing and tools within Wikibooks. Would outlining and planning tools, for instance, enhance the final product and the percentage of Wikibooks that are, in fact, completed? These and other differences between Wikipedia and Wikibooks are explored later on in Table 2.

The Future of Wikibooks

We were interested in how these experienced Wikibookians viewed the future of their Wikibook work. Based on their experience, did Wikibooks even have a future? And what tools and features might enhance it? As Participant 6 rightfully pointed out, the spirit of a wiki aims to “make the world a juster place by putting the tools of education into the hands of every person.”

Future Growth and Success of Wikibooks

Some seemed concerned about the lack of reader interests at this early stage of Wikibooks:
Twin Wiki Wonders?

It’s difficult to tell at this stage. Wikibooks is faced with a sort of “chicken and egg” problem -- it needs readers to attract writers and writers to attract readers. The project will recruit more and more talented writers as it picks up steam, and will have better and better books in its library. ... But Wikibooks may never take off at all. ... (Participant 4)

The so-called “chicken and egg” issue was shared by Participant 1, who believed Wikibook will be either successful or die. As he stated, “There is no ‘some people will use it.’ Because when you want your book to become used, it has to be used by a large amount of people, not by a few.” He also felt that a single dedicated person could make a huge difference in determining the ultimate success or failure of Wikibooks. “Now that is some incentive to participate!”

Then the next logical question arises. Why do few people use the books at the Wikibook Web site? Is it because “there has not been an example yet of a book that goes all the way through and is put into use” or perhaps it is because “People have not seen it work enough for them to believe in it, and there are not mechanisms in place that convince educators of the value of Wikibooks as a teaching or learning tool?”

Academic Acceptance

In their responses to our online survey questions, Wikibookians seemed to strongly believe in Wikibooks as an online library (64%), a learning tool (40%), and a supplement to classroom or training resources (36%). In addition, it was a place for communities of writers (60%) and learners (34%) to form. However, making Wikibooks a teaching and learning tool and enabling the educational community to embrace it proved a difficult task. Academics might be the largest potential users of Wikibooks; they might hold the key to Wikibooks’ success. The following quotes indicate the shared concerns and hopes of Participant 6 and 7:

I don’t think the concept will catch on except among small niches until there are some very well-developed textbooks available on the site. If academics turn to using it regularly for free introductory textbooks, Wikibooks could explode with interest. But we aren’t there yet. Maybe in the next 5 years or so. (Participant 7)

This is a very valuable project with very important goals, and any educator who is able to contribute a bit or to draw his or her students or colleagues into the process will be doing groundbreaking work in education which is worthy of praise. Things can only continue to go up from here. (Participant 6)

FUTURE TRENDS

Each of the previously mentioned themes provides interesting data for further wiki-related research and development; especially that related to Wikibooks. Table 1 summarizes our major findings according to the five themes.

COMPARING WIKIPEDIA AND WIKIBOOKS

As indicated in the literature review, there are many distinct differences between Wikipedia and Wikibooks. As shown in Table 2, they differ in terms of the types of communities that they foster, the resources created, size of user community, technology supports required, the goals and needs of both experts and novices, and many other variables.

FUTURE RESEARCH DIRECTIONS

After their birth in 1995, wikis proliferated quickly into the mainstream of human life. From users’
**Table 1. Key themes from interviews with Wikibookians**

<table>
<thead>
<tr>
<th>Theme 1: The Expression of Authority in Wikibooks</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Authority:</strong> Each one of us possesses unique knowledge that could contribute to the creation of a Wikibook.</td>
<td>“not one person in charge”  &lt;br&gt;“need at least two specialists, as both have understand the subject very good”</td>
</tr>
<tr>
<td><strong>Control:</strong> Some liked to be able to monitor changes and most believed in personal accountability.</td>
<td>“When a lone writer is trying to open people’s minds to the reality of things and closed minded indoctrinated individuals that in all reality could be a 13 yr old who has been given admin powers can be judge and jury over your work..”</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Theme 2: Collaboration Process in Wikibooks</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Coordination:</strong> Writing a Wikibook together might be more of a social issue than a technical one.</td>
<td>“Above all, a collaborative writing community must have a common vision”</td>
</tr>
<tr>
<td><strong>Communication:</strong> Communicating among writers proved essential.</td>
<td>“…requires communication in order to get the project off the ground and into something tangible…”</td>
</tr>
<tr>
<td><strong>Collaboration:</strong> Finding someone else who is also interested in your book might not be so easy.</td>
<td>“…there have been isolated contributions, no one else has taken an interest in making a real investment in the book…”</td>
</tr>
<tr>
<td><strong>Resolving Disagreements:</strong> One would revert the changes, some would discuss them first, and still others did not know since they had yet to experience such situations.</td>
<td>“I usually either talk to them via the ‘Talk’ pages or send them a private message regarding the change(s) if they are not an anonymous user.”</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Theme 3: Completion, Success, and Happiness Regarding One’s Wikibooks</th>
<th></th>
</tr>

<tbody>
<tr>
<td>8. Technology Tools, Features, and Resources</td>
<td>Tools for tracking the history of document changes, talk pages, edit pages, hyperlinking, lounges, site statistics, and so forth.</td>
<td>Same tools as Wikipedia but could also use book planning, outlining, and overview tools, enhanced discussion tools, mark-up and commenting tools, enhanced tracking of book contributions and contributors, and ways of fostering collaboration and interaction among those in a Wikibook project.</td>
</tr>
<tr>
<td>10. Qualification and Participant Filters</td>
<td>None, open to all to contribute or edit a document.</td>
<td>None, open to all to contribute or edit a document.</td>
</tr>
<tr>
<td>11. Novices</td>
<td>Wikipedia is more of a collection of articles with random people adding information here and there, then as a way to communicate, collaborate, and protect good work (Bryant, Forte, &amp; Bruckman, 2005).</td>
<td>Wikibooks is a collection of books to which one can contribute to or read.</td>
</tr>
<tr>
<td>12. Experts</td>
<td>Wikipedia is a community of coauthors who use their talents to help establish and maintain the quality of Wikipedia; Wikipedia is more important than any single article or set of articles or resources (Bryant, Forte, &amp; Bruckman, 2005).</td>
<td>Wikibooks is a place wherein one can coordinate a book project that can contribute to the movement of making open knowledge more accessible.</td>
</tr>
<tr>
<td>13. Generation, Distribution, and Maintenance of Ideas</td>
<td>Many to many.</td>
<td>One to many as well as many to many.</td>
</tr>
<tr>
<td>14. Speed of Content Development</td>
<td>Tends to be fast. Assisted by a huge army of volunteer contributors as well as by news and media features or stories. Tends to be fast.</td>
<td>Tends to be relatively slow. Book projects take longer than Wikibookians often expect; many incomplete or unfinished books and resources (Sajjapanroj et al., 2007).</td>
</tr>
</tbody>
</table>
Twin Wiki Wonders?

perspectives, wikis offer common knowledge resources, whether they be dictionaries, encyclopedias, books, or sets of morals, fables, and quotes. At a basic knowledge level, then, wikis provide community-driven access to information resources when needed. From a contributing writers’ viewpoint, on the other hand, wikis are a penultimate example of collaboratively written and socially negotiated texts. Contributions in a wiki can be small pieces of information or media for a presentation, train schedules for a trip to the UK, places to eat at the riverwalk in San Antonio during a conference, and synonyms for a word being defined in Wiktionary. At the same time, they might also be entire chapters or modules of a book or an entire book as in the case of Wikibooks.

As the scope of wiki-work increases from an informational focus at the word, sentence, or paragraph level, as is often the case in Wikipedia or Wikiquotes, to something much more substantive, as in the case of Wikibooks or other online book sites, the problems, issues, and challenges also significantly change. The same wiki tools, approaches, and procedures that work so effectively for Wikipedians may not to be sufficient for Wikibookians. In addition, the level of expertise required to help write a book is at a higher level of specificity and depth than most arriving at a wikibook type of site would likely have. At the same time, the communities of practice that form around such a book have to negotiate issues of chapter coherence, book organization, and topical relevance that those in other types of wiki-related sites do not typically need to consider. Such issues place serious challenges as well as opportunities in the face of wiki researchers as well as designers of new generations of wiki-related technologies.

CONCLUSION

As we pointed out in this chapter, wikis offer a unique window into knowledge negotiation and collaboration processes. The coming decade will undoubtedly witness new tools and resources to track and better understand such negotiation and interaction processes. Now is the time to begin organizing a set of research initiatives, agendas, and questions that will allow for responsive research that helps in the formation of new tools, as well as enhances understanding of the power of wikis. Wikipedia and Wikibooks and many other wiki sites are wondrous tools and resources for twenty-first century working, learning, and living. With these wiki wonders, YOU can now all participate in the human race in new and exciting ways! Engage.

Chapter 3.18
Wikis as Tools for Collaboration

Jane Klobas
Bocconi University, Italy, & University of Western Australia, Australia

INTRODUCTION

Tim Berners-Lee, the inventor of the World Wide Web, envisioned it as a place where “people can communicate … by sharing their knowledge in a pool … putting their ideas in, as well as taking them out” (Berners-Lee, 1999). For much of its first decade, the Web was, however, primarily a place where the majority of people took ideas out rather than putting them in. This has changed. Many “social software” services now exist on the Web to facilitate social interaction, collaboration and information exchange. This article introduces wikis, jointly edited Web sites and Intranet resources that are accessed through web browsers. After a brief overview of wiki history, we explain wiki technology and philosophy, provide an overview of how wikis are being used for collaboration, and consider some of the issues associated with management of wikis before considering the future of wikis.

In 1995, an American computer programmer, Ward Cunningham, developed some software to help colleagues quickly and easily share computer programming patterns across the Web. He called the software WikiWikiWeb, after the “Wiki Wiki” shuttle bus service at Honolulu International Airport (Cunningham, 2003). As interest in wikis increased, other programmers developed wiki software, most of it (like WikiWikiWeb) open source. Although wiki software was relatively simple by industry standards, some technical knowledge was required to install, maintain and extend the “wiki engines.” Contributors needed to learn and use a markup language to edit pages, and even if the markup languages were often simpler than HTML, non-technical users did not find these early wikis compelling.

In the early years of the twenty-first century, a number of developments led to more widespread use of wikis. Wiki technology became simpler to install and use, open source software was improved, and commercial enterprise-grade wiki software was released. The not insignificant issues associated with attracting and managing a community of people who use a wiki to share their knowledge were discussed in forums such as MeatballWiki (http://www.usemod.com/cgi-bin/mb.pl?action=browse&id=MeatballWiki&olid=FrontPage). The public’s attention was drawn to wikis following the launch, in January 2001, of the publicly written Web-based encyclopedia,
Wikipedia (www.wikipedia.org). And wiki hosting services and application service providers (ASPs) were established to enable individuals and organizations to develop wikis without the need to install and maintain wiki software themselves.

By July 2006, nearly 3,000 wikis were indexed at the wiki indexing site www.wikiindex.org, popular wiki hosting services such as Wikia (www.wikia.org) and seedwiki (www.seedwiki.org) hosted thousands of wikis between them, and Wikipedia had more than four and a half million pages in over 100 languages. Moreover, wikis were increasingly being used in less public ways, to support and enable collaboration in institutions ranging from businesses to the public service and not-for-profit organizations.

**THE NATURE OF WIKIS**

Wiki software allows users to collaboratively edit pages for the Web or intranets. The pages created with wiki software are called “wiki pages” and sites that contain wiki pages are called wiki sites, or simply “wikis.”

Technically, wikis consist of four basic elements:

- Content
- A template which defines the layout of the wiki pages
- Wiki engine, the software that handles all the business logic of the wiki

**Figure 1. How wikis work (Adapted from Klobas & Marlia, 2006)**
Wikis as Tools for Collaboration

- Wiki page, the page that is created by the wiki engine as it displays the content in a browser.

Figure 1 shows how these elements work together.

Wikis consist of pages accessible from a Web browser. They are edited by opening an editing screen in the browser and using either a simple markup language or, increasingly, a rich text editor to edit the text. Links to pages internal or external to the wiki site can be added using simple conventions. These conventions allow a link to be created to a page that does not yet exist; the wiki engine flags such links for future editing. Unless the wiki managers decide otherwise, the content is updated in real time, and once an author saves and closes their changes on the editing screen, the changes are immediately visible online.

Almost all wikis keep track of changes. Older versions of a page can be viewed and, if necessary, restored. Most wikis include a page where recent changes are listed. This feature helps members of the wiki community to keep up to date with changes in content, and can help newcomers get a quick feel for the current concerns of the wiki community. Increasingly, wiki software is integrated with news aggregators like RSS or e-mail notification to alert users to changes without their having to enter the wiki itself.

Another important feature of wikis is the simple permissions structure. Typically, there are three levels of permission: reader, editor, and administrator. Reading permissions may be open to anyone on the World Wide Web or limited to specific, registered individuals. When reading permissions are limited, the wiki is known as a "private wiki."

Various wikis offer support for non-Latin character sets, different media and file types, mathematical notation, style sheets, conflict handling, spam handling, and facilities for merging, exporting and backing up. The different features available in different wiki engines can be seen at the wiki engine comparison site, WikiMatrix (www.wikimatrix.org).

Wiki features are based on design principles established by Ward Cunningham. These principles address human as well as technical goals, for example (in the terms used by Wagner, 2004), wikis are:

- **Open:** If any page is found to be incomplete or poorly organized, any reader can edit it as he/she sees fit.
- **Organic:** The structure and content of the site evolve over time.
- **Universal:** Any writer is automatically an editor and organizer.
- **Observable:** Activity within the site can be watched and revised by any visitor to the site.
- **Tolerant:** Interpretable (even if undesirable) behavior is preferred to error messages.

Wikis usually adopt “soft security,” social conventions that assume that most people behave in good faith, establish that users (rather than the software or a system administrator) operate as peer reviewers of content and behavior, allow that people might make mistakes but that mistakes can be corrected, and emphasize the importance of transparency in their management (Meatball, 2006). Together, these technical features and social principles provide a supportive environment for human collaboration.

**HOW WIKIS ARE BEING USED FOR COLLABORATION**

Wikis are used by groups of people who collaborate to produce information resources that range from meeting agendas to Web sites. They are used in business, government, research, and education.

Public wikis are often built by communities of practice, hobbyists and other interest groups.
Most of these wikis are concerned with quite specific topics such as a specific sport, book, author, religion, or philosophy. Often, they are maintained and read by small groups of friends and colleagues. An example is ukcider, a wiki that provides information about real cider (http://ukcider.co.uk/wiki) and supports advocacy for real cider enthusiasts and small producers.

Wikis can be used to create and maintain knowledge repositories for communities of practice (Godwin-Jones, 2003; Roberts, 2005). Members of the community update the repository with information and solutions to problems. As with other types of wiki, the communities served might be public or private. Potential uses of private wikis to increase autonomy among US intelligence workers were described by Andrus (2005).

Committees and working groups, particularly those that work across institutional and/or geographical boundaries, use wikis to develop and maintain agendas and documentation. The DCMI Education Working Group Wiki (http://dublincore.org/educationwiki), for example, contains work plans, FAQs, agendas, notes, documentation, and links to key references for the group.

A common organizational use of wikis is project support (Bean & Hott, 2005). Wikis are used to support the sharing of agendas, ideas, resources, plans and schedules. Documents can be jointly produced within the wiki or made available as attachments. Angeles (2004) describes how wikis have been used by Lucent Technologies for project documentation including preparation of meeting notes, product specification notes, product requirements documents, project deliverables, content audits, technical documentation, and style guides. Other companies that use wikis for project support include Michelin China and the investment bank, DrKW (Paquet, 2006).

Wikis are also being used to write and maintain system documentation. A public wiki has been developed by Mozilla, the provider of the Firefox Web browser, to maintain Mozilla product documentation (http://kb.mozillazine.org). Any member of the public can contribute. Some companies have established private wikis to maintain documentation for their internal information systems (IS). Users contribute to documentation based on their experience with the system.

Organizations and groups can use wikis to produce reports of news or events. Schools, in particular, appear to be experimenting with this type of wiki, in which parents, teachers, administrators, and students can all contribute reports, photographs, audio and video of a school event.

Some groups use wikis to plan conferences or meetings and to continue discussions that were begun at a meeting. Examples include the American Library Association (ALA) 2006 Conference wiki (http://meredith.wolfwater.com/ala2006/) and the Yale Access to Knowledge wiki (http://research.yale.edu/isp/a2k/wiki/). Some experiments in use of wikis during conferences have found them valuable (Boyd, 2004; Suter, Alexander, & Kaplan, 2005). Boyd describes how workshop participants quickly learnt to use wikis to capture “their own streams of consciousness or the comments of others.”

Wikis are used in a variety of ways for collaboration in classrooms ranging from primary school to university (Bold, 2006; Ferris & Wilder, 2006; Lamb, 2004; Skiba, 2005). Mitchell (2006) notes that wikis are consistent with modern theories of learning such as “connectivism” (Siemens, 2004), the idea that learning occurs in a complex and changing environment that cannot be controlled. In the classroom, wikis are used in collaborative writing, student projects and group assignments. Collaborative writing tasks can be given to develop writing and collaboration skills or to develop information resources for use by other students.

Wikis are particularly well adapted to shared creation of directories and lists such as bibliographies, staff lists and job vacancies. In schools and universities, teachers who use wikis in this
way assign groups of students or whole classes the task of jointly preparing annotated lists of information resources. Although most educational wikis are private, some become public resources. An example is the Wiki for IS Scholarship maintained by the Information Systems Department in the Weatherhead School of Management at Case Western Reserve University (http://isworld.student.cwru.edu/tiki/tiki-index.php) which contains summaries of major books and articles in IS as well as reviews of the contributions of major IS scholars. Often, wiki-based directories also provide access to resources. Participants in the Government Open Code Collaborative (http://www.gocc.gov) use a public wiki to list and describe source code that can be shared among its members.

Wiki software is also being used to create Web sites that draw on the contributions of a number of people. One example is the site developed by the Bach-Academie of Montreal to publicize a series of concerts. The musicians themselves added details to the wiki, which was then published to the Web (http://www.bach-academie-de-montreal.com/).

ISSUES IN WIKI MANAGEMENT

The ease with which individuals can contribute to wikis, the open nature of contribution, and the philosophy that the guardians of the content are the people who create the wiki can produce outstanding knowledge resources. On the other hand, these very characteristics can also be associated with problems such as reluctance to contribute or chaos through unstructured contribution. Some management is therefore required by the person or group that wishes to develop and maintain the wiki. The most significant management issues tend to be those of encouraging people to contribute, and managing intellectual property, problem users and spam.

As with any knowledge resource, people need both a reason to contribute to a wiki and a sense that they have the ability to do so. Wikis created for small groups or communities with a specific purpose should quite readily attract users if those users also know how to access and use the wiki. For example, a wiki established for the purpose of jointly preparing an agenda or document, where all members of the group responsible for preparing the document are motivated to contribute and know how to access the wiki and use the editor, is likely to be used by the intended users for the intended purpose. The more diffuse the purpose and the user group, the more uncertainty there will be about the development and continuation of a wiki. In practice, however we usually find a core group of regular contributors and a peripheral group of occasional contributors and people who read the wiki but do not contribute to it. (This pattern is common in online communities; see, for example, Wenger, McDermott, & Snyder, 2002). The core users can act as role models for other users. Other patterns that have been observed include the champion pattern (“single wiki-nut, encourages coworkers to add, view, improve”) and the trellis pattern (“egregiously boring content calls for fixing ... My [contribution can be] far more interesting than that!” Confluence, 2006).

Techniques for ensuring that potential contributors feel able to contribute include providing simple, easy to follow documentation for editing pages and assurance that mistakes are permitted and can quickly be remedied. Anti-patterns that discourage use include the gate pattern, “too many procedural barriers to adding content” (Confluence, 2006).

Where the content of a wiki may include information, images and files drawn from other sources, the intellectual property of the original sources must be respected. Standard policies for dealing with material that is the intellectual property of others include: (1) only material that does not
violate the copyright of the original creator can be included in the wiki and (2) the sources of all included material should be acknowledged. Equally, a decision has to be made about ownership and conditions for re-use of original material included in a wiki. The fact that the content of any single wiki page is usually produced by multiple authors needs to be acknowledged. A typical statement of the intellectual property in a wiki acknowledges its joint authorship and permits re-use, provided the wiki page is acknowledged as the source of the material. The GNU Free Documentation License used by Wikipedia provides an example (Free Software Foundation, 2002).

The more open a wiki to the public, and the larger the wiki user community, the greater the potential of encountering a problem user. Problem users may post unacknowledged copyrighted material, post material designed to offend or anger readers or contributors, remove material or otherwise “vandalize” the wiki. Some wikis use registration to limit the possibility that a problem user will continue to damage the wiki, but many wiki communities prefer to adopt the soft security principles described earlier in this article. It may be sufficient simply to let someone know (privately, by e-mail) the first time they post unacceptable content, that this type of content is not appropriate for the wiki (Turnbull, 2004). A wiki page that contains problem content can easily be replaced by an earlier, “clean” version. The active members of a wiki community often share the task of watching pages and dealing with problems.

Another potential problem, for public wikis in particular, is spam. Pages can be watched for spam in the same way that they are watched for other problem content, but this can be a time-consuming task. Some wikis use registration processes that require human intervention, such as CAPTCHA (Carnegie Mellon University School of Computer Science, 2000-2005), to prevent mass spam attacks. Spam capturing services are being added to wiki engines to reduce the amount of spam that reaches a wiki page.

FUTURE TRENDS AND CONCLUSION

At the time of writing, wikis were still the domain of early adopters, rather than a part of the mainstream. Despite widespread use of Wikpedia, knowledge of what wikis are and how they can be used for collaboration, particularly for private use, is not widespread. As of the end of 2006, only two non-technical books about wikis had been published (Klobas, 2006; Tapscott & Williams, 2006). Nonetheless, in October 2006, Google Inc. bought the wiki software and Web hosting service, JotSpot, an indication that consumer use of wikis is on the rise. The Gartner Group envisages wikis reaching maturity for business use some time before 2010 (Fenn & Linden, 2005). As wiki software matures, we can expect improvements in technical qualities such as ease of implementation and stability, as well as improvements in editing interfaces and graphical quality. These improvements, along with the positive experiences of early adopters, should help gain the interest and confidence of potential users and result in further diffusion of wikis as tools for collaboration.

KEY TERMS

Editor: The authors of wiki pages may be called “editors” because they have editing permissions.

Soft Security: Social conventions for trust, peer review and correction of errors adopted by contributors to wikis.

Wiki: An information resource that is created by multiple authors who use Web browsers that interacts with wiki software.

Wiki Engine: The software that handles the business logic of a wiki.

Wiki Page: A page of wiki content displayed in a Web browser.

Wiki Site: A set of related wiki pages. When a wiki site can be viewed on the World Wide Web, it is also a Web site.

Wiki Software: The suite of software used to produce and manage a wiki. This software may include, in addition to the wiki engine, add-ons and extensions that extend the feature set and functionality of the wiki.

WikiWikiWeb: The first wiki engine, written by Ward Cunningham.

INTRODUCTION

Although scientific research has always been a social activity, in recent years the adoption of Internet-based communication tools by researchers (e.g., e-mail, electronic discussion boards, electronic mailing lists, videoconferencing, weblogs) has led to profound changes in social interaction and collaboration among them. Research suggests that Internet technologies can improve and increase communication among noncollocated researchers, increase the size of work groups, increase equality of access to information by helping to integrate disadvantaged and less established researchers, help to coordinate work more efficiently, help to exchange documents and information quickly (Carley & Wendt, 1991; Nentwich, 2003). There is abundant research on new forms of group work originated from the use of computer technologies. Carley and Wendt (1991) use the term extended research group to refer to very large, cohesive, and highly cooperative research groups that, even being geographically dispersed, are coordinated under the supervision of a single director. The term collaboratory is also used to refer to similar groups (Finholt, 2002). Although there is much research on how Internet technologies are used by unified and cohesive work groups to collaborate (e.g., Moon & Sproull, 2002; Walsh & Maloney, 2002), less attention has been paid to how the Internet facilitates collaboration among researchers outside these highly cohesive groups. Weblogs (blogs) can become a useful tool for this type of collaboration and for the creation of virtual groups. Weblogs are frequently updated Web pages, consisting of many relatively short postings, organized in reverse chronological order, which tend to include the date, and a comment button so that readers can answer (Herring, Scheidt, Bonus, & Wright, 2004). They enable users to communicate with a worldwide nonrestricted community of people in similar fields, which leads to several forms of collaboration. The purpose of this article is to
present a brief overview of the uses of weblogs as tools for research e-collaboration.

Defining the concept of “research e-collaboration” precisely is extremely difficult. Here we assume that members of a virtual community engage in research e-collaboration when they use e-collaborating technologies in order to share information and discuss issues which contribute to advancing knowledge in a specific area.

BACKGROUND

The term Weblog was coined by Jorn Barger in 1997 to refer to personal Web sites that offer frequently updated information, with commentary and links. Blood (2002) classifies blogs into two “styles”: the filter type, which includes links pointing to other sites and comment on the information on those sites, and the personal-journal type, with more emphasis on personal self-expressive writing. There are many other types of blogs described in the literature, defined on the basis of different criteria; for example, knowledge blogs (k-blog), community blogs, meta-blogs.

The capabilities of blogs make them helpful tools for communication between members of a community or organisation. Some types of weblogs have originated as an answer to the communicative needs of specific communities; for example, knowledge blogs, weblogs for personal knowledge publishing. Kelleher and Miller (2006) describe “knowledge blogs” as “the online equivalent of professional journals” used by authors to document new knowledge in their disciplines. A related concept is that of “personal knowledge publishing,” defined by Paquet (2002) as “an activity where a knowledge worker or researcher makes his observations, ideas, insights, interrogations, and reactions to others’ writing publicly in the form of a weblog.” Many corporate and academic blogs make use of capabilities that afford collaboration: they enable scholars to communicate with a wide community, fostering peer review and public discussion with researchers from different disciplines. These weblogs have a precedent in what Harnard (1990) terms “scholarly skywriting”: using multiple e-mail and topic threaded Web archives (e.g., electronic discussion) to post information that anybody can see and add their own comments to.

There are many types of academic blogs (blogs from journal editors, individual scholars’ blogs, research groups’ blogs, PhD blogs), each of them used for different purposes. For instance, while the main purpose of the weblogs implemented by universities is discussion, weblogs by PhD students are mainly used to comment on the day’s progress and on the process of PhD writing, and blogs from journal editors are usually filter blogs, which provide links to articles or which comment on news related to the journal topic.

The uses of weblogs in research have been discussed in several papers and blog posts (Aïmeur, Brassard, & Paquet, 2003; Efimova, 2004; Efimova & de Moor, 2005; Farmer, 2003; Mortensen & Walker, 2002; Paquet, 2002). These researchers depict blogs as facilitating scientific enquiry in two ways: (1) they help to access and manage content, through features such as archives, RSS (an automated system that enables bloggers to syndicate their content to other blogs), searchable databases, post categories; and (2) they are tools for collaboration, through communication and network features. These features include hyperlinks, comments, trackbacks (records of the Web address of the blogs that have linked to a blog posting), RSS, or blogrolls (a list of blogs the author usually reads, and that, therefore, deal with similar topics). But the most important “ingredient” for collaboration is the bloggers’ perception of blogs as a means to point to, comment on, and circulate information and material from other blogs.

As a tool for collaborative research, blogs have several uses: (1) supporting community forming; (2) helping to find other competent people with relevant work; (3) facilitating connections
between researchers: blogs make it easier for researchers to develop, maintain and activate connections with others; (4) making it possible to obtain speedy feedback on ideas; (5) fostering diversity and allowing for radical new ideas to be acknowledged, circulated and discussed; (6) fostering communication and collaboration between researchers from different fields; (7) supporting the initiation and development of conversations. In weblogs, ideas can be generated and developed through discussion with others.

**E-COLLABORATING THROUGH ACADEMIC WEBLOGS**

We used a corpus of 100 academic English-language weblogs, collected between January and March, 2006, in order to analyse how they are used as tools for e-collaboration and how the elements of weblogs contribute to this purpose. Many academic weblogs are not intended as collaborative tools and thus do not include social software. In other cases, although comments are allowed, interactivity is very limited, and the weblogs are not really used as conversation tools. Therefore, for the purpose of this research, we have selected only active weblogs that include and make use of the comment feature. Drawing on previous research on blog analysis (e.g., Herring et al., 2004) and on our initial inspection of the blogs of the corpus, we identified the functional properties that make interaction and collaboration possible (e.g., comments, links). Then, we analysed the function of the 15 most recent entries in each blog (e.g., ask for feedback), the function of the comments to these entries (e.g., disagree with a post), and the types of links included in the postings and comments (e.g., to other blogs, to news sites, to Web sites by others, to the blogger’s own site).

The analysis showed that academic weblogs can be used to support the following forms of collaboration (or collaboration stages):

1. **Finding like-minded peers and establishing contact and collaboration with them, thus helping to create a virtual community of people interested in the same topic.**

Weblogs share features of personal and public genres. As personal genres, they are used by researchers to keep records of their thoughts, ideas or impressions while carrying out research activities. They also have an open nature, since anybody can access and comment on the author’s notes, and they are in fact intended to be read. By revealing the research a researcher is currently involved in and, at the same time, providing tools for immediate feedback on that research, weblogs facilitate collaboration. In addition, since weblogs are open to the public, not restricted to peers working in the same field, they facilitate contact among scholars from different disciplines and invite interdisciplinary knowledge construction (Aïmeur et al., 2003).

Blogrolling lists enable readers of a weblog to find peers with relevant work. These lists do not only point to related work, but also function as signs of personal recommendation, which help others to find relevant contacts faster (Efimova, 2004). Links and comments are also useful to expand a researcher’s community. Other researchers read the postings in the research blog and leave comments, usually including links to their own research. Authors of weblogs can also include links to articles on similar work carried out by other researchers, thus enabling the readers to get into contact with them.

Many researchers use the comment feature to explain that they are working on areas similar to the ones dealt with in the original posting and to suggest the possibility of collaboration or contact, in a more or less direct way (e.g., “I would like to keep in touch about your findings”). Community blogs are sometimes used by bloggers to summarize briefly their research and invite collaboration and contact with others.
Academic Weblogs as Tools for E-Collaboration Among Researchers

a. I am in the middle of a research project that looks at (...). I have a research log in which I make occasional observations, related and sometimes unrelated, to the ongoing work. Interested? Let me know and I will give you the URL.

The entry above got several comments of people eager to exchange ideas; for example:

b. I'd love to exchange ideas (...). How can we establish contact?

2. Asking for and receiving advice/feedback from others.

Weblogs enable researchers to post an idea or theory and have it circulated and discussed, thus helping the author revise and refine it. Authors who want to use weblogs for this purpose embed elements that facilitate hyperlinked conversations into them, such as links, comment software, and trackback features.

Very frequently, authors use weblogs to explicitly request feedback, comments, suggestions, and so forth on a paper, presentation, or idea. Comment software facilitates the discussion between the researchers asking for feedback and anybody wanting to contribute: Other bloggers state their agreement and disagreement with the author and with other commentators, ask questions, offer new perspectives, and so forth.

a. I was asked by the editors of the New Palgrave Dictionary of Economics to contribute a short article on the analysis of variance (...). Here's the article. Any comments (...) would be appreciated.

The entry above got eight comments suggesting ways to improve the paper; for example:

b. * Missing from the draft is a discussion of ANOVA versus regression (...)

* Here is one question you might address: When is ANOVA preferred to linear regression? (...)

Comments may also include links to other blogs with similar topics and thus help the original author with other people's perspectives. The weblog becomes a forum for discussion of the paper prior to publication, similar to that of a conference. When a blogger requests and gets feedback on a paper, he/she usually acknowledges the help from the others and shows the result of the revision in an update to the original entry. The result is a more consensual paper, which makes use of knowledge from other researchers.

Posting articles for peers to comment on in a weblog has several advantages. In the first place, the author can get immediate and public feedback, thus accelerating the development of new knowledge and involving many people in the review process: Anybody can contribute, even people unknown by the author, nonestablished researchers who are not usually involved in peer-reviewed publishing, and researchers from different cultural backgrounds. Besides, since bloggers usually comment on other's ideas on their own blogs, feedback may come from others than just immediate readers. Authors can post any idea, even very innovative or radical ideas which would not be accepted in traditional publishing, and, as Paquet (2002) points out, they can use weblogs to let others know not only about positive results, but also about negative results, blind alleys and problems. Peers can help by providing their ideas, suggestions, and so forth, and this way knowledge construction becomes a communal activity.

In many cases, researchers do not ask for feedback, but for references, information or resources on a topic, or help to solve a problem, hence using blogs as a tool to get information on a topic from competent peers they may not know personally.

3. Discussing topics or theories in which several researchers are interested, thus
Academic Weblogs as Tools for E-Collaboration Among Researchers

contributing to developing or articulating an idea and to reinforcing the links between the members of the virtual community.

Efimova and de Moor (2005) show how weblogs can serve as conversation tools which support the exchange of multiple perspectives and fast and meaningful reactions and facilitate the joint development of ideas. They define a new form of conversation enabled through the use of weblogs, “distributed weblog conversation”: conversations across many weblogs, where several authors link their ideas to construct a collective piece of knowledge.

The joint articulation of ideas by several researchers relies on elements such as links, comments and trackback features. Links may be to text but also to audio or video documents presenting or illustrating an idea, to simulations, to other Web pages or to other posts. Scholars use links to present and discuss an idea by someone else, or to articulate and summarize a previous discussion, before contributing their own idea and presenting it for others to comment on. Very frequently, when presenting others’ arguments on a topic, scholars include quotes accompanied by links to the original post, that way allowing the reader to follow the conversation in the original blog.

The comment feature facilitates discussion based on the posting. Bloggers write their comments, get answers back from the author of the original post, comment on other bloggers’ comments, and so forth, thus engaging in a conversation that may contribute to the development of innovative ideas. Comments are used for many different purposes: to show agreement or disagreement with the blogger, to ask for clarification on a specific point that the commentator does not understand or does not agree with, to request further information, to strengthen a point, to provide links to one’s own blog, and so forth. This back-and-forth may lead to collaborative revision and refinement, and even permuting, of an idea or argument, e.g.:

a. * In general, I really side with your post. Over at Anthropology.net, there have been a couple posts and discussions on (...). However, this post of yours, much more eloquently advocates breaking the boundaries between the West and non-West (...)

* Thanks, X. I’ll have a look at the posts you link to (…)

Since discussion of an idea may be distributed across several weblogs, it is necessary to have mechanisms to keep track of the discussion that one’s posting may have sparked. One such mechanism is trackbacks. Trackback is a special feature of the program Movable Type, which notifies the blogger when another weblog has linked to his/her weblog. Other users can view the trackbacks and thus follow the discussion in other weblogs.

FUTURE TRENDS

Weblogs are a genre whose capabilities offer a great potential for collaboration among researchers. However, there are still few academics who engage in blogging, and in many cases academic blogs are used for purposes other than collaboration. Several reasons have been suggested: the risk of sharing information and having ideas stolen or attacked before the research is published, the fear of damaging credibility, the time that blogging takes away from more traditional research activities (Lawley, 2002; Mortensen & Walker, 2002).

Since the weblog is quite a recent genre, there is little research on how weblogs are used for enquiry and knowledge creation. Their open nature makes weblogs appropriate for nonestablished researchers, who can that way collaborate with peers they don’t know, and researchers who seek collaboration with a worldwide non-discipline-restricted community of researchers. There are many different types of weblogs written by
academics and researchers. Further research is needed to determine which of these weblogs are more involved in collaboration, which form of collaboration takes place in the different academic weblogs, and how bloggers use language to engage in collaboration.

CONCLUSION

In this article, we start from the assumption that, since scientific knowledge is socially constructed, scientific knowledge creation is collaborative in nature. Thus, rather than considering collaboration as restricted to the work by unified and cohesive groups involved in a project under the supervision of a coordinator, we see it as any sharing of information and exchange of perspectives which contribute to advancing knowledge in a specific area.

Weblogs are a genre whose capabilities allow the exchange of any type of information and support conversations with a rhizomatic structure, thus being an appropriate tool for collaboration and for the sharing of ideas among several researchers in different places around the world. Weblogs can represent and distribute knowledge in different forms; that is, text, multimedia, simulations. They have a modularized format, relying highly on hypertext: weblogs consist of different postings, linked together to postings in other weblogs, on which they comment or which comment on them, making it possible to construct a web of knowledge on a topic. Links and comments allow connecting different pieces of related research into a coherent whole, thus facilitating the development of cumulative knowledge.

The use of CMC tools (and specifically of weblogs) does not only lead to an increase in collaboration, but also to a change in collaboration patterns. Weblogs enable almost instantaneous communication and feedback among a worldwide community, thus allowing for a much more interactive generation and articulation of ideas and theories and for the constant revision and update of theories. The informal and open nature of weblogs facilitates collaboration among anybody interested in a topic and, hence, fosters interdisciplinary collaboration.

Academic Weblogs as Tools for E-Collaboration Among Researchers

KEY TERMS

Blogroll: A list of links to Web pages the author of a blog finds interesting.

Comment: A link to a window where readers can leave their comments or read others’ comments and responses from the author.

Personal Knowledge Publishing: The use of Weblogs by knowledge workers or researchers to make their observations, ideas, insights and reactions to others’ writing public.

Research E-Collaboration: The use of e-collaborating technologies in order to share information and discuss issues which contribute to advancing knowledge in a specific area.

Scholarly Skywriting: Using multiple e-mail and topic threaded Web archives (e.g., electronic discussion) to post information that anybody can see and add their own comments to.

Trackback: A link to notify the blogger that his/her post has been referred to in another blog.

Weblog: A frequently updated Web page, consisting of many relatively short postings, organized in reverse chronological order, which tend to include the date and a comment button so that readers can answer.

INTRODUCTION

Education is one of the key sectors that has benefited from the continuous developments and innovations in information and communication technology (ICT). Web-based facilities now provide a medium for learning and a vehicle for information dissemination and knowledge creation (Khine, 2003). Accordingly, developments in ICTs provide opportunities for educators to expand and refine frameworks for delivering courses in innovative and interactive ways that assist students achieve learning outcomes (Kamel & Wahba, 2003). However, the adoption of ICTs has also created tensions between traditional control and directiveness in teaching and student-centred learning, which relies on flexibility, connectivity, and interactivity of technology-rich environments.

This chapter examines the introduction of Web-based technologies within a media studies course. The objective was to establish a community of learning, which provides students with a portal or entranceway into a common work area and out to networks of media-related organizations. So doing, a pilot study was conducted within the Department of Communication at Texas A&M University to blend Weblog facilities with a classroom setting to enhance students’ interpersonal and content interaction, and build citizenship through participation and collaborative processes. Four key aims frame this study:

1. provide an accessible, interactive online environment in which students can participate with peers and engage with new media technologies within a learning community setting;
2. develop an instructional technology framework that enhances the learning experience and outcomes within online educative environments;
3. establish a portal or gateway for students to access media advocacy and special interest groups and enhance and diversify perspectives on global media; and
4. evaluate student-learning experiences facilitated through innovative online instructional technologies.

BACKGROUND

Early approaches to integrating ICTs into education environments emerged from conventional learning models, originating from the objectivist approach in which a reality exists and experts instruct individuals of that reality (Belanger & Slyke, 2000). However, such teacher-centric, information-based approaches failed to adequately prepare students to become independent learners. Responding to these limitations, educators embraced learner-centric approaches such as constructivism, which leaned weight to the empowerment of individuals to take charge of their own learning environments. As Wilson (1996) suggests, the constructivist movement in instructional design emphasized the importance of providing meaningful, authentic activities that can help the learner to construct understandings and develop skills relevant to solving problems and not overloading them with too much information. Solis (1997) supports this position, suggesting that student-centred learning “… relies on groups of students being engaged in active exploration, construction, and learning through problem solving, rather than in passive consumption of textbook materials” (p. 393).

In spite of these favorable positions, Khine (2003) warns that creating such learning environments supported by ICTs can be intrinsically problematic. Accordingly, it is critically important that careful planning and design is employed at the early stages of instructional design to provide proper support and guidance, as well as rich resources and tools compatible to each context. When adequate consideration is given to new learning and teaching strategies that incorporate ICTs, real opportunities exist for educators to provide students with a dynamic environment to learn, to think critically, and to undertake productive discussions with their peers in supportive, constructive environments. Given the potential of such technology-rich learning environments, educators have the opportunity to make student learning more interesting and enriching, preparing them for the demands of the future workplace. Accordingly, instructional designers must consider matching the strengths of new technology (flexibility, connectivity, and interactivity) with traditional forms of education (control and directiveness) to inspire, motivate, and excite students in ways that maximize the individual’s learning potential.

Achieving these goals requires the development of individual competencies in problem solving, participation, and collaboration, and communities of learning (Kernery, 2000; Khine, 2003; Wilson & Lowry, 2000). Problem solving provides ways for students to engage with authentic episodes, providing opportunities for students and educators to examine events and reflect on solutions. One way of maximizing the benefits of problem solving is to support these through collaborative processes, which can be built around these “episodes” by focusing on the use of instructional methods to encourage students to work together as active participants on such tasks. Such efforts can be facilitated through structuring and organizing online interactions using computer-mediated communication, which provides the means to overcome limitations of time and place (Harasim, Calvert, & Groeneboer, 1997). Based on the principles of the transformative paradigm, multiple perspectives, and flexible methods, it is possible for students to adapt, to process and to filter content into their own logical frameworks, resulting in outcomes that may not be thoroughly predictable (Bento & Schuster, 2003). As Morrison and Guenther (2000) note, such collaborative environments provide a forum for students to discuss issues, engage in dialogue, and share results. However, Bento et al. (2003) also warn that one of the main challenges in Web-based education...
is to achieve adequate participation. They offer a four-quadrant taxonomy of learner behaviours when participating in interpersonal and content interaction--missing-in-action, witness learners, social participants, and active learners—as a way of understanding this dynamic.

When building components of problem solving, participation, and collaboration around small group processes, or learning communities, it is critical that these dynamics have beneficial effects on student achievements and psychological well-being. As Khine (2003) suggests, building community imparts a common sense of purpose that assists members grow through meaningful relationships. Accordingly, learning communities can be “… characterized by associated groups of learners, sharing common values and a common understanding of purpose, acting within a context of curricular and co-curricular structures and functions that link traditional disciplines and these structures” (p. 23). Rickard (2000) equates the notion of common values to that of “campus citizen,” in which students not only engage in educative endeavour but also learn networking and become “life-long members of our communities” (p. 13).

Such communities though should not be limited to just participants within narrowly defined student groups or the domain of institutional environments. ICTs also provide opportunities for students to connect to other informative communities related to their area of discipline or study via the Web. So doing, the educator can build into the instructional design gateways or portals to direct participants of small learning communities to other relevant organizations, groups, and individuals to extend campus citizenry and enhance knowledge creation. Tatnall (2005) suggests that such portals can be seen:

... as a special Internet (or intranet) site designed to act as a gateway to give access to other sites. A portal aggregates information from multiple sources and makes that information available to various users .... In other words, a portal offers centralised access to all relevant content and applications. (pp. 3-4)

In accessing Tatnall’s (2005) notion of portals, it is possible to think of these starting points in diverse ways. While no definitive categorization of the types of portals exists, Davison et al. (2003) offer a list of possible alternatives: general portals, community portals, vertical industry portals, horizontal industry portals, enterprise information portals, e-marketplace portals, personal/mobile portals, information portals, and niche portals. However, it is important to point out that these categories are not mutually exclusive, highlighting the malleable nature of these gateways for educators to blend the strengths of one with advantages of others to achieve a more effective portal design.

Even though portals are conceptually difficult to categorize and define, there exist a number of important characteristics that assist in facilitating the objectives of gateways as access points to, and aggregators of, information from multiple sources. For example, Tatnall (2005) draws from a number of scholars to present a general guideline of beneficial characteristics employed to facilitate community collaboration amongst users and the rapid sharing of relevant content and information. For example, the characteristics of access, usability, and functionality, as well as sticky web features like chat rooms, e-mail, and calendar functions, have been used to assist in maintaining user interest, attention, and participation within a site.

Within the education sector, portals offer great potential to achieve the kinds of goals laid out so far. However, portal development in these learning environments present a number of challenges for universities as they continue to grapple with a variety of business, organizational, technical, and policy questions within the framework of a larger technology architecture. For example, Katz (2002) highlights the following challenges:
build standards to create compelling and “sticky” Web environments that establish communities rather than attract surfers;
• create portal sites that remain compelling to different members of the community within the short-term and throughout student lives;
• create the technical and organizational infrastructure to foster “cradle-to-endowment” relationships via virtual environments; and
• integrate physical and virtual sites to foster social and intellectual interactions worthy of the university’s mission.

Within this framework of challenges, the emphasis continues to return to the realization that bringing education and ICTs together strategically relies less on technology per se than on the educator’s ability to design portals that are instructionally sound (to meet learner needs), customizable and personalized (for each member of the community), meets the institutional vision and mission, and fits within the larger technology infrastructure. However, Katz (2002) argues that while the challenges are great, opportunities can be realized. With universities engaged in relationship management enterprises, the situation requires a proactive role in developing a “…belief system, a worldview, a set of approaches and technologies organized to arrange and rearrange both our front door and our rich holdings” (p. 13).

To achieve and maintain such connections, TAMU implemented a three-tier model for development and implementation of foundation, cornerstone, and capstone learning communities within the university setting (see Figure 1). In developing this model for establishing learning communities, a number of recommendations were made:

1. Draw from faculty and staff knowledge to create initiatives that make existing educational opportunities even better.
2. Provide resources and incentives to develop, implement, and access learning communities; and encourage innovative pedagogies to support and reward the implementation of technology-mediated instruction, use of peer instructions and collaborative learning.
3. Provide a clearinghouse so the benefits from experience and expertise can be utilized in future design and implementation of learning communities. (TAMU, 2005)

With this framework in mind, a Weblog was integrated into the COMM 458 Global Media course using a generic blogger.com template as part of pilot study funded by a $3,000 TAMU Summer Institute for Instructional Technology Innovation Grant. The template included an archive (of posts and comments), calendar function, a database of user information including e-mail links to registered members, e-mail notification facility, and links to other relevant websites. In providing 22 students access to Weblog facilities,
the study set out to establish a model of content production and platform interoperability for inspiring innovative and creative appropriation of Web-based facilities by TAMU students and faculty. Accordingly, the Weblog was strategically integrated into the course to achieve the following outcomes:

- facilitate community building and understandings of social networking and citizenship at local, national and international levels;
- provide a platform for students to evaluate, communicate and critique current issues and problems within informal and engaging online environments;
- improve content, information and knowledge management within the course structure;
- improve teaching and learning through understanding the dynamic between participation and collaborative processes within a blended educative environment; and
- develop alternative pedagogical and technological strategies to support and encourage each student to become an independent learner.

All students were invited to be members of the Weblog community by e-mail, which contained a hyperlink that directed them to blogger.com’s registration site. There, students selected a user name and password, which brought them into the course Weblog site (see Figure 2). Once in the site, members could interact with each other by posting summaries of readings (including discussion points and questions), comment on posts in which

Assessing Weblogs as Education Portals

students raised issues and problems (moderated by the course instructor), and source stories and information from national and international news services (e.g., CNN, BBC, or Aljazeera). Users were also given the task of building a database of relevant links to outside media organizations and advocacy groups to assist each other in answering problems and issues posed within online and classroom discussions. All students were assigned administration rights to the Weblog to instil a sense of ownership among members.

FUTURE TRENDS

Participation within the Global Media course (online and classroom) was measured in several ways, including the number of entries (posts and comments), user log-ins, survey, interviews, and observations. Overall, students and instructor made a total of 303 entries (72 posts and 231 comments) over the 10-week period from September to November of the 2005 Fall Semester. On average, there were 3.25 comments per post. However, included in this number were 108 comments (81% response rate) by students to a series of six quizzes (which accounted for 15% of the course’s total grade) implemented throughout the semester to test students’ general knowledge of key theories and concepts. When the quiz comments were excluded and the figure re-calculated, the average number of comments per post significantly decreased to 1.70. These figures would suggest a relatively poor level of participation in online interactions. However, these figures do not reveal the complexity of the online-classroom dynamic in catering for different learner preferences. Another way of assessing student participation
is to categorize their behavior into types of interactions through observing participation in both settings.

Drawing from Bento et al. (2003) four-quadrant taxonomy, it is possible to map the types of behaviors these learners engaged in as part of the participatory and interactivity components of the Global Media course (see Figure 3). Quadrants I and II share the characteristics of low interpersonal interaction. However, whereas Quadrant I students do not care about course content and their peers, “witness learners” are actively engaged with the course materials and discussion (high content interaction), log in frequently and do all the readings but do not actively contribute to course discourse (low interpersonal interaction). On the other hand, Quadrants III and IV share the characteristic of high interpersonal interaction. Students in Quadrant III (high interpersonal interaction, low content interaction) thrive on...
the social aspects of education, demonstrating characteristics of great conversationalists, with high communication and interpersonal skills. Such students, though, engage in social interaction most often at the expense of reflection and thoughtful consideration of course content. Quadrant IV represents what educators define as “good participation,” with high content interaction and interpersonal interaction. Their contributions in discussions are substantive and frequent. Accordingly, Bento et al. (2003) argue that these students contribute not only to the problem-solving task but also to building and sustaining relationships in the learning community.

Given the findings of the study, the Weblog added value to the learning community by providing students with access into a common area to connect and interact with one another and as a gateway out to sources of information beyond the confines of the institutional environment. Through student-established links to media organizations and advocacy groups, members connected to important and divergent understandings and knowledge of the role of media in a global context. One student comment encapsulates the general feeling of course participants toward the Weblog facilities:

... Even if all students had equal enthusiasm to participate in class discussion, class time limits everyone from making significant contributions and feeling part of learning. Blogs provide a place for sharing related material [discussion and provision of links to outside sources] that the classroom setting does not, and a way to question or comment on material we have already covered. In general, blogging let’s students engage with each other in a way different from class. By allowing discussions to continue and expand, it helps students who struggle with the material or who are afraid to ask questions in class. It certainly helped me to learn much more than just reading textbook information.

In spite of these positive responses, the chronologically organized Weblog structure offered insufficient flexibility and functionality to increase online participation. Given the findings, the study recommends re-designing the Web-based learning environment using software, innovative interfaces, and workflows. So doing, there is a need to:

1. Develop a technology interface that acts as an entranceway into a series of linked, embedded pages so (a) information storage and retrieval; (b) discussion and commentary; (c) communication; and (d) project facilitation can be purposefully compartmentalize to improve technology, content, interpersonal and intellectual interaction.

2. Integrate chat room facilities into the portal design to create more compelling, sticky Web-environments for participants to interact in real-time with peers and instructor.

3. Introduce more comprehensive monitoring facilities to track technology, content, interpersonal and intellectual interaction, providing instructors with timely diagnostic metrics to enhance decision making during course implementation.

4. Develop more strategic collaborative, problem-solving tasks and exercises to increase participation and improve content, interpersonal, and intellectual interaction.

CONCLUSION

This article presented pilot study findings on using weblog facilities to increase participation and improve interaction in Web-based learning communities. The study revealed a number of aspects to assist educators in providing more structured and comprehensive online learning environments. The most important of these are people-related functions such as creating strategically-focused collaborative learning environ-
ments and improving the quality and quantity of, and accessibility to, course metrics to help educators make informed, timely decisions in online instructional environments. Accordingly, it is anticipated that the recommended strategies will improve participation and interactivity and contribute to more productive, supportive learning communities.

REFERENCES

KEY TERMS

Constructivism: Learning as interpretive, recursive, building processes by active learners interacting with physical and social worlds.

Information and Communication Technology (ICT): Refers to an emerging class of technologies—telephony, cable, satellite, and digital technologies such as computers, information networks, and software—that act as the building blocks of the networked world.

Learning Communities: Characterized as associated groups of learners, sharing common values, and a common understanding of purpose.

Portal: Considered an all-in-one Web site that acts as a centralized entranceway to all relevant content and applications on the Web.

“Sticky”: Web Features include chat rooms, e-mail links, and calendar functions.

Student-Centred Learning: Focuses on the needs of the students rather than on teachers and administrators, resulting in implications for the design of curriculum, course content, and interactivity of courses.

Weblog: A personal dated log format that is updated on a frequent basis with new information written by the site owner, gleaned from Web site sources, or contributed to by approved users.

Chapter 3.21
Innovative Technologies for Education and Learning: Education and Knowledge-Oriented Applications of Blogs, Wikis, Podcasts, and More

Jeffrey Hsu
Fairleigh Dickinson University, USA

ABSTRACT

A number of new communications technologies have emerged in recent years that have been largely regarded and intended for personal and recreational use. However, these “conversational technologies” and “constructivist learning tools,” coupled with the power and reach of the Internet, have made them viable choices for both educational learning and knowledge-oriented applications. The technologies given attention in this article include instant messaging (IM), Weblogs (blogs), wikis, and podcasts. A discussion of the technologies and uses, underlying educational and cognitive psychology theories, and also applications for education and the management of knowledge, are examined in detail. The implications for education, as well as areas for future research are also explored.

INTRODUCTION

For many years, the mediums employed for education have remained fairly constant and traditional: tried and true methods such as the blackboard and chalk, whiteboards, flipcharts, and overhead projectors. The employment of computing technologies has resulted in the use of PowerPoint, e-mail, and Web-based course portals/enhancements such as Blackboard and WebCT.

There have been numerous studies done, and papers written, about the use of technology in the classroom, together with work on the related areas of e-learning, Web-based learning, and online learning. The usage of computing technologies in education has been examined in numerous studies, and there is a sizable body of work on Web and online learning, including the studies by Ahn, Han, and Han (2005), Liu and Chen...
(2005), Beck, Kung, Park, and Yang (2004), and numerous others.

In particular, some of these technologies have been recognized as useful in the classroom, and have been engaged in innovative ways. The technologies of particular interest are those that are referred to as “conversational technologies,” which allow for the creation and sharing of information (KPMG, 2003; Wagner, 2004). Another term often used to describe these technologies is the concept of “constructivist learning tools,” which encourage, and are focused on, users creating, or constructing, their own content (Seitzinger, 2006).

The interest in employing these kinds of technologies stems not only from the unique pedagogical benefits gained, but also from the basic need to stay in tune with the focus and strengths of today’s students. Prensky (2001) suggests that the students being taught today are “no longer the people our educational system was designed to teach” and that while the students of today can be termed “digital natives,” many educators could be better termed “digital immigrants.” Yet another way to look at this is to view earlier educational approaches as “print-based,” while those of the current environment can be called “digitally-based, secondly-oral” (Ferris & Wilder, 2006).

The purpose of this article is to examine these technologies and explore both the evolution of their use from personal applications to that of educational tools, and also to examine the key educational applications for which these are being used. Relevant research and applications are examined and analyzed. The future of these technologies for educational and professional use, together with viable research areas, is examined as well.

CONVERSATIONAL TECHNOLOGIES AND CONSTRUCTIVIST LEARNING TOOLS

The notion of conversational technologies is not a new one, as it encompasses many types of systems that have been widely used for some time, including e-mail, video conferencing, and discussion forums.

The term “conversational technology” is derived from the work of Locke et al. (2000) relating to conversational exchanges and his Cluetrain Manifesto. One of the key concepts here is that “markets are conversations” and that knowledge is created and shared using question and answer dialog. Specific theses that relate to this form of “conversational knowledge management” suggest that aggregation and abstraction of information helps to create information. Other characteristics of conversational knowledge management include the fact that it is fast, stored in different locations, and does not require sophisticated technologies in order to be accomplished (Wagner, 2004).

Conversational technologies encompass a wide range of systems and software, many of which are familiar, including e-mail, instant messaging, Web pages, discussion forums, video and audio content/streaming, wikis, and Weblogs. While there are specific aspects that are of interest in terms of the more mature technologies, the ones that will be given attention in this article are the issues, impacts, and applications relating to IM, blogs, wikis, and podcasts. These are technologies that are newer, have a growing base of users, and are starting to become recognized as viable tools for education.

The term “constructivist learning tool” has also become associated with these, particularly blogs and wikis, in that they have a key characteristic of allowing users to develop and maintain their own content. Some of the characteristics of con-
Innovative Technologies for Education and Learning

Structivist learning include engagement, active learning, collaboration, real world based, and the usage of reflection as a part of the learning process (Seitzinger, 2006).

It should be noted that these technologies and tools are best suited to course structures where class collaboration and communication are encouraged, rather than those with an emphasis on lectures and a presentation of factual information. In addition, in courses where there is substantial group work, or projects where a collaborative document is created, the use of these would be especially helpful and useful. Both hybrid and full distance learning courses would be situations where these could also be used effectively.

TEACHING AND LEARNING: NEW TRENDS

Conversational and constructivist technologies are certainly here to stay, as evidenced by their extensive role in our society. It would therefore be useful to examine their applicability in the educational realm. While usage based on popularity or student preference seems to be one factor, there are also theoretical and conceptual bases for employing these kinds of technologies in the classroom.

Earlier paradigms of teaching emphasized print-based materials for instruction, which included printed textbooks, paper-based instructional materials, and written tutorials, all of which are grounded in the notion that the teacher, lecture, and instructional materials form not only the basis, but also the authority in the educational process. The transmission of material from the teacher (lecture) and/or textbook to the student (called the “print model”) is still the central basis of most teaching, even if they are supplemented with other methods including discussion and other forms of student interaction/participation (Ferris & Wilder, 2006).

However, the advent of digital and conversational technologies has brought forth the new concept of secondary orality (Ong, 1982). This concept emphasizes that teaching and learning should go beyond printed materials toward a greater emphasis on group work, fostering student communities, and encouraging student participation. The concept encourages a greater sense of interaction with and “ownership” of knowledge, emphasizing self-awareness and expression, and effectively using electronic tools (Gronbeck, Farrell, & Soukup, 1991).

The use of conversational technologies can have a positive impact, because they attempt to not only improve upon the print approach, but also use secondary-oral techniques. In other words, while a student can still be presented with material (in different formats) using the print model, the introduction of secondary-oral methods can be used to improve the overall learning experience. Using the latter, there is the opportunity to work and learn collaboratively, explore, analyze, engage in discussion, and otherwise “learn” in new and innovative ways (Ferris & Wilder, 2006; Wallace, 2005).

INSTANT MESSAGING (IM)

It is unlikely that there would be many college students who are unfamiliar with the use of IM. Allowing for interactive and real-time synchronous communications with instant response, instant messenger is truly conversational in that it allows for “chat” and communications between both individuals and groups. The major instant messaging systems in use include AOL (AIM), MSN Messenger, Yahoo! Messenger, and ICQ.

IM is a means for users to “chat” and communicate in real-time. While originally the domain of personal users, over time the unique benefits and effectiveness of this medium were realized, and IM started to become accepted as a form
of communication in businesses (particularly high-tech firms), and now has been studied and tested as an educational tool (Kinzie, Whitaker, & Hofer, 2005).

The important features of IM include both its synchronous nature and its ability to support both chat and phone-like interaction. While real-time interaction allows for rapid communications to occur, there is also no need to enter an interaction “space” as with chat rooms. Instead, the main usage of IM is in one-on-one communications, which can be more formally termed as a dyadic “call” model, which more closely resembles phone call interaction. It should be noted that even though

|                   | Real-time communications that allow for informal communications to be conducted easily and quickly | Availability and acceptance by students  
Social presence (know the status of other users online)  
Real-time (synchronous) communications  
Encourages collaboration  
Reduces formality in communications | Distracted attention, especially in a classroom setting  
“Time waster” that is not directed toward course content, but on personal discussions  
Expectations of 24-7 instructor access  
Can be time consuming for instructors  
Benefits are uncertain in classroom settings | Virtual office hours (instructor-student)  
Collaboration on group projects  
Real-time class discussions  
Mentoring | Courses with group projects and assignments  
Distance learning support | Active learning  
Dual (verbal and visual) processing |
much of the communication is done between two individuals, there are some systems that support multiparty instant messaging.

Some of the salient features of IM include the ability for users to see user details as to current status (online, idle, away, out to lunch), and also on a user’s changes in status (active, logged out, etc.). Lists of users can be displayed on the screen, so that contact can be made when desired. If a “chat” is initiated, a special window comes up, and the interaction can commence, provided that both parties are online and willing to proceed.

The real-time nature of IM has resulted in the technology being used for reasons aside from personal “chat.” In business, IM has become in some industries an accepted form of communication. A number of studies have concluded that instant messaging is ideal for informal interaction. In particular, the use of IM has been shown to be helpful in cases where collaborative coordination and problem solving is involved. Social bonding and interaction, which is a component contributing to the success of more complex collaboration situations, is also enhanced by using instant messenger technology (Nardi & Bradner, 2000).

An important difference between IM and e-mail is the tendency for instant messenger interaction to be more casual and informal than e-mails, which helps to bring about a more “friendly” communication atmosphere. This may in part be due to a reduction in the formalities that are typically involved when using e-mail or the phone. In particular, IM has been considered more suitable for such tasks as scheduling meetings, asking or answering quick questions, and for other kinds of tasks that are brief, require a prompt response, or are less formal. It is perceived to be far simpler to IM someone to ask a quick question, for example, or to confirm a meeting or lunch, rather than to e-mail or call (Nardi & Bradner, 2000).

It is also of interest that IM communications tend to be more flexible in terms of their uses (everything from task-related questions to a new joke), and can allow for greater expressiveness in terms of emotion, humor, and personality (Nardi & Bradner, 2000). Another interesting aspect is what Nardi and Bradner (2000) refer to as “outeraction,” which focuses on the processes associated with IM. These include conversational availability, communications zones, intermittent conversations, awareness, and conversational progress/media switching. IM is useful in certain communications situations, since it tends to be less disruptive and interrupting, while at the same time a user’s availability is more clearly known (scanning buddy list status, for example). It is also a convenient means for setting up more formal interactions, such as arranging a conference call (media switching). Intermittent, dispersed communications can be conducted over a longer period of time, which includes interruptions. Another benefit includes the knowledge that others are “there” and available, even if not currently in chat mode; however there is always the opportunity to make contact, whether through IM or a different form of communications.

While some educators may scoff at and even express criticism at the thought of instant messaging as a viable educational tool, others believe there is potential in the medium.

In terms of educational uses for IM, they are being explored and tested. Clearly, IM not only allows students to collaborate more effectively on homework assignments and projects, but also helps to maintain a closer social network between students, which could have a positive impact on learning. In addition, if IM is carefully targeted and focused toward the material or lecture topic in hand, the use of IM may actually help and stimulate deeper and more active learning.

On the other hand, it has been hypothesized that the distraction of working on various other tasks in parallel with IM, known as “distracted attention,” may have a negative impact on learning (Hembrooke & Gay, 2003).

Active learning (Grabinger, 1996) and dual (verbal and visual) processing (Clark & Paivio,
Innovative Technologies for Education and Learning

1991) are at work here. It could be said that using IM to encourage greater discussion and reflection on the course contents would be likened to the use of discussion boards; however, since IM is a real-time technology, the interaction is conducted during the lecture or class, not afterward. Some studies have reported positive effects and student satisfaction from IM being used to discuss course subjects in real-time (Guernsey, 2003).

A study by Kinzie et al. (2005) examined the use of IM during classroom lectures and found that while the general idea of using IM online discussions was positively received, the actual process and experience of using IM to conduct discussions during class lecture sessions was not found to be less than a positive experience by both teachers and students. It was suggested that the difficulties of multitasking and dividing one’s attention between the lecture and instructor, doing the IM discussion, contributed to the lack of satisfaction with the process.

Burke (2004) used instant messaging as a medium for creating course diaries in three different mathematics courses. IM was chosen since it was thought to be popular, widely used by students, and considered more “fun,” so there was some hope that this popularity would transfer over to greater and more enthusiastic usage by students. In fact, the choice was made to use IM over a seemingly more suitable choice, blogs. A bot was created that would retrieve IM diary entries from students and store them in a PostgreSQL database, and there was also a program set up to display diary entries from each student, viewable by both the student and the instructor. The main finding of the study was that the IM media was not ideally suited for all kinds of courses, especially those that involved creating longer portions of text, or involved diagramming. Error detection and recovery was also not that well developed, and also there was a need for better editing tools.

In summary, while instant messenger can be appropriate for various applications, in particular for information communications in a business setting, the results from educational studies appear to be mixed, with both positive and negative effects noted. While there seem to be advantages to real-time communications between students, between students and instructors, and also between groups working on a project, it appears that there are problems and limitations if the technology is used in a classroom setting. The challenges of focusing on a class lecture, together with maintaining a conversation online, seem to be a problem that has not yet been resolved. In addition, while instructors can often establish closer relationships with students using IM, there is also the problem of unreasonable student expectations of continuous teacher access, which may not be present if IM was not available as an option. In connection with this, using IM for student help can result in a greater time commitment, since sessions can become lengthy with many questions and responses being sent back and forth.

BLOGS (WEBLOGS)

Blogs started as a means for expressive individuals to post online diaries of themselves. Complete with text and photos, these logs were essentially an individual’s online narrative or diary, with events, stories, and opinions. While its original use was for personal expression, recently its effectiveness as a tool for education has been discovered, including its use as an extension of “learning logs,” which are created online (Barger, 1997). One of the earliest blogs, as we know and use them today, was Dave Winer’s Scripting News, which was put online in 1997. While the use of Weblogs can be considered generally new, the concepts of keeping a “log” or “learning log” is not.

The concept of “learning logs” has been in use since before the advent of the Weblog. The concept of this is to enable someone to document his or her learning, and also to do some critical reflection (Fulwiler, 1987) and self-analysis. The use of a learning log or journal is related to action research
learning strategies (Cherry, 1998) and attempts to link previous knowledge and new information learned. Blogs are a natural extension of learning logs/journals in that they are electronic and can be made available (“published”) more easily (Armstrong, Berry, & Lamshed, 2004).

The use of electronic Weblogs as educational tools offers the benefits of increased information sharing, simplified publication of information, and improved instructor monitoring and review (Flatley, 2005; Wagner, 2003). The use of blogs has been expanding, as Perseus Development reported that there were some 10 million blogs in 2004, and the number is ever increasing (Nussbaum, 2004). The growth in this area is expected to increase in the years to come.

Blogs can be defined more formally as being “frequently updated Web sites consisting of dated entries arranged in reverse chronological order” (Walker, 2005) and can take several forms, including the personal diary/journal, knowledge-based logs, and filter blogs. The first, an electronic, online diary of one’s life events and opinions, is probably the most common. The online diary/journal blog is one that, being on the Internet, is public, as opposed to the traditional (typically paper) diaries, which are generally kept private. It should come as no surprise that there are many different online diary/journal blogs that are currently online, where one can find out details, often much more than one might want to know, about someone’s life and thoughts. Personal blogs form the majority of the blogs that are currently online and available, which make up roughly 70% of all the blogs in existence (Herring et al., 2003).

The second type (knowledge-based) captures knowledge and places it online in various formats. The third type (filter) attempts to select, rate, or comment on information contained in other sites (Herring et al., 2004).

There are software packages that are designed to help users create blogs, including Blogger, Xanga, Blurt, and MovableType. While the basic features of most blog software emphasize the creation of blog pages, some of the more sophisticated ones offer the capability to track readership, see who followed what links, add photos, and set up more advanced structures. When online, blogs can range from being totally public (listed in the blog service directory), to being “unlisted” but still open to being highly restricted (password-protected).

Blogs are also interesting and unique in that they are not merely online versions of paper diaries and journals. Rather, as a communications medium under the control of the main writer (author), it is reflective of the fact that an audience is “watching and listening.” What is put on a blog is not merely a one-sided set of thoughts and reporting of events; there can also be responses to feedback and reactions from the “viewing audience.” Therefore, blogging is considered a highly social activity, rather than a personal one.

In fact, recent work has indicated that the momentum for creating, and also updating a blog, came about as a result of encouragement from friends and the viewing audience (Nardi et al., 2004). In addition, blogging can have negative repercussions when posted information is perceived to be confidential, proprietary, or improper. In some cases, employees posting what was considered by their employers as “confidential” information can cause problems.

Blogs do not, in general, exhibit a free-flow of information between the blogger and the outside audience. While feedback is often requested, received, and desired by the blogger, the level and quantity of feedback from readers is generally limited compared with the output from the blog writer. In addition, while blogs may have sections where hyperlinks are mentioned, the number of hyperlinks in blog pages is frequently not very large (Schiano, Nardi, Gumbrecht, & Swartz, 2004).

More formally, Weblogs can be considered to be objects motivating human behavior, which is related to activity theory. Activity theory states that there are objects that have motives that respond to a human need or desire, and that they manifest a person’s desire to accomplish that motive (Leontiev, 1978; Vygotsky, 1986). The objects that connect bloggers to their own social networks include letting people know what is happening in their lives, voicing opinions, asking for feedback, and “letting off steam” about certain challenges or difficulties currently being experienced, to name a few (Nardi et al., 2004).

Blogs have been categorized by Krisnamurthy (2002) as being categorized into four different types, along the dimensions of individual versus community, and personal versus topical. A blog can therefore range from being very individual...
Innovative Technologies for Education and Learning

and personal, all the way to being open to the community, however very focused on a particular topic.

The acceptance of blogs for educational purposes is gaining interest, with one university, the University of Maryland, attempting to implement blogging software campus-wide (Higgins, Reeves, & Byrd, 2004).

In addition, the educational uses of blogs take advantage of their ability to encourage expression and the development of online relationships. Blogs allow for learning and interaction to be more knowledge-centered, especially if the assignments are structured in the format of encouraging feedback and input from the instructor and outside experts. Blogs also allow students to gain a better understanding of a subject’s knowledge domain (Glogoff, 2005). As an example of this type of blog-enhanced class structure, students might be provided with a Weblog from which to complete certain course assignments. After researching the indicated subject, the student would present the new information by “publishing” it to the Weblog. The Weblog would constitute the student’s assignment, which would then be subject to review and critique by not only the instructor, but also by other students in the class. Supplementing this could be discussion boards, where threads would be devoted to discussions on the Weblogs created by the students. This kind of assignment and interaction would be especially useful for both hybrid and fully online distance learning courses (Glogoff, 2005).

There are other benefits of Weblogs. These could be expressed using the learning theories and concepts of guided discovery, directive learning, receptive learning, and social/community-centered instruction.

Guided discovery allows for the exploration and study of a certain topic, which is then followed by assignments that emphasize the synthesis of information. In effect, a student can be asked to research an area and “construct knowledge” using the Weblog as a medium. Part of the assignment goes beyond merely explaining or presenting the material, and asks for the application of the concept using a real-world situation. The ability for students to post and make comments about other students’ blogs provides an atmosphere of interactivity and collaboration. One of the advantages of using blogs together with guided discovery is that it encourages the use of cognitive scaffolding, where students would approach learning (together with the use of blogs and interaction) by repeatedly seeking information, reflecting and thinking about what has been learned, and then going back and obtaining more information, so as to build upon and dig deeper into the subject area. This can result in a more active and productive form of learning (Betts & Glogoff, 2004; Glogoff, 2005).

Directive learning, where responses from students are followed by prompt feedback from instructors, can also be supported using blogs. In this case, students would not only use a blog to submit assignments, but also to review instructor feedback. In addition to feedback, there would be opportunities for the instructor to ask additional questions, in effect, to encourage further exploration and “drilling down” into the subject (Betts & Glogoff, 2004; Glogoff, 2005).

Receptive learning is where instructional modules are presented that focus on certain broader areas, from which certain sub-areas within these are highlighted for a student to research and report on. Generally, the areas are contained within a designated theoretical context (Betts & Glogoff, 2004; Glogoff, 2005).

Social/community-centered instruction is a logical component of educational work using blogs, and in particular the use of peer and social interaction as a part of the learning process. The use of blogs functions as an easily accessible medium for students to present their findings (and to be read by others) and also to integrate not only the information presented, but also related links and references to other resources. This form of
interaction helps to encourage further exploration by students. A blog-based discussion can then be continued by conducting peer reviews of other students’ blogs, which may include commentary, critique, the posing of questions, and opening up the way for further inquiry. The ability to share and benefit from the findings of other students (and to explore further) is another important outcome. The theories of community practice (Snyder, 2002), social cognition (Vygotsky, 1978), and communities of inquiry (Lipman, 1991) provide support for the blog-related techniques mentioned previously.

Ducate and Lomicka (2005) discuss their experiences in using Weblogs to support foreign language classes. Weblogs help the foreign language student to learn during the process of reading, and then creating blog entries. Students can learn by reading blogs that are written in the new, target language, including learning new vocabulary, checking out links and further information on words, and learning associated cultural information. The reading and absorption of blogs on the culture associated with the target language, including literature and lifestyles, all would contribute to the learning process.

Another approach would be to have students maintain blogs written in their new, target language, and then the goal would be to seek commentary and critique on these blogs by others in the class. Yet another innovative method might be to share blogs with other classes studying the same language, and for students to read and comment on each other’s postings. In the case where students travel to a country where the target language is spoken, the compilation of travel blogs would be a useful learning tool as well (Ducate & Lomicka, 2005).

Wang and Fang (2005) looked at whether the use of blogs encouraged or enhanced cooperative learning in an English rhetoric/writing class taught in Taiwan. The main premise was that blogs can encourage students to spend more time working within a class “community” and can benefit from a greater sharing of contributions and inputs. In general, cooperative learning benefits can be divided into three different types: formal, informal, and base groups. Formal cooperative learning is where the instructor explicitly provides course materials and assignments to a group and then observes the students’ learning processes. When the instructor provides information more generally (such as detailing how to use a blog for course assignments) and then lets the group work out their own methods for handling an assignment, that is known as informal cooperative learning. When a learning-oriented group is maintained for an extended period of time, such as throughout a semester, then this form of cooperative learning is known as a cooperative base group (Johnson & Johnson, 1998; Johnson, Johnson, & Holubec, 1991). The study, run over the course of a semester, found that the use of blogs contributed not only to cooperative learning in general, but also to autonomous learning. Autonomous learning is focused on how much students take responsibility for their own learning, and also develop self-confidence in the task or skill (Wenden, 1991). The use of blog technologies was also found to help improve information processing, learning self-evaluation, and effective time management (Wang & Fang, 2005).

Martindale and Wiley (2005) also used blogs in their courses and looked at two cases of the impact of this technology on teaching and learning. Martindale taught a doctoral-level course on instructional design and technology. In it, students were introduced to blogs and used them throughout the course, which overall tended to promote higher levels of quality in their course work. Blogs were used to post ideas and abstracts of their projects, and also to place links for relevant research papers and Web-based resources. The end result was a course “knowledge base” that represented the cumulative output of the students in the course. The blogs were also used for article critiques,
which were an integral part of each weekly class. Students were given access to the blogs of other students and were able to offer feedback.

Wiley taught two different courses, one on online learning research, and the other on online interaction culture. Both included the use of blogs as a supporting technology, the first employing a general course blog where information about the course, student assignments, and class updates and student/instructor interaction exchanges were posted on an ongoing basis. In the second, blogs were used to discuss experiences using different online communications technologies, causing students to become highly engaged, resulting in passionate discussions and detailed commentaries posted to the blogs, far exceeding the level and depth of feedback that was expected (Martindale & Wiley, 2005).

In summary, blogs can be useful for educational purposes, particularly where there is the need to encourage and stimulate critical thinking and reflection on a work, concept, or idea. The submission or publication of a document or text as a blog can then lead others in a class to review and comment, setting the stage for greater analysis and study. In particular, blogs are suited to writing courses, where a text can be analyzed and critiqued, or for a situation where a peer review is desired. The blog approach is also considered useful for group study of a certain focused problem or case, such as those used in graduate courses and seminars.

WIKIS

Yet another technology, known as the wiki, has emerged, which allows for improved collaboration compared with Weblogs. While the major emphasis of Weblogs is the creation of a set of pages and documents primarily by a single individual, the strength of a wiki is the ability for numerous interested readers and users to express ideas online, edit someone else’s work, send and receive ideas, and post links to related resources and sites. As a result, wikis go a step further and allow for greater collaboration and interactivity (Chawner & Gorman, 2002). Wikis have been found to have value for educational purposes, and their use has begun to be integrated into a number of university courses, in particular (Kinzie, 2005).

The term “wiki” comes from the Hawaiian word “wikiwiki,” which means “fast.” The technology is computer-based and can be generally described as a knowledge sharing and creation system that has as its basis a set of Web pages, which can be created and updated on an iterative and collaborative basis, and is in many ways a form of groupware. A wiki is designed to run on the Internet and World Wide Web, uses the HTTP protocol, and resembles traditional Web sites in terms of its underlying structure. Some of the benefits of wikis include the ability to easily create pages (using a simplified form of HTML or basic HTML) and the ability for a document to be authored collaboratively and collectively. In particular, simplicity is the key to wikis, and wiki pages have been designed to be easy to create, (simpler than the process of creating standard Web pages). One of the better-known examples of a wiki is www.wikipedia.org, which is an online encyclopedia with entries authored and edited by different persons worldwide, and in several different languages as well. In essence, it is an online information resource that is authored by interested and knowledgeable persons from around the world.

Wagner (2004) developed a set of design principles that relate to wikis. These are the principles of open, incremental, organic, mundane, universal, overt, unified, precise, tolerant, observable, and convergent wikis. Open means that anyone can edit a wiki, creating an “open
source” environment for the sharing of knowledge. *Incremental* means that new pages can be added, even if they do not yet exist. *Organic* means that the information can be continuously evolving, as changes and edits are made. Wikis are *mundane* because they involve the use of a simplified set of essential commands. The design of wikis is also *universal*, meaning that writing and editing is a “combined” activity, formatting is related to input (overt), page names are not context specific (unified), and pages are generally named with some precision (precise). Wikis should be *tolerant* of error; activity should be *observable* by all, and duplications are undesirable and should be deleted (convergent).

There are a number of software programs that enable the effective creation of wiki pages, including TikiWiki, TWiki, and Pmwiki. These allow for the effective creation, modification/editing, and management of wikis, including creating pages, creating links, formatting, and feature modules (discussion forums, photo pages, download areas, etc.) (Chawner & Lewis, 2006)

Wikis are set up to allow for easy collaboration, and more specifically, editing. Rather than passively reading a passage of text or related information (which may include graphics, multimedia, hyperlinks, etc.), a reader of a wiki can also take on the role of a writer, making changes to the text (re-organizing, editing, re-writing, and marking up) at will. In essence, the document is open to changes by a “collaborative community,” which allows for the secondary-oral model in education to be applied.

</table>
One reservation on the part of educators to embrace wikis is the fact that wikis are designed to allow for open and free access and editing by all members of a “community.” As a result, if improperly managed, a wiki’s content can become an unreliable, inaccurate, or biased source of information due to its largely unmonitored format. There is also the issue of having little or no “quality control,” resulting in a wiki not being trusted by its readers and users. An example of this was the controversy over the accuracy and reliability of Wikipedia, in the case of John Seigenthaler, in which the subject alleged that false and incorrect statements were posted in his biography (Seigenthaler, 2005). However, other studies have attempted to prove that Wikipedia was overall an accurate information source. One article reported that after analyzing a set of Wikipedia’s science articles, they were judged to be, by the British journal Nature, as reliable as the Encyclopedia Britannica (BBC News, 2005).

Wikis are useful for education in that they help to promote student participation and also a sense of group community and purpose in learning. Indeed, an important element of this is the relaxed sense of control over the content, allowing students to have a greater role in managing its focus and direction.

Wikis are not all the same, and there is significant diversity between various forms and implementations of wiki systems. In fact, it could be debated what features truly characterize a “true” wiki. The features inherent in most include the ability for users to both read and edit information, without the need for security or access restrictions. The emphasis is on simplicity, and the informal, “never finished” nature of wikis, which may constitute the contributions of multiple authors, is another key characteristic. While the emphasis of many wikis is on simplicity and a lack of access restrictions, that does not mean that all wikis work this way. In reality, there can be a continuum of features from simple to complex. At the complex end of the scale can be capabilities for security/access restrictions, complex organizational structures, and for integrated with content management systems (Lamb, 2004).

Now that the strengths and weaknesses of wikis have been established, it would be useful to examine the educational applications of wikis. In general, the most suitable applications are those that take advantage of the wiki’s free, open structure. As such, the use of wikis as discussion/bulletin boards, brainstorming tools, and online sketchpads is appropriate. Meeting planning is another viable application area, in that the organizer can start with a preliminary agenda, from which the other participants can then add their own additions or make modifications or comments.

An important application area for wikis has been identified in knowledge management (KM). The use of wikis for knowledge management may allow for an improvement over existing systems and technologies. Currently, with existing KM systems, there does exist a number of bottlenecks relating to knowledge acquisition, namely acquisition latency, narrow bandwidths, knowledge inaccuracy, and “maintenance traps.” Basically, these knowledge acquisition bottlenecks result from a time lag between when the knowledge is created, and then distributed. In addition, there are the problems of limited channels of knowledge input, possibilities of erroneous information being received, and also the difficulties of maintaining the knowledge base as it grows larger (Land, 2002; Wagner, 2006; Waterman, 1986).

The use of wikis to elicit a “bazaar” approach to knowledge management, rather than a “cathedral” approach, is proposed as a better alternative. These terms are derived from software development, whether the “bazaar” allows for more continuous and open access to code (or information), as opposed to the “cathedral” approach where access is only provided on certain (release) dates to certain persons. The difference between the “cathedral”
(closed), sources of knowledge acquisition management and “bazaar” (open) could be illustrated by the difference between encyclopedias that are created by a single firm, such as Encarta or the Encyclopedia Brittanica, and those that obtain information from readers and users, such as the well-known Wikipedia.

The emphasis therefore is on teamwork, continuous review and testing, and the development of conversational sharing (Wagner, 2006). Inherent in the workings of wikis is support for an open, collaborative environment, where many people can contribute to the development of knowledge instead of being limited to a set of “experts.” It appears that conversational knowledge acquisition and management are appropriate for wikis (Cheung, Lee, Ip, & Wagner, 2005). As for educational applications and KM, a study by Raman, Ryan, and Olfman (2005) examined the use of a wiki to help encourage and support collaborative activities in a knowledge management course. More specifically, using wikis in the course helped to encourage openness and better sharing and updating of knowledge bases. Many-to-many communication is supported, and the persistence of the created pages formed the basis of a knowledge repository. In short, the impact of easy page creation and improved updating and editing, together with effective maintenance of knowledge histories, were seen as positives (Raman et al., 2005; Bergin, 2002).

Activities in the KM course activities included group article review assignments, answering questions about sharing knowledge and uses of the wiki technology, and also creating a wiki-based knowledge management system. Students were asked to create, update, refine, and then maintain a class knowledge management system. In terms of these experiences, while the use of the wiki technology was generally viewed positively, feedback received indicated that, since the goals of using the wiki were not made clear, using one was perceived to be counter-productive. More specific guidance on goals and objectives, a clearer system structure, and advanced training were suggested as ways to make the wiki a more effective educational tool. The availability of too many features made the task of doing the course activities more difficult, since much time was spent learning the various features rather than focusing on the task at hand. A simpler, less feature-rich version was therefore preferred (Raman et al., 2005).

Another popular application of wikis in the classroom is in supporting writing courses. The use of this technology can help to foster the impression that writing is “fun,” and that there can be a shared and collaborative side to writing, revising, and commenting on written work. In other words, the technology can benefit not only the writing and editing process, but also in bringing about an awareness that writing is being done for a specific audience.

An example of the use of wikis in English is the Romantic Audience Program at Bowdoin College, where students used a wiki to discuss and examine Romantic literature, focusing on poetry, poets, and related topics. The technology was used to elicit discussion and analyses by the group, encourage elaboration on areas where further study or insight was sought, and to seek out linkages to additional sources and commentary. Another project is Auburn University’s Wikifish, which was created by one school within the university, where questions are posed, and opinions and comments by all are encouraged.

Difficulties encountered in using wikis for education include the difficulty of tracking the new pages and contributions made by students, since modification can be made to another student’s text without specifically identifying the author or editor. As a result, it can be difficult to monitor, and properly attribute, what contributions were made by whom, on a particular page. A proposed solution to this was an instructor’s use of categories and topics, requiring that students link to and add, rather than simply modify, the contributions of other students. Another issue was how much of a balance in terms of the tradeoff between
Innovative Technologies for Education and Learning

total freedom, and total control, was ideal. Since
a clear benefit of a wiki is the emphasis on free
expression and on spontaneous inputs, reducing
this may have a negative effect on open interaction
and student contributions (Lamb, 2004).

An interesting application of the use of wikis
in the classroom was the work by Bruns and
Humphreys (2005), where wikis were used in a
New Media Technologies course to collaboratively
develop entries for an online wiki encyclopedia
called the M/Cyclopedia of New Media, an ac-
tual live wiki resource made available online.
The effort to develop entries involved over 150
students spanning six classes in the program.
Feedback indicated that while students had little
difficulty with using the wiki system, obstacles
came about more with the writing and format of
the encyclopedia entries.

Another study examined the use of wiki
technology in German-speaking communities
in Switzerland (Honegger, 2005), while Desi-
lets, Paquet, and Vinson (2005) looked at how usable wikis are and found that the main prob-
lems encountered related to the management of
hyperlinks. Wikis were also examined from the
perspective of structure: how did the use of cer-
tain templates affect the appearance and layout
of wiki pages? The results suggested that they
are useful in certain circumstances and could be
helpful overall to end users (Haake, Lukosch, &
Schummer, 2005).

In summary, wikis are best suited to course
and activities where there is a document, text, or
other project to be worked on jointly by a class
or group. In a sense, it is a tool for collaboration,
and a form of groupware. The compilation of a
class or group report or project, the creation of a
knowledge base, or brainstorming sessions ap-
pear to be viable applications. The free and open
structure, however, can fall prey to disorganization
and degradation in quality, and so it is important
to have safeguards and procedures in place to
ensure an effective result.

PODCASTS

While the terms “pod” and “podcast” at first
mention might evoke visions of “Invasion of the
Body Snatchers,” for most tech people in the
know, the reference to Pod is almost certainly a
reference to Apple’s popular and ubiquitous iPod.

However, podcasts are in actuality not what
their name might imply them to be. A “podcast,”
a combination of “iPod” and “broadcast,” neither
refers to a technology specifically requiring an
iPod, nor broadcasts information to users. Instead,
podcasts are multimedia files (typically audio or
video) that are downloaded to users on a subscrip-
tion basis. Because of the potential confusion due
to the use of the word “pod,” some have called for
the letters to mean “personal option digital” or
“personal on demand,” rather than iPod.

Podcasts can be played back on any device or
system that can play digital audio (typically MP3)
or video files, and are not broadcast to a large au-
dience, in the way that television, radio, or spam
e-mails are sent. Instead, they are sent to users who
have specifically subscribed to a podcast service,
and as such, files are automatically downloaded
to the user’s computer when they are ready and
available. In addition, podcast files are generally
not streamed (as video is streamed), but rather
are downloaded for later playback (Lim, 2005;
Lum, 2006). Podcasts are delivered to subscrib-
ers through the use of RSS or RFD XML format
media feeds, rather than more traditional forms
of downloading (Descy, 2005).

Podcasts are considered to be a viable educa-
tional tool for several reasons. First, because of
the popularity and wide use of devices such as
the iPod and similar units, it would seem like a
good medium from which to distribute educational
materials. Secondly, the ease with which informa-
tion can be retrieved and accessed makes this
a good choice for students, who are using these
devices on a regular basis for music and should
have few technical difficulties or learning curves
(Lum, 2006).
There are multiple facets to podcasts. First, there is the consumption perspective, where someone downloads the podcast and then listens or views it. This involves subscribing to a service (or enrolling in a course), finding the relevant file, and then downloading and playing it. Alternatively, someone can actually create podcasts; an instructor can produce lessons for students, or students can produce an assignment in the form of a podcast file (Lum, 2006).

Education is one area where the power of the podcast has been used in various ways. At Duke University, orientation material was distributed as podcasts, loaded onto iPod units, and given to students in its 2004 incoming freshman class. The units were provided not only for orientation purposes, but also for use in playing podcast lectures when the students take certain courses at the university. At Mansfield University, students were sent podcasts about various student life issues, and at Arizona State University, President Michael Crow used podcasts to deliver messages to the university community (Lum, 2006).

While there appear to be sound reasons for using podcasts, there is also a theoretical basis behind the use of podcasting. This is based on cultural-historical activity theory (Engestrom, 2002) and is based on the fact that podcasting

</table>
can be considered a tool that can be used to help learners to better interact with or understand a task and its environment. Vygotsky (1978) argues that the effectiveness of podcasts rests in its linkage between social/cultural influences present in the environment and the cognitive development of the learner. Expressed another way, the concept is that since so many student have access to iPods and MP3 players, it would make sense to explore the viability of using such a device for learning and educational purposes.

Lim (2005) discussed experiences in using podcasts for teaching geography. Because of the nature of the subject, it was found that video would have a greater impact and result than audio. Students were asked to submit assignments to be created and submitted as podcasts. Overall, this helped to bring about satisfaction and interest in terms of the subject. Ractham and Zhang (2006) looked at the potential for podcasts in a classroom setting. While there are the obvious benefits in terms of being able to distributing class materials, there also are benefits in terms of contributing to social networking in the class and continuing a flow of academic knowledge. Class discussions, announcements of research activities and conferences, and also campus activities could be distributed as podcasts. Review materials could be distributed effectively on an automatic basis to interested students. In addition, the ability for students to create podcasts to be distributed to others would also be a new means of submitting assignments or expressing creativity.

Podcasts, unlike IM, blogs, and wikis, offer a greater emphasis on providing engaging auditory and visual course materials to students, rather than on collaboration and group work. While not generally a substitute for traditional lectures and knowledge presentation, they offer the benefits of easily accessible and “digestible” course material. Whether it is excerpts from class lectures, highlights from a guest speaker, or an oral test review, the use of podcasts provides a means by which students can obtain and easily receive course-related information. In addition, it also provides a means by which students can express and present their work, which can then be “published” and distributed in podcast format.

DISCUSSION AND CONCLUSION

The face of education, whether online, hybrid, or classroom, is constantly changing, and it is important for educators to stay abreast of the many opportunities and possibilities that are available.

In this article, several technologies, generally termed as conversational technologies due to their interactive and collaborative nature, were discussed in detail, together with their capabilities, benefits, and educational applications. Relevant research and case studies as they relate to classroom and educational applications were discussed.

In general, the tools discussed here fall into the class known as “conversational technologies” or “constructivist learning tools.” As such, they emphasize student interaction, group learning, and collaboration, rather than the more traditional classroom mode. In light of this, they are more suited to educational courses or environments where the emphasis is on student communication, where students have access to technology, and where creative output and thinking is encouraged.

In the situation where a course is primarily lecture-based, or is mainly concerned with the delivery of factual or conceptual information, these tools may have limited applicability. The one application that may be helpful in this case may be for interaction to be extended outside of the classroom, through the use of instant messenger, or for supplemental materials to be distributed as podcasts.

Since each of the tools has its own characteristics and suitable applications, it would be up to the
Innovative Technologies for Education and Learning

The educator to select those that are most appropriate to one’s course and activity.

Instant messenger, which is commonly used by students for personal use, has found its way not only into the business community, but also into the classroom, because of its strengths in terms of informal communications that are conducted real-time. There are some mixed results regarding the use of IM for use for education; benefits are claimed by some, but there are limitations as well. The use of IM would best be employed in situations where group work, student communication, and real-time discussion would be helpful. However, it should be used cautiously, since it can be distracting, and students may end up carrying on personal, rather than course-related discussions.

Both blogs and wikis have been hailed as useful tools for education, and the specific advantages and disadvantages of each are noted and discussed. Blogs tend to be more one-sided, with an author presenting his or her information, with generally limited input from the readers and public. However, the use of the technology has been used effectively to promote information sharing and to support writing courses. The use of blogs to support online learning journals, class article/peer reviews, creating online portfolios and galleries, and for solving a specific problem or case would be advantageous. It would also appear to be a good medium for graduate research seminars, where papers and studies are analyzed and critiqued.

Wikis, which allow freedom in creation and in editing and enhancement by others, are especially useful in collaborative situations where the input of an entire group is desired instead of a single person’s contribution. In the classroom, wiki support for collaborative writing and group activities, where students contribute to the creation of a common result, would be useful. In general, any kind of learning activity that involves the collection and maintenance of knowledge or information may benefit from the use of wiki technology.

The use of podcasts, which may include audio or video, is growing in popularity and is being used for delivery of information to subscribers on an automatic basis. Educational podcasts, both for the delivery of audio and video-based knowledge to students, and also as a new medium for the creation and presentation of assignments, appear to have potential. While podcasts are useful as a means for publishing and distributing files of multimedia-based class materials, there also exists the potential to create new podcast content, both for educators and as a course activity.

Clearly, the use of these new conversational technologies is allowing for the enhancement and continued evolution of new and innovative forms of support for teaching and learning.

FUTURE RESEARCH AREAS

Certainly, there are many benefits to the use of conversational technologies and constructivist tools for educational use. However, more research needs to be done, not only in terms of identifying additional types of applications and uses, but also in terms of how to more effectively identify and apply new approaches to learning with the aid of these kinds of technologies.

Some of the broader research issues that can be examined include measuring both learning, and the perceived quality of education, depending on the specific technology or tool employed. Are there measurable benefits to using a certain technology in terms of the material learned, better class performance, or more subjective factors? It would also be useful to determine, particularly when using blogs and wikis, the neutrality or bias in the entries, and how much these contribute to (or detract from) the material submitted for a course assignment.

Other research areas are more technology specific. It was mentioned earlier that wikis can be a useful tool in knowledge management. The application of wikis to effective knowledge man-
Innovative Technologies for Education and Learning

agement deserves further attention, both in terms of developing or adapting the wiki structure and features to knowledge management uses, and also for identifying various kinds of user interfaces and functionality that would improve usability. The establishment of wiki-supported communities of practice is one area where the tool could possibly be useful.

Podcasting also has many areas that are ripe for further investigation. There are issues that can be explored in the areas of knowledge management, collaboration, and the adoption of podcasts. Some of the specific topics of interest include the management and sharing of knowledge using podcasts, examining whether their use actually improves learning, studying their effects on collaboration and networking, and what the factors (or features) are that would help to promote its use.

There also has been work on the psychological aspects of distance learning and online courses (Dickey, 2004), and a study of learners’ reactions to using IM, blogs, and wikis, for example, would yield insights into its appropriateness for its further use in education. Does the use of these technologies contribute to the satisfaction of students, or is more classroom face-to-face still better?

The realm of these new technologies is certainly ripe with a host of opportunities for both interesting and meaningful research studies.

ABSTRACT
The prosperous development of wireless communication and sensor technologies has attracted the attention of researchers from both computer and education fields. Various investigations have been made for applying the new technologies to education purposes, such that more active and adaptive learning activities can be conducted in the real world. Nowadays, ubiquitous learning (u-learning) has become a popular trend of education all over the world, and hence it is worth reviewing the potential issues concerning the use of u-computing technologies in education, which could be helpful to the researchers who are interested in the investigation of mobile and ubiquitous learning.

UBIQUITOUS LEARNING: THE NEW AGE FOR EDUCATION
In recent years, digitalization around the globe has been proceeding toward wireless communication and sensor technologies, which are able to detect the contexts of our daily lives, and provide personal supports accordingly. Such technology has been called ubiquitous computing (u-computing). The innovation and advance of those new technologies have led to a new research issue in education; that is, to develop an innovative learning environment so that the students can learn in any place at any time. Moreover, with the help of context-aware (sensor) technology, the learning system is able to detect the student learning behaviors in the real world, and hence
more active and adaptive learning activities can be conducted. Such a learning scenario is called context-aware ubiquitous learning (context-aware u-learning), which has gradually become a popular trend of education.

Researchers have demonstrated how a context-aware u-learning environment can be used to help the learners in increasing their ability for solving problems in the real world. For example, a group of researchers in Japan has employed u-computing technologies to conduct students to learn Japanese under real-world situations. The systems can provide learners with appropriate expressions according to different contexts (e.g., occasions or locations) via mobile devices (e.g., PDA, Personal Digital Assistant).

**Ubiquitous Computing Technologies that Facilitate Education**

U-computing technologies can be used to provide personalized services in the context-aware u-learning environment. For instance, when a student enters a lab or stands in front of an instrument, the context-aware devices are able to detect the location of the student and transfer the information to the server. Based on the decision of tutoring program in the server, relevant information, such as the operating procedure for each device, the need-to-know rules for working in the lab and emergency handling procedures, will be timely displayed to the student based on the personal and environmental contexts. Some ubiquitous computing technologies that might be useful in educational applications are given as follows:

- **Sensors for Detecting Personal Contexts**

  Researchers have proposed several significant characteristics of u-learning, which make it different from conventional e-learning, including seamless services, context-aware services, and adaptive services. In an ideal context-aware u-learning environment, the computing, communication and sensor equipment will be embedded and integrated into the articles for daily use. In addition, researchers also indicated that “time” and “location” might be the most important parameters for describing a learner’s context.

  There are several ways to detect the timely location of a learner. GPS (Global Positioning System) is one of the popular technologies for continuously detecting an object’s position by satellites, which trace air waves shot from the IC chips embedded in the objects. The object’s location is described with longitude, latitude and elevation. Other sensors, such as RFID (Radio Frequency Identification), which is an automatic identification method relying on storing and remotely retrieving data using devices called RFID tags or transponders, can also be used to detect the location of a learner by reading the messages from the tags, and then calculating the learner’s position based on the intensity of the signals.

- **Advanced Technologies for Detecting Personal Contexts**

  Learners might feel distressed or confused while encountering problems in the u-learning environment. Under such circumstances, a u-learning system could actively provide timely hints or assistance if the contexts concerning human emotions or attitudes can be sensed. Recent studies have depicted the possibilities for detecting such advanced personal contexts. Sensing devices with affective aware ability can not only capture the expressions of human faces, but also tell apart their emotional conditions. For example, the Affective Computing Group in MIT Media Lab of America have presented significant progress in this field, which can be used to create more friendly interaction between human and computer by the detection of affective computing. Other studies concerning facial expression detec-
Ubiquitous Computing Technologies in Education

In addition, for some labs with special purposes (e.g., precise instruments, biotechnology and medical science), it is necessary to detect the volume of particles in the air. Taking semiconductor as an example, these particles may cause instruments a short circuit and even disable the devices.

RESEARCH ISSUES AND TARGET SUBJECTS

In Taiwan, the Conference on Mobile and Ubiquitous Learning was initiated in 2006 (which is called Ubilearn’2006). Based on the issues discussed in Ubilearn’2006 and Ubilearn’2007, several potential issues have been taken into account:

1. Architectures and infrastructures for ubiquitous learning systems
2. Adaptive and adaptable learning environments using mobile and ubiquitous devices
3. Agent support for mobile and ubiquitous learning
4. Architectures and implementations of context-aware learning technology systems
5. Designs for wireless, mobile and ubiquitous technologies in education
6. Design of learner-supportive interfaces of ubiquitous learning applications
7. Evaluation and evaluation methodologies for ubiquitous learning
8. Entertainment computing for ubiquitous learning
9. Mobile and ubiquitous computing support for collaborative learning
10. New pedagogical theories for ubiquitous learning environments and society
11. Innovative and practical use of wireless, mobile and ubiquitous technologies for education, learning and training
12. Psychological or theoretical foundations for mobile and ubiquitous learning and training

Moreover, a special interest group on Mobile and Ubiquitous Learning Environment (MULE) was established in 2007. Based on the previous experiences from these researchers, some potential applications of context-aware ubiquitous learning have been given, including art courses (painting or drawing from life or nature), physical education courses (motor skill training), language courses (conversation training), natural science courses (plant and animal classification) and engineering courses (equipment operating and work flow training).

Nowadays, u-learning is gradually becoming an important learning style owing to the popularity of sensor and wireless network technologies. As long as we strive toward the aim and develop a feasible and effective learning model, the ideal learning environment will become reality. In this innovative learning environment, the system can more actively provide more adaptive assistance to the student based on their learning behaviors in the real world, which have revealed the coming of a new educational age.

ABSTRACT

Team-based learning is an active learning instructional strategy used in the traditional face-to-face classroom. Web-based computer-mediated communication (CMC) tools complement the face-to-face classroom and enable active learning between face-to-face class times. This article presents the results from pilot assessments of computer-supported team-based learning. The authors utilized pedagogical approaches grounded in collaborative learning techniques, such as team-based learning, and extended these techniques to a Web-based environment through the use of computer-mediated communications tools (discussion Web-boards). This approach was examined through field studies in the course of two semesters at a US public technological university. The findings indicate that the perceptions of team learning experience such as perceived motivation, enjoyment, and learning in such a Web-based CMC environment are higher than in traditional face-to-face courses.
In addition, our results show that perceived team members’ contributions impact individual learning experiences. Overall, Web-based CMC tools are found to effectively facilitate team interactions and achieve higher-level learning.

INTRODUCTION

Instructors of both traditional face-to-face and online classrooms seek active learning techniques that engage the learners. The increased use of Web-based computer-mediated communications (CMC) as support tools that supplement the face-to-face classroom (“blended learning”) and enable active learning between face-to-face class times fit this quest. CMC is regarded as an efficient computer support tool to facilitate student participation (Phillips & Santoro, 1989). Prior research (Wu & Hiltz, 2004) reports that adding asynchronous online discussions through CMC platforms enhances students’ learning quality in a face-to-face class setting. Although various Web-based computer-mediated communications learning strategies have been applied in the field (e.g., online collaborative learning), limited research focuses on computer-supported team-based learning in a face-to-face classroom. Team-based learning (TBL) is an instructional strategy that promotes active learning in small groups that form a team over time (Michaelsen, Fink, & Knight, 2002).

Our goal is to assess the impact of team-based learning when introduced in a face-to-face classroom that utilizes Web-based CMC as a supplemental learning tool between classes, thus increasing team interaction across the semester. A Web-based computer-mediated communications tool called WebBoard™ was utilized in our computer-supported team-based learning research to facilitate team learning activities and communication. This paper describes results from this experience. The paper begins with a literature review building on constructivist learning, collaborative learning, small group learning, and Bloom’s taxonomy theories. It then provides examples of the Web-based interface and pedagogical implementation, introducing a model for assessing computer-supported team-based learning. Research questions, hypotheses, and data analysis results are presented. Finally, the limitations of the study and future research efforts are discussed.

We believe that our contribution is two-fold. First, we describe an approach for transferring a grounded pedagogical approach to a Web-based environment by supplementing the experiences from a face-to-face classroom. Second, we document preliminary assessment results that support the feasibility and effectiveness of the proposed approach. This discussion should be of interest to educators and researchers in expanding the use of current Web-based learning management systems with a structured modular approach through the integrated use of discussion forums to achieve higher-order team learning outcomes.

THEORETICAL BACKGROUND

Constructivist Learning Theory

Leidner and Jarvenpaa (1995) classify learning models and discuss their relevance and impact in information systems educational approaches. The broadest categories of this classification are objectivism and constructivism. Objectivism posits that learning occurs in response to an external stimulus. Learners respond to the stimulus by modifying their behaviors. This model assumes that abstract representations of reality and knowledge exist independently from the learners. Teaching consists of transferring knowledge from the expert to the learner. Opposite to objectivism, constructivism posits that learning is not a process of knowledge assimilation, but an active process of constructing individual mental models, in which knowledge is created.
in the mind of the learner. In this model each individual controls the pace and depth of his/her instruction. The instructor is only a moderator in the process of hypothesizing, questioning, and discovering the conceptual relationships between and among various objects.

Team-based learning uses a constructivist approach, which converts the learner from a passive to active learner. This differs from the traditional teacher-learner or objectivist approach. Students in this constructivist learning environment play a more active role as learners, since they need to be well-prepared in order to effectively engage in various class activities, such as to facilitate class discussions, to be able to take challenges from their peer learners and instructors, and so forth. Therefore, the constructivist approach is aimed to facilitate students’ critical thinking to achieve higher-level learning.

This research explores how the constructivist approach can be utilized to promote team-based learning in a Web-based CMC tool environment. Building on experiences from face-to-face team-based learning teaching (Michaelsen et al., 2002), computer-mediated communication tools are adopted to expand the collaboration opportunities via online team activities between weekly classes. Suitable technologies used in this context are listservs (email distribution lists with a Web-based interface) and asynchronous learning network systems (e.g., WebBoard, WebCT, BlackBoard, or similar technologies provide both a synchronous and an asynchronous discussion environment).

Collaborative Learning

Built upon the constructivist theory, collaboration suggests that learning quality enhances through shared understanding of more than one learner. Due to social interactions and intensive sharing among collaborative learners, collaborative learning results in higher learning compared with individual-oriented learning (Leidner & Fuller 1996). Schlechter (1990) found that learners perceived higher-order learning by generating more creative ideas and more diverse reasoning in collaborative small study groups.

Our computer-supported team-based learning approach takes advantage of collaborative learning strategies, with more structured teams, which exist for a relatively longer period (in our case, in the entire semester) and with a stable team setup (i.e. same team members), in comparison to other approaches where most teams are built much more casually and temporally.

Small Group Learning and Team-Based Learning

The importance of small groups learning and knowledge creation has been increasing in both education and industry. Team-based learning focuses on fixed small groups, which are established for semester long collaboration instead of temporary purposes. Small groups promote each other’s learning and success by holding each member personally responsible for the fair share of the work (Johnson, Johnson, & Smith, 1991). This turns the learning experience into a process, which improves the quantity and quality of the learning by leveraging long-term caring and peer relationships (Johnson & Johnson, 1999). Team-based learning simulates the similar peer collaboration experience in a real world. Therefore, the team-based learning experience may represent a useful training for students’ long-term career success.

The main emphasis of team-based learning is the organization around modules (work units) across the semester, consisting of 5-7 three phase sequences (Michaelsen et al., 2002). Each sequence includes preparation, application and assessment before moving to the next unit. Teams should be five to seven members in size. They evolve through four essential procedures: team formation, student accountability, team activi-
ties, and high quality feedback (Michaelsen et al., 2002). Our research uses these four procedures as the basis for the introduction of computer-supported techniques.

**Phased Cognitive Development Perspectives**

The approaches presented in this study are based on pedagogical theories that recognize the role of incrementally promoting higher-level learning through progressive team activities. Bloom, Englehart, Furst, Hill, and Krathwohl (1956) organize learning based on different phased cognitive development stages of information elaboration, starting from knowledge and comprehension to the higher levels of evaluation and synthesis. Bloom et al.'s taxonomy of learning goals and objectives summarizes the way student learning progresses through various stages of increasing complexity.

Bloom's taxonomy is particularly useful to identify a progression of learning, which is applied to the computer-supported team-based learning process. In the lower levels of the taxonomy (knowledge, comprehension, application) students absorb knowledge that is presented to them, comprehend it, and learn how to rank order and make inferences in other contexts. In the higher levels of the taxonomy (analysis, synthesis, and evaluation), students learn to generalize and transfer what they learned to their personal interpretation of reality. They learn to analyze and classify the models they have created. While the synthesis and evaluation levels of the taxonomy can also be accomplished by individual learners, collaborative methods and working in teams provide opportunities to excel in integrating associations and making judgments through communication with peers. In this collaboration mode, students can reach the higher levels of the Bloom’s taxonomy.

**WEB-SUPPORTED TEAM-BASED LEARNING EXPERIENCES**

Computer-supported team-based learning conducted via a Web-based CMC tool was introduced in a 15-week semester, face-to-face graduate course at a US public technological university during the Fall 2004 and Spring 2005 semesters. The first class period introduced the computer-supported team-based learning instructional strategy. The class was divided into teams of five to six students, including at least one woman and at least one student with a wireless laptop. The course materials were divided into six modules, with no midterm or final. Two out-of-class individual article reviews were assigned to the students.

The graduate courses in which we conducted this research was re-modeled, according to Michaelsen et al. (2002). Several steps of the TBL instructional strategy were modified to incorporate the use of a Web-based CMC tool called WebBoard (http://www.webboard.com/) intended for active learning activities between weekly face-to-face classes. A phased approach to active learning assignments via WebBoard was implemented across the two semesters of the study (Gomez & Bieber, 2005). Particular emphasis was placed on additional individual preparedness pre-module activities and team post-module activities through the use of WebBoard; a learning management system that provides a flexible interface for classroom discussion management. Figure 1 shows a typical discussion interface in WebBoard. The left frame provides an organized list of class activities. The right frame shows the details of each individual posting. For example, in the first semester, students posted preparation materials on WebBoard (http://www.webboard.com/) and wrote their post-team activity results on a poster in class. In the second semester, teams posted results of their work on WebBoard instead of handwriting on posters.
The team-based learning activities are based on an iterative process that divides the course into five to seven modules (themes/work units), as Michaelsen et al. (2002) suggests. A module is defined as a work unit or theme. Each module introduces increasingly complex materials that students must master before a subsequent module is introduced. A module can span more than one week’s worth of course materials, but a single activity should not span more than one class. Web-based CMC tools enable spanning beyond the single class time (when materials are hard to understand) by enabling the team to work between scheduled class times. Each of the modules must then be subdivided into individual preparation (reading materials and discussions), readiness assessment tests (individual and team), multiple team activities, and post module assessment.

The instructor acts as a facilitator across each module. He/she is responsible for hypothesizing, questioning, and discovering the conceptual relationships between and among various concepts (Passerini & Granger, 2000), and spending more time on preparation of the readiness assessment tests (RAT) and team activities, rather than course lecturing. The instructor plays a pivotal role in the TBL process, both for the course organization and ongoing module activities. In lieu of class lecturing, the instructor actively participates in the classroom as a task coordinator and time manager while observing each team’s discussions to readily intervene either as a subject matter expert or to clarify points of the task. Timely grading and feedback are essential aspects of the TBL process and should not be overlooked when planning. The instructor also provides feedback when team activities come together for sharing across the classroom.

Our emphasis with the introduction of Web-based tools to the TBL process is on the individual

preparedness of the student before taking the individual readiness assessment test for a given module and subsequently taking the team readiness assessment test. To accompany the reading assignments, students were asked to post a short reading summary and then reply to another student’s reading summary. In the Fall 2004 semester, the reading summaries were discussed online across the classroom. In the Spring 2005 semester, the reading summaries were discussed within each team. Our observations across both semesters indicate that discussions within the team demonstrated two benefits: extended discussions with the team and increased discussions prior to the team readiness assessment tests, reinforcing the preparation at the start of a new module. This suggests that discussions between team members are more effective and rewarding than discussions.
across the entire classroom. In reviewing the discussion board postings, the length and depth of the discussions were richer and more engaging when individuals were discussing within their team. This provides the additional benefit of increased team cohesion; a quantitative measure to be included in future research.

The student transition from their individual preparedness activities to the readiness assessment tests. Individual preparedness activities include all reading materials for the module, reading summaries, and individual exam notes for sharing with teammates, requiring students to organize their preparation time. It is suggested the questions for the readiness assessment tests should span the modules reading materials and be geared toward concepts; not detailed questions typically categorized as “by rote”. The questions should be broad enough to cover all of the module’s reading materials. Michaelsen et al. (2002) suggests approximately twenty multiple choice questions at the start of each new module for the readiness assessment test (RAT). Our research used a point system for the team readiness assessment test where teams were given a scratch card and were allowed to select more than one answer. Points were awarded in decreasing value (e.g. five points first try, three points second try, one point third try). Teams are permitted to appeal a question, with five to ten supporting sentences to ensure a concise and well thought out rebuttal. Students build cases with convincing evidence to persuade the teacher to award credit for an answer missed by the group on the test (Michaelsen et al., 2002).

Multiple team activities per module are needed with increased levels of complexity and are not assigned until after the team readiness assessment test. Typically team activities span two or three weeks for a single module, but a single activity does not carry over from one week to the next.

**Figure 2. Computer-supported team-based learning events**
The ideal activity is one that is a case study or has a problem-solving aspect to the activity. After each team activity, deliverables were reviewed and critiqued by the other teams, possibly for extra credit. The review and critique occurred in the FtF classroom for the first semester and using WebBoard for the subsequent semester. The premise was to deepen the learning and reinforce the objectives of the activity, while providing the instructor an opportunity to comment. Upon completion of a team activity, students should review the other teams’ deliverable and provide feedback to generate discussion.

Figure 2 summarizes the team-based learning iterative process and where computer-supported activities were introduced in this study.

ASSESSING COMPUTER-SUPPORTED TEAM-BASED LEARNING

The constructivist approach, cooperative, and collaborative theories and models, provide the background for the elaboration of the team-based learning assessment framework reviewed in this study (see Figure 3). Earlier research on Web-supported participatory examinations (Wu, Bieber, Hiltz, & Han, 2004) and collaborative examinations (Shen et al., 2004), informs the proposed team-based learning constructs and expected relationships. In order to succeed in this TBL process, students should prepare first, so that they can contribute their insights to the whole team (*individual preparedness* construct). We assume that their individual preparedness might bring more confidence for them on the value their team member’s contributions to problem solving, and they can also integrate and gain more insights from their team members. During this TBL process, students can learn more by communicating efficiently, and by building trust among their team members. Overall, we expect that the whole TBL process will provide the students an enjoyable learning experience, and will motivate them think at the higher levels of Bloom’s learning taxonomy, enhancing the quality of the learning experience. Figure 3 lists the key constructs and hypotheses tested in this study.

*Figure 3. Team-based learning (TBL) framework*
Definitions: Perceived Individual Preparedness is a self-reported student assessment of deep versus superficial study of the materials (Gomez, Wu, Passerini, & Bieber, 2006; Michaelsen et al., 2002); Perceived Team Member Value or Contributions is the positive perception of the value of teamwork (Isabella & Waddock, 1994); Perceived Trust/Communication Skills refers to the openness of communication within the teams (Coppola, Hiltz, & Rotter, 2004); Perceived Motivation refers to the intrinsic and extrinsic factors that influence students’ interest and attitudes towards the learning experience (Malhotra & Galletta, 2003); Perceived Enjoyment is the extent to which the learning activity (the team-based learning experience) is pleasant and satisfactory to the learners (Davis, Begozi, & Warshaw, 1992); Perceived Learning focuses on perception of the course quality; usefulness and extend of individual learning experiences as reported by the learners (Wu et al., 2004).

In exploring the relationships and impacts of computer-supported team-based learning, we focused on a number of factors that could impact students’ perceptions of learning. We adopted and modified a few validated constructs—“perceived learning,” “perceived motivation” and “perceived enjoyment”—from asynchronous online discussion research (Wu & Hiltz, 2004). In addition, we created two new constructs called “perceived individual preparedness” and “perceived team members’ value/contributions.” More specifically, we expect that the collaboration experiences and team-based activities completed by the teams throughout the courses will have a positive impact on perceived learning. Individual preparedness, measured as a self-reported student assessment of their deep versus superficial study of the materials, will positively impact the perceived value and contribution of the team-learning experience. This assumption follows Michaelsen et al.’s (2002) findings that individual contributions to team-output will promote team development and reduce social loafing and, therefore, will have a higher impact on the overall team-based learning experience.

Prior asynchronous learning networks research (Wu & Hiltz, 2004; Wu et al., 2004) shows a positive correlation between perceived motivation, enjoyment, and learning, when students participate in designing, answering, and grading exam questions on an asynchronous learning networks tool. These findings occur in the context of students’ learning experience from online discussions through computer-mediated communications platforms for blended classes, which mixed traditional classroom lecturing with asynchronous online discussions.

Individual preparedness and perceived member contribution to computer-supported team-based learning are expected to have a positive impact on learning, as well as on motivation and enjoyment of the team-based learning experience. In particular, motivation and enjoyment will act as intervening variables (see Figure 3). We also expect motivation to positively impact the overall enjoyment of the team-based learning exercises. Following Thorndike’s “Law of Intensity” and “Law of Readiness” (Thorndike, 1932), we expect that students who are engaged in the learning process through the multiple collaboration experiences embedded in the course organization, will be more motivated to learn, and will enjoy the learning experience better.

Lastly, we expect that the independent variables of individual preparedness, perceived team member value and contribution to computer-supported team-based learning will impact the level of trust and openness of communication within the teams, indirectly influencing communication and enjoyment. Establishing trust early (swift trust) in on-line communities has been found to have a positive impact (Coppola et al., 2004) on the learning experience. While we do not report results on trust measures (further analysis and
reiteration are needed as trust measures were collected only in the Spring 2005 reiteration of the field study, we include trust and communication as an important variable to consider in a computer-supported team-based learning model, which will be influenced by the individual preparedness and team contributions. As discussed in the future research section of this paper, additional observations in the Summer and Fall semester 2005 will supplement our preliminary observations.

Research Questions and Hypotheses

Based on the above discussion, our research is set out to investigate the following general questions:

- Does students’ perception of team contributions impact their learning from the computer-supported team-based learning process?
- Does individual preparedness affect perceptions of computer-supported team-based learning experiences?

A number of research hypotheses are therefore derived from the proposed research framework (see Figure 3).

**Hypothesis 1a&b:** Higher individual preparedness will increase students’ perceived motivation and enjoyment from computer-supported team-based learning process.

**Hypothesis 1c:** Higher individual preparedness will increase the perception of team members’ value and contribution to the computer-supported team-based learning process.

**Hypothesis 2a&b:** Higher perceived team members’ contributions to computer-supported team-based learning will increase perceived motivation and enjoyment from this process.

**Hypothesis 2c:** Higher perceived team members’ contributions to computer-supported team-based learning will enhance perceived learning in this process.

**Hypothesis 3a&b:** Higher perceived motivation will lead to higher enjoyment and learning from the computer-supported team-based learning.

**Hypothesis 4:** Higher perceived enjoyment from the computer-supported team-based learning will lead to higher learning.

Methods and Sampling

To test the hypotheses, survey questionnaires were used in the same masters-level information systems course called “Information Systems Principles” during Fall 2004 and Spring 2005 semesters. A total of 73 students volunteered to participate in our computer-supported team-based learning study. Among 73 respondents, 61 students disclosed their demographic information. Over 50% of them are full-time students, about 33% are part-time, and the rest are non-matriculated students, who are studying without officially being admitted to degree programs. About 60% are males, 36% are females, and three people did not provide their gender information. The majority of the respondents are between 21 to 30 years old, about 16% are between 31 to 40 years old, and the rest are between 41 to 50 years old.

Data Analysis and Discussion

In this study, the majority of data was collected from the surveys, which covered all variables proposed in the computer-supported team-based learning research framework (Figure 3). The primary data analysis methods to analyze our survey are descriptive analysis, factor analysis, and correlation analysis. First, descriptive data analysis was conducted to evaluate the validity of the constructs and the reliability of the scale used in the study. All the constructs returned a
Cronbach’s Alpha higher than 0.70. The detailed question items for each construct are listed in Appendix section.

The factor analysis was then performed to confirm the loading of the questions to the respective factors. In general, the question items show high reliability of the constructs they represent. The exploratory factor analysis technique was used in this study to verify whether the grouping of the survey questions maps to the model constructs.

Table 3. Components extraction matrix
An exploratory factor analysis (EFA) was run to identify the underlying model, the number of factors in the model, and the variables (by type of questions) associated with each factor. Within the factor analysis technique, a principal components analysis (PCA) was used to highlight the number of factors to be extracted from the model. The confirmatory factor analysis (CFA), in its rotated version (VARIMAX rotation) helps to identify the underlying model. The Principal components analysis yielded six factors with eigenvalues >1. We focused on the first five components corresponding to the research model constructs (Table 3) because of the limitation of one of the research constructs (individual preparedness) that yielded ambiguous results and because the additional variance explained by the additional factor did not substantially alter the model (as it is the lowest incremental cumulative variance). In addition, we did not test the trust/communication construct, with a possible impact on the overall model. Limitations of this approach as introduced at the end of this section.

**Extraction Method:**
**Principal Component Analysis**

Table 4 shows the bivariate correlations among variables and provides intriguing results. In particular, it shows that perceived enjoyment and motivation are highly correlated with the dependent variable of perceived learning (R>0.63 for both constructs). It also shows that perceived team member’s contribution positively correlates to learning, enjoyment and the motivation constructs. However, the bivariate correlation analysis shows that individual preparedness is not significantly related to the other variables, and the relationship, if any, is negative.

Based on the results of the above bivariate correlations, we identify that hypothesis 1 (a, b, and c) are not supported. The other hypotheses are supported at the p=0.01, with the correlation between team contributions and motivation significant at the p=0.05 level (see Figure 4).

From the above data analysis results, it is suggested that how individuals value their team
Utilizing Web Tools for Computer-Mediated Communication to Enhance Team-Based Learning

members’ contribution has significant correlations with their perception of enjoyment and learning quality from computer-supported TBL (Gomez et al., 2006). These results address the first research question on how team interactions positively impact the whole computer-supported TBL learning experiences. In addition, individual opinions on team members’ contributions also have a positive impact on their perceived motivation, although the Pearson’s R value is not high (R = 0.28). It might be caused by other potential factors from the computer-supported TBL experience, which could decrease students’ motivation. For instance, if the team leader is more dominant, his control might impact other team members’ motivation.

Surprisingly, individual preparedness does not impact perception of the team-based learning experience. The correlation values among individual preparedness and other variables are not significant. The results also show that their correlation values are negative. There might be a few reasons. First, as indicated earlier, the ambiguous two question items for the “individual preparedness” construct (i.e. ambiguous statement, negative factor loading) have a negative impact on the research framework. The individual preparedness tasks associated with studying differences may not be self-evident to the student increasing the ambiguity of the questions. Moreover, our observations indicate the importance of individual preparedness on the entire iterative nature of the module whereas our focus of the current individual preparedness construct was driven from the importance of the readiness assessment test process. The bivariate correlation analysis does not show any significant relationships between “individual preparedness” and other constructs in the framework. This is evidently one of the limitations for this research. For future research, we plan to refine the “individual preparedness” construct with question items targeted at the individual preparedness process more than studying specifically for the tests. Second, there might be an interaction effect of the experimental conditions: the computer-supported TBL process design itself might also impact the results. The team assessment tool (tRAT) is the same test as the individual readiness assurance test (iRAT). Although the overall team scores are better than individual test scores, the test repetition may explain the decrease in the students’ motivation and enjoyment. Also they could not perceive more value from their
Utilizing Web Tools for Computer-Mediated Communication to Enhance Team-Based Learning

respective team members. We also speculate that the test questions may not have lent themselves well to interesting team discussions, leaving the tRATs uninteresting. Alternatively, this simply may indicate that many students found the TBL process valuable even when they did not prepare in the manner the instructor expected. These results show that our second research question on the role of individual preparedness needs further investigation and analysis to span the iterative cycle of each module (preparation, test, activity) and not simply focus on the readiness assessment test aspect.

There are a number of limitations to this study. First and foremost, we found that some of the constructs could be better specified. Our factor analysis displayed the possible existence of another significant factor which should be further analyzed in future research. This additional factor was associated with an ambiguous question in the individual preparedness construct. Looking at the articulation of the questions in that construct, we identified an instrumentation bias (one item in the construct was weak), which may explain our concerns with the specific construct. In addition, because some of the constructs and the extension of this grounded team-based learning approach to a Web-environment is novel, we should supplement our conclusions with an in-depth analysis of qualitative factors (observations, open-ended questions, and content analysis of discussion boards) that may help better understanding the learning outcomes more objectively in a way that complements the perceived learning measures. Adjusting the activities layout in the Web-based environment with our phased approach and the nature of the individual preparedness activities indicate the complexities of this construct. Our qualitative analysis indicates that spanning beyond the individual preparedness question items related to the readiness assessment test to also include question items that measure perceived preparation of the materials related to team activities.

SUMMARY AND FUTURE RESEARCH

Computer-supported team-based learning provides a powerful instructional experience and reduces some of the disadvantages many instructors and students have found with traditional small-group work. Blending the benefits of the face-to-face classroom with computer-mediated communication extends the learning process between the weekly face-to-face sessions keeping the team learning progress and group dynamics growing.

Our research places emphasis on key variables that affect learning in computer-supported team-based learning. Computer-supported team-based learning is still a relatively new pedagogical approach, and to the best of our knowledge, this is the first study blending computer-mediated communications with the iterative team-based learning modular approach proposed by Michaelsen et al. (2002). The use of Web-based CMC learning techniques places emphasis on individual and team learning outcomes. The surveys indicate a high-perception of learning, motivation, and enjoyment. These findings deemed computer-supported team-based learning an approach for further investigation both in the face-to-face classroom and for online learning.

The emphasis of future research will be on team-assessments and group cohesion in a purely Web-based learning environment. The findings around the team activities will allow for additional adjustments in the team-based learning process before it is introduced in a completely online learning mode. Blending the face-to-face class with computer-mediated communications provides a means to gauge the asynchronous learning network process. Future studies will extend the analysis of the computer-supported team-based learning model and research framework using the structural equations model (SEM), trust, com-
Utilizing Web Tools for Computer-Mediated Communication to Enhance Team-Based Learning

munication, and team leadership factors. Further review of individual and team preparedness is also needed. The progressive nature of the readiness exam process and team activities should ensure individual preparation. Because of the novelty of the preparedness and team contributions constructs, we will also implement content analysis of team activities posted on WebBoard to support the evaluation of individual preparedness for each module. Adding qualitative data and observations will enhance our understanding of the constructs. Actual grades and peer evaluation results will also support the measurement of task completion levels.

Team-based learning presents a promising technique employing small teams that actively engage students in learning. We look forward to the day when instructors can effectively use computer-supported team-based learning as a standard approach in both face-to-face and online classrooms.

ACKNOWLEDGMENTS

We gratefully acknowledge partial funding support for this research by the United Parcel Service Foundation, the New Jersey Center for Pervasive Information Technology, the New Jersey Commission on Science and Technology, and the National Science Foundation under grants IIS-0135531, DUE-0226075 and DUE-0434581, and the Institute for Museum and Library Services under grant LG-02-04-0002-04. An earlier version of this paper was presented at the IRMA 2006 International Conference in Washington DC, May 2006.

ABSTRACT

From the authors’ perspective, technology is both a tool and a developing factor that can foster culture and learning development. This chapter focuses on the interrelations that interleave education, technology, content accessibility, and intercultural issues. With an introduction and related background, language learning is used as an example further to explain these issues. This chapter then discusses authoring and content development for e-learning applications (including authoring tools, virtual communities, and forums), and examines technology and accessibility issues in this context. The current state of e-learning is introduced along with a description of different tools and approaches. The chapter concludes with an overview of e-learning and the marketplace.

INTRODUCTION

Major developments in culture and civilisation are based on a combination of factors including personal abilities, societal, and economical environment, and so on. According to Maslow (Abraham, 1943), subsistence needs have to be met before other and “higher” aims are reached for (Figure 1). Nevertheless, the search for a solution to a problem (even a very practical one) may provide the core of our evolution in technology, science, culture, art, or education.

From the authors’ perspective, the issue regarding the relation interleaving technology, culture, and education is twofold. On one side, technology has often been a major cause of disruptive advances in the evolution of science, culture, art, and education. On the other side, scientific
How Technology Can Support Culture and Learning

For example, the present development of western culture has been reached thanks, in large part, to the technical innovation introduced by Gutenberg, which made possible the diffusion of culture through print, making learning affordable for everyone and therefore, also accessible. Yet were it not for Braille, all the culture and knowledge available in printed form would be totally inaccessible to visually impaired people unless they could afford to have a personal reader. This technical support is therefore a clear example of how technology can support culture and learning in the wider sense.

It is worth taking into account historical notes related to the impact of technology on the learning process and therefore, also on the evolution of society.

**SOME HISTORY NOTES**

The art of teaching and learning has a long history. Initially it was a matter of subsistence and therefore, the elders in a community would act as tutors, trainers, and mentors for the younger members. This process then evolved from mere subsistence to something that became much valued by the learner and rewarding for the teacher.

Due to the very nature of this process (based on knowledge acquired through personal practical experience), teachers were numerically very...
limited in respect to potential learners; moreover, not everyone could benefit from mentoring, as most of the individuals would have to work hard to support the group’s living needs. Therefore, only the most brilliant, or the more influential members, would be granted such a precious gift as “formal learning” and this had a strong social impact.

For a long period of time, education and culture has been accessible only to upper classes; religion played a relevant role in this, as knowledge was mainly held by “priests” or “monks,” who would also act as tutors and mentors for nobles, ruling classes, and their earls or illegitimate sons.

This phenomenon was so strong that during the “Middle Ages” the term “clerices” was used generically to indicate the people with an education. This is also the period of the birth of the first universities like the “Alma mater” in Bologna (1088), the “Sorbonne” in Paris, “Montpellier,” the “Scuola Medica Salernitana,” “Heidelberg,” “Salamanca,” and many other ancient and prestigious universities in Europe. The “clerices vagantes,” in their roaming through Europe, spread culture, teaching in the various universities they visited, rivalling each other to achieve eternal fame thanks to the universal language of the time (Latin). A famous example is Abelard (the well-known character of Abelard and Eloise). Most people consider this as a tale while it actually was a real event in European history.

The main academic subjects at the time would have been literature, philosophy, religion, and law, while science was more limited in scope than now. In this sense, it is interesting to find out how some of the presently most reputed universities started, for example Oxford and Cambridge. Their origins date back to 1167 when Henry II ordered all English students on the Continent to return to England. Many of them decided to settle in Oxford in an attempt to create a university as they had seen in Europe. Unfortunately, disputes between the students and residents led to riots and a number of students fled to Cambridge, where they established a new university. In turn, the loss of students hurt Oxford’s local economy and in 1214, traders and merchants invited them back again. The competition between Oxford and Cambridge colleges probably dates back to those times when William of Durham founded University College in 1249. Balliol was established in 1263 and Merton, the first residential college, followed a year later. Merton set the collegiate pattern, which became standard in both Oxford and Cambridge. These colleges were self-governing institutions where teachers and students lived together. Fourteen other colleges were founded by the end of the 16th century (http://www.spartacus.schoolnet.co.uk/EDoxford.htm).

In another part of the world, the “clerices” role was covered by other scholars; it is remarkable that most of them would still be monks, hermits, or anchorites like Buddhist and Confucian scholars in Asia, or Imams and Ayatollahs in the Muslim world. Moreover, to most people, the universities previously mentioned seem to have had an extremely early start, but if we look at the records of Nalanda, we find out that this is actually mistaken.

Nalanda was a Buddhist monastic centre, often referred to as a university, in the North Indian state of Bihar. Though it is traditionally placed in the time of the Buddha (6th—5th century B.C.), archaeological excavations date its current foundations to the 5th century A.C.; it housed a population of several thousand teachers and students. The topics covered spanned logic, grammar, astronomy, and Ayurvedic Buddhist medicine; the Chinese pilgrims Xuanzang and Yijing provide vivid accounts of Nalanda as early as the late 7th century. Nalanda continued to flourish through the 12th century and became a centre of Buddhist religious sculpture, but was probably sacked during Muslim raids around 1200, and has never recovered since (http://www.ayurveda-tcm.com/Buddhist_ayurveda_monastic_college_Nalanda.htm).
In China, the First Emperor (259 B.C.) established a process to formalize a set of hierarchies and exams related to the acquisition of public roles (becoming a Mandarin or an emperor’s officer). In similar fashion measures, rules, laws, and even the way of writing were standardized and formalized so that the same characters are still in use. Since then, in China, culture has always been highly valued; there is even a common saying related to this that translates as “a word is worth a 1,000 pieces of gold.”

The origin of this common Chinese saying can be found in the famous book Shiji (or Historical Records) by the historian Sima Qian (around 145-87 B.C.). He describes an episode from the time when Lü Buwei (the natural father of the first emperor) was prime minister. Lü Buwei was hosting and protecting over 3,000 scholars, so he compiled the best of their writings in a book, claiming that it was the encyclopedia of his time covering science, literature, and all the knowledge that was under heaven. Actually, the prime minister did more; he had a collection of texts engraved onto rock and an edict proclaimed stating that: “Whoever would have been able to improve all that is collected and written by simply adding or removing even a single word would have been granted a 1,000 pieces of gold.” For fear of offending the prime minister, a very powerful man, no one dared to attempt this, but since then it was clear why even a single word would be worth a fortune (http://www-chaos.umd.edu/history/ancient2.html, http://www-chaos.umd.edu/history/imperial.html#first, http://www-chaos.umd.edu/history/toc.html)(Mah, 2003).

Coming back to Europe, culture and education started to spread only with the rise of the middle classes and the development of the publishing industry, even though remaining the prerogative of a minority. Only in the last century, well in line with Maslow’s theory (Abraham, 1943), did education become a patrimony “for everyone.”

Figure 2. Evolution in educational models and results in relation to technology innovation
How Technology Can Support Culture and Learning

This is mainly due to the social and economic evolution that occurred after the industrial revolution, bringing better living conditions.

In the process of providing access to education and culture, technology had a crucial role. For example, the evolution in educational models and achievable results (in terms of educational objectives) in relation to technology innovation, along with major driving forces, is presented in Figure 2. In the diagram, the role played by economical forces as a push factor (companies demanding new learning services in order to have a more highly skilled work force) is shown. At the same time there were also socio-political forces pushing for more flexible and decentralised approaches, both in work and in education, to keep on track with society’s evolution.

In all this, technology was playing a twofold role. On one side, it was a driving force providing solutions to issues and needs arising from market and production environments. On the other side, many spin-offs of this evolution were also fed back into everyday life. Education and training could also benefit from technologies by providing new tools and methods to convey content and knowledge; thanks to the introduction of factors like simulation and interactivity at first, and then collaboration and personalisation, dramatic developments were achieved. At present, the new evolutionary step will likely be lead by the effective combination of these factors and the introduction of new technologies.

To better understand this, we will look at the origin of open and distance learning (ODL). This began in areas where the educational system was facing huge challenges due to distances and the spread of population over territory, combined with a growing demand for access to education, as in the USA, Australia, and Canada. To meet the requests (coming from all levels of society) for a higher level of education/training, a form of “distance learning” needed to be developed. This new learning process was initially supported by regular mail, then by radio and television. Then tools initially developed to support totally different scopes, like the Internet, started to be used for scientific and educational purposes. The initial spread of data among researchers fostered the exchange of knowledge; this brought on the rapid evolution of the so called “wired-world” that nowadays plays a crucial role in education, yet all previously mentioned media are still in use depending on needs and available budgets. As a matter of fact, available solutions cover almost all forms of training and teaching, from traditional class learning to e-learning.

Early examples of e-learning were the computer-based training applications often referred to as CBTs, mainly developed to foster professional (re)training. Then low-cost computers were developed, with reasonably good performance, and able to sustain multimedia applications and made available to the mass market. In more detail, it was the advent of the CD-ROM (mainly seen in this case as a mass storage device), along with easy access to the Internet that fostered the launch of the first mass-market-oriented CBT (mainly devoted to language teaching). Initially, products were conceived in a stand-alone fashion. Then hybrid versions (CD plus Internet) emerged to achieve a higher level of modularity and flexibility (including periodic product update), and now there are many online training courses.

According to IDC, e-learning means “educational content, learning services, and delivery solutions that support and enable Internet-based learning” (IDC, 2002). Thus, e-learning is a subset of what is defined as technology-based training (TBT) that includes CD-ROM and other technology-delivered training. In turn, TBT is a subset of what is called enhanced learning, which includes support to disability for learners, and so on. Finally, enhanced learning is a subset of the overall training and learning including instructor-led training (ILT) and text-based training, as shown in Figure 3, which elaborates on the basis of concepts exposed from the already quoted IDC report (IDC, 2002).
How Technology Can Support Culture and Learning

According to Tomita (1980) and Neuman (1991), the scenario presented in Figure 4 shows evidence of “a media gap.” Blogs, Wikis, virtual communities, and many other forms of communication and social/educational experiences are quickly arising and filling this “media gap.”

The availability of new and more pervasive technology support, as well as the growth and spread in access to culture and education, is ultimately addressing the issue of a “lifelong learning” process to avoid knowledge obsolescence, especially in environments like science or technology. We must bear in mind Novak (1998), when saying that the rote-meaningful learning continuum is distinct from the reception-discovery continuum for instruction (see Figure 5). As a matter of fact, it is not enough to have availability of information and technology that can assist in accessing the related knowledge.

A common mistaken notion is that “inquiry” studies will assure meaningful learning. The reality is that unless learners possess at least a rudimentary conceptual understanding of the phenomenon they are investigating, the activity may lead to little or no gain in their relevant knowledge. In this respect, it is worth noting that this aspect has been taken into account in the e-learning sectors and therefore, cognitive modelling and ergonomics have been closely investigated (Sussman & Sedivy, http://www.umass.edu/psychology/div2/eyelab/).

Studies on cognitive architecture have been carried out by taking into account perception, cognition, action (motor), and memory (Hornof & Halverson) as well as studies on eye movements and visual attention (Kowler). These results are extremely interesting and promising, as the use of these technologies could be very successful if employed to foster the learning process and support full accessibility, regardless of gender, race, language, and impairment. The introduction and combination of wireless communication, agents, adaptive user profiling, virtual reality, and eye-tracking (http://www.vr.clemson.edu/eyetracking/, http://www.nottingham.ac.uk/education/maps/eye.html) with artificial intelligence and other technologies can move the frontier for e-learning applications exactly in this direction.

The use of “multimedia” is probably one of the most relevant approaches to properly support education in all environments. It is an excellent way to support teaching activities, not only because it enables one to enrich the quality level of the service, but also because it allows one to attract the learner’s attention, and stimulates the mind from several perspectives. However, this is not enough unless the effort involved in overcoming accessibility problems and impairments in the learning process is taken into account. To achieve this result, the accessibility issue has to be addressed in the design phase and the available and emerging technologies, regardless of their origin and major field of application, have to be fully exploited. In other words, to examine carefully how accessibility-related needs, in general, and impairment could be tackled and use whatsoever technology that could fit to solve, or work-around, the problem so as to grant full access to education and culture and therefore, also greatly contributing to societal development.
Figure 4. The media gap (Adapted from Neuman, 1991)

Figure 5. Relation between learning autonomy and learner satisfaction in relation to media richness and bandwidth (Adapted from Novak, 1998)
As stated, in theory (as well as in practice), it is possible to devise usage of technologies presently applied in other sectors in the learning field to empower better and more compete forms of e-learning. As an example, just think how eye tracking has been exploited in the military environment to control firing systems⁵, and how it is presently used to support reading and comprehension exercises and other learning activities, but still well below its huge potential.

Another example may be the adoption of tools and methods used to teach diction, or opera singing, in the language learning environment (at least as far as pronunciation is concerned), especially when teaching languages like Chinese or Japanese to westerners or English to easterners. In this case there is a real need to learn things such as breath control, tone usage, phonation, and so on, just as it is done for opera singers or for actors.

**LANGUAGE LEARNING**

Most professional sectors have adopted technologies to support the learning process. Probably the first one to do so was the professional training sector (pilots, train conductors...) and language learning. Later came the informatics sector (programmers, EDP operators...), then the finance and banking sector (initially jointly with the informatics sector, then on its own, due to the increase in complexity of the environment itself), and lastly the medical training sector (initially in imaging and diagnostic to progressively shift towards a full coverage)⁶. This section focuses on the language-learning environment as an example, given that it represents a case where technology has already been widely adopted to properly support learning processes over a long period.

It is possible to find self-learning materials based on a widespread set of technologies (from vinyl audio support, to tapes, and now CDs or DVDs) and furthermore, many different learning methods have been adopted to support different classes of learners (businesspeople, primary and secondary students, home users, and so on). This illustrates the relation between e-learning and technology as a support for culture and education.

It is widely accepted that to master a language, the four linguistic skills (speaking, listening, reading, writing) have to be acquired, but the social and cultural background also have to be understood. Therefore, the study processes can be enhanced through the guided use of contemporary media such as newspapers and magazines, film and television, video, CD-ROMs, and Internet. Certainly, literature is an important part of the study of language and culture, especially at the more advanced levels, as it constitutes the most versatile and complex of language usages. Literature essentially represents a compendium of the past and present culture(s) of the language in which it is written. Therefore, it also represents the most difficult part to master when learning a foreign language as a second language.

When using a foreign language, words will turn out to be cages for concepts the learner wants to express. Unless the learner is natively bilingual, thinking directly in another language may be achieved only partially. For some people it is easier to learn the sound of the word/sentence and to note it down in their own language. This depends on many factors, starting from the degree of knowledge and mastery of the meanings associated with a word in a specific language, to end with the personal cultural background that may bias the nuances given to a specific word or expression (just think of all forms of professional jargon and disambiguation needs encountered when translating a word or a sentence out of its context). Many problems, misunderstandings, and issues have been caused by improper usage of words among people. Therefore, there should be a basic concern when teaching/learning a foreign language:
Concepts are expressed by words. If certain English words are missing in Chinese, it follows that the concept expressed by those words will be absent in China, and vice versa. (Mah, 2003)

When taking all this into account, it is evident that mastering a language is much more than learning its vocabulary and grammar; it implies also learning the culture behind the language; the history, the traditions, the costumes, and the related ways of thinking. In other words, all meanings, structures, metaphors, sounds, and tastes of a language need to be learned, in the same way a child from the country in question does this. This lesson has been used by scholars working in the language-learning domain, and is progressively being widely adopted in regular language learning in primary and secondary education. For example, as far as the “sound of a language” is concerned, exploiting songs, and their lyrics, has become a common way to support teaching, as is evident from the following quote by LeLoup and Ponterio (LeLoup & Ponterio, 2001):

Most foreign language teachers enjoy studying song lyrics as authentic text in their classes. Songs can be used at all levels and for a wide variety of activities and purposes such as comprehension, vocabulary introduction, illustration or recognition of grammar structures, and reinforcement of topics. Traditional or new children's songs, musical classics, or the latest pop hits are all fair game. The rhythm and melody of songs can make the words and expressions easier to remember and more enjoyable for students than other sorts of texts.

Unfortunately, teaching the culture behind a language is a long and difficult task, usually unfeasible in the timeframe of regular classroom teaching during primary and secondary education. However, this issue is being addressed more frequently than in the past, and is also often addressed by using e-learning in a lifelong learning approach. Furthermore, there exists class-based intercultural training devoted to specific audiences. Nowadays, learning words, sentences, and polite phrases in a foreign language, mainly to manage human/business relations when abroad, is becoming a common habit among far-sighted businesspeople, and therefore, it is essential to also teach proverbs, phrasal verbs, idioms, and so on. In the diplomatic environment, this has a long tradition; for example, in China, the first emperor studied Tibetan costumes and the language, to be able to properly welcome the Dalai Lama7 (Mah, 2003). Similarly, the Jesuit missionaries in Japan or China would spend long years in training before being sent to their final destination. During their training, they would learn how to behave, talk, act as if they were locals, and this training was finalised to achieve a specific purpose: the conversion of the locals to Christianity. In this, they reached such a level of perfection that Matteo Ricci is accounted among the classical Chinese authors in maths, geography, 8 and other topics, despite the fact he was an Italian.

The power of multimedia-based e-learning lies in the possibility to convey several media and all the related content richness to the user (in a single framework). For example, on a DVD, it is possible to convey as much data as in an ordinary encyclopaedia, with high-quality audio and good quality video. The Internet allows the updating of e-learning sources and tools in a combination of self and assisted teaching, making it possible to learn at one’s own pace and having tutor support only when needed. Synchronous activities can be performed along with asynchronous ones. Reinforcement tools are available, and all this is “virtually” usable by the learner.

There is a clear need to stress the word “virtually,” as disability support can be provided as well, but if this is lacking, then all this power may be lost for a relevant part of the population. From a technical point of view, it is possible to take ac-
cessibility (in the wider sense) into consideration from the very beginning, thus ensuring the widest possible coverage of user needs (from impairment to aging support). Nevertheless, this implies that proper development tools and strategies have to be used.

The outcomes from a 2001 European Commission open workshop to examine the future of e-learning expected the research focus to be on virtual and remote labs, emotional characters, handwriting recognition, and eye tracking in e-learning usability. All this should be combined with situational-based training and mobile access to resources so that: “Research on eLearning will support the development of innovative models for the provision of learning services, fully exploiting the potential of ambient intelligence technologies, enabling ubiquitous, interactive, personalized and tailored access to learning and knowledge on demand to individuals at home, at work or on the move. It will build advanced learning schemes for schools, universities, the workplace and for lifelong learning in general, reflecting the needs of the knowledge economy.” In other words, the pillars of the knowledge society and economy are ubiquitous access to personalized learning throughout life for everyone.

Traditional and Innovative Language Learning

Traditional class-based language courses are structured according to a well-codified approach that regards grammar and vocabulary to be the core of the study. The main differences that are worth noting in class-based learning are mainly related to target audience and objective of the class. Basically, we can distinguish the following categories of class-based learning:

- Basic institutional curricula (primary or secondary education level).
- Advanced institutional curricula (post secondary education level).
- Specifically oriented curricula (business, summer schools).

For each of these, there are specific programmes, schedules, and methods aimed to maximise the training outcome.

Except for literature or business-oriented courses, dialogues and drill downs are considered as complementary or support activities, just like exercises. Therefore, dialogues are usually linked to curiosities and hints on culture and civilization.

Figure 6. Language course levels according to several classifications

![Diagram of language course levels]

- Beginner – Berlitz 1 – A1 – ILR 1
- Beginner / Intermediate – Berlitz 2 – A2 – ILR 2
- Intermediate – Berlitz 3-4 – B1 – ILR 3
- Intermediate / Advanced – Berlitz 5-6 – B2 – ILR 4
- Advanced – Berlitz 7-8 – C1 – ILR 4
- Proficiency – Berlitz 9-10 – C2 – ILR 5

User proficiency
How Technology Can Support Culture and Learning

related to the language being studied. Classes are usually organized in terms of language knowledge prerequisites that are assessed via admission texts (this applies only to noninstitutional training). Yet even when assessment is not performed in advance, content and course structure reflect a similar approach with the presentation of the most difficult/uncommon concepts, authors, or issues at the most advanced level. A gradual approach to learning has always been adopted (see Figure 6), and is reflected in the courseware and content structure. This is certainly a harsh generalization, but still reflects a good part of the present class-based offers on the market.

The levels reported provide indications according to different classification approaches: UCLA, Berlitz (http://en.wikipedia.org/wiki/Berlitz_Language_Schools), common European framework of reference for languages (http://culture2.coe.int/portfolio/inc.asp?L=E&M=$t/208-1-0-1/documents_intro/common_framework.html), and Interagency language roundtable (http://www.utm.edu/staff/globeg/ilrhome.shtml, http://en.wikipedia.org/wiki/ILR_scale). Usually the passage from one level to the other is bound by the accomplishment of a specific (and in most cases well codified) exam. The schema also visualises the usual decline in participants from the basic to the more specialized training levels that are often not only more demanding in terms of prerequisites, but also in terms of competences and capacities of the trainees. Inside each course level, the typical learning unit could then be structured as follows (Figure 7).

This is a harsh schematisation, as the more advanced the course is, the less such a grammar-centric schema is followed, as there is a natural shift towards a more content-centric schema that is best tailored to the form of advanced learning provided. In fact, while the grammar-centric schema perfectly suits certain pedagogical purposes (like teaching how to teach a language), it is

---

**Figure 7. Typical structure of a grammar-centric learning unit**

<table>
<thead>
<tr>
<th>Level</th>
<th>Dialogue Structure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beginner</td>
<td>Listen &amp; repeat (1)</td>
</tr>
<tr>
<td>Advanced</td>
<td>Listen &amp; complete (2)</td>
</tr>
</tbody>
</table>

(1) Here level is referred to the kind of exercises and not to the overall course that may be beginners, basic, intermediate, advanced, or proficiency.

(2) The student has to listen to a sentence and then repeat. There is not much interaction except repetition.

(3) The sentence is first heard, then repeated with blanks that the student should fill, and then repeated again.
not suitable for others, such as teaching literature or business/professional usage of a language. Obviously, a full range of intermediate models and combinations are also possible in order to accommodate the various needs and objectives of the training. A very similar approach has also characterised the evolution of e-learning-based language training content that was initially following the grammar-centric and is now shifting towards the content-centric unit. One of the main reasons for this shift also lies in the “blended” approach to teaching that combines traditional class-based to self-paced learning.

The difference in structure between the two approaches is quite apparent. Only a few products on the market are offering the user the chance to listen and modify voice samples or dialogues at playback speed. Some of the most effective online language courses, for Latin-based speakers willing to learn foreign languages, focus on reading/listening comprehension, grammar, and vocabulary. Users are provided with feedback on achieved performances, and exploit a pedagogical philosophy based on the following principles:

- The approach is student centred (user chooses own learning path).
- Each course level revolves around a central theme.
- Activities have a pedagogical rationale.
- The content is interesting and related activities are challenging.

Usually language training is divided into at least four different levels organized in about six courses. On average, each course is composed of more than 10 units plus a unit test. Units are, in turn organized, in several stimuli alternated with an average of five activities per stimulus plus tests. The course becomes progressively harder while progressing through units. For e-learning solutions foreseeing the adoption of CD/Internet-based content delivery, it is worth limiting the duration of each learning session to around 15-20

minutes for usability reasons, as schematically described in Figure 9.

On average, each stimulus is accompanied by a set of activities focused on different subskills, related to the various abilities, plus grammar and vocabulary. Listening is taught using slideshows, videos, or pictures with captions, while reading comprehension, and/or grammar are taught using texts.

Test units are presented at the end of a set of units aiming at providing feedback on what has been learned. Units may be repeated several times and should last no more than 30 minutes each. The structure will comprise a set of stimuli, each followed by a set of questions. At the end of the session, a score is provided as feedback. The score provided is in the format X out of Y correct answers (i.e., 3/5). If the same exercise is repeated several times, only the best score is reported. There may also be entry test units focused on comprehension and containing at least three graded texts. They should last no more than 20 minutes, be timed, and drawn from a bank containing several versions of the test (at least three). These entry units assign both a level and a course to the user upon completion, based on the decision schema reported in Figure 10.

According to the SCORM standard, a tracked course expects the user to complete the full unit before being granted the chance to proceed any further. Thus, if there are exercises for knowledge assessment, they can usually add conditions to the overall navigation procedure, for example, preventing the user from accessing any other section of the content until the present one has been completed and related tests passed positively.

---

Figure 9. Typical fruition scheme of a learning unit (innovative case)

Figure 10. Typical learner access level evaluation scheme of a language course
How Technology Can Support Culture and Learning

In general, content should be interesting and appealing. Tests should stimulate user curiosity and willingness to access the available content, providing exercises for the issues that generate most interest.

From the information presented, the structure of a typical learning course can easily be derived (see Figure 11). Please note that in most environments, the courseware structure is structured in levels according to the “European Council Curriculum” and to Flesch-Kincaid Grade Level Score, or to Flesch Readability Ease Score (at least as far as the English language is concerned).

Over time, several approaches to language teaching have been developed, starting from the traditional ones centred on grammar and stemming from the study of Latin and classical Greek. This evolution has been led by the following factors:

- Recognition that “live-languages” (currently spoken) differ from “dead-languages” and are constantly evolving; therefore, Understanding & Comprehension should come first, and the implied grammar could then be studied (and in some cases even derived).
- Spoken languages often rely on a smaller set of vocabulary, and the most common phrases structure is simpler. The usage of verb tenses and cases is also typically more limited in spoken language than in literary usage.
- Recognition of different needs for different audiences (business or technical trainee un-

Figure 11. Typical navigation scheme of an e-learning language course structured in levels
dertake a learning process to be able to communicate, usually in short timeframes).

- Provision of situational training better supports the retention of acquired knowledge than the extensive study of grammar and vocabulary.

A good example is the “Berlitz” method, or other derived ones like “inlingua” (http://www.inlingua.com/English/Services/main.asp?RefNav=rnav3). It is now clearer why there has been a progressive shift from a grammar-centric to a content-centric approach. This process greatly contributed to the need for effective and efficient self-learning that is now converging towards a “blended” approach, where the self-led activities can be even performed on the move, with the support of specifically designed tutoring assistance. This can be summed up in terms of distinctions applied to language learning depending on learning scope, the institution providing the training, trainees’ backgrounds, and domains, as illustrated in the Table 1.

### Language Labs

The setup of language labs dates back to at least the 1970s, when language teachers would use this infrastructure for practices and for assessing students’ progress, especially in two of the four abilities, namely listening and speaking, while reading and writing ability would be aligned with class work. The most frequent usage of the language lab would be either in “listening and comprehension” or in “listening and repeating.” Often (but this was much dependent on the teacher) in language labs, students would encounter audio sources that could span a wide range of topics, from read-aloud literature to radio programmes conversation, or even music (folk, traditional, pop).

In the late 1980s and early 1990s, the traditional language lab started to be sidelined by multimedia labs (initially devoted to purposes other than language learning). Only in very recent times has there been a convergence of language and multimedia labs into a single entity, a “multimedia language lab,” even though it is still quite popular.

Table 1. Distinctions applied to language learning
How Technology Can Support Culture and Learning

(especially for certain forms of studies) to retain the “classical” configuration.

Classical Language Lab Configuration

The classical configuration of a language lab is based on a set of audio equipment (tape recorders eventually combined with auxiliary inputs) usually divided into three categories: the teacher unit (the most richly featured and complete unit, comprising several inputs), the student unit (limited to a recording unit), and a set of supportive infrastructures (comprising the switch and control board available to the teacher). The control console and the switch and control board are physical, even though there are implementations using a computer-based approach (Figures 12, 16 and 17).

A classroom may contain only a few workstations, depending on the target usage, availability of room, complexity of cabling, and costs. The control unit available to the teacher is usually analogical (in the most advanced perhaps computer based) and so is the student unit. In the latter case, the schema becomes the one of Figure 13.

Multimedia Language Lab Configuration

The configuration of a multimedia language lab is based on a combination of computers and a set of equipment (including tape recorders combined with auxiliary inputs). Additionally, in this case, the whole setup is divided into three categories:

- The teacher unit
- The student unit
- A set of supportive infrastructures

While in the traditional language lab the control unit available to the teacher is usually analogical, in multimedia labs, the control unit is implicitly computer based. Moreover, in multimedia labs, it is often possible to find equipment and applications devoted to a wider set of usages.

Figure 12. Typical structure of a classical language lab configuration

Figure 13. Typical structure of a computer controlled language lab configuration
than language learning, as they were originally created to support ICT teaching and then extended to support language learning.

Presently, multimedia labs are also being provided with extensions enabling the usage of e-learning solutions. This allows for a varied set

**Figure 14. Typical structure of a basic multimedia language lab configuration**

![Basic Multimedia Language Lab Configuration](image1.png)

**Figure 15. Typical structure of an extended multimedia language lab configuration**

![Extended Multimedia Language Lab Configuration](image2.png)
of possible configurations and setups, like the following ones (see Figures 14, 15 and 16).

As is apparent from the previous schemas, the usual structure is based on a network connecting the individual positions, each equipped with the specific sets of supportive tools needed, comprising specific HW (recorder) and SW (applications). The class could be either fully physically bound (all work places are in the same physical location) or dispersed (not all work places are in the same physical location, but some are remotely connected); furthermore, the class could also be connected to external resources (like a VOD server, Internet, and so forth.). Audio/video conferencing equipment can also be used to support open and distance learning.

Additionally, in this case the overall arrangement will be then complemented with a proper layout that will provide two different sets of workstations for teachers and students. Again, a

Figure 16. Typical structure of a multimedia language lab class and teacher work place

Figure 17. Typical structure of a multimedia language lab teacher’s console
classroom may contain only a few workstations, depending on the target usage, availability of rooms, complexity of cabling, and costs of the overall setup, as in the following images.

Content Production

In the publishing environment, the content production chain follows well-codified and standardised processes that have been developing over several years. This process, and the actors involved, are schematically reported in Figure 18.

Cost control and overall IPR and copyright management are usually undertaken in a parallel stream, to ensure constant monitoring of high-risk factors. As far as the economic impacts are concerned, cost control has to monitor process development and ensure that it is kept in line with expectations and budgets, retaining its profitability (or even increasing it whenever possible) and therefore, is a good part of the standard management process.

On the other hand, IPR and copyright management interactions occur whenever an asset cannot be cleared and therefore, has to be replaced. This event may occur at any step, and the impact may be marginal or relevant, depending on a set of possible combinations of factors:

- The relevance for the publishing project of the object that could not be cleared.
- The reason for lack of clearance.
- The stage of the publishing process.
- The availability of a replacement/equivalent object, and so forth.

This refers to traditional, desktop and multimedia publishing as they present the highest number of contact points and overlaps.

A similar approach applies to the editorial process of any product, yet digital TV, serials, movies and in general products requiring video production are somehow different as the design and planning phase is much longer and has several by-products (storyboards, drawings, scripts, books...) that in certain cases will have their own existence and production cycle, which is reported in Figure 19 with the same approach of Figure 18.

Authoring Tools and E-Learning Content Development Applications

Standard document creation tools rank at the top of the list of utilities used to create e-learning content. Most of them are oriented to achieve specific results and do not require specific programming skills, even if they may have extensions, they are therefore often used in combination.

According to Brandon and Hall, over 40% of companies use an e-learning solution to provide services to their own personnel, including language learning, mainly due to globalisation. Most e-learning solutions adopted are used to provide self-paced e-learning courses and live e-learning sessions using virtual classroom applications, while tracking results using a learning management system (LMS).

Unlike conventional training, a good instructor cannot rescue bad online learning; the materials’ successful implementation is decided by the quality of the design. Therefore, in e-learning, content and design have remained the most critical dimensions of success. Not surprisingly, the shortage of well-designed, engaging, and relevant e-learning products is still high on the list of reasons for limited acceptance of e-learning in many organizations.

A Contextualised Example of Content Development for E-Learning

To provide a better understanding and to highlight the benefits of the adoption of certain technologies as a support tool for the production of educational content, we examine the process followed in a successful European RTD project conducted in IST-FP5 dealing with the application of technologies developed for the support of dyslexia to adult

L2 language learning, named FLIC (Foreign Language Acquisition through the Instinct of a Child) (FLIC, 2004, 2005a, 2005b, 2006); (MediTECH, 2005a, 2005b); (Lasnier, 2005). The results of the project, in terms of pedagogical and neurological validation, have been conducted by Sheffield University, while the original idea and method at the basis of project development has been based on the experience gained by MediTECH in respect of the development of supporting tools for dyslexia treatments.

Given this content production process, it is apparent that producing content for multimedia applications, especially in the educational field for language learning, is a rather complex task per se; the introduction of new technologies that alter
such a process is often opposed due to the potential cost impact. FLIC proved that the additional effort required to take into account the specific solutions that will lead to product improvement is not excessive if this is done from the product design phase (FLIC, 2004, 2005a, 2005b); (MediTECH, 2005a); (Lasnier, 2005). For the sake of reference, we will briefly report here the process followed in FLIC.

In FLIC, the audio content was using dummy stereophony (see Figure 20) for recorded sounds. The dummy head simulates the human head in an acoustic sense, as far as possible, as in place of eardrums, the dummy head has suitable microphones whose directional characteristics and other physical properties correspond to the properties of human ears (FLIC, 2005a).

The need for this special recording procedure was strictly connected with the special learning support provided by the FLIC equipment, namely the lateralisation (MediTECH, 2005a), the multichannel voice fusion (HW/SW versions) (MediTECH, 2005a, 2005b), plus the time alignment and voice modification (SW version only).

The Lateralisation process is based on a quite simple principle related to the fact that specific aural circumstances generate both a higher level of attention in the listener, and also an instinctive synchronisation effect. This is achieved in three phases, namely:

- **Phase 1:** Learner hears model voice from CD and reads along silently phoneme by phoneme hearing the model voice “wandering from side to side.”
- **Phase 2:** Learner silently reads along with the model voice (mouthing the words), again perceiving it as “wandering from side to side.”
- **Phase 3:** Learner reads aloud in synchrony with the model voice, hearing his and the model voice in opposite ears and both “wandering from side to side”; this automatically tends to put the two in sync.

Table 2. Documentation tools used with e-learning
The multi channel voice fusion (MCVF) technology divides the audio information of the left and right canal into eight (8) bands each, without losing any information during the splitting. The wave bands are differentiated in the following way: Band 1 (low-pass filter till 200Hz), Band 2 (250-315 Hz), Band 3 (400-630 Hz), Band 4 (800-1000 Hz), Band 5 (1250-1600 Hz), Band 6 (2000-2500 Hz), Band 7 (3150-4000 Hz), and Band 8 (high-pass filter from 5000 Hz). Consequently, two times 8 canals are generated. The mutual mixture of the canals causes an overlay of the separate audio information (left and right) to a single frequency composition of both canals. This principle is shown in Figure 22.

If MCVF and its effect are firstly used without lateralisation, while speaking through the microphone and listening to one’s own voice with and without the MCVF, it is impossible to locate the direction of the voice, which is precisely the desired effect, produced by the FLIC-unit for the benefit of the learner. Furthermore, a time-alignment procedure was also implemented (SW version only) to help the learner better understand the pronunciation aspects of the reference voice. The logic diagram of the adopted solution is shown.
How Technology Can Support Culture and Learning

It was mentioned that technology could support culture and learning by lowering access barriers. Technology has made access to content and

in Figure 23. Last, but not least, it was possible to modify the reference voice to enhance the possibility to understand mismatches occurring between the learner’s and the reference voice. This proved extremely useful (and was often needed) whenever the two voices belong to different genders. The result could be achieved with a voice modification engine (SW version only) that would operate according to the logics presented in Figure 24, transforming the original (reference voice) to achieve the result presented in Figure 25.

TECHNOLOGY AND ACCESSIBILITY

It was mentioned that technology could support culture and learning by lowering access barriers. Technology has made access to content and
sources mobile and ubiquitous, and it has also made it possible to overcome other barriers related to impairment. This is clear to a good part of the technical community, but not in totality, nor to the wider public. Such a lack of understanding of the importance of “accessibility from scratch” represents, at present, a real obstacle to societal evolution.

To get a clearer picture of the problem, it is sufficient to note that people with disabilities number nearly 1 billion worldwide, representing a formidable force of employees and customers. In Europe, according to the EU Commission, people with disabilities comprise about 15% of the population, and many of them face barriers when using ICT products and services.

Despite these data, many people still consider impairment to be a marginal problem and accessibility not a relevant issue. With aging, however, everyone starts experiencing (to some extent) impairments, and accessibility is a major issue.

The number of elderly people is actually rising fast, according to UN figures (18% of the population was aged over 60 in 1990; while 30% will be over 60 by 2030), and very often, elderly people encounter knowledge or usage barriers when using ICT products and services. This, therefore, brings back the issues of “lifelong learning” and “accessibility from scratch.”

Surprisingly, the technology required for achieving accessibility dovetails with technology required for pervasive computing, as nonimpaired customers need increasingly flexible, multimodal interfaces to accommodate IT access under varying environments, and with numerous devices. Therefore, taking impairment into account in the design phase of products and services automatically widens the market perspective and the societal benefit.

In 1998, the United States of America Congress amended the Rehabilitation Act to require Federal agencies to make their electronic and
information technology accessible to people with disabilities. This decision was based on the fact that inaccessible technology interferes with an individual’s ability to obtain and use information quickly and easily.

Section 508\(^{13}\) was enacted to eliminate barriers in information technology, to make available new opportunities for people with disabilities, and to encourage development of technologies that will help achieve these goals. The law applies to all Federal agencies when they develop, procure, maintain, or use electronic and information technology. Under Section 508 (29 U.S.C. ‘794d), agencies must give disabled employees and members of the public access to information that is comparable to the access available to others.

This process has brought about a major societal change in the USA and the upcoming spread of e-government solutions worldwide (http://www.w3.org/WAI/Policy/, http://www.w3.org/WAI/), and more specifically in Europe (Council Resolution of 25 March 2002 on the eEurope Action Plan 2002) means that the adoption, in the near future, of procedures and tools to make “full accessibility” a reality is now a necessity. E-learning will therefore be no more exception or something only for professionals (including or limited to training or retraining). Furthermore, the increase in the societal understanding of accessibility-related issues will favour a selection process where accessible products will be chosen over nonaccessible ones, even overriding the factors of pricing and brand name recognition.

All this leads back to the accessibility issue in the wider sense; as technology has reached a point where the objective could be reached to a great extent; what is lacking is both the application and regulation framework, along with a broad acceptance and recognition of this need for a real broad accessibility to content and education.

Previously, we have already provided a definition for e-learning and how it has come to the stage where, when talking about learning and accessibility, it is necessary to point out that e-learning is one of the terms that has emerged from the rapidly developing world of the Internet, and is broadly defined as “Internet-enabled learning.” This is usually referring to accessibility in terms of possibility to access, despite distance and time constraints, to sources, not in terms of impairment support. This is certainly not a minor issue.

Much expectation surrounds the Internet and its role in education, as e-learning can contribute to the improvement of standards and to the effectiveness of teaching and learning. Yet when claiming this, almost no reference is made to impairment support. Most Web-based content producers are often not even aware of W3C guidelines for accessible design of Web-based applications. The reason for this can probably be found in the fact that Internet access has generally only been available to society as a whole for the last 10-15 years, and to schools in the last 2-5 years. Such access is able to provide:

- Support for needs and individual learning requirements of both children and adults.
- A means of empowering children, helping them to learn more effectively.
How Technology Can Support Culture and Learning

- Access to vast volumes of information, mostly free.
- Communication tools and facilities that can be used on different levels.
- Access to content and learning processes that used to be confined to schools and colleges.

Summing up, the availability of Internet access provides a challenge to traditional forms of teaching and learning, and opens up opportunities previously denied to the majority. Yet all aforementioned factors are usually taken into account regardless of proper accessibility and usability related issues (in the sense that most content available on the Internet may fail either to meet accessibility issues in respect to regulations like the U.S. 508 one or similar, or usability criteria for certain user communities like elderly people or people with cognitive impairments).

This has happened largely due to the most widely adopted and common definition of e-learning. According to the IDC report “E-learning: The Definition, the Practice, and the Promise,” we can say that a good, working definition for e-learning (and in more general sense of e-anything) is “electronic” or “Internet-enabled.” Internet-enabled learning, or e-learning, strictly means learning activities on the Internet. Those events can be “live” learning that is led by an instructor or “self-paced” learning, where content and pace are determined by the individual learner.

The only two common elements in this process are a connection to the Internet (either physical or wireless) and learning. In 1996, a program for bringing technology into education was launched in the U.S. Its primary goals were:

- All students and teachers will have access to information technology in their classrooms, schools, communities, and homes.
- All teachers will use technology effectively to help students achieve high academic standards.

- All students will have technology and information literacy skills.
- Research and evaluation will improve the next generation of technology applications for teaching and learning.
- Digital content and networked applications will transform teaching and learning.

Presently, these objectives have almost been fully met in the U.S. Furthermore, according to the report “A Vision of eLearning for America’s Workforce,” developed by the Commission on Technology and Adult Learning, the global e-learning industry comprises approximately 5,000 suppliers offering every imaginable method of e-learning. The vast majority of these suppliers are private.

Even if it is generally accepted that the driving force behind the 21st-century economy has been knowledge, in many European countries, these objectives are still far from being realised.

What is driving the market in real time can be split among present and future trends, while drivers and inhibitors are illustrated in Tables 3 and 4.

A direct consequence of this is that technology needs to be used in order to lower costs. This can be achieved by reusing content (even if usually an increase of richness is also requested), and adding value by offering custom solutions and new approaches (performance support, customer education, and so forth.). Yet the most important issue regarding e-learning systems is related to its effectiveness in transferring knowledge to the user. Learners’ comprehension depends strongly on course structure. Therefore, particular attention must be paid to effective navigation and look-and-feel features. In addition, content should be designed, developed, or adapted for multimodal delivery for effective content reusability. Such integrated approaches are more likely to have an impact as the meta-adaptivity system design domain emerges.
How Technology Can Support Culture and Learning

It has been pointed out that at present, there is a shift in education that is moving from an approach in which individuals undergo a specific period of training and then start their professional life to an approach in which the learning process is a lifelong one. In this second perspective, companies also have to tackle the issue of continuous education.

For a rather evident set of constraints, including but not limited to time and costs, companies have been always trying to find alternative solutions to class-based learning. Thus, it is not surprising that some of the early adopters of e-learning have been major corporations like IBM, HP, AT&T, Boeing, and many others. In this respect, it is interesting to note that according to Brandon and Hall (Chapman, 2006; Chapman, 2006a Chapman & Nantel, 2006; Nantel & Vipond,

How Technology Can Support Culture and Learning

2006), “organizations’ eLearning practices are what turns tools and content into real learning.” Furthermore, to be successful in the design of e-Learning courses, the following factors should be taken into account:

1. **Faced problem and expected results:** Matching the e-learning solution to the problem at hand; achieving intended results.
2. **Instructional design and integrity:** Structuring, relevance and quality of content; focus on real-world competencies; selecting the right strategies for the content and context. This also means focussing on the intended users.
3. **Evaluation and assessment:** Applying imagination and rigour to the design and implementation of evaluation or assessment.
4. **Interactivity:** Using creativity and expert design practices to achieve instructionally powerful interactions of all kinds.
5. **Usability and interface:** Creating an effective, easy-to-use interface.
6. **Motivation and aesthetics:** Motivating learners to follow and successfully complete the training; hitting the right tone and aesthetic notes.
7. **Media and technology:** Smart selection and application of media, development tools and delivery technologies.
8. **Money and time:** Achieving excellence under constrained budgets and time lines.

In this process of integrating education into the employees’ daily life within a company, several aspects should be taken into account. For example, the need to keep certain components of company know-how inside the company, or how to foster practical skills acquisition, or how to handle the mapping of individual characteristics onto a professional job description to then derive, thanks to a gap analysis, the individual training needs.

Most of these items correspond in practice to one or more tool-sets that are used by the human resource department, the IT/ICT infrastructure, the employees, and the company management to address the various issues. The most relevant ones are described next, and could also be used in the “formal” education process to improve what is presently achievable, or to complement it in order to tackle specific issues.

**Authoring Tools, KMS and (L)CMS**

Authoring tools are generally desktop, single-user applications used to construct learning content by assembling and combining text, graphics, audio, video, and animations into e-learning courses. Yet there is also a current trend to have Web-based development tools. They have been initially derived by visual HTML editors and are often used to create standard Web pages, but they can also be used for creating learning applications. In addition, there exists a growing number of authoring tools focused on rapid, template-based development of learning content, sometimes with a specific focus on a particular type of learning application, such as software simulations.

Authoring tools, even though offering a rather broad range of solutions, represent only one category of tools aimed at properly editing and formatting content/knowledge. This is undoubtedly the first step in the process. Yet once content has been prepared it has to be managed, and a set of solutions has been developed for this purpose over time. Notably the most interesting are represented by:

- **Content management systems (CMS):**
  Systems for organizing and facilitating col-
laborative creation of documents and other content, using a range of technologies and techniques, including portal systems, wiki systems, and Web-based groupware; sometimes Web based, though in many cases, requiring special client software).

- **Knowledge management systems (KMS):** Systems for organizing and facilitating collaborative creation and management of knowledge and expertise, either at company or at individual level, using a range of technologies and techniques, including portal systems, wiki systems, and Web-based groupware.

- **Learning content management system (LCMS):** A solution for the creation, management, and transfer of learning content; it is apparent that LCMS are a subcategory of CMS devoted to learning content.

**E-Learning, ODL, and Lifelong Learning**

Computers are moving out of laboratories and into classrooms in learning new languages, understanding complicated math formulas, and exploring other countries. Technology is changing basic notions of schools and education and creating classrooms without walls that offer students a valuable view of the world, and enable them to experience and interact with other students and resources around the globe. With numerous forms of distance learning now available, public education is moving away from a need for students and teachers to assemble in school buildings for education to occur. This trend has far-reaching implications for the structure of state education budgets.

According to analysis performed by government and research institutions, the rapid growth in such areas as distance learning, technology-enabled assessment, and the increasingly diversified and expanded public-private learning marketplace require the development of new strategies for quality and consumers’ protection. Important priorities for the public and private sectors include:

- Providing reliable and universally accessible quality information for consumers.
- Developing quality assurance mechanisms.
- Ensuring that learners have the support they need to make the right decisions about their e-learning options.
- Developing policies and practices to ensure privacy.

Traditional, institution-based approaches to assessment and certification are not well suited to an e-learning world in which the focus turns from a record of classes taken and degrees received, to measures of what an individual actually knows and is able to do. As a result, private and public sector leaders need to take steps to create new approaches such as developing and promoting outcome-based assessments of learning results, and creating an electronic system for tracking those results.

Government and commerce must play a leadership role in making quality e-learning opportunities more widely available to all, from supporting the development of common technical standards to promoting broader access in under-served communities. The challenge and the opportunity are the same: to realize e-learning potential for reducing the divide between “haves” and “have nots.” Therefore, it is necessary to:

- Create the highest-quality e-learning experiences possible.
- Implement new measures and methods for assessing/certifying what users know and are able to do.
- Ensure broad and equal access to e-learning opportunities.

The potential return on investment for both the public and private sectors is enormous. The
challenge for businesses is to realize the full potential of e-learning as a driver of productivity and performance gains by making it an integral part of organizational strategy and operations. For government, the challenge is to create a nurturing policy environment for e-learning, firstly by removing barriers that restrict access to e-learning benefits and, secondly, by promoting industry self-regulation while balancing citizens’ interests and needs.

By adopting e-learning standards like the one defined by IEEE, AICC, and so forth, it is possible to achieve full interoperability of e-learning platforms and to have real, full portability of produced content. A learning object respecting all features described in those standards will be available in whatsoever platform and therefore, full independence from a specific vendor is achieved. Moreover, it is possible to package objects developed with different tools and for different delivery platforms, achieving a consistent and interoperable object, where the tracking will also be kept across editing, aggregation, and reuse. Other emerging standards that focus on personalisation are likely to have an influence in the near future, such as the internationalization of the IMS AccessForAll approach in ISO, the Individualized Adaptability and Accessibility in e-learning, Education and Training Standard.

Virtual Reality and Multisensorial Approach

The use of virtual reality is progressively becoming widespread. Usually the primary applications are either professional training or gaming. In the first case, the simulation is devoted to enable trainees to have access to equipment and situations that may be too risky and too costly to be faced otherwise. At the same time, only big organisations can presently afford costs related to simulations. On the other hand, namely in gaming, customers are demanding more and more in terms of appearance, and the huge numbers involved allow developers to achieve high levels of quality, despite the production costs.

With today’s technology, it is possible to achieve results unforeseeable just a few years ago. In detail, it is now possible to achieve multisensorial stimuli by combining visual, tactile, and sound experiences into a unique new one experience. The real challenge is to be able to generate similar situations (potentially involving even smell) for edutainment purposes. What is still lacking is a paradigm to convey all those rich stimuli into a single mainstream that may be used to both entertain and educate at the same time.

Virtual Communities and Forums

In many cases, establishing user communities is an extremely powerful and convenient way to foster a learning process. Community users will exchange ideas and cooperatively support each other in the learning process. This approach has a long history, and was initially born among scholars in the scientific domain as a way to support research results exchange, documents, and papers peer reviews, and other forms of interaction. With the wide diffusion of Internet, this approach has progressively widened its application, and presently there are thousands of communities, forums, and so forth. Given this, it is nevertheless essential to note that starting up a new community or forum is a difficult process. Table 5 reports the most relevant factors that would cause user retention or loss.

Table 5 reports the most relevant factors that would cause user retention or loss.

According to Table 5, actions that help in starting up the discussion in a new-born forum/community can be summarised as follows:

- Promote forum existence by direct contact with a set of people that may be interested to take part in forum activities and provide useful cooperation.
- Provide interesting threads.
- Periodically provide contributions from experts.
How Technology Can Support Culture and Learning

- Select key themes and collect them.
- Generate FAQs starting from relevant threads.
- Simplify the process to manage messages and replies, for example introducing the concept of a follow-up message that is not a reply but a related issue.

Another success factor that has to be taken into account is “need.” If the users needs to be part of a certain community, or if the users may find, in such a community, replies to their own needs, or even a sense of belonging/ownership, then community success is almost assured (the only real threat in that case may be economical sustainability). An interesting example for this is the German School Net; up to when it was strongly supported (in terms of costs and equipment) by Deutsche Telekom, it grew and developed. It turned out to be extremely important, full of users (both teachers and students) and data exchange. When Deutsche Telekom stopped supporting its activity, then community subsistence was greatly endangered. Now with the start-up of the European School Net, the German portal has also gained new vitality. Also of note is the case of eSchoolnet, the European Teachers’ portal.

### E-LEARNING AND THE MARKET

To complete the panorama provided so far to at least the relation presently existing between e-learning and the market should be addressed. According to IDC (2002), the e-learning market is segmented in three main areas: Content, Delivery solutions, and Services.

Content providers offer courseware core material (like multimedia assets and course structure), and testing/assessments are included in their expertise. Companies that provide delivery solutions offer products oriented at course preparation and organisation, such as training authoring tools and learning management systems (LMS), including collaborative software to help course fruition. Services include all additional features that can lead to better course preparation (content design), and that are related to course maintenance (management and hosting) and CRM (online mentoring). Some products/platforms provide solutions in different areas, covering partially or totally the entire range of e-learning offers. Figure 26 describes the situation and introduces market players and their
positions in the market as it appeared at the time of the previously mentioned IDC study.

**Asynchronous Web-based software suites** attempt to group suites of tools that quickly allow an instructor to convert existing basic electronic documents to a hierarchical system with relative ease. Although most of these suites may require limited HTML knowledge to fully exploit them, relatively little programming or other technical expertise should be needed to effectively use these software suites. Key characteristics of major players in asynchronous suites typically include capability for secure student login via standard Java browser, centralized database-
How Technology Can Support Culture and Learning

centred syllabus with links to internal or external Web pages, online, time-monitored quizzes with randomised dynamically-generated testing, discussion groups, and integrated e-mail. Systems also provide instructor development tools to ease transition from other media to these products. The academic user audience is dominated by two vendors: WebCT and Blackboard, with only a few additional competitors targeting academic audiences specifically. Corporate/government learning organizations have a much larger number of competing systems.

**Synchronous (real time) Web-based training solutions** are the most appropriate to facilitate relatively formal, instructor-led, hierarchical learning events, such as a seminar or interactive classroom. A number of these products incorporate "talking head video"; most video-enabled products suffer from poor video quality and tend to require 128KBPS (a.k.a. ISDN class) dial-in connections for acceptable performance; although a compelling sales feature tending to appeal to instructors familiar with videoconferencing, at present current "talking head video quality" over dial-up Internet connections is not worth the effort; most students ignore such poor images very early into the course. Leading members of this class generally have also the following characteristics:

- Browser-based (works with Netscape and Internet Explorer, though often PC-centric).
- Online testing (designed for use over Internet dial-up connections or corporate intranets).
- Live streaming audio (generally one-way, often two-way)
- Text chat, and occasionally private text chat, among students or between participants and presenter.
- Sequencing is controlled by a presenter-leader; a secondary/copresenter is available for the higher end products.
- Ability to show PowerPoint presentations.
- Ability to record sessions and make them available for on-demand viewing at any time.
- Shared whiteboard, with ability for students and faculty to import images that can be annotated on the whiteboard.
- Web-page sharing/cobrowsing.
- Application sharing ability for presenters to share applications running on their desktop.
- Integrated polling/surveys.
- Virtual “hand/raising,” to indicate when participants have questions.
- Firewall friendly.

**Application service providers (ASP)** choose to make their products available as hosted solutions only; they do not sell the software for organizations to create and run their own servers under license. This license arrangement may better fit specific needs, especially where institutions do not have the in-house capability to sustain tech support teams and servers. Vendors in this category generally offer the following feature set:

- **Browser-based:** All functionality is provided within a standard browser. Updates are added automatically.
- **Presentation sharing:** allows any meeting participant to spontaneously share any presentation (generally PowerPoint).
- **Document sharing:** allows meeting attendees to view content with multilevel zooming and annotation capabilities.
- **Application sharing:** Run any software application for effective live demos and training.
- **Desktop sharing:** Presenters can share anything on their PC system, including applications.
- **Web browser sharing:** Allows easy sharing of Web-based information.
How Technology Can Support Culture and Learning

- **Polling**: Lets presenters solicit quantitative feedback from attendees online.
- **Internationalization**: Ability to change the menus for selected languages.
- **Text chat**: Generally available as group chat and a separate channel for interaction during a session. A controversial feature in academics, as it is perceived by faculty as the electronic equivalent of note-passing or whispering in class.
- **Record and playback**: Permits recording of all interactions in a meeting for later reference, training, or demos. Anyone can play back a recording.
- **Application share control**: The presenter can share control of any software application with others in a meeting, for unmatched interactive meetings on the Web.
- **Scalable**: Supports multiple concurrent meetings with thousands of participants.
- **File transfer**: Users can conveniently upload and download files as desired.
- **Event tech support**: ASP vendor’s customer support personnel can take control of a user’s PC system (with the user’s approval) to instantly provide live assistance and resolve problems.

**Learning portals** are an emerging variation of Personal Collaborative Environments, and are an attempt to combine student services and community building through an integrated Web-enabled system, very much like the search engine portals Yahoo and Lycos. The use of the term “Learning portal” could imply either the basic software product needed to develop a portal or the actual use of such software to create a learning experience.

**Collaborative software**, an emerging category of software, allows individuals to interact one-to-one, peer-to-peer, or in small groups. The category may also be referred to as “Instant Messaging,” or “Buddy Systems,” although a number of products in this category also represent the older “listserve” e-mail-broadcast technology. This type of tool will become integral in advanced Web-based learning programs. Typically, tools in this category allow “awareness” of user-selected individuals and the ability to instant message (i.e., “chat” one-to-one) with individuals. Most programs provide for ad-hoc chatting in small groups. Some of these programs permit application sharing, voice-over-IP, or other useful over-the-Web features designed to allow individuals to interact. Currently, this category of software lacks interoperability. The Internet Engineering Task Force’s Instant Message and Presence Protocol represents the current form of standards proposed in order to solve these interoperability issues.

**Team groupware** is a new subset of collaborative software aimed at creating virtual project groups. “Team groupware” is distinguished from personal collaborative environments by these characteristics:

- Ability to develop documents synchronously and review asynchronously.
- One-to-one, one-to-many, and many-to-many capability.
- Centralized user management.
- Real-time Internet communications by at least one of the following:
  - Enterprise-ready systems scalable to hundreds of users.

Advanced software in this category includes group scheduling, ability to store and review older version of documents, and ability to route items. Systems should also require relatively little technical expertise for management after installation, as projects must be easy to create, edit, or terminate.

**Web-based education development tools** attempt to collect basic and single-purpose tools that meet specific needs but are not themselves intended to be a turnkey implementation sys-
How Technology Can Support Culture and Learning

tem. They are generally visual authoring tools or programmers toolkits, or meet a very specific Web-based need. This category has undergone substantial consolidation since the high-flying days prior to the dot.com crash in 2000/2001. A late 2002 study from Market Data Retrieval revealed that one-third of K-12 schools are already offering a number of distance learning programs for their students. High schools, in particular, have been attracted to the virtual classroom environment, with 53% offering such programs to students in rural states where students do not have access to specialized teachers. Furthermore, 36% of schools reported to have distance learning programs for their teachers, allowing them to access professional development programs, which is similar to the applications corporations are finding for e-learning.

Chapter 3.25
Tangible User Interfaces as Mediating Tools within Adaptive Educational Environments

Daria Loi
RMIT University, Australia

ABSTRACT

This chapter proposes that, as approaches to human computer interaction (HCI), tangible user interfaces (TUIs) can scaffold rich classroom experiences if they are coupled and generated within multi-pedagogical frameworks that adopt concepts such as Multimodality, Multisensoriality, and Multiliteracies. It overviews some necessary conditions for these tools to be effective, arguing that tangible user interfaces and multi-pedagogies are efficient when they are conceptualized as part of adaptive educational environments—teaching and learning ecologies where learners and teachers are seen as co-creators of content and of new ways of interacting with such content.

INTRODUCTION

Information and communications technologies (ICTs) enable types of learning experiences involving HCI that other means do not easily achieve (Simon, 1987; Underwood & Underwood, 1990). While digital spaces are traditionally manipulated via simple input devices (e.g., keyboard and mouse) that are used to manipulate representations displayed on output devices (e.g., monitors), tangible user interfaces remove this input-output distinction and connect physical and digital worlds using physical objects as interfaces to digital information (Ullmer & Ishii, 1997).

This chapter discusses the potential role of tangible user interfaces in scaffolding rich HCI classroom experiences and some necessary conditions for such tools to be effective. I argue that these interfaces can have a key role in contemporary teaching and learning environments if they are coupled and generated within multi-pedagogical frameworks that adopt concepts such as Multimodality (Kress & Van Leeuwen, 2001), Multisensoriality (Ceppi & Zini, 1998), and Multiliteracies (Cope, Kalantzis, & New London Group, 2000).
Tangible user interfaces and multi-pedagogies are, however, effective when they are conceptualized as part of adaptive educational environments (Loi & Dillon, 2006)—teaching and learning ecologies where learners and teachers are seen as co-creators of content and of new ways of interacting with such content.

This chapter is divided into four sections. In the first part I overview why and how tangible user interfaces can enrich classroom experiences, while in the second I outline the importance of coupling them with multi-pedagogical frameworks. The third section overviews the notions of adaptive educational environments and proposes that tangible user interfaces can be conceptualized as mediating tools enabling a shift of such environments to become creative spaces. In the last section I offer a number of concluding remarks, highlighting future implications and the need for new ways of conceptualizing contemporary learning environments.

One of the key objectives of this chapter is to highlight the importance of designing tangible user interfaces for teaching and learning by considering them part of larger ecological HCI frameworks where pedagogy, people, and context play a crucial role.

TANGIBLE USER INTERFACES AND LEARNING ENVIRONMENTS

Ullmer and Ishii (1997) point out that while graphical user interfaces (GUIs) have proven to be “a successful and durable model for human computer interaction,” the GUI approach to HCI “falls short in many respects, particularly in embracing the rich interface modalities between people and the physical environments they inhabit” (p. 1). Within this context, a range of alternatives has been explored, from ubiquitous computing to augmented reality. However, these attempts often rely on exporting the GUIs paradigm to world-situated devices, failing in capturing the richness of physical-space interactions they want to enhance (Ullmer & Ishii, 1997).

This understanding was the basis on which the notion of tangible user interfaces—user interfaces that adopt surfaces, instruments, physical objects, and spaces as physical interfaces to digital information—was constructed through initial explorations by Fitzmaurice, Ishii, and Buxton (1995) and the original work of Ullmer and Ishii (1997). Tangible interfaces put emphasis on touch and physicality in both input and output and are often coupled to physical representations of actual objects (O’Malley & Stanton Fraser, 2004). Examples of tangible user interfaces include rehabilitation tools (Edmans, Gladman, Walker, Sunderland, Porter, & Stanton Fraser, 2004), drawing and designing tools (Ryokai, Marti, & Ishii, 2004), collaborative and management tools, browsers and exploratory tools (Piper, Ratti, & Ishii, 2002), multimodal interactive tools (Raffle, Joachim, & Tichenor, 2002), music creation and performance (Patten, Recht, & Ishii, 2002; Weinberg & Gan, 2001), and toys/educational tools (Mazalek, Wood, & Ishii, 2001; Vaucelle & Jehan, 2002).

O’Malley and Stanton Fraser (2004) stress the beneficial role of physical manipulatives in learning environments by highlighting that:

• physical action and concrete objects are important in learning;
• physical materials trigger mental images that inform future problem solving in the absence of physical materials;
• learners can abstract symbolic relations from a variety of concrete instances; and
• familiar physical objects are more easily understood by children if compared with more symbolic entities.

This suggests that children are capable of demonstrating their knowledge via physical actions (e.g., gestures) and can solve problems by working with given concrete materials even if they cannot
solve them symbolically or in their heads. This is confirmed through the work of Bruner (1966), Piaget (1953), Church and Goldin-Meadow (1986), Goldin-Meadow (2003), and more recently Martin and Schwartz (2005).

Many thinkers have developed tools/environments that recognize the significance of children’s interactions with the physical environment: Pestalozzi (1894) and his method; Dewey (1938) and his philosophy of experience and relation to education; Montessori (1917, 1949) and her method; Kamii & DeVries (1978, 1980) and their take on Piaget’s theory; and Gardner and Hatch (1989) and their multiple intelligences.

The role of physical materials in triggering mental images useful for problem-solving has been discussed by several authors and teachers, including: Montessori (1917); Dienes (1964); Bruner (1966); Stigler (1984); Uttal, Scudder, and DeLoache (1997); and Chao, Stigler, and Woodward (2000).

The capacity to abstract symbolic relations from concrete instances is discussed by Bruner (1966) when he talks about enactive, iconic, and symbolic forms of representation and by Karmiloff-Smith (1992) and her theory of representational re-description where children’s representations move from implicit to more explicit forms.

In synchrony with the previous body of literature, tangible user interfaces and manipulatives have a number of characteristics (O’Malley & Stanton Fraser, 2004) including:

- they allow for parallel input (e.g., two hands) improving the expressiveness or the communication capacity with the computer;
- they take advantage of well developed motor skills for physical object manipulations and spatial reasoning;
- they externalize traditionally internal computer representations;
- they afford multi-person, collaborative use;
- physical representations embody a greater variety of mechanisms for interactive control;
- physical representations are perceptually coupled to actively mediated digital representations; and
- the physical state of the tangible embodies key aspects of the digital state of the system.

There are a number of examples of tangible user interfaces that enrich HCI in classroom experience through these characteristics. O’Malley and Stanton Fraser (2004) have reviewed several of such examples, dividing them into three main categories.

The first category is that of digitally augmented paper and books, such as Listen Reader (Back, Cohen, Gold, Harrison, & Minneman, 2001), MagicBook (Billinghurst & Kato, 2002), the KidStory project (Stanton, Bayon, Neale, Benford, Cobb, Ingram, et al., 2001), which adopts the KidPad storytelling software (Druin, Stewart, Proft, Bederson, & Hollan, 1997), and LeapPad®. Another category of tangible user interfaces is that represented by phicons (physical objects—such as toys, blocks, and physical tags—used to trigger digital effects), such as the CACHET project (Luckin, Connolly, Plowman, & Airey, 2003), Storymat (Ryokai & Cassell, 1999), the Tangible Viewpoints system (Mazalek, Davenport, & Ishii, 2002), and Chromarium (Rogers, Scaife, Gabrielli, Smith, & Harris, 2002). There are also digital devices with embedded computational properties, such as Triangles (Gorbet, Orth, & Ishii, 1998), Curlybot (Frei, Su, Mikhak, & Ishii, 2000), Topobo (Raffle, Parkes, & Ishii, 2004), Thinking Tags (Borovoy, McDonald, Martin, & Resnick, 1996), and sensors and digital probes (tangible devices based on physical tools that act as sensors or probes of the environment), such as Storytent (Green, Schnädelbach, Koleva, Benford, Pridmore, & Medina, 2002), I/O Brush (Ryokai et al., 2004),
Tangible User Interfaces as Mediating Tools within Adaptive Educational Environments

and the SENSE project (Tallyn, Stanton, Benford, Rowland, Kirk, Paxton, et al., 2004).

Tangible user interfaces have a beneficial role in learning environments due to their physical and tangible characteristics and trigger HCI learning experiences that can have different qualities from those in which a learner can engage by using other digital resources such as the Web. Moreover, these tools can enable many different ways of integrating face-to-face and virtual learning, creating hybrid interactions via their tangibility and manipulability nature. However, tangible user interfaces cannot operate and should not be developed in isolation from other key factors, as discussed in the next section.

TANGIBLE USER INTERFACES AND MULTI-PEDAGOGIES

As mentioned, tangible user interfaces enable numerous ways of integrating face-to-face and virtual learning. However, I propose that to be effective in the classroom and to enhance rich HCI learning experiences, these media devices need to be coupled with multi-pedagogical frameworks. Failing to do so implies the development of technology for technology sake instead of rich ICT tools that can enhance, support, and scaffold rich HCI learning experiences. As Reimann and Goodyear (2004) highlight, “technology is not so important in itself: what matters is how the technology is used” (p. 2)—pedagogy and pedagogical choices in making good use of technology have crucial roles.

I define multi-pedagogical frameworks as scaffolds that refer to and integrate notions of Multiliteracies (Cope et al., 2000), Multimodality (Jewitt & Kress, 2003; Kress & Van Leeuwen, 2001), and Multisensoriality (Ceppi & Zini, 1998).

The term multiliteracies refers to the variability of meaning making in different cultural, social, or professional contexts and to the nature of new communications technologies (Cope & Kalantzis, 2005). Cope et al. (2000), drawing from a number of theories, generated the Multiliteracies model by merging four approaches to teaching and learning: situated practice, overt instruction, critical framing, and transformed practice. Deepening the notion of multiliteracies, Kalantzis and Cope (2003) look at pedagogy in terms of eight knowledge processes, which are selected and deployed by the teacher and define the mindful and premeditated use of such processes as learning-by-design (Cope, Kalantzis, & the Learning by Design project group, 2005). In the Learning-by-Design project, “the teacher becomes a reflective designer of learning experiences (teacher-as-designer), and classroom plans become shareable designs-for-learning” (Burrows & Loi, 2006, p. 2). In this model meaning is generated in the space where visual, audio, gestural, and spatial patterns of meaning interface written-linguistic modes of meaning (Cope & Kalantzis, 2005). To Kress (1999) the visual “is becoming more prominent in many domains of public communication” and is “taking over many of the functions of written language” while displacing the written language “from its hitherto unchallenged central position in the semiotic landscape” (p. 68).

Building on the preceding considerations, the notion of multimodality implies a paradigm shift in how the communication and representation of meanings can be interpreted. A multimodal text adopts several modes of communication (such as image, writing, and speech), and, while multimodality characterizes many modern texts, “in the age of digitisation, the different modes have become the same at some level of representation, and they can be operated by one multi-skilled person” (Kress & Van Leeuwen, 2001, p. 2). The notion of multimodality has been to date discussed by a number of authors from various disciplinary domains. Besides Kress and Van Leeuwen (2001), the works of Norris (2004), Levine and Scol-
Tangible User Interfaces as Mediating Tools within Adaptive Educational Environments

lon (2004), Kramsch, A’Ness, and Lam (2000), and Jewitt (Jewitt & Kress, 2003) represent key examples.

Ceppi and Zini (1998), when discussing the characteristics that learning environments should have, talk about multisensoriality and multisensorial spaces: complex environments “made up of sensory contrasts and overlappings that are phenomenologically distinct” (p. 17). To the author, the space should not simply be about “being simply rich in stimuli,” but it should have “different sensory values so that each individual can tune into his or her own personal reception characteristics,” implying that “standard univocal solutions cannot be conceived” (Ceppi & Zini, 1998, p. 17).

In multi-pedagogical frameworks teachers deploy a number of knowledge processes in a premeditated and mindful way (multiliteracies), becoming reflective designers of learning experiences where meaning is represented and unfolded in multimodal ways (multimodality) and enriched by different sensory values (multisensoriality). As already highlighted, pedagogy and pedagogical choices have crucial roles in making good use of technology in the classroom, and technology for the classroom should be conceived and developed in light of and interlinked with such pedagogical choices. Within this context, this chapter argues that the design and development of tangible user interfaces for the classroom should be coupled with multi-pedagogical frameworks.

TANGIBLE USER INTERFACES AND LEARNING ECOLOGIES

Tangible user interfaces have a key role in scaffolding rich HCI classroom experiences, and they should be coupled with multi-pedagogical frameworks. To amplify these notions, I suggest that tangible user interfaces and multi-pedagogical frameworks are in fact part of learning ecologies, together with learners, teachers, and context, and, of course, the relationships among all actors (refer to Figure 1). These five actors are interrelated similarly to how context, people, practices, and relationship interact within collaborative workspaces (Loi, 2003). Reggio Emilia schools offer an exemplary instance of how HCI can be part of the learning ecologies (Project Zero & Reggio Children, 2001).

This model of learning ecology describes a situation where actors are deeply interrelated and co-dependent—there is a sense of wholeness and rich complexity. This implies that tangible user interfaces cannot be developed in isolation from other key actors, but rather conceived in light of their users (teachers and learners), contexts of HCI use, and designed learning experiences (multi-pedagogical choices).

Previous work (Loi & Dillon, 2006) discussed how ideas about collaborative workspaces (Loi, 2005) and integrativism (Dillon, 2006) can be incorporated and extended to look at the ecological nature of learning environments and to unfold notions of adaptive educational environments—spaces that accommodate changing relationships between people and resources—and creative spaces—environments that have been modified through designed interventions. Creative spaces
I suggest that tangible user interfaces could be employed as HCI mediating tools within learning ecologies that are conceptualized as adaptive educational environments. This implies that the dynamic flow underpinning the previous model (in Figure 1) requires a refinement (refer to Figure 2). This model maintains the ecological nature of Figure 1, while underlining the possibility to consider tangible user interfaces as mediating HCI agents (or brokers). This role and its positioning within educational environments impact how tangible user interfaces can be conceived, developed, and adopted. In line with Loi and Dillon (2006), the notion of tangible user interfaces as HCI mediating tools can be extended to re-conceptualize them as designed interventions that can trigger the development of creative spaces. These concepts will be explored in future work.

To address the development of tangible user interfaces in the described HCI context, I suggest that a participatory design approach (Sanoff, 1990; Schuler & Namioka, 1993) should be adopted to ensure that all parts of the whole are active participants in the design process. This proposition implies that teachers and learners must be involved in the design process; designers and technologists must operate in multidisciplinary teams together with teachers and pedagogy experts; and the contexts where technology will be adopted/embedded must be considered at all times. There are a number of examples of teams currently developing tangible user interfaces within these participatory paradigms. An interesting example within the educational context is offered by the Children as Design Partners project.

As previously mentioned, Reimann and Goodyear (2004) propose that in educational environments, “technology is not so important in itself: what matters is how the technology is used” (p. 2). Their statement, which implies that pedagogical choices in making good use of ICT have crucial roles, should be amplified because when considering HCI learning ecologies, the design of ICT has an equally crucial role, as it strongly impacts what pedagogical choices can be conceived and enacted. The interrelations and co-dependencies of technology and pedagogy should not be underestimated. In light of this, I suggest that tangible user interfaces can offer significant opportunities for effective use of HCI within the classroom if:

- they are conceptualized as actors within learning ecologies, together with multi-
Tangible User Interfaces as Mediating Tools within Adaptive Educational Environments

- there is a strong appreciation of the deep interrelationships and co-dependencies existing among learning ecologies’ actors;
- they are conceived as mediating tools within learning ecologies;
- the learning experiences that are mediated by tangible user interfaces are designed adopting multi-pedagogical frameworks; and
- they are developed adopting a participatory design approach.

The adoption of a participatory design approach can be extended to the development of rich HCI learning experiences. When looked at through such lenses, teaching and learning practices can be expanded to notions of teachers-creators, learners-creators, and teacher-student as space for content emergence (O’Malley & Stanton Fraser, 2004); teachers as author-publishers and project-consultants (Burrows, 2005a, 2005b); teacher-as-designer (Brown & Edelson, 2003); and teachers and learners as co-researchers (Loughran, Mitchell, & Mitchell, 2002; Phelps, Graham, et al., 2004).

Tangible user interfaces offer some significant benefits to classroom activities, in particular from (1) creativity, (2) diversity, and (3) collaborative perspectives. These are discussed in the following paragraphs.

Creativity is an “essential life skill, which needs to be fostered by the education system(s) from the early years onward” (Craft, 1999, p. 137). In her literature review on creativity, technology and learning, Loveless (2003, p. 13) overviews the characteristics of learning environments that are conducive to creative developments, including opportunities for exploration and play with materials, information and ideas (Craft, 2000), flexibility in time and space for the different stages of creative activity (Claxton, 1999), and opportunities to take risks and make mistakes in a non-threatening atmosphere (Davies, 1999). These are in synchrony with some characteristics typical of tangible user interfaces, such as their physicality, manipulability, concreteness, and familiarity (O’Malley & Stanton Fraser, 2004).

Tangible HCI enables learners to combine and recombine the known and familiar in new and unfamiliar ways (Hoyles & Noss, 1999) and to unfold the world through discovery and participation (Soloway, Guzdial, & Hay, 1994; Tapscott, 1998). As Hoyles and Noss (1999) stress, “it is this dialectic between known and unknown, familiar and novel, that provides a motor for creativity” (p. 19). Moreover, combining familiarity with unfamiliarity can promote reflexiveness (Rogers et al., 2002; Scaife, 2002), stimulating awareness and enhancing learning (Ackerman, 1996; Piaget & Inhelder, 1967).

Green, Facer, Rudd, Dillon, and Humphreys (2005) have suggested that as mobile, tangible, and networked technologies are increasingly deployed in facilitating creative work, educational environments will be characterized by a high degree of personalization where individuals will have greater influence over how they choose and use learning resources. The education system is constantly challenged by diversity issues, and researchers/educators are regularly looking for ways to enable learning for diverse learners (refer, for instance, to Cope et al., 2000). Through his work on the Internet generation, Prensky (2001) argues there is a need to radically rethink teaching practice to mirror current ways of learning. The diversity issue implies a need to change the education system so that it can conform to learners. Interestingly, learners are already shaping their own learning outside the classroom, using digital resources to create personalized learning environments for themselves outside of school. As a matter of fact, it has been suggested that by the age of 21 the average person will have spent 15,000 hours in formal education, 20,000 hours in front of the TV, and 50,000 hours in front of a computer.
Tangible User Interfaces as Mediating Tools within Adaptive Educational Environments

screen (International Futures Forum, Futuribles, European Journal of Education, & Université de Paris Dauphine, 2005). Various studies provide practical example of this tendency (for instance, Ba, Tally, & Tsikalas, 2002; Marsh, 2004).

The preceding data reiterates the need to find ways to shift the educational system so that it can conform to learners, better addressing their diversities. As Green et al. (2005) observe, the logic of education systems should be reversed so that it is the system that conforms to the learner, rather than the learner to the system. Thanks to tangible user interfaces, their intrinsic characteristics (physicality and active-oriented nature; sensory engagement; accessibility; concreteness and stimuli to abstract symbolic relations; capacity to trigger mental images that inform future problem-solving; familiarity) could offer interesting possibilities to this needed shift, enabling interactive HCI classroom activities where diverse learners can be in charge of how they choose and employ available learning resources.

A third significant benefit to classroom activities offered by tangible user interfaces is represented by their capacity to encourage collaboration as they afford multi-person, collaborative use (O’Malley & Stanton Fraser, 2004). A number of researchers have discussed and tested the benefits of: children working together (Rogoff, 1990; Stanton et al., 2001; Wood & O’Malley, 1996); collaborative practices on learning (for instance, Brandt, 1990; Hurley, Boykin, & Allen, 2005; Johnson, 1994; Johnson, Johnson, & Scott, 1978; Johnson, Maruyama, Johnson, Nelson, & Skon, 1981; Slavin, 1987); information technologies in peer and cooperative learning (for instance, Anderson, 2005; Chen & Morin, 2006; Topping, 2005); and that of tangible media in collaborative classroom practice (Africano, Berg, Lindbergh, Lundholm, Nilbrink, & Persson, 2004).

CONCLUSION AND FUTURE WORK

Although ICTs are already integrated into teaching across the curriculum, more encouragement might be given to teachers in terms of incorporating everyday technologies into the classroom, and the development of physical and multisensory activities, increasingly part of the curriculum, should occur with regard to the use of ICT (O’Malley & Stanton Fraser, 2004). In particular, tangible user interfaces could be considered and designed as mediating agents between pedagogy, teachers, learners, and context. This can occur only if more emphasis is placed on learners’ practices and teachers’ pedagogical choices and if teachers and learners are co-designers in the development of tangible HCI for learning.

There is a need to expand the ways in which tangible HCIs are researched, developed, deployed, evaluated, and implemented, and it is necessary to bridge the gap between technologist, designers, researchers, and teachers as their technical, pedagogical, and methodological knowledge and skills differ while complementing each other. A way to translate, mediate, and share ways of doing, thinking, and creating effective HCI must be developed.

As O’Malley and Stanton Fraser (2004) stress:

More research is needed on the benefits of tangibles for learning—so far the evaluation of these technologies has been rather scarce. More effort is also needed to translate some of the research prototypes into technologies and toolkits that teachers can use without too much technical knowledge. Teachers also need training in the use of non-traditional forms of ICT and how to incorporate them into teaching across the curriculum. And finally, new forms of assessment are needed to reflect the potential of these new technologies for learning.
The notion of **tangible user interfaces** as mediating agents within educational environments implies a shift in how the learning process is viewed, a shift in the roles of teachers and learners, and a shift in how learning spaces are shaped and interacted with.

O’Malley and Stanton Fraser (2004) express their hope that teachers will **take inspiration from the whole idea of technology-enhanced learning moving beyond the desktop or classroom computer by, for example, making links between ICT-based activities and other more physical activities.** I share this hope, and this chapter aims at nurturing this notion by linking technological aspects of HCI with pedagogical, ecological, and methodological considerations under the same holistic framework. The proposed HCI scaffold fosters a different way of looking at technology-design and technology-deployment, while promoting the opportunity to re-conceptualize roles, practices, and the relationships among key actors.

As discussed in this chapter, **tangible user interfaces** offer some significant benefits to classroom activities that involve HCI, in particular from creativity, diversity, and collaborative perspectives. However, these benefits imply a need for educational institutions to re-consider and re-address how they view the professional development of teachers, the classroom space, and how curriculum development and learning resources should be designed and deployed.

In the next phase of this work and building on current work around creative educational spaces, I propose to investigate the opportunities to re-conceptualize **tangible user interfaces as designed interventions.** Future research in this field might also include longer term qualitative studies to: (1) test **tangible user interfaces** in specific HCI contexts—living laboratories—with particular emphasis on their capacity to scaffold collaboration, creativity, and diversity; (2) further explore their agency in learning ecologies and (3) their impact on the HCI classroom space; (4) investigate specific benefits and challenges for instructors that decide to use the proposed model, coupling multi-pedagogical framework with **tangible user interfaces;** (5) look at how teachers can be scaffolded from a professional development perspective in their deployment of HCI tangibles; and (6) what type of learning resources can be designed for **tangible user interfaces** to deeply enrich the HCI classroom experience.

**ACKNOWLEDGMENTS**

My special thanks go to Prof. Patrick Dillon for sharing with me the adaptive educational environments journey. Thank you also to Mary Featherston for her contagious spaces-for-learning-enthusiasm. Finally, many thanks to Dr. Peter Burrows for our discussions and shared visions, which truly enrich my work.

Facilitating E-Learning with Social Software:
Attitudes and Usage from the Student’s Point of View

ABSTRACT
This article explores how social software tools can offer support for innovative learning methods and instructional design in general, and those related to self-organized learning in an academic context in particular. In the first section, the theoretical basis for the integration of wikis, discussion forums, and Weblogs in the context of learning are discussed. The second part presents the results of an empirical survey conducted by the authors and explores the usage of typical social software tools that support learning from a student’s perspective. The article concludes that social software tools have the potential to be a fitting technology in a teaching and learning environment.

INTRODUCTION
One major task of higher education is to train students for the requirements of their future work by applying and adapting their knowledge to specific workplace-related requirements and settings. Due to the ongoing pressure on enterprises to cut costs, the periods of vocational adjustment in a company will become shorter and shorter.
Facilitating E-Learning with Social Software

On the one hand, the rising pressure of innovation and fast-paced development in the economy results in increased demand for continuous employee training. On the other, growing global competition forces enterprises to use available resources very economically so that employee training is considered to be necessary and desired even though it is conducted under considerable time and cost pressure (Köllinger, 2002).

According to these goals, the settings of the education must be changed adequately: “While most of higher education still ascribes to traditional models of instruction and learning, the workplace is characterized by rapid changes and emergent demands that require individuals to learn and adapt in situ and on the job without the guidance of educational authorities” (Sharma & Fiedler, 2004, p. 543).

In the field of higher education, it has become an important goal to develop “digital literacy” and educate learners as competent users and participants in a knowledge-based society (Kerres, 2007), but it can be assumed that there is a new generation of students, the “digital natives,” who are accustomed to digital and Internet technology (Prensky, 2001a, 2001b).

Oblinger and Oblinger (2005) characterize next-generation students (called “n-gen,” for Net generation) as digitally literate, highly Internet savvy, connected via networked media, used to immediate responses, preferring experiential learning, highly social, preferring to work in teams, craving interactivity in image-rich environments, and having a preference for structure rather than ambiguity.

According to a study conducted by Lenhart and Madden (2005), half of all teens in the USA may be considered “content creators” by using applications that provide easy-to-use templates to create personal Web spaces.

Classical face-to-face learning is seen as rigid and synchronous, and it promotes one-way (teacher-to-student) communication. Thus, it is not surprising that more and more students are opting for Web-based education as a more flexible and asynchronous mode (Aggarwal & Legon, 2006).

The higher education system should provide answers to this new generation of students who enter the system with different backgrounds and skills. They are highly influenced by social networking experiences and are able to create and publish on the Internet (Resnick, 2002).

Educators and teachers therefore have to consider the implications of these developments for the future design of their courses and lectures.

In 2002, a new term, “social software,” entered the stage to refer to a new generation of Internet applications. One focus of this new generation is the collaboration of people in sharing information in new ways such as through social networking sites, wikis, communication tools, and folksonomies (Richter & Koch, 2007).

Wikis, Weblogs, and discussion forums will play a central role in the new context, so the areas of application and possibilities will enlarge enormously. It can be assumed that this will also have considerable influence on learning and the usage of these instruments as learning tools.

This article presents the results of an empirical survey in order to highlight the benefits of the above-mentioned Web-based social software tools from the student’s point of view; 268 first-semester students, all in the first term of their studies at Austrian universities from different study programs, took part in this survey. The students were asked to use one or more of these tools as a learning tool. Participation in this survey was voluntary.

The presentation of the results of this survey is divided into three parts: first, the use of the tools by the students (before they started their studies); second, the experiences the students had made with the tools during the study; and third, the potential future usage.

The article concludes with a discussion of the results of this survey in contrast with other empirical studies already published. Also, the
Facilitating E-Learning with Social Software

limitations of this survey and ideas for further research are pointed out.

THEORETICAL FRAMEWORK

This part refers to the necessary theoretical background required for the following empirical study, especially the areas of social software and learning.

Social Software

The term social software emerged and came into use in 2002 and is generally attributed to Clay Shirky (2003). Shirky, a writer and teacher on the social implications of Internet technology, defines social software simply as “software that supports group interaction.”

Another definition of social software can be found in Coates (2005), who refers to social software as “software that supports, extends, or derives added value from human social behaviour.”

Users are no longer mere readers, audiences, or consumers. They have the ability to become active producers of content. Users can act in user and producer positions and they can rapidly change the position.

Nowadays the term social software is closely related to “Web 2.0.” The term Web 2.0 was introduced by Tim O’Reilly (2005), who suggested the following definition:

Web 2.0 is the network as platform, spanning all connected devices; Web 2.0 applications are those that make the most of the intrinsic advantages of that platform: delivering software as a continually updated service that gets better the more people use it, consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others, creating network effects through an “architecture of participation,” and going beyond the page metaphor of Web 1.0 to deliver rich user experiences.

Web 2.0 technologies such as blogs, wikis, podcasts, and RSS feeds or discussion forums have been dubbed social software because they are perceived as being especially connected and allow users to develop Web content collaboratively and publicly (Alexander, 2006).

Until now, the Internet (Web 1.0) has one big disadvantage: It is easy to get information in it, but it is quite complicated and inconvenient to act as an author and take part in the development of content. Web 2.0 should enable all Internet users to actively take part in the further development of the Internet. Everyone should be able to contribute easily. The focus of Web 2.0 is on the behaviour of the user. It should empower people to communicate, collaborate, contribute, and participate.

This growing phenomenon is very interesting and ought to be examined carefully in order to understand how the Web is evolving and how this continuously regenerative cycle of performance and technological innovation empowers “learning by sharing” (Thijssen & Vernooij, 2002).

Based on the key principle of the architecture of participation, social software can be seen as part of Web 2.0. Wikis, Weblogs, and discussion forums are tools that are seen as social software applications and were selected for further research and the empirical study presented below.

Related Empirical Research

Institutions in the field of higher education have made efforts to introduce various IT-supported learning tools in the daily routine of students and lecturers (Aggarwal & Legon, 2006; Dooley & Wickersham, 2007; Duffy & Bruns, 2006; Evans & Sadler-Smith, 2006; McGill, Nicol, Littlejohn, Grierson, Juster, & Ion, 2005).

Published results of the usage of Weblogs in the Prolearn project (http://www.prolearn-project.org) have shown that a large majority of respon-
students considers personalization and adaptation of the learning environment as important and crucial factors. Learning should be individualized to become more effective and efficient. Personalization is a key element of the learning process, and specific problems need specific solutions as students differ greatly in their backgrounds and capabilities.

Learning materials are typically too general in order to cover a very wide range of purposes and personal learning needs. Compared to classical learning, personalization can be the most important added value that e-learning can offer. With it, education can be optimized and adjusted to various working conditions and needs because students have different goals, interests, motivation levels, learning skills, and endurance (Klamma et. al., 2006).

Chao (2007) explored the potential uses of wikis in the field of software engineering (38 participants), especially for software project team collaboration and communication. Overall, 25 students agreed and 1 student disagreed (2 were neutral) that the wiki is a good tool for project collaboration. Concerning the applications of wikis, more than 23 students found that a wiki is a good tool for maintaining a group diary, managing user stories (project requirements), and project tracking and reporting. While a majority of students found that a wiki is a good tool for updating a project plan, managing acceptance tests, tracking defects, and developing user documents, there were also a significant number of students who disagreed.

First results using wikis for collaborative writing (about 40 participants) also reported similar results. In this study, students used wikis to write articles partly together with the lecturer.

After early problems with using the software and writing contributions in the wiki, students were able to write articles by themselves or in teams. The motivation among students was on different levels, so the lecturer had to increase it during lessons. Other students, however, were highly motivated and were creating the content and adding them to the wikis (Bendel, 2007).

**Constructivism and Learning: Presentation of the Learning Model**

A constructivist point of view focuses on the learning process by looking at the construction of knowledge by an individual. As a consequence, there is a recommendation to align learning environments, especially in the academic context, and associated complex learning objectives with constructivist learning principles (Du & Wagner, 2005; Jonassen, Mayes, & McAleese, 1993; Tangney, FitzGibbon, Savage, Mehan, & Holmes, 2001). Learning is not seen as the transmission of content and knowledge to a passive learner. Constructivism views learning as an active and constructive process that is based on the current understanding of the learner. Learning is embedded in a social context and a certain situation (Schulmeister, 2005).

The constructivist approach shifts learning from instruction and design centered to learner-centered learning and teaching. The role of the educator changes from directing the learner toward supporting and coaching the learner.

Baumgartner (2004) has suggested three different prototypical modes of learning and teaching. These three different modes of learning and teaching can be neutral or specific so they can be applied across all subject domains. Therefore, each teaching model can be used to teach, for example, sociology subjects as well as to teach technical sciences. Learning can be portrayed as an iterative process that can subsequently be subdivided into different phases, which are summarized in Figure 1.

In particular, these three different prototypical modes for learning encompass the following.
Learning and Teaching I: Transferring Knowledge

At the starting point, the learner needs to be provided with abstract knowledge to lay the theoretical foundations and to understand relevant signposts, road markings, and orientation points. This kind of factual knowledge is static and has little value by itself in real and complex situations. It merely serves as a shortcut to prevent pitfalls and to help to organize the student’s learning experiences.

The knowledge of the student is based on knowledge possessed by the teacher. Students have to learn what teachers ask them to learn. The teacher has the responsibility to make the knowledge transfer as easy as possible.

Learning and Teaching II: Acquiring, Compiling, and Gathering Knowledge

In this section of the individual learning career, the student actually applies the abstract knowledge and gathers his or her own experiences. In order to limit the action and reflection possibilities, the learner interacts within a somewhat restricted, artificial environment, which is reduced in complexity and easy to control by the teacher. To provide feedback, the learning environment is designed to include relevant devices where students can deposit their interim products and teachers can inspect them.

The emphasis in this model lies on the learning process of the student. Teachers try to help the students overcome wrong assumptions and wrong learning attitudes, and assist in the reflection process of the subject domain.

Learning and Teaching III: Developing, Inventing, and Constructing Knowledge

Teacher and learner work together to master problems. This model includes problem generation and/or invention. The environment is constructed in such a way that it represents, at least in certain aspects, reality or reality in a constrained form.

Figure 1. Prototypical modes of learning and teaching (Baumgartner, 2004)
Facilitating E-Learning with Social Software

This model includes two-way communication on equal terms, using either linguistic representations or other adequate kinds of language.

Teaching III has strong links to constructivism. From a constructivist point of view, learning is considered as an active process in which people construct their knowledge by relating it to their previous experiences in complex and real situations in life. In their practical lives, people are confronted with unique, unpredictable situations whose inherent problems are not readily observable (Baumgartner, 2004).

Students should be enabled to invent new things, and produce or generate new knowledge. Consequently, learning and teaching at universities in most cases can be assigned to the requirements presented in Learning and Teaching II and III. In order to achieve this goal, a special learning environment must be provided.

Consequences for IT-Supported Learning and Teaching

Computer software can be used for all three models, ranging from programmed instruction (Learning/Teaching I) to problem-solving software (Learning/Teaching II), to complex simulations and/or so-called micro worlds (Learning/Teaching III). It is said that the inherent nature of the Internet brings the real world into the classrooms, and with its hyperlink structure it clearly advocates the model of Teaching III (Baumgartner, 2004).

The use of the Internet, especially through its social software, gains importance because it can contribute to exceed the limits of classical teaching models. By adapting learning and teaching models to the new technical possibilities, the roles of learner and teacher are becoming more indistinct because the learner can take a central part in the design and arrangement of the learning process (Kerres, 2006).

Systems that support learners with respect to the Learning Model III are called personal learning environments (PLEs). PLEs are mostly Web-based applications and are based on learning management systems (LMSs; Seufert, 2007).

PLEs are personal and open learning environments, and they are suitable for cross-linking content and people. Learners can use PLEs to manage individual learning progress. They are ideally available for lifelong learning and are supported by the following processes.

• setting up individual learning goals
• planning and controlling one’s own learning concerning the content as well as the learning process
• combining formal and informal learning activities
• communicating with peers during the learning process
• establishing social networks or communities of practice
• using Web-based services, for example, syndication
• verifying the learning process with respect to the learning goals

Unlike an LMS, which is usually related to one special institution or to one special course, a PLE is focused on the individual learner. A PLE should combine a broad mixture of different resources and subsystems in a “personally-managed space” (Attwell, 2006).

In the previous decade, learning management systems were developed that moved toward enterprise-level applications, “but the wealth of new, user-friendly, tools in the Web 2.0 environment suggests that the all-in-one monolithic e-learning systems may be entering a phase of obsolescence by the ongoing development of the web” (Craig, 2007).

Social software applications have the potential to cope with these requirements (Brahm, 2007).
DESCRIPTION AND CLASSIFICATION OF SOCIAL SOFTWARE TOOLS

In the following section, three social software tools—Weblogs, discussion forums, and wikis—are described in more detail and the tools are compared. Students were able to select these tools during the empirical study.

Weblog

A Weblog, a compound of Web and logbook, usually just called “blog,” is a Web site that contains new articles or contributions in a primarily chronological order, listing the latest entry on top.

Primarily, a Weblog is a discussion-oriented instrument especially emphasizing two functions: RSS feeds and trackback. RSS feeds, also called RSS files, can be read and processed for further use by other programs. The most common programs are RSS readers or RSS aggregators that check RSS-enabled Web sites on behalf of the user to read or display any updated contribution that can be found. The user can subscribe to several RSS feeds. Thus, the information of different Web sites can be retrieved and combined. Preferably, news or other Weblogs are subscribed to.

Trackback is a service function that notifies the author of an entry in a Weblog if a reference to this contribution has been made in another Weblog. By this mechanism, a blogger (person who writes contributions in a Weblog) is immediately informed of any reactions to his or her contribution on other Weblogs (Hammond, Hannay, & Lund, 2004).

Forum

A discussion forum or Web forum is a service function providing discussion possibilities on the Internet. Usually, Web forums are designed for the discussion of special topics. The forum is furthermore subdivided into subforums or subtopics. Contributions to the discussion can be made and other people may read and/or respond to them. Several contributions to a single topic are called a thread.

The application areas of the two instruments, Weblogs and forums, are quite similar. The most essential differences between Weblogs and discussion forums can be described as follows:

• A forum is usually located on one platform while many bloggers develop their own, individual environments. They connect their Weblogs via RSS feeds and trackback functions.
• Through the integration of RSS files and trackback functions, a discussion process can be initiated and continued, crossing the boundaries of the bloggers’ own Weblogs without authors having to observe other Weblogs.
• Weblogs tend to be more people centered whereas forums are more topic focused. Through the use of Weblogs, learner-specific learning environments can be constructed without interfering with the learning environments of others (Baumgartner, 2004).

Wiki

A WikiWikiWeb, shortly called wiki, is a hypertext system for storing and processing information. Every single site of this collection of linked Web pages can be viewed through a Web browser. Furthermore, every site can also be edited by any person. The separation between authors and readers who write their own text, and change and delete it is obsolete as also third parties can carry out these functions (Augar, Raitman, & Zhou, 2004).
Facilitating E-Learning with Social Software

Learning Activities Supported by Social Software

The integration of different social software tools offers support in the following learning activities:

- **Learning from different perspectives**: The integration supports the exchange of ideas as well as finding like-minded people. Furthermore, social software tools simplify the process of establishing connections between people of the same or similar interests. Simultaneously, its open and expandable philosophy supports going beyond the thinking in groups (of a common interest) by supporting diversity and bringing together different perspectives and backgrounds (Efimova & Fiedler, 2004; Schulmeister, 2004).

- **Synergies of self-organized and joint learning**: Social Software tools provide a personal learning area for their authors. However, this does not force a general learning flow or learning style. Learners are not alone and can profit from the feedback of a community in order to examine and enhance the development of their own ideas (Böttger & Röll, 2004; Efimova & Fiedler, 2004; Fiedler, 2004).

- **Digital apprenticeship**: Through reading other wikis, forums, or Weblogs regularly, beginners are enabled to learn from experts. At the same time, they can actively participate in discussions beyond geographic or thematic borders (Efimova & Fiedler, 2004; Fiedler, 2004).

- **Support for the development of the ability to learn (learning to learn)**: Through the publication of one’s own thoughts and reflections, content is made available for assessment as well as for further development, thereby improving self-observation and self-reflection skills. The knowledge change of the learner will be improved (Baumgartner, 2005).

- **Support for reflexive writing**: The simple but efficient and rather robust encoding standard usually used in social software allows for the explicit modeling of content flows, feedback loops, and monitoring procedures of various kinds, thus supporting an ongoing iterative process of explication and reflection (Fiedler, 2004).

Integration of Social Software Tools and the Learning and Teaching Modes

Baumgartner (2004) has integrated different types of content management systems in relation to the most suitable learning and teaching mode. He clearly states that the boundaries are overlapping and that every tool, in one way or another, could be used for every teaching model. Figure 2 presents the integration of the social software tools and the learning and teaching modes.

Weblogs and forums can be defined as discussion-oriented tools because the discourse and exchange of ideas related to a certain topic is the preeminent aim. Weblogs offer the possibility to support all three phases of the learning process. However, the main focus can be assigned to Modes II and III.

Based on the multitude of interaction possibilities, wikis can be attached to Teaching III (Baumgartner, 2004). Additional functions were added to Weblog tools that go beyond the scope of the central use of Weblogs; for example, longer articles can also be stored. Through the creation of directories, a structured collection of links can be implemented.

Through the additional linking of Weblogs, wikis, and forums, there is the possibility to develop a personal knowledge collection (Kantel, 2003).
Facilitating E-Learning with Social Software

The purpose of this survey was to determine if the integration of Web-based social software tools (wikis, discussion forums, and Weblogs) are suitable to foster learning from the student’s point of view.

Aim of the Survey and Methodology

Scrubbing the possibilities and constraints of social software tools (wikis, discussion forums, and Weblogs) as personal learning environments, students at Austrian universities were asked to use one or more of the offered tools for their research, homework, and documentation purposes. In most cases, the collaboration of students was required to perform the assigned tasks.

The students were asked to use the tools for one course only during the winter term of 2006. Furthermore, there was no obligation for the students to use a tool at all; they were just encouraged to do so. Students were also offered the possibility to use two or three tools; the selection was up to the students.

The courses were organized as blended-learning courses so they included on-campus lessons and off-campus work in which the students could work face-to-face or using the social software tools.

More than 90% of the students attending the courses took part in this survey. In order to give the participants an impression of the functionality and usage of the tools, short presentations of the tools were made by an instructor before the students made their choice.

At the end of the testing phase—after 4 weeks of using the tools—selected students reported their experiences with the tools used. Students who had decided not to use the tools in the first place got an impression about the usage, advantages, and disadvantages of the tools from their fellow students. Following these short presentations, a questionnaire was completed that provided the basic findings for further inspection and research.

A total of 268 first-semester students of different Austrian universities in five selected courses took part in this survey. The majority of the participants were between 18 and 20 years old. The portion of female students was about 17%.

Figure 2. Prototypical modes and social software tool
According to a survey conducted by Seybert (2007) concerning gender differences in computer and Internet usage by young people (aged between 16 and 24), there is no gap between men and women in Austria. The proportion of women and men (in the relevant age class) that use a computer (almost) once a day is 72% the same. A study by Otto, Kutscher, Klein, and Iske (2005) indicates that there is a positive correlation between a formal educational background and the usage of the Internet in Germany: “Beside socio-cultural resources like family background, peer structures and social support in general, the formal educational background turns out to be the main factor for explaining differences in internet usage” (p. 219). As a consequence, for the analysis of the results of this survey, no distinction between male and female students was made.

Table 1 presents the distribution of the participants concerning the degree programs the students are attending.

For the further analysis of the results, no distinction according to degree programs will be made.

The questionnaire asked each participant questions about her or his subjective impression of the application of the tools. It included 5-point Likert scales for rating constructs such as eligibility, perceived quality, or enjoyment.

The study was conducted to find answers about the:

- usage of social software before the study started,
- selection of the offered tools,
- perceived quality of the contributions and the support for learning,
- applicability of the instruments to support communication and community building,
- correlation of the usage for private and educational purposes of the tools,
- fun factor in using the instruments, and
- potential future usage.

The results of the study are presented in three parts:

- Part 1: Analysis of the usage of wikis, discussion forums, and Weblogs of the students before the study was started
- Part 2: Experiences made with the tools during the study
- Part 3: Potential future usage of the tools

### Part 1: Tool Selection and Prestudy Usage

Due to the fact that the students could select the tools on their own, the Table 2 shows the results of this selection process.

According to Table 2, the combination of wikis and discussion forums is the most selected combination of tools (42.9%), followed by wikis only (23.1%) and discussion forums only (22.4%). In the end, only five students (1.9%) did not take part in the study; they did not select a tool, although they first had the intention to do so. Only one student used Weblogs only. Generally, Weblogs were not used very intensively by the participants.

Table 3 shows the usage of the tools by the participants before they took part in the study. It indicates that wikis (76%) and discussion forums (78%) are currently the most widely used.

Table 5 presents the results for the statement “I often use wikis or forums for educational purposes.”

A huge majority (90%) stated that they use wikis for educational purposes and about two thirds (68%) used wikis for private purposes. Wikis are therefore more intensively used for educational purposes than for private purposes, whereas the usage of forums is exactly the opposite: They are more used for private purposes than for education.

The responses of the students concerning these statements were that wikis are foremost considered as a source of serious information, whereas forums are ideal for getting hints or clues to problems because of their privacy. Questions about computer problems, computer games, leisure activities, and so forth were mentioned. A repetition of this image can be identified when the disagreement with the statement is analyzed; 29% of the students do not or rarely use forums for private purposes compared to 36% for education.

**Part 2: Experiences Made During the Study**

This section presents the results of the study concerning experiences with the usage of the tools during the study.

### Quality and Support for Learning

The following refers to statements concerning the quality of the contributions of wikis and discussion forums and their support for learning.

The results of the statement “The quality of contributions in wikis or forums is in general good” are presented in Table 6. The contributions of wikis are evaluated to be much better than those of forums.

The surveyed pupils had the opportunity to give reasons for their assessment concerning the quality of contributions via additional qualitative feedback. The following summarizes the addressed reasons.

One reason for the excelling grade for the quality of wikis is the “Wikipedian community.” The term *wiki* is often seen as a synonym for the free online encyclopedia Wikipedia (http://www.wikipedia.org). Wikipedia is widely used for a great variety of tasks, including research on all topics needed for educational and private purposes.

In contrast to the good evaluation of the contributions of wikis, the open architecture of wikis was also mentioned. In most cases, this open architecture allows everyone to edit entries, which results in the uncertainty of whether the knowledge presented is correct or not. The quality of contributions in discussion forums was rated

Facilitating E-Learning with Social Software

rather mediocre. Forums are primarily used for technical problems, especially computer-related problems; to get in contact with experts on certain topics, and to get information on online games.

The next statement, “The usage of wikis or forums leads to misunderstandings and confusion,” is about the clarity of the contributions.

Only a minority think that the contributions are not clear and may lead to misunderstandings. In this case, wikis are also rated better than forums.

The next statements addressed the support of these instruments for learning. Table 8 summarizes the results for the statement “When reading contributions in wikis or forums, it is easier for me to acquire the learning contents.”

More than half of the students express that reading contributions in wikis is helpful for learning, whereas only about 8% think that it is not helpful. Compared to forums, wikis were again much better evaluated, especially considering the big difference from the negative evaluations of forums.

Table 9 presents the learning support achieved by writing contributions. (“When writing contributions in wikis or forums, it is easier for me to acquire the learning contents.”)

A different picture emerges in the statistics when comparing the evaluation of how writing an article or post supports the learning process. Here, forums take the lead when it comes to positive assessment. In both cases, there was a large number stating that writing is neither positive nor negative. The majority of the students read rather than wrote, while more students wrote in forums than in wikis.

Facilitating E-Learning with Social Software

Applicability for Communication and Community Building

The statement was formulated as follows: “Wikis or forums are appropriate to support communication.”

The results clearly demonstrate that discussion forums are made for communication whereas wikis are rather seen as a kind of reference book or encyclopedia, as already mentioned above.

The results of the next statement, “Wikis or forums support the setup of communities,” can be seen in Table 11.

Opinions about the applicability of wikis to establish a community is split. About 35% say that wikis are supportive of building a community compared to 25% who said that wikis do not support community building. The support of forums to build a community is rated much better: 50% indicated that forums are well suited to build a community. These results were to be expected because they confirm the nature of the instruments.

Fun Factor in Using the Instruments

In surveying whether students gain pleasure (“I enjoy using wikis or forums”), wikis again came out on top.

A majority enjoy using wikis (62%) and forums (56%). Considering the percentage of students who said that there is no (“I disagree”) or little (“I slightly disagree”) fun when using these instruments, wikis (6%) are much better rated than forums (18%).

Part 3: Potential Future Usage of the Tools

The third section of the empirical study deals with the potential usage by students who had not used the instruments before the study. Students gained knowledge and experiences by using the tools during the study by themselves or on the basis of the reported experiences made by their fellow students.

</tbody>
</table>
The first statement, “I will use wikis, forums, or Weblogs for educational purposes in the future,” yielded the results in Table 13.

According to this study, wikis will have a bright future and will be used often for educational purposes, whereas forums will be used less often. About 54% of the surveyed students had the intention of using wikis more or less often in the future. About 16% did not think that they will use wikis often in the future and 30% are not yet sure if they will use this instrument.

The results for forums and Weblogs indicate no clear trend, but forums were rated slightly higher than Weblogs; 39% of the students stated that they can imagine using forums in the future for their education compared to 36% for Weblogs. At the other end of the scale, 45% did not have the intention to use forums (40% for Weblogs).

The statement “I will use wikis, forums, or Weblogs for private purposes in the future” leads to similar results.

From this point of view, wikis are again the leading instrument, followed by forums and then Weblogs.

It must be said that the responses to this set of statements represented feelings, attitudes, and opinions about instruments that had not yet been used by the asked participants. The purpose of posing these statements was to gain insight into the mind-set in regard to these instruments.

**DISCUSSION**

The results clearly show that wikis are currently the most often used instrument and furthermore have the greatest potential as a tool for learning and knowledge management in the field of learning; these findings are in line with other empirical studies (Bendel, 2007; Chao, 2007).

Other studies (McGill et al., 2005; Nicol & MacLeod, 2004) report that a shared workspace helps to support collaborative learning; the possibility of being able to access and contribute to the development of resources at any time and from any location was especially appreciated by the students.

The survey at hand made a distinction between reading and writing contributions to wikis and discussion forums. The results show that 59% of students said reading contributions in wikis is helpful for learning (stating “I totally agree” and “I generally agree”) while only 21% stated that writing in wikis is helpful for learning. Reading contributions in forums helped 29% of the participants, whereas writing in forums was helpful to 26%. This survey supports the general statement that a shared workspace that supports a constructivist and learner-centered approach is helpful for learning.

The pedagogical value in the context of learning is described in several publications (Babcock, 2007; Hurst, 2005). Weblogs can foster the establishment of a learning and teaching environment in which students and teachers experience a greater degree of equality and engagement. Du and Wagner (2007) published results of a study of an information systems undergraduate course (31 participants). This study indicated that the performance of students’ Weblogs was a significant predictor for learning outcomes, while traditional coursework was not. Moreover, individuals’ cognitive construction efforts to build their own mental models and social construction efforts to further enrich and expand knowledge resources appeared to be two key aspects of constructivist learning with Weblogs. According to this study, there is a potential benefit of using Weblogs as a knowledge construction tool and a social learning medium.

According to the survey at hand, Weblogs are not yet widely used, and their potential seems to be limited. It can be assumed that these limited prospects will change when the penetration of Weblogs into the daily routine of the students increase—for private as well as for educational purposes.
To avoid possible pitfalls about the application of these instruments in the context of learning, some social and psychological issues must be taken into consideration (Kreijns, Kirschner, & Jochems, 2003). Social interaction is essential for members of a team to get to know each other, commit to social relationships, develop trust, and develop a sense of belonging in developing a learning community. The size and the composition of the learning communities seem to be important factors in how interaction and communication within the learning community will take place (Dooley & Wickersham, 2007). There are also many unresolved issues, like the provision of the technology and the services, intellectual property rights and digital rights management, the security of data, access restrictions to the content, and information ethics (Attwell, 2006; McGill et al., 2005; Sharma & Maleyeff, 2003).

CONCLUSION

The aim of this contribution was to investigate the experiences of students using social software tools in the context of learning. Wikis, Weblogs, and discussion forums are typical social software tools and were used for this survey.

The results clearly show that wikis and discussion forums can support learning and collaboration. The usage of Weblogs in this study was limited and hence no statements about their applicability can be made. In order to assure a successful implementation of these tools, social and psychological issues must be taken into consideration as well.

The results of this study are the basis for the introduction of social software into education to help students set up individual learning environments. These learning environments should support lifelong learning.

There are likely to be other unplanned consequences of the intensive use of the Internet in general and social software especially. Further research is needed to explore possible problems and solutions.

The results of the empirical survey indicate that a long-term study in combination with the further development of social software tools may be promising.

Section IV
Utilization and Application

This section introduces and discusses the ways in which particular technologies have impacted humanity and proposes new ways in which IT-related innovations can be implemented within organizations and in society as a whole. These particular selections highlight, among other topics, ubiquitous computing applications in an educational setting and computer-mediated communication. Contributions included in this section provide excellent coverage of today’s world and insight into how our interaction with technology impacts the fabric of our present-day global village.
Chapter 4.1
Human Computer Interaction and the Best Mix of Face-to-Face and E-Interactions in Educational Settings

Bolanle A. Olaniran
Texas Tech University, USA

ABSTRACT

Recent trends and rapid improvement in technology such as computer-mediated communication (CMC) and increasing bandwidth in the Internet are facilitating increased electronic interactions (i.e., e-interactions otherwise known as or commonly referred to as the human computer interaction (HCI)). CMC technology systems are a common occurrence in educational institutions as administrators attempt to encourage technology usage and instructors race to learn and implement CMC use in their classrooms and students demand greater flexibility and control in how they learn. Notwithstanding is the need to decide which forms of HCI technology to use, how to use them, and what benefits can accrue from such usage. The discussion here explores each of these issues, but more specifically will focus on addressing the case for blending e-interactions with the traditional face-to-face (FTF) communication medium while addressing the appropriateness of such combination.

INTRODUCTION

Human computer interaction (HCI) occurs through a host of information communication technologies (ICT), specifically computer-mediated systems (e.g., e-mail, computer conferencing, video-conferencing) that facilitate electronic interaction among people. A multitude of organizations involved in the knowledge management industry are finding ways to incorporate computer-mediated communication (CMC) technologies into their day-to-day operations as coordination tools and learning curriculum dissemination tools. HCI has also found explosive growth in educational settings such as traditional and non
traditional universities to extend current instructional content delivery and to tap into distance educational settings. The idea of CMC systems for the instructional delivery tool to provide both uniform and customized training is called electronic learning, which is otherwise referred to as e-learning. Contemporary research has discussed at length the potential benefits of CMC systems in general and within distance education in particular (Barnard, 1997; McIsaac & Gunawardena, 1996; Yakimovicz & Murphy, 1995), but research on joint use of the CMC system and face-to-face (FTF) communication in regular classrooms is scarce (Olaniran, 2004). This chapter will address how using a combined CMC and (FTF) interaction could benefit courses in communication and other social sciences.

Teachers are challenged to incorporate information communication technology (ICT) into their curriculum to enhance learning and to prepare students for future careers (Althaus, 1997; Craig, 2001-2002; Snoeyink & Ertmer, 2001-2002; Witmer, 1998). ICT offers opportunities for facilitating discussion and presenting forums for varieties of opinions (McComb, 1994; Olaniran, 2001; Olaniran, Savage, & Sorenson, 1996, Witmer, 1998). HCI technology, specifically, CMC, offers the opportunity for active and experiential learning and its benefits in group activities have been acknowledged (Craig, 2001-2002; Gasker & Cascio, 2001; Olaniran, 1994; Olaniran, et al., 1996).

In spite of the identified advantages, incorporating ICT especially CMC into classrooms remains challenging. Some challenges facing instructors regarding implementation of CMC in classrooms and courses include selection and usage long after adoption decisions are made. In addition to technology issues, instructors need to focus on pedagogical issues surrounding course structure, and course management.

**COMPUTER MEDIATED COMMUNICATION AND LEARNING FACILITATION**

The rampant effect of information communication technology (ICT) is constantly being felt in contemporary organizations, interpersonal interactions, and academic settings. ICTs are instrumental in facilitating human computer interaction, which underlies the computer mediated communication (CMC) in organizations, classrooms, groups, and interpersonal contexts. As a matter of fact, the issue facing most institutions today (academic and non academic organizations) is not whether to use CMC systems but rather how to use them effectively.

There is a significant volume of literature on CMC systems and distance education (e.g., Abrahamson, 1998; Twigg, 1997, Wegrif, 1998), however, not all usages of CMC in learning environment are exclusively distance education. Some research in CMC technologies concentrates on the social effects of communication technologies (e.g., Hiltz & Turoff, 1978; Sproull & Kiesler, 1986). No doubt, the demand for distance education contributes to the proliferation of ICT as a way to provide education and training. However, there is a need to look at how CMC and other technologies facilitate learning and to identify other key variables that must be accounted for in order for effective learning to occur. This chapter seeks to provide a practical guide to educators and learners for enhancing learning through communication technology.

The globalization trends in contemporary organizations are putting priority on uniform and customized training to the extent that institutions are looking at e-learning to meet their curriculum needs. As a result, varieties of online universities like the University of Phoenix and Westwood College Online are developing in order to meet the needs of non traditional students (e.g., corporate travelers and expatriates). Furthermore, several universities are throwing their support behind
the development of technological centers such as the teaching, learning, and technology center (TLTC) to assist instructors in incorporating CMC into teaching and learning. Specifically, the developments in the use and adoption of ICTs in the educational arena necessitate a closer look at learning that takes place where these technologies are being deployed.

There are several areas to examine when dealing with e-learning or incorporating CMC into courses. These include areas such as: the interaction between students and technology, the interaction between students and teacher, the interaction between students and students. Robson (2000) argues that learning theories are mediated by technologies given that students often establish relationships with varieties of technologies. In essence, it is important to examine how students learn when using CMC systems (Alavi, 1994; Du & Wagner, 2005). Furthermore, it is hoped that examining how students learn and interact with technology will help instructors and, perhaps, designers to determine the best way to apply technology in course curricula.

**HOW STUDENTS LEARN WITH COMPUTER MEDIATED COMMUNICATION SYSTEM**

Perhaps the most prominent reason administrators and instructors offer for incorporating HCI and other CMC technologies into course design is the vision of personalizing learning to meet the idiosyncrasies of students’ learning styles. Innovative teachers see computers as tools to help students in their learning needs with the goal of tailoring course content to suit each student. Similarly, personalized learning is closely related to active or transformational learning in the sense that it allows for students to apply instructional content while retaining information longer than the lecture and print mode that is characterized by traditional modes of instruction (Olaniran, Stalcup, & Jensen, 2000). Students apply computers to learning in several ways (1) to access information, (2) to develop skills, and (3) to cultivate appropriate behaviors and other social skills (Robson, 2000). Each of the uses is explored in the following paragraphs.

**INFORMATION ACCESS**

CMC offers students the opportunity to scan information through Website navigation (browsing) and by searching for particular information. For instance, in Web-assisted methods of CMC, students are able to navigate instructors’ Web pages to access course notes and other instructional resources provided by instructors. However, access to information is not restricted to just instructors’ Web pages. Students can use a browser to seek additional information or to research similar topics and other topics of interest. General browsing is categorized as low cognitive activity in learning (Jacobson, 1995). Browsing can, however, facilitate a high cognitive thinking because students learn as they seek varieties of information and when they develop a method to categorize information in a structured manner (i.e., retention and recall) at a later time (Jacobson, 1995; Robson, 2000). At the same time, one must not forget that students differ even in the way they search and learn. For instance, Robson (2000) argues that some students prefer general browsing to specific keyword searches. Students also differ in the way they avoid disorientation or get lost in the multitude of information (Hara, Bonk, & Angeli, 2000; Wegrif, 1998). For example, some students are able to navigate through multiple sites and keep track of information obtained, while others are stressed and are unable to distinguish one network from another (Duchier, 1996).

As far as information access and personalized learning is concerned, Olaniran (2004) argues that a mixed or combined CMC and face-to-face communication media (CMC/FTF) offers a good
way of addressing students’ needs and at the students’ convenience and comfort levels. In a study evaluating the combined CMC/FTF media, Olaniran (2004) finds that students using CMC were three times more likely to initiate contact with the instructor about course content than in an FTF setting. Specifically, the results also indicate that students are twice as likely in the use of the CMC medium when compared to FTF medium to address questions relating to individualized learning. Thus, the CMC/FTF design structure offers a way to compare both media while presenting a method for accounting for individual students’ interest, knowledge level, and learning styles in a gradual manner (Gasker & Cascio, 2001; Olaniran, et al., 1996). CMC structure allows teachers to target different learning styles and knowledge levels without confusing other students through individualized contacts and course designs.

Other factors influencing access include the propensity to adopt and use communication technologies. Adopting CMC for course design and students’ learning starts with access to technology and the willingness to use it (Olaniran, 1993). A study on attitude and perceptions of e-learning found ease of access as the top reason in students’ use of CMC at 47 percent, while course relevance to future careers and user friendliness were at a distant second and third (i.e., 29 percent and 24 percent respectively) (Vaughan & MacVicar, 2004). This finding reinforces the need for instructors to pay specific attention to issues of accessibility. It is often taken for granted that students have access to e-mail and Internet especially in the USA. This may be obvious because some students have access to internet while on campus whereas they do not have access at home. More troubling on most university campuses is the fact that students often shy away from using a university assigned e-mail account for other third party client e-mail such as Yahoo, MSN, and Hotmail and the likes. The challenge is that some university are clamping down on the use of these third party e-mail accounts as a preventive measure against the spread of viruses and worms to their systems (Curran, McIntyre, Meenan, McCloy, & Heaney, 2004). Consequently, some students are unable to access materials sent by instructors.

**SKILL DEVELOPMENT**

Skills take two forms. The first deals with the technical skills that allow both student and instructor to use hardware and software or evaluate data. The second involves the social skills that are deployed by technology users during interactions (Robson, 2000). The technical skills address the issue of competence with the technology in use, while social skills deal with issues of etiquette and discernment of contextually appropriate behaviors. In CMC research, Olaniran (2004) addresses the adjustment process that accompanies students’ interaction, which range from use of all caps to protocols of posting messages in a threaded discussion. Personal experience in threaded discussions also suggests that students often participate in threaded discussion by breaking the thread; that is, starting a new thread while still on the same topic.

**NURTURING APPROPRIATE ATTITUDES**

As students use CMC they develop attitudes toward the technology medium (Olaniran, 2004) as well as developing professional attitudes and values consistent with the course content or discipline. Robson (2000) argues that the learning of concepts, skills, and development of attitudes equates “cognitive development” on the part of the student, which represents an important goal in all forms of education. However, it is not certain that attitude development toward technology translates positively to professional attitude development. For instance, how users (i.e., students) perceive a
CMC medium based on ease of use affects decisions to adopt and continue using the technology (e.g., Olaniran, 1993; 2004; Vaughan & MaeVicar, 2004). Thus, one could argue that when students are frustrated within a CMC system, they may abandon the technology or fail to adopt it.

At the same time, students never get to develop professional attitudes or achieve high cognitive development when they fail to use a particular communication technology and thus, they rob themselves the opportunity to learn the technology even when they know it might be beneficial to them. For instance, in a course utilizing Web authoring tools, I have found few students deciding to skip certain assignments (designing personal Web page) simply because of the perceived difficulty with the technology software. Students discuss the lack of competence in the Web authoring tools offered through the university computing services center. Therefore, it is imperative for instructors to realize that simply because the tool is available and the instructor has offered some training on the tools does not mean that students grasp the concept and are ready to perform certain tasks on their own. This is especially the case with non-technically oriented courses in liberal arts and social sciences. Robson (2000) echoes this assessment when arguing that “access to knowledge through technology does not guarantee improved outcomes” (p. 157). Instructors are then critical about facilitating students learning; how they design the learning experience is what will facilitate the desired outcomes. This raises the issue of how instructors can assist students in learning, which is discussed in the next section.

CRITICAL THINKING AND TRANSFORMATIVE LEARNING

The use of CMC in teaching courses can foster transformational learning. The transformation learning provides an opportunity to contrast experiential knowledge (i.e., previously acquired information) with new information in order to make informed decisions about which to accept (Olaniran, 2004). The transformational learning identifies three factors (1) Validation of prior knowledge, (2) modification of prior knowledge, and (3) replacement of prior knowledge (Craig, 2001-2002; Salaberry, 2000). The process is facilitated through the direct communication process enhanced in CMC (Alavi, 1994; Mason & Bascich, 1998). Olaniran (2004) reported evidence of transformation learning when students challenged their existing beliefs about both CMC and FTF media, that is, some changed their prior beliefs after they were confronted with new information and experience. The best evidence of transformation learning reported by the learners is illustrated in the understanding of the reason for the change however.

It is possible that the change in opinion of both communication media could be attributed to the course design. The CMC and FTF format helped fortify the transformational learning experience by providing students with practical use of communication technology, which provides students with the opportunity to validate information (beliefs and facts) about both study and the communication media (CMC vs. FTF). The learning

HELPING STUDENTS TO LEARN WITH CMC

Incorporating CMC to a course design is not a panacea. However, how technologies are applied will be the major determinant of the learning that takes place. CMC platforms can be used simply as a conduit to create printed materials or it can be used as an all-encompassing learning forum (access, knowledge, interaction forum etc.). Electronic media provide a platform for interaction and can be a source of knowledge (Du & Wagner, 2005; Leidner & Jarvenpaa, 1995). For instance, the Internet is viewed as a gateway to information (Uys, 1997) and a source of knowledge.
process that occurs can then enhance greater retention of information about course content and attitudes toward technology. Furthermore, interaction occurring when course materials are provided with CMC is said to be in line with the principles of contemporary learning strategies (Du & Wagner, 2005; Hoare & Race, 1991). As a result students are able to develop skills in critical thinking, which requires the ability to reflect on the interaction with the aid of the record storage provided by CMC technologies. While self-reflection is possible in FTF setting as well, it is usually more difficult to do in the absence of good note taking with FTF context than it is in CMC, because note taking is flawed with inaccuracies due to failed memory recall. Robson (2000) puts things into perspective when arguing that in the past, students achieved cognitive learning by linear texts and discussion. However, with technology, students are able to seek information in order to extend their knowledge, reflect on information, and then, develop their own views of the information and the foundation upon which the information is based. Du and Wagner (2005) on Weblogs refer to power of CMC to prevent free-riding that often occurs in FTF groups and other collaborative learning because assessment is graded on individual effort. Students have to take ownership of their individual contribution knowing that it will be evaluated in direct comparison with their peers.

**GIVING STUDENTS THE CONTROL**

Incorporating CMC into a course allows students to take charge of how they learn. The interaction with technology provides some level of flexibility in how students adapt technology to meet their individual needs. Olaniran (2004) argues that the ability and the freedom to ask the instructor questions directly show that CMC has a tendency to foster a greater sense of control in how they learn and in the process of learning. For instance, students do not have to wait in line to talk to the instructor or wait for appointment. The significance is that the traditional gate-keeping role of a secretary is reduced. The notion of “direct manipulation” (Fong & Kwan, 2003) speaks to the idea, where a task as simple as icon dragging or cursor position on a computer screen provide students the knowledge about the technology and also about the task. Indirectly, Rubens et al. (2005) address control when discussing the flexibility that technology design affords for knowledge building. By knowledge building, students instead of passive participation in class discussion are individually responsible for identifying ideas and to expand their knowledge base on those ideas.

Furthermore, Olaniran (2004) finds that increased control in access to instructors with CMC provides students opportunity to share more personal information with the instructor, which further aids learning as students are able to develop a rapport and comfort with an instructor, course, and the technology. On the contrary, traditional FTF interaction limits time for sharing such information. At the same time, a balance needs to be struck between offering users or students the control to accomplish a task versus control that can be counter productive. Fong and Kwan (2003) offer the following advice for effective electronic learning that users need to have technologies that provide them with knowledge of getting their work done without destroying their data. While technology is supposed to provide a means for accomplishing a task in both an effective and efficient manner, they are known to be problematic either through mistake or malfunctioning. Thus, it is advised that technology offer tool box or alert box (i.e., wizards) that can notify students of impending mistakes such as accidental deletion of document (Fong & Wang, 2003).

**COURSE MANAGEMENT**

The goal of any course regardless of the communication medium (technological or traditional) is
to help students build knowledge and demonstrate mastery of the concepts. Thus, it is important that instructors use technologies in a way that facilitates this process by selecting CMC hardware and software that create the context where students are actively engaged in the knowledge building and overall learning process. The emphasis on individualized or personalized instruction can enable students to learn, however, a mismanagement of the process can be counterproductive and inhibit learning. For instance, technology media can serve as a teaching mechanism in which case a good interface between the technology and students is required. Students must not be left to fend for themselves (e.g., learning to use the technology features). Robson (2000) hints at this when she suggests that teachers’ roles call for them to manage rather than mere pointing students to information. As instructors perform their managerial duties, attention must be given to how students learn, process information, and select technology that can help accomplish these goals. For example, in CMC using computer conferencing or threaded discussion, students need to know that they do not have to depend only on the instructor or their own ability to obtain answers to questions (Olaniran, 2004). Students can post their questions on the discussion board and ask others for help. Then instructors can monitor the discussion to mine information for areas of course or learning that instructor can offer assistance and foster deeper knowledge.

As managers, instructors can input messages to keep discussions focused on task goals and to prevent disruptive students from taking over class interaction. The CMC/FTF course design can allow instructors to identify concepts from the electronic discussion that are suitable for further FTF discussion. Similarly, tools offered within CMC media should allow for students to focus on learning rather than housekeeping tasks. Features such as auto save, auto archiving, and Wizards are tools that instructor can use to assist students to focus on learning rather than technical component that can frustrate students experience and learning. The degree which CMC technologies incorporate course management tools will influence the quality of the course and ultimately students’ learning and experience.

Instructors must decide ahead of time the degree to which a course needs to facilitate relational development among students. Therefore, it may be necessary for CMC users to establish relationships with one another and gain confidence in the system before proceeding in its use. The need for relational development in student-to-student interaction reinforces the need for supplementing CMC design courses with the FTF interaction (Olaniran, 2004; Wilson & Whitelock, 1998).

Another issue of course management in CMC courses is the degree of shift in learning control and responsibilities. CMC can shift the burden of learning from teachers to others such as students and other experts, such that teachers are able to concentrate on other aspects of learning. For instance, Olaniran (2004) finds a considerable drop in the proportion of direct teacher-student FTF interaction in comparison to the traditional FTF course. However, the reduction in time spent in FTF interactions was supplanted by increase in time needed for course management because instructors had to spend more time reading students contributions and providing individualized feedbacks. Specifically, the study reported increase in the proportion of “students contributing to in-class discussions on a consistent basis from 56 percent for FTF to 79 percent in CMC” (Olaniran, 2004, p. 152).

DESIGNING CMC INTO COURSES

A major challenge facing institutions and instructors today is not whether the CMC technology works. The challenge is making the technology work within different pedagogical goals in a way that accomplishes the idiosyncratic needs of different instructors and disciplinary demands. This
is where CMC teachers, vendors, and software designers come in and can make a difference.

One of the major benefits of any communication technology in a learning environment is to increase interactivity or active participation among students. But more importantly, CMC technologies must offer students a way to apply and extend course contents beyond the confines of their classrooms. CMC, if used appropriately, can foster critical thinking along with greater interactivity with other students (Olaniran, et al., 1996). By implication, it appears that students are expected to take initiative not only in their classrooms but also in their socio-cultural environments. Thus, educators are increasingly demanding more out of their students with the expectation that students will become active cultural change agents who are critical consumers of information (McComb, 1994). Contemporary education must find a way to engage learners’ experiences, concerns, and voices (Alavi, 1994; Du & Wagner, 2005; Freire, 1983; Leidner & Jarvenpaa, 1995). This is a paradigmatic shift from the traditional mode of education that stresses passive reaction to learning contents to the one that emphasizes active or proactive creators and participants in how they learn (McComb, 1994; Olaniran, 2004; Olaniran, et al., 1996). CMC systems designers must find a way to create suites of hardware and software that help accomplish the following:

- Allows students to connect with other learners’ experiences
- Puts teachers in a position to study and understand how best to adapt technology to students experiences in a way that leads to learning
- Allows learning to take place outside the linear mode of instructors’ transmitting or being the sole provider of knowledge
- Allows technology to extend the boundaries of learning

CMC is not a cure-all but it can offer instructors the opportunity to turn over learning responsibilities to the direct control of learners. Olaniran (2004) argues that simply adding CMC to a course will be counterproductive, however, when it is used to facilitate course goals, then it will make a significant contribution to learning processes and students, as well as instructors, would benefit from its deployment. McComb (1994) concurs when she suggests that CMC should not be used as a simple replacement for FTF communication. Other scholars have argued that using CMC in a course design does not mean that students will take advantage of it by taking the required initiatives (Olaniran, et al., 2000; Witmer, 1998). Quite the contrary, as Olaniran (2004) reported an initial indifference in communication course among graduate students who are expected to show greater latitude in taking responsibility for how they learn than the undergraduate students. Students’ resistance to technology is to be expected but this can be overcome by instructors. One way of making sure that initial resistance is overcome is by making sure that a significant portion of course evaluation is tied to performance and usage of the system (Olaniran, 1995, 2004). Furthermore, CMC can be explored or promoted by teachers from the standpoint that it offers students opportunity to allow their voices to be heard and consequently, it is useful for curricula that aim to facilitate students’ involvement and in encouraging them to develop initiatives (Du & Wagner, 2005; McComb, 1994).

FEEDBACK AND ASSIGNMENT TURNAROUND

CMC facilitates direct feedback without having to go through traditional gate-keeping roles of secretaries. However, affecting feedback is the issue of assignment turnaround. While CMC allows for assignment to be electronically submitted and graded, it is important for instructors to
understand that they would have to develop the habit of turning assignments and projects around expeditiously. Students can become impatient and frustrated when their assignments are not returned in a timely manner. The resulting frustration can also lead to failure to continue to use the technology (Olaniran, 2004). Thus, it is imperative that instructors understand that rules that work in other classes where CMC is not in use may fail miserably when applied in the CMC course design.

Another challenge with feedback in CMC lies in the fact that CMC is immune to large class size when participation is concerned. Accompanying large class sizes is also the need to grade a large number of assignments, yet the demand for fast turnaround time persists. One way to overcome this is to develop an electronic toolkit consisting of a glossary of commonly found errors, which consists of pre-written short text files about different errors (McComb, 1994). When an error is encountered, an instructor can quickly insert the accompanying text comments in student papers. First the short text files allow standardization of certain feedback on papers while allowing flexibility for personalized feedback. Second, the process allows instructors to meet the goal of fast turnaround. Third, the process allows instructor to move quickly through large volume of papers with relative ease. Fourth, the process safeguards against bad handwriting that may defeat the original purpose of feedback.

In the process of feedback, McComb (1994) considered the record-keeping feature of CMC as a useful tool for training students from comparison standpoint. Specifically, she indicates that she can refer to her notes to see if students follow her suggestions. The record also provides a good way to monitor students’ progress on activities and over a period of time. The record offers teachers the means for comparing a particular assignment with those of other groups and to present examples of poorly completed assignments against those that are exceptional (Du & Wagner, 2005; McComb, 1994; Phillips & Santoro, 1989). Furthermore, CMC allows students, when given access, to monitor their individual or collective performance on a regular basis and at their own convenience. For instance, my university provides online course management tool (i.e., Raiderlink) that instructors can use to provide students their grades and other performance evaluation measure. However, students also use it to stay on top of their grades and they use it to contact instructors about any discrepancy during the course, rather than having to wait until after the course is over or when grades have been submitted to the registrar’s office.

When designing CMC system into courses, one of the benefits is the ability to post messages and share files with participants. This becomes an invaluable tool that instructors can explore with learners especially in group interactions and other problem solving contexts. Readings, course notes, and supplemental resources can be disseminated via Internet and CMC forum. Learners can interact by sharing their comments with one another and engage in in-depth discussion with their peers and instructors. According to Bailey and Cotlar, (1994) instructors can ask different questions to stimulate interaction and thinking in CMC forum between students and multiple instructors.

**CHALLENGES AND RECOMMENDATIONS FOR CMC STRUCTURE**

A major challenge facing instructors in incorporating CMC into course design involves deciding which technology to use and when to use it. Asynchronous CMC (e.g., threaded discussion, bulletin board, e-mail) are popular because of the set up ease. The fact that asynchronous design allows participants (students and Instructors) to reflect before posting contributions is also appealing.
At the same time, the design offers the quickest solution because most existing university and IT infrastructure require little modification to add CMC to course structure. However, synchronous CMC course design (e.g., chat, video conferencing) where participants interact, at the same time, offer a greater level of interactivity and immediate feedback (Olaniran, 1994). Furthermore, synchronous interaction allows participants to interact using combination of voice, video, and audio channels, which can enhance students learning experience. With multiple channel cues’ media the barriers of time, distance, and culture can be overcome. (e.g., Solomon, 2001)

Synchronous CMC course structure could be problematic for distance learning where participants are spread across different geographic time zones. However, a recommendation for overcoming the challenge is to offer a mixed structure design, where asynchronous CMC may be the primary design. At the same time, offering synchronous interaction features such as the chat feature would significantly enhance student-to-student interactivity. Courses requiring group writing or decision making would also benefit when participants can either set up a time when all or most group members can meet to put the project together or write a paper. An alternative is for the instructor to devote class time to accommodate synchronous interactions for students, provided the infrastructure exists.

It is also recommended that software designers needs to help instructors overcome some of the challenges in CMC. One is the issue of bandwidth, which prevents against implementing more sophisticated CMC applications such as those allowing audio and video channel cues, the likes of computer videoconferencing and internet protocol television (IPTV). Creating third-party software that offers multiple cues and ease of deployment by instructors and easy access by students is called for. In the meantime, Olaniran (2004) recommends a combined method that allows for both FTF and CMC such that users do not feel like they are giving up one medium for another. Furthermore, a combined media design simulates interactions similar to those found in most organizational settings, where members are often allowed to use multiple communication media for interaction. Similarly the combined FTF and CMC design provide students time to adapt to the CMC system. Thus, while people may be using the CMC medium, they are still able to interact via FTF. The use of combined media in course design is not about CMC technology, but rather about the use of CMC to facilitate interaction and learning.

ADDRESSING STUDENTS’ NEEDS

Another challenge facing CMC and course design involves the students’ needs. Outside course content, the primary challenge facing an instructor is in accommodating different needs (e.g., learning styles and preferences) of the students. Consequently, instructors must develop a way to identify students’ needs and use the CMC system in a way that facilitates personalized learning through multiple strategies. Therefore, it is recommended that teachers break away from the linear mode of teaching that characterizes a lecture style. This can be done via prompt feedback through e-mail or posting to bulletin boards, discussion forums, along with reflective Weblogs. Another pressure placed upon instructors is that they need to be well informed by having current and adequate information to deal with individual students’ problems. Instructors can overcome this challenge by offering students “toolkits” or resource links where students can go to obtain desired information. Resources links are useful in empowering students to take control of the way they learn and recognize that learning exists beyond the classroom walls. The need for stressing individualized learning also demands some changes in procedures and course design. It is recommended that the training manual or Web
Human Computer Interaction and the Best Mix of Face-to-Face and E-Interactions in Educational Settings

Information must be easy enough for inexperienced users to understand. This simplification will help to reduce some anxieties with computer. However, the CMC training manual or Web page should not prevent sophisticated users from enjoying the system’s benefits. Olaniran (2004) advises that CMC should be used in a way that facilitates creativity. Encouraging creativity can be done when students are allowed to explore the medium for other uses that deviate from the course’s primary purpose such as socialization and recreation activities (Olaniran, 1993). A benefit from creative use of CMC is that it allows “meta-interaction” whereby students are able to explore and develop the novel use of the system as well as to seek help from one another when they encounter problems. Finally, the opportunity for students to help or coach one another in CMC forum may alleviate the need for instructors to be the only source of help.

REFERENCES

KEY TERMS

Computer-Mediated Communication (CMC): Computer-mediated communication involves communication interactions that exist over computer networks.

Critical Thinking: Involves a mental process of analyzing or evaluating information in an attempt to attain higher level of understanding. Person or learner is what has been learnt.

E-Learning: involves the process of knowledge dissemination and acquisition taken place over electronic networks.

Electronic Toolkit: represents wizard-like database that can be invoke in electronic communication by both learners and instructors to provide general but customized feedback.

Human Computer Interaction (HCI): Involves the study of interaction between people and computers where the interface of computer and people enables goal accomplishment.

Globalization: Involves economic and sociocultural ideas where organizations are able transcend national geographic and cultural boundaries through convergence of space and time in attempt to accomplish goals.

Transformational Learning: Involves knowledge acquisition that individuals and students can adapt to transform old knowledge about a given idea or topic. In other words it represents a process of getting beyond factual knowledge alone.

Chapter 4.2
Human Computer Interaction for Computer-Based Classroom Teaching

Wolfgang Hürst
Albert-Ludwigs-Universität Freiburg, Germany

Khaireel A. Mohamed
Albert-Ludwigs-Universität Freiburg, Germany

ABSTRACT

This chapter focuses on HCI aspects to overcome problems arising from technologies and applications that may hinder the normal teaching process in ICT-ready classrooms. It investigates different input devices on their usage and interactivity for classroom teaching and argues that pen-based computing is the mode of choice for lecturing in modern lecture halls. It also discusses the software design of the interface where digital ink, as a “first class” data type is used to communicate visual contents and interact with the ICT.

INTRODUCTION

Utilizing information and communication technology (ICT) in modern classrooms for the purpose of teaching offers several advantages. These include (worldwide) access to digital materials during lectures, recording and archiving of both the presented materials as well as the whole live event, and transmitting the lecture (live or recorded) to remote locations—a concept of tele-teaching. Consequently, conventional equipment, such as blackboards and chalk as well as overhead projectors and transparencies, have almost disappeared from the classrooms and lecture halls at many institutions and have been replaced with computers and data projectors. Integrating ICT in the classroom raises a myriad of technical questions related to the implementation of the respective devices and services. It is generally agreed, that details of the technical installation should be hidden from the presenters and teachers. Thus, in an ideal scenario, the teacher walks into the lecture room and, if anything, just has to
press one button in order to switch on the whole equipment and having all the infrastructure readily available. In this chapter, we are concentrating on the user’s perspective once all equipment is up and running and operated by the teacher during the lecture. In doing so, we focus on questions related to human computer interaction (HCI): How can people access the functionality offered by the installed ICT? How do they interact with the available infrastructure? What are the best possible approaches for the interface design in order to support the teaching process? And so on.

Generally, the way in which people interact with any kind of ICT is influenced by two aspects. The first aspect is the input devices, that is, the hardware that specifies what information is exchanged between man and machine and how this exchange takes place. For example, by moving a mouse, a user sends “events” to a computer that encodes information such as relative coordinates representing mouse movements. The second aspect is the software design of the user interface and the way in which the technical signals exchanged by the hardware are interpreted. For example, incoming signals from mouse movements (representing relative coordinates) are generally mapped to absolute pointer movements on the screen and as such visualized to the user. Unfortunately, traditional HCI concepts, such as conventional “desktop” input devices (the keyboard and mouse) and their related classical interface designs are not well suited for the tasks appearing in a classroom, forcing teachers to modify and adapt their teaching styles to the used equipment.

Following the point of view described before, this chapter is organized into two parts. First, we address input devices, that is, hardware-related issues for operating and using ICT in classrooms. We describe current and future trends in the usage of different devices using examples and case studies from our past and ongoing research projects as well as our experiences in actual teaching scenarios. We identify a subtle, yet promising trend that can be observed developing in the educational world—more and more pen-based input devices are used in classrooms and lecture halls. Examples of such devices include interactive electronic whiteboards, graphics tablets, Tablet PCs, and personal digital assistants. The second part of this chapter is devoted to the software designs and interaction paradigms for interactive classroom teaching using ICT. We describe different aspects in relation to pen-based interaction with the installed ICT. “Digital ink” is described as a new, “first-class” data type serving both, an exchange of information between teacher and students, as well as a new metaphor for interacting with the installed ICT via newly introduced gesture commands. Generally, we concentrate on instructional talks and presentations, where a presenter (i.e., the teacher) faces an audience (i.e., the students) and presents some content in a typical classroom setting. More interactive classroom settings, such as seminars or other arrangements involving group work, are discussed in a concluding future trends section at the end of this chapter.

HARDWARE-RELATED ISSUES: INPUT DEVICES

Background: Ubiquitous Computing Environments

As mentioned in the introduction, ICT usage in classrooms offers great opportunities to support and improve teaching. However, traditional input and output devices often prove to be a hindrance for the direct interaction between teacher and students. They draw too much of the lecturer’s attention to the operation of the respective hardware. Keyboard and mouse cannot be used to provide content to the students as naturally as chalk is used to write on blackboards. Monitors, even the small ones from laptop computers, can stand between the audience and the teacher building a
virtual barrier, and so on.

In a perfect scenario, all ICT equipment should be seamlessly integrated into the environment, that is, the classroom, and not interfere with the activity of teaching but support the lecturer in the best possible way. Presenters must be able to naturally access and handle the additional functionality provided by the respective devices alongside in a way that enables them to fully concentrate on their teaching and the interaction with the audience. Hence, the appropriate usage of ICT in classrooms is an ideal example for a concept of computing introduced by Marc Weiser in 1991 as ubiquitous computing (Weiser, 1991). Generally, the term ubiquitous computing refers to “an environment in which a large number of computers, ranging from hundreds of palm-sized to a few wall-sized units will be seamlessly integrated into our immediate surroundings, connected by wireless networks” (MacIntyre & Feiner, 1996, p. 251). While originally being applied mainly in the academic world, we now have the technology available to make Weiser’s vision of a ubiquitous computing environment a reality by building a classroom where all computing functionality is integrated into the environment. Many universities are already equipped with wireless networks. Large touch sensitive displays for integration into classrooms are available at prices affordable by most universities, and so forth.

However, to really create an “intelligent” classroom that does not constrain teachers but fully supports them, some open problems and challenges still remain, especially related to HCI. In the following, we give a historical overview about the usage of computers and different input devices in the classroom over the last couple of years. We discuss our experiences gained from utilizing such devices at our university and from observing other project- and user-groups. The aims of this overview are to highlight the advantages and disadvantages of the respective devices, identify interaction and usage styles, provide advice for the appropriate usage of the technology, and pinpoint open problems for further HCI-related research. Pen-based interfaces are identified as a trend-setting and essential aspect for ICT-based classroom teaching. Afterward, two case studies of innovative usage of pen-based input-devices are presented, which give direction to the future usage of pen-based interaction in an interactive classroom.

**Input Devices for Computer Usage in Classrooms: An Historical Overview**

*Traditional teaching: blackboards, overhead projectors, and freehand writings.* Teaching a class involves a lot of interaction between teacher and students, through the freehand writings on blackboards or chalkboards. Blackboards have traditionally been by far the most widely used medium for lecture presentations in institutes of higher learning, and they are very effective. Not only do they allow instructors to communicate all or part of the course materials in natural handwriting, but they also take away the attention to details for their use. Freehand writings and annotations take an important role in classroom teaching, even if a lesson is delivered via previously prepared slides or transparencies that are presented to the students using an overhead projector. Essentially, as classes progress, teachers will write, highlight, underline, draw, and formulate on those slides to put forth their points to the students. By using “empty” slides, they can spontaneously write on them, what actually facilitates discussions amongst students, helps to illustrate complex mathematical proofs, and demonstrates diagrammatic facts more clearly. Studies show that the combination of handwritten annotations, the development of thoughts through freehand writings, and the verbal explanations of the lecturers, are indeed crucial in assisting students’ understanding of the subjects (Mukhopadhyay & Smith, 1999; Zupancic & Horz, 2002).

*Early computer usage: data projectors and presentation software.* With the rising popularity
of presentation software tools, such as Microsoft’s PowerPoint, in the mid and late 1990s, a sizable number of teachers moved from using chalk and blackboards or overhead transparencies to using electronic slides and computers for classroom teaching. The increase of processing power and the decrease in hardware pricing led to the augmentation of lecture halls and classrooms with data projectors connected to background computer systems. By observing how teachers took to using these new tools, three different trends can be discovered:

1. Due to the lack of a flexible and effective input device such as the pen and partly due to a less than perfect interface design, some lecturers adapted from their very lively teaching style, to a scenario where the materials presented to the students were prepared electronically in advance and shown in a pure “slide show” style presentation. Hence our observation that whenever computers are exploited in classrooms, the teaching styles of the instructors are often made to adapt to the currently available interfaces and not vice versa.

2. Some teachers have tried to revert back to their old, traditional approach of slowly developing a topic by continuously adding and annotating their contents. This often results in their sitting down behind a computer screen and using traditional input devices, such as the keyboard and mouse, to add and modify the presented materials during the lecture. Where instead of writing in freehand and annotating on the slides, they type the text with the keyboard and make annotations by drawing straight lines and boxes with the mouse. So, again, the teachers go off their traditional way of teaching and adapting to a new and less appropriate style of interaction. In addition, sitting down and “hiding” behind a big computer monitor led to a loss of contact with the students.

3. Chong and Sakauchi (2000) observed that when presentation slides are available (either as overhead projected slides or PowerPoint slides from a data projector), the use of the chalkboard is significantly reduced during the course of the lecture. However, when it comes to facilitating questions and answers, the chalkboard is conveniently used again to demonstrate facts, confirm equations, and diagrammatically illustrate flowcharts. But making a direct reference from the chalkboards to any of the slides can be a hassle, and sometimes the instructors resort to annotating on those slides in whatever little space is available, and may even compromise on legibility.

In all three scenarios, we can observe that forced by inappropriate user interfaces, teachers generally adapt their teaching style in a less preferable way to the available technology. As for the students, they normally appreciate the fact of having an electronic version of the presented material after the lecture. It enables them to pay more attention to the class, and it gives them the time to make more appropriate and “intelligent” annotations during the live event because they do not have to copy everything the presenter shows them. However, pure slide shows are generally considered too exhaustive. Students often complain that such presentations are too fast for their liking, while the required speed for handwriting naturally slows down the pace of the lecture to a speed that is generally considered more appropriate and pleasant.

Initial usage of pen-based devices: Graphics tablets and touch screens. Considering the negative observations described previously, it is no surprise that with the advent of devices for pen-based computing, presenters quickly started to experiment with them in their classrooms and lecture halls. People first started using touch screens (where users communicate with the computer by direct touching of the screen) and
digitizing or graphics tablets (where a digital pen is moved over a separate surface in order to remotely control and operate the computer, similar to moving a mouse in order to operate the mouse pointer on the screen, cf. Figure 1). These input modalities improved the situation in so far as teachers are at least able to write natural freehand annotations. The devices, however, still lacked the usability and simplicity of markers or chalk. For example, in the case of graphics tablets, not every teacher feels comfortable with the remote control of a digital pen, but prefers to write directly onto the visualized electronic slide. Touch screens are hard to write on when the monitor is standing upright. Ideally, the screen should be mounted horizontally. However, touch screens do not only react to pen input but to any kind of physical contacts, thus making it impossible for teachers to rest their hand on the surface while writing. A detailed discussion about the initial usage of pen-based input devices in the classroom can be found in [*].

Advanced pen-based input devices: Interactive LCD panels and electronic whiteboards. The previously described input devices represented an improvement over traditional ways for human computer interaction such as keyboard and mouse. However, it was only after large, blackboard-like electronic whiteboards and LCD panels with integrated tablet became available at a reasonable price when pen-based computing became a real alternative to chalk and blackboard usage.

Originally targeted toward special interest groups and professions (such as graphic designers), the first LCD displays with integrated tablet, in the following called interactive LCD panels (cf. Figure 2), became available for the average consumer by the end of the 1990s. These devices operate like regular graphics tablets described before with the main difference being that the tablet is transparent and mounted on top of an LCD panel. Hence, compared to common touch screens, the surface does not react to any kind of contact, but only to the input of a special pen, thus enabling presenters to naturally write on a horizontally mounted screen. Using the pen, people can directly interact with the applications (e.g., by making annotations on the presented slides, navigating through subsequent slides, etc.). Teachers generally see this as a big improvement compared to normal touch screens or graphics tablets. However, early versions often proved to be too small, had a resolution that was too low, and a limited processing power that resulted in a noticeable time delay during freehand writing. Nowadays, we observe significant advancements.
in display size, screen resolution, as well as processing power, paired with lower prices. Hence, when mounted horizontally such devices provide the same ease of use as traditional overhead projectors while at the same time enabling users to access and use the full functionality offered by the underlying ICT installation.

An electronic whiteboard (cf. Figure 3) is the equivalent of a chalkboard, but on a large, wall-mounted, touch-sensitive digital screen that is connected to a data projector and a computer (see, for example, Smart Technologies Inc. [Online]). This computer can be controlled directly from the digital screen with a digital pen or by simply using a finger to touch it. Other known terminologies of the electronic whiteboards include the “eBoard,” “digital whiteboard,” “smart board,” or “interactive whiteboard.” They carry slightly different meanings to different people depending on their environment of application. However, these terms all describe in general, the group of technologies that are brought together to support classroom activities. Different versions exist that rely on front or rear projection. In the case of front projection, there are also whiteboard solutions that do not react to any kind of contact, but (similar to interactive LCD panels) use a special pen for interaction. While such an approach is preferable for LCD panels or any kind of horizontally mounted input surface, it is less important for vertically wall-mounted boards since users generally do not rest their hand on the board during writing.

Similar to early interactive LCD panels, first versions of electronic whiteboards had limitations regarding size, resolution, and processing power and were often too expensive for large-scale usage. Again, the situation is improved significantly today, and we can observe how more and more classrooms are becoming equipped with such devices. In fact, there is a growing trend amongst learning institutions approving the integration of electronic whiteboards into their classrooms. There are also many reports in the emerging body of literature suggesting that vendors of education and teaching instructors alike find the electronic whiteboards relatively easy and compelling to use (BECTA, 2003; Glover & Miller, 2001). However,
The authors also caution that becoming confident in their use often requires effort in commitment in terms of both training and independent exploration.

The situation today. As described previously, we saw that pen-based input devices offer promising perspectives for usage in classroom teaching, but initial versions had limitations and disadvantages. Due to advancements in hardware (such as size, resolution, and processing power) and dropping prices we can now say that electronic whiteboards and interactive LCD panels have become a real alternative to traditional blackboards and overhead projectors, respectively. Both devices offer a similar ease of use as their traditional counterparts while at the same time opening various new opportunities by providing full access to the underlying computer systems and infrastructure. In addition, new developments such as Tablet PCs (cf. Figure 4) incorporate the pen-based input technology and are more and more used for giving presentations and classroom lectures as well. Tablet PCs are a special kind of computer in the size of a laptop with a pen-operated graphics tablet integrated into the screen, similar to the interactive LCD panels described previously. Some Tablet PCs purely rely on pen-based user interaction, while others, called **convertibles** or **hybrids**, offer pen-based operation in addition to a regular keyboard and mouse or touch pad input.

Based on the feedback we received in various situations at our university, we argue that the equipment available today can finally be used to replace blackboards and overhead projectors through their electronic counterparts in a reasonable way. We observed that even people who are rather skeptical about using computers in classrooms and still stood with the old, traditional form of classroom teaching are more and more switching to computer supported presentations due to these new input devices. Overall, we can conclude...
that pen-based computing will be an important if not essential part of computer usage in future classrooms. It seems likely that in the near future, more and more classrooms will be equipped with pen-based input devices, in a similar way as not so long ago, blackboards and overhead projectors were complemented and slowly replaced with electronic data projectors.

In the following section, we describe two case studies of actual equipment used at our university for teaching. The purpose of this description is to describe the respective technology and how it is best used, to illustrate how people take advantage of it, and to identify open problems and future trends. We will see that with this technology we are able to build real ubiquitous computing environments as described before as the ultimate goal in the “Background” section.

**Case Studies of Actual Equipment Used in a Ubiquitous Computing Environment**
